#### I. BACKGROUND

Drivers between the ages of 16-25 are consistently overrepresented in traffic accidents, including fatal accidents. Young male drivers comprise a substantial portion of single vehicle accidents and alcohol involved fatal accidents.

Fatal accident involvement has been shown to be related to driver alcohol consumption. It has been determined that the risk of accident involvement increases as a function of driver blood alcohol content (BAC). In addition, alcohol related traffic accidents have been shown to be highly correlated with driver involvement age and sex. Also, studies show that most alcohol related accidents occur during nighttime hours. 1, 4/

Driver sex, driver age, and accident hour are characteristics with which alcohol involved accidents are identified. Previous work  $\underline{4}$ / has shown that lowering the minimum legal drinking age increases the number of accidents involving drivers less than 25 years of age. Fourteen States since 1976 have passed legislation raising the minimum legal drinking age. Raising the legal drinking age has been found to reduce nighttime alcohol-involved accidents with younger drivers. <u>10</u>, 11/

Eight States (Florida, Georgia, Iowa, Minnesota, Montana, New Jersey, Rhode Island, and Tennessee) raised their minimum legal drinking age from 18 to 19. Maine, Massachusetts, and New Hampshire have raised the age from 18 to 20. A recent study of the raised legal drinking age in Maine  $\underline{8}$ / found a reduction in traffic accidents for drivers in the affected age groups.

-1-

Nebraska raised its minimum age from 19 to 20. In Michigan, where the legal drinking age was raised from 18 to 21, a recent study 10/ found a reduction of 31 percent in alcohol involvement for those drivers affected by the law change, the 18-20 year old drivers. Increases of 9 percent and 5 percent in alcohol involvement were found for drivers 21-24 years old and 25-45 years old, respectively.

Illinois raised its minimum legal drinking age in January 1980 from age 19 to 21 years. As a result, drivers age 19 and 20 who could previously purchase alcohol can no longer do so. This analysis attempts to determine what reduction, if any, in alcohol involvement can be attributed to the law change in Illinois.

#### II. LEGAL DRINKING AGE LAN--IMPACT ANALYSIS

Data for single vehicle male driver involvements (SVNMD) occurring between 8 pm - 3 am were obtained from the State of Illinois. SVNMD was used as a surrogate for alcohol related accidents. Surrogate measures for alcohol involvement are typically used since BAC reporting for driver accident involvement is often incomplete.

Figures 1-9 (see Appendix) are graphs of each SVNMD raw data series along with the 12-month moving average. Monthly involvements by age group for 1977-1980 were analyzed as an impact measure. A total of nine series, each consisting of 48 data points were used.

-2-

The nine age groups used are shown in Table 1.

TABLE	1
-------	---

EQ22		Driver	Age	Equals		22
GT22		Driver	Age	Greater	- Than	22

\*Ages affected by law change.

A statistical evaluation model was developed for each series (age group) to quantify the relationship between the impact measure (SVNMD) for the affected ages and a possible explanatory variable, the intervention of the legal drinking age law. The method used is a least-squares analysis technique known as Box-Tiao Intervention Analysis. 2, 3/ This approach has been used extensively to determine traffic safety program impact (e.g., the 55 MPH National Maximum Speed Limit) using State and National data. 6, 7, 8/

If a statistically significant reduction was found in the impact measure for the affected ages, 19-20 years old, and not found for the other age groups,

-3-

we could reasonably conclude that these drivers exhibited behavior unlike the others. Therefore, this reduction is attributable to the law change.

The first step in the analysis was to develop a univariate model for each series. The univariate models would relate future SVNMD based on its own past. This was done to examine the time series characteristics exhibited in the raw data, which would serve as a basis for constructing impact assessment models 9/ relating changes in SVNMD to the intervention, i.e., law change.

Figures 1-9 were used to identify possible similarities in the behavior of SVNMD for the nine age groups.

Univariate models were estimated for each series and are summarized in Table 2. Eight of the series were characterized by nonstationary behavior, i.e., observations at time period show high correlation with observations 12, 24, 36, etc. months apart. Nonstationarity was accounted for by taking a seasonal (12-month) difference of the original series and estimating a moving average parameter of order 12. Box-Jenkins Time Series Analysis was used to arrive at univariate model estimates.  $\underline{2}/$ 

All series except LT16 required a seasonal (12-month) difference and a seasonal moving average parameter. The EQ19, EQ20, EQ21, and GT22 univariate models also required a moving average parameter of order 1. All model parameters were significant and residual analysis indicated that the models were adequate.

-4-

TABLE 2 SVNMD Univariate Models

,

EQ21	Seasonal	0.49	0.15	0.73	0.07
EQ22	Seasonal	-	-	0.79	0.07
GT 22	Seasonal	0.42	0.16	0.74	0.07

\*Ages Affected by Law Change.

The next step in the analysis was to create a variable to represent the (intervention) raising of the legal drinking age in Illinois. The dummy variable LAW was created where:

> $LAW_{t} = 0, t < January 1980$ 1, t  $\geq$  January 1980

to represent the absence/presence of the new legal drinking age law.

Next, a model was developed for each series which would relate SVNMD and the intervention, LAW. This impact assessment model would provide a measure

-5-

of the change associated with the raised minimum legal drinking age in Illinois. The following model form was entertained:

$$Y_{t} = w_{o} LAW_{t-b} + N_{t}$$
  
ere 
$$Y_{t} = SVNMD age group at month t$$
$$w_{o} = impact of raised minimum legal drinking age, i.e., monthly average change in SVNMD$$
$$b = delay time before impact is "felt"$$
$$N_{t} = noise series, a function of normal, independently distributed error, N (0, \sigma^{2})$$

Impact assessment models were estimated for each SVNMD age group. For driver age = 19 (EQ19) and driver age = 20 (EQ20) the following models were estimated:

EQ19 
$$Y_t = -17.7 \text{ LAW}_t + N_t$$
  
where  $N_t = (1 - .69B^{12}) a_t$   
 $(1 - B^{12})$ 

100

EQ20  $Y_t = -11.2 \text{ LAW}_t + N_t$ where  $N_t = \frac{(1 - .77B^{12})}{(1 - B^{12})} a_t$ 

Values appearing in parentheses represent the standard errors of the estimates.

The model parameters and their standard errors for each of the SVNMD age groups are given in the Appendix. The values for  $W_0$ , impact of the raised legal drinking age, are summarized in Table 3. Delay time for all series was 0.

	Impact			
<b>Se</b> ries	Wo	s.d. (w <sub>o</sub> )	t-valué	
LT16 -	-11.5	15.1	0.76	
E016	-4.6	6.6	-0.70	
E017	-5.1	8.3	-0.61	
E018	-5.7	9.7	-0.59	
F019	-17.7	8.7	-2.03	
F020	-11.2	6.4	-1.75	
F021	11.3	7.6	1.49	
F022	2.5	7.7	0.33	
GT22	31.9	102.2	0.31	

TABLE 3 Impact Assessment Estimates

· . .

÷.

-

\*Significant at  $\alpha = 0.05$ 

Both impact estimates for the affected ages were statistically significant (using a one-sided t-test 5/) at the  $\propto$  = 0.05 level. Impact assessment estimates for the other age groups were not statistically significant.

Analysis of the model residuals revealed no model inadequacies.

From these models, estimates can be made of the steady state reduction in single vehicle night male driver involvements for the affected ages attributable to Illinois legal drinking age law change. The steady state estimate of the reduction attributable to the law change for drivers age 19 and age 20 is 17.7 and 11.2 per month, respectively. Those reductions can be compared to annual SVNMD for EQ19 and EQ20. Annual SVNMD are shown in Table 4.

-7-

#### TABLE 4

#### Annual SYMD

	1977	<u>1978</u>	<b>Base</b> 1979	Avg.	<b>19</b> 80	All Yrs. <u>Avg.</u>
E019	2,145	2,243	1,965	2,118	1,897	2,063
TOTAL	4,008	4,088	3,673	3,923	<u>1,689</u> 3,586	<u>1,776</u> 3,839

Thus, the 1980 reduction in single vehicle night male driver involvements, using the model estimates and comparing these to base year (before the law change) averages yields:

# TABLE 51980 Reduction in SVNMD

	No.	*
EQ19	212	10.0
TOTAL	346	<del>7.4</del> 8.8

#### III. CONCLUSION

From the above results, the raising of the legal drinking age law has been effective in the reduction of single vehicle night male driver involvements for drivers ages 19 and 20 in Illinois. Single vehicle night male driver involvements was used as a surrogate measure for alcohol involvement in accidents for these drivers.

The percent reduction attributable to the law change in Illinois in single vehicle night male driver involvements for 1980 totals 8.8 percent.
