## POLYFIT PROGRAM USERS' GUIDE

### 1.0 DESCRIPTION

POLYFIT is a user friendly program written in Microsoft Fortran for the IBM PC/AT and compatibles to perform polynomial regression analysis. This program allows the user to create and modify XY files (ie, sample data containing from 5 to 50 XY pairs, X is the independent variable, Y is the dependent variable), or use an existing XY file as data input to the program. Menus are displayed to simplify program use. The program was designed to do polynomial curve fits for the given data set for orders 1, 2, and 3. A summary and plot of the fit for a selected order (1, 2, or 3) is provided, as well as the option of hardcopy (i.e. : printer output) if desired.

Confidence intervals are computed and displayed as part of the summary of the chosen order of curve fit for the given sample data.

A flow diagram of the program is included in Appendix A.

### 2.0 USE

#### 2.1 Startup

To start the POLYFIT program, load the "TSC STAT PK" bootable disk into the "A" disk drive and boot up the computer (ie., turn on the computer or hit the CTRL-ALT-DEL keys simultaneously). A list of data files from the disk will be displayed, followed by a pause. All data files are assumed to have an extension of ".DAT". To input a file name, just type the name without the extension (eg, "DATA1"). The Main menu will be displayed as follows:

## MAIN MENU

TYPE        0 - TO STOP  
             1 - TO CREATE AN XY FILE  
             2 - TO USE AN EXISTING XY DATA FILE  
             3 - TO MODIFY AN EXISTING XY FILE

TYPE DECISION:

### 2.2 Data Input

#### 2.2.1 Create a New File

Type "1" from the Main menu to create a new file. A file name prompt will appear on the screen. The file name chosen must not already exist on the disk in the directory currently in use. The program will reprompt if this condition is not met. After inputting a valid file name, the user is prompted to input the number of observations (ie, X,Y pairs). The number of input pairs must be between 5 and 50, otherwise the program will reprompt.

The user is then asked to input the actual X, Y values. Each X value must be followed by a comma then a Y value followed by a RETURN/ENTER. If there is an error in data input an error message will appear and the data must be re-entered

The program displays the X, Y pairs along with an index number on the screen. Only 14 X, Y pairs will be shown at any time. To view additional data, hit the Enter/Return key to display the next consecutive 14 X, Y pairs.

### 2.2.2 Use an Existing File

Type "2" from the Main menu to use an existing data file. A file name prompt will appear on the screen. The file name entered must already exist on the disk or the program will reprompt.

After inputting a valid file name, the program opens the file and reads in the number of X, Y pairs and assigns an index number. Data is outputted to the screen and automatically sorted in increasing order on X.

### 2.3 Data Edit

Type "3" from the Main menu to modify an existing file. An Edit menu is displayed on the screen as follows:

#### EDIT MENU

- TYPE 0 - TO STOP FILE EDIT
- 1 - TO ADD X, Y PAIRS
- 2 - TO DELETE X, Y PAIRS
- 3 - TO MODIFY X, Y PAIRS

#### TYPE DECISION:

#### 2.3.1 Edit an Existing File

A file name prompt will appear on the screen. The file to be edited must already exist in the directory. The program will reprompt if this condition is not met.

After inputting a valid file name, the program opens the

file and reads in the number of X, Y pairs. This data is output to the screen, and automatically sorted in increasing order of X.

#### 2.3.1.1 Add an X, Y Pair

Type "1" from the Edit menu to add X, Y pairs. The program checks to see that the data file does not exceed 49 pairs. If the file does exceed 49 pairs an error message is displayed and the program pauses and then redisplay the data and the Edit menu. If the data file does not exceed 49 pairs, a prompt for a new X, Y pair is displayed. Each X value typed must be followed by a comma, then a Y value followed by a RETURN/ENTER. If there is an error in the data input, it must be retyped.

After all valid pairs are entered, the data is sorted and the number of observations are increased accordingly. The program then redisplay the complete data, followed by the Edit menu.

#### 2.3.1.2 Delete an X, Y Pair

Type "2" from the Edit menu to delete X, Y pairs. The program checks to see that the data file exceeds 5 pairs. If the file does not exceed 5 pairs an error message is displayed and the program pauses. The data and the Edit menu are redisplayed.

If the data file does exceed 5 pairs, a prompt for the index number of the X, Y pair to delete is displayed. An invalid index number will result in an error message. A valid input number causes the program to delete the associated X, Y pair, and decreases the number of observations by 1. The data and the Edit menu are redisplayed.

### 2.3.1.3 Modify an X, Y Pair

Type "3" from the Edit menu to modify X, Y pairs. A prompt for the index number of the X, Y pair to be modified is displayed. If the number typed is invalid, an error message is displayed. A valid index number causes the program to prompt for a new X, Y pair. All data that is improperly entered, must be retyped.

When a valid pair is entered, the old X, Y pair associated with the index number is replaced, and the observation pairs and index numbers are resorted. The program then redisplay this data, followed by the Edit menu.

### 2.3.2 Terminate File Edit

Type "0" from the Edit menu to stop file edit. The file is transferred to the disk with the latest changes, and control returns to the Main menu.

## 2.4 Data Output

### 2.4.1 Output Selection

The polynomial regression analysis is performed for orders 1, 2, and 3. The program suggests an order of polynomial that best fits the plot of the data set. The program achieves this by selecting the degree where the correlation coefficient is closest to the value of one and where the residual variance produces the largest decrease over it's predecessor. This will insure that the variance about the regression and the difference between observed and calculated values will be kept to a minimum. The user is cautioned to evaluate this suggested value by examining the statistical data and plotted curves, provided by the program, to see if the degree suggested indeed produces the best fit.

A Summary and Plot menu is displayed as follows:

```
SUMMARY AND PLOT MENU
TYPE 0 - TO STOP
      1 - FOR SUMMARY & PLOT OF POLY. OF ORDER 1
      2 - FOR SUMMARY & PLOT OF POLY. OF ORDER 2
      3 - FOR SUMMARY & PLOT OF POLY. OF ORDER 3
      4 - TO CHOOSE A NEW DATA SET
TYPE DECISION:
```

#### 2.4.2 Summary And Plot Display

Type "1", "2", or "3" from the Summary and Plot menu to get a summary data tabulation and plot of the respective order polynomial. The program will display least square coefficients, correlation coefficient, coefficient of determination, standard error of estimate, and residual variance of Y, on the top part of the screen followed by the index number, X (independent), Y (dependent), Y (calculated) and the confidence interval in columnar form. The program continues by generating the plot of the regression curve superimposed over the actual data points on the screen anywhere between 8 - 16 equidistant divisions of the X range. Observation of the fitted curve will help determine if the degree inputted best fits the data and that obvious erroneous data points has not forced a higher degree polynomial than necessary.

Type "4" from the Summary and Plot menu to choose a new data set. Choosing a new data set will take the user back to the Main menu.

### 2.4.3 Summary And Plot Hardcopy

After the summary data tabulation and plot is performed, a HARDCOPY menu is displayed as follows:

#### HARDCOPY MENU

TYPE 0 - TO CONTINUE  
1 - FOR HARDCOPY  
2 - CALC CONF INT FOR ADDITIONAL X VALUES  
TYPE DECISION:

Type "0" from this menu to return to the Summary and Plot menu. Type "1" from the Hardcopy menu to send a copy of the summary data tabulation and plot of the previously chosen polynomial to the printer anywhere between 20-40 equidistant divisions of the X range.

Type "2" from the HARDCOPY menu to calculate confidence intervals for additional X values. The program prompts the user for the number of X values. The program prompts to input the X values. If there is an error in data input a prompt will appear and the data must be retyped. The confidence intervals for these additional X values are computed and displayed on the screen. The program returns to the HARDCOPY menu. At this point, type "1" to obtain a hardcopy of the summary data tabulation, a plot of the previously chosen polynomial, and a table of confidence intervals for additional X values.

### 2.5 Polynomial Regression

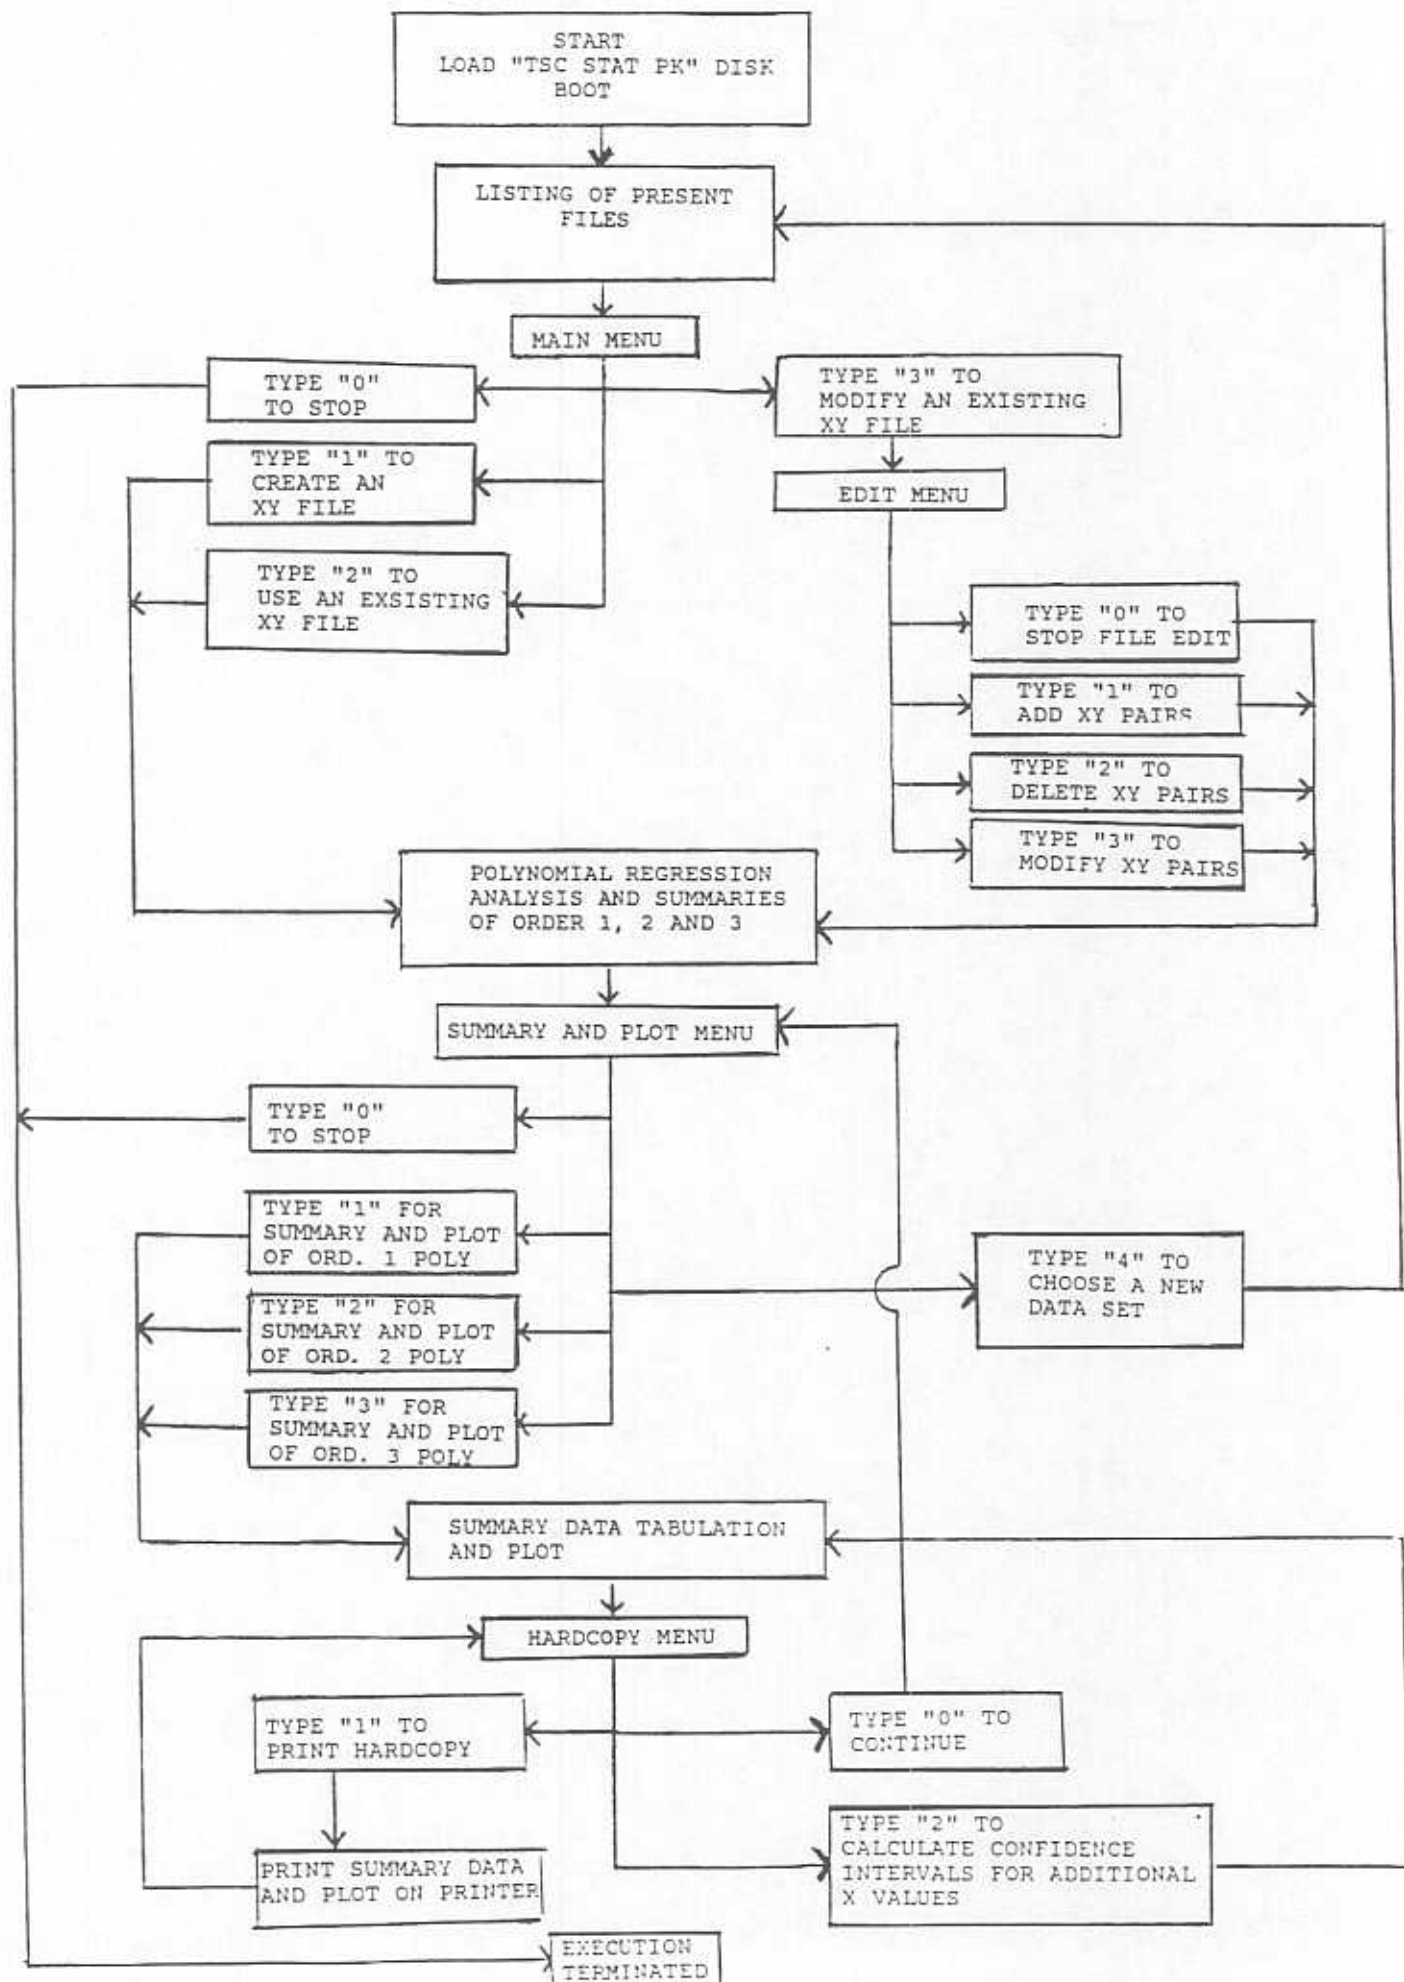

After data is input, the regression analysis is performed on the sample data for polynomials of order 1, 2, and 3 with the results of each case displayed on the screen. See the program listings for the method used. Output examples are provided in

## Appendix B.

### 2.6 Program Termination

When "0" is typed from the Main or Summary and Plot all files connected to the program will be closed and the program will return to the DOS operating system prompt.
