#### PREFACE

This survey was conducted in the Aviation Department of The Port of New York Authority under the initiative and direction of Mr. Norman L. Johnson, Chief of the Forecast and Analysis Division.

The report was written under the direction of Mr. Albert J. Raebeck, Supervising Analyst of the Market Research Section of this division.

Sampling design and mathematical aspects of the report were supervised by Mr. Frederick V. Hurst, Jr., assistant to Mr. Raebeck.

Mr. Johnson came to the Port Authority in 1948. In 1952 he was appointed Chief of the Forecast and Analysis Division of the Aviation Department, in charge of economic analysis of the Port Authority Airport development program. This work includes traffic analysis, forecasting, and market research.

He served as Budget Officer for the Civil Aeronautics Authority from 1939–1942. During the war years he served with the War Shipping Administration. He was Director of Planning and Development for the Airline Terminal Corporation from 1946– 1948. This corporation was formed by the Air Transport Association in 1946 to operate the Willow Run and Greater Cincinnati Airports.

Originally a telephone company commercial engineer in the Bell System, he joined the I. T. and T. Corporation in 1927 and made basic telephone market studies and organized the commercial department of the Puerto Rican, Mexican and Roumanian telephone companies.

He entered government service in 1933 and became Chief of Management Analysis Division of the Home Owners Loan Corporation. He left this post in 1939 to join the C.A.A. under the new organization which resulted from the C.A.A. Act of 1938.

Mr. Raebeck joined the Port Authority in 1953. He was previously a statistician in the Division of Statistical Standards, Bureau of the Budget, and formerly an instructor in economics at Princeton.

Mr. Hurst is a mathematical statistician with advanced degrees from Columbia University.

## FOREWORD

This survey was conducted by The Port of New York Authority with the collaboration of all domestic air carriers serving New York City airports, and Air France. It is probably the first of its kind conducted in this country.

Because of its uniqueness and informative nature, it could well be the forerunner of other profitable studies of all carriers and other major transportation areas.

It is published with the permission of The Port of New York Authority.

The Eno Foundation extends its kindest appreciation for the privilege of publishing it.

**ENO FOUNDATION** 

## INTRODUCTION

The survey which is the subject of this report was conducted as a joint undertaking by the domestic airlines serving La Guardia, New York International, and Newark Airports and The Port of New York Authority, to determine some of the basic characteristics of air travelers using these airports. The rapid and undiminished growth of air travel volume during the last few years has clearly indicated the changing character of air travel and travelers, and the development of a new dimension in the air transportation market.

The Airlines and the Port Authority have a joint interest and obligation in developing and serving the untapped potential market for air transportation. One of the ways to foresee the nature and volume of air travel in the future, as it will affect the terminals and airlines serving the New York-Northern New Jersey Metropolitan Area, is to analyze the changing composition and characteristics of the people who use the airlines serving this area today, and periodically to conduct similar surveys in the future to determine and project the changing nature of the air travel market. Since most of the information considered relevant to the analysis can be supplied most readily, or exclusively, by travelers themselves, a questionnaire technique was used in this survey.

It is necessary to study the characteristics of sufficient air travelers selected by methods that will assure the general validity and applicability of the findings within precise limits of accuracy. Since it is impracticable to study the characteristics of all ten million passengers who pass through the New York and Newark Airports during the year, the Port Authority proposed, in the summer of 1954, a sample survey of passengers departing from the three airports for domestic destinations, to be conducted jointly by the Port Authority and the thirteen airlines serving these airports. The airlines agreed to this proposal. The survey was conducted in accordance with the agreed plan, and significant findings are reported herein.

## **ACKNOWLEDGMENTS**

This survey could not have been conducted without the full collaboration of the management and personnel of the participating airlines. In addition to the airline officials who authorized the survey, dispatchers, station managers, and, particularly, flight attendants on the sample flights gave, without exception, wholehearted assistance to the survey.

The following airlines collaborated in the study:

Air France	National Airlines
Allegheny Airlines	Northeast Airlines
American Airlines	Northwest Orient Airlines
Capital Airlines	Trans-Canada Air Lines
Colonial Airlines	<b>Trans World Airlines</b>
Eastern Air Lines	United Air Lines
Mohawk Airlines	

The methods used in drawing the sample, in assigning weights to the responses, and in estimating reliability of findings, were developed by the Port Authority. These methods were reviewed by the Survey Research Center of the University of Michigan, and the Center found them to be satisfactory. The responsibility for the conduct of the survey and for all calculations, findings and conclusions presented herein belongs solely to the Port Authority.

# Will you take just Minutes

# to complete this questionnaire?

To provide better service to the traveling public, the Airlines serving the New York -- Northern New Jersey Area, in cooperation with the Port of New York Authority, are seeking information about air passengers. You alone can give this information. You need not sign your name.

Your flight attendant will collect the completed. questionnaire.

П

THE QUESTIONNAIRE, left: front cover, right; inside pages

## CONDUCT OF THE SURVEY

The Questionnaire: To make it easier for passengers to record answers to the questions and to speed tabulation, questions were designed where possible to be answered with a check-mark. The only exceptions were location names and number of trips. The questionnaire was printed on folded card stock, to form a booklet. Therefore, it was possible to write the answers without any backing for the questionnaire, and the answers were folded into the booklet to assure privacy. The statement on the cover of the questionnaire made clear the anonymity of the response. The categories employed in questions on income, industry and occupation are comparable to U. S. Census classifications.

Information concerning the following characteristics of air travelers was considered the most valuable data obtainable by in-flight survey methods:

Local Origin of Trip	Family Income
Flight Destination	Frequency of Travel
Purpose of Trip	Mode of Ground Transportation
Age and Sex of Traveler	to the Airport
Occupation of Traveler	Type of Ticket Purchased

Airline Responsibility: Each airline operating domestic scheduled flights from La Guardia, New York International, and Newark Airports cooperated with the Port Authority in conducting the survey. One of the airlines agreed to test a preliminary questionnaire on two of its flights. The results of the pre-test were used in refining the questionnaire, but the data themselves were not used in final tabulations.

The flight attendants distributed questionnaires and pencils to all passengers on the outbound flights selected. They encouraged the passengers to fill them out, then collected them. They then put the questionnaires into an envelope and mailed them back to the survey supervisor.

Port Authority Responsibility: The Port Authority conducted the survey up to the point at which the questionnaires were delivered to the flight attendants of the selected flights, and after the completed questionnaires were returned by the flight attendants.

The first stages in planning the design of the survey involved selection of the subjects to be covered, representative types of flights to be surveyed, and the time period to be included. The questionnaire was then designed, pre-tested, and refined, and a probability sample of flights was drawn, in the fashion described in Appendix I.

A field supervisor met the flight attendant at the terminal shortly before the selected flight was scheduled to depart. He obtained from the airline dispatcher the number of adults and children boarding at the New York Airport. This information was used in computing response rates and in determining how many persons were represented by the actual respondents. He gave the attendant the necessary number of questionnaires and pencils, and an addressed, stamped envelope, and explained how to distribute and pick up the questionnaire on board the plane.

When the completed questionnaires were returned, codes were assigned to answers, the responses were recorded on punch-cards, and machine tabulations of the results were run off.

Each questionnaire was assigned its proper statistical weight so that the summary of all questionnaires, and certain meaningful sub-groups of questionnaires would accurately represent all passengers departing on all flights during the survey period.

In accordance with established policies and understandings, each airline has been provided with a complete set of punchcards covering questionnaires returned by its own passengers if it so desired. Special studies and tabulations that may be of interest to the airlines covering the entire sample will be provided by the Port Authority under special arrangements, but information concerning the passengers of specific airlines is restricted to each airline concerned.

# SCOPE OF THE SURVEY

The results of the survey are the summary of answers supplied by 7,783 passengers who constitute a probability sample of the 240,000 passengers on scheduled domestic flights leaving La Guardia, New York International and Newark Airports during the period September 9–29, 1954. The validity of the sample as a measure of the entire group is discussed in Appendix I.

Although the sample was limited to passengers on flights leaving the New York Area and therefore can only represent with assurance the total number of *departing* passengers, it is reasonable to assume that in many respects the sample did, in fact, closely represent total inbound domestic passengers as well. As shown in records submitted by the airlines, the number of inbound passengers approximately equalled the number of travelers leaving the airports during this period.

In the long run, inbound and outbound passengers are the same people, and will have the same incomes, occupations, industries and like characteristics although, during a particular threeweek period, this may not be true. During September, for example, there may have been a disproportion of outbound business travelers, and inbound vacationers. In addition, inbound and outbound travelers may behave differently with respect to ground transportation used between the airport and the local terminus of the trip.

As the survey findings concentrate on passengers whose trip originated at the New York Area Airports, travelers who changed planes in New York, the so-called transfer passengers, are excluded from the basic tables and are treated separately in the last section of the findings. Excluding transfer passengers, there were 6,456 questionnaires representing 194,100 passengers. This number is the base of most of the tables in this report.

The basic tables, therefore, reflect the characteristics of locally originating passengers, departing from La Guardia, New York International, or Newark Airports on scheduled domestic flights during the period September 9–29, 1954. All points in the continental United States, Canada and Mexico are included as domestic destinations. The extension of the results to transfer passengers, to inbound passengers, or to outbound passengers during other times of the year, involves knowledge of travel habits beyond what is known from the survey itself.

However, there will be many circumstances in which the data from this survey will be useful, even though applied to groups of passengers who are not specifically represented by the sample.

#### FINDINGS

#### The Air Trip

Destination and Purpose of Trip: Table 1 reflects the answers to two items on the questionnaire. One is the destination of the passenger's trip, and the other is the purpose of the trip. The first was an open question, asking the respondent to fill in his destination. The second gave him a choice between "personal" and "business." In addition, if he answered "personal," he was asked to choose among four types of personal travel, or if none of these categories fitted his purpose, he was requested to write it out. A few respondents (about 1 percent) checked both the "business" and "personal" purposes, and these were included in the "business" column of Table 1.

It is important to distinguish "personal" from "pleasure." As will be seen in Table 4, an appreciable number of passengers expressed their purpose as "personal" without indicating that the trip was part of a vacation or holiday.

Sixty percent of the people traveled for business reasons, while 40 percent traveled for the various personal reasons. This preponderance of business travel is reflected in the destinations to which most of the passengers were going. Over half of the passengers were destined for the commercial and industrial New England, Middle Atlantic and East North Central states. The East North Central region alone accounted for 29 percent of the traffic. Two-thirds of the trips made to this area were for business, compared to 60 percent for the survey as a whole.

Business travel was also more important among passengers to New England and the Middle Atlantic states than for passengers generally. A substantial portion of travelers to Boston had a business purpose, and flights to that city constituted over half of all trips to New England. The purpose of trips to New England points other than Boston matched the United States average very closely.

The South Atlantic region ordinarily is not considered to be primarily an industrial area, and its relatively low percentage of

() Measure is probably accurate, but based on too few cases to assure that it is within the prescribed range of reliability.

business travel in total appears to support this belief. Closer examination, however, shows that this ratio is greatly influenced by Miami; 65 percent of the travel to all *other* places in the South Atlantic states was in fact for business purposes.

Except for the small number of passengers going to the

mountain states, each of the remaining regions drew a higher proportion of passengers traveling for personal reasons than did the country as a whole. Non-business travelers constituted over half of those going to Canada.

Table 2 tells the magnitude of travel to each region, and to some cities, for all business travel and for all personal travel. The differences in percentages among the three columns reflect

#### Table 2

#### DESTINATION OF PASSENGERS TO REGIONS AND PRINCIPAL CITIES BY PURPOSE OF TRIP (Excludes Transfer Passengers)

Number of Passengers	194,100	117,200	76,900

the proportions of business and personal travel shown in Table 1. The greatest differences are for the Pacific Coast and Canada, each of which had approximately twice its share of personal trips compared with its share of business trips. This is a reflection of the fact, seen in Table 1, that these were areas to which many people traveled for personal reasons.

#### Table 3

#### DESTINATION OF PASSENGERS TO THE FIFTEEN MOST FREQUENT DESTINATIONS BY PURPOSE OF TRIP (Excludes Transfer Passengers)

Percent of Passengers

	Destination			by Purpose		
Rank		Percent of Passengers	Number of Passengers	Business	Personal	
1	Chicago	11	21,500	67	33	
2	Boston	7	14,400	69	31	
3	Washington	7	13,700	73	27

5	Cleveland	4	8,100	67	33	
6	Pittsburgh	4	7,100	74	26	
7	Detroit	3	6,000	57	43	
8	Montreal	3	5,900	50	50	
9	Los Angeles	2	4,500	55	45	
10	San Francisco	2	4,000	(41)	(59)	
11	Cincinnati	2	3,200	(80)	(20)	
12	Milwaukee	2	3,100	(66)	(34)	
13	Dallas	1	3,000	*	*	
14	St. Louis	1	2,900	(60)	(40)	
15	Denver	1	2,900	*	*	

() Measure is probably accurate, but based on too few cases to assure that it is within the prescribed range of reliability.

\* Based on too few cases to merit publication.

Boston, Pittsburgh, Washington, Chicago and Cleveland combined accounted for 41 percent of all business travel, but only 25 percent of travel for personal reasons. Miami, on the other

hand, was the destination of 9 percent of the personal trips, contrasted with 2 percent of business trips.

Table 3 ranks the top fifteen cities to which people went dur-

ing the survey period. The first six cities accounted for about 40 percent of the scheduled domestic passengers. With the exception of Miami, all of these cities had a high percentage of business travel. Miami had about 5 percent of the total traffic, and recorded a very high percentage of pleasure travel.

A surprising note in Table 3 is the fact that Detroit registered a lower-than-average percentage of business travel. The reasons for this are not apparent, although a possible answer is that in addition to the number of people going to Detroit itself, many passengers may have listed Detroit as their destination when in fact they were going to Michigan resort areas. Montreal, which is a center of financial and commercial activity, as well as a vacation spot, reflects these characteristics by the equal distribution of business and pleasure travel to that city.

Confidence in the distribution of traffic among cities during the survey period is strengthened by the Civil Aeronautics Board Origination and Destination survey of September 1953, which indicates a similar distribution of traffic out of New York. Though the 1953 survey reflects activity that occurred a year earlier, there is no reason to expect any radical change in the destinations of air passengers over a relatively short period of time. A comparison of the data from the two sources is given in Appendix III. Data from the September 1954 C.A.B. O & D survey are not yet available.

Purpose of Trip and Class of Ticket: The relationship between the purpose of a passenger's trip and the type of ticket he buys is shown in Table 4. Three-fourths of all passengers, irrespective of the purpose of their trip, traveled first-class. Examination of the purpose of the passengers' trips shows a strong relationship between purpose of trip and type of ticket. Among business travelers, 87 percent had first-class accommodations, compared with only 56 percent for those who traveled for personal reasons. The various categories of personal travelers shows a similar distribution of the various types of ticket, with the exception of those who accompanied their husbands on a business trip. Onefourth of these travelers had family-plan tickets.

#### PASSENGERS RESIDENT AND NON-RESIDENT IN THE METROPOLITAN AREA, LEAVING NEW YORK DURING CERTAIN PERIODS OF THE WEEK (Excludes Transfer Passengers)

Period	Passengers	Percent of Passengers by Residence in Metropolitan Area	
		Resident	Non-Resident
All Days	194,100	41	59
Sunday	27,800	42	58
Monday before 4 P.M.	17,500	60	40
Weekdays <sup>a</sup> before 4 P.M.	64,000	60	54
Weekdays <sup>a</sup> after 4 P.M.	45,800	26	74
Friday after 4 P.M.	15,100	32	68
Saturday	23,900	34	66

• Monday before 4 P.M. and Friday after 4 P.M. were not considered as weekdays, and are shown separately.

# RESIDENT AND NON-RESIDENT PASSENGERS LEAVING NEW YORK DURING CERTAIN PERIODS OF THE WEEK

\*Monday before 4pm and Friday after 4pm were not consideredas weekdays, and ore shown separately. Source: Table 5 FIGURE 4

A family-plan traveler is one who has a ticket that entitles him to travel at a reduced price with a relative who has a first-class ticket, subject to certain regulations. Thus, the 25 percent of those accompanying their husbands who traveled family plan, are traveling on first-class flights. Combining this 25 percent with the 55 percent who had first-class tickets results in a total of 80 percent on first-class flights for this group. Therefore this distribution closely and logically resembles that of the business travelers. Table 4 indicates that about 6 percent of all business travelers took their wives with them.

The largest purpose category among personal travelers is the one in which the respondents stated that they were traveling on vacation, holiday or leave. This group accounted for 25 percent of all passengers during the survey and 63 percent of all those traveling for personal reasons. Although more than half of the passengers traveling for personal reasons were on first-class flights, this group's proportion of coach passengers was three times that of the business group.

Day and Hour Preference of Trip: Table 5 shows that residents of the Metropolitan Area have a preference for leaving early in the day and early in the week. This tendency is evidenced by the fact that the residents' percentage of all passengers ranges from a strong 60 percent on Mondays before 4 P.M. through 46 percent on weekdays before 4 P.M., and dips to 32 percent on Friday evenings, and 26 percent on weekday evenings. The residents' preference for an earlier departure during the day is probably due to their desire to remain home, rather than leave later during the previous day and spend the night away from home. Similarly, their tendency to leave the city early in the week probably reflects the preference to return home for the weekend.

Non-residents of the Metropolitan Area indicated an opposite pattern. They preferred to leave later in the day and later in the week, probably for the same reasons that passengers residing in the New York Area did the opposite. Non-resident passengers tend to leave later in the day, probably in order to avoid spending an extra night away from home. They also leave later in the week so as to be home for the weekend. If they had preferred to spend a weekend in New York, Monday's early traffic would have been more heavily affected by non-resident passengers. This explanation cannot be expected to apply to vacation trips, but these were seen to constitute only 25 percent of the total.

FIGURE 5

#### The Trip to the Airport

In addition to providing information about where and when these passengers travel, the in-flight survey provides data about the local origin of their trip, how the passengers divided their patronage among the three airports and the means of ground transportation they used in getting to the airports.

Local Origin: It is evident by the distribution of the total traffic

among airports, as seen in Table 6, that La Guardia gets the lion's share (59 percent) at this time. However, this distribution is quite different among the various counties from which passengers originate. The county of origin is not necessarily the same as residence, inasmuch as many people who begin their trip from a county are not resident there, while others who are

resident in the county may begin their trip elsewhere. Data on residence are treated in a later section

The counties on either side of the Hudson River are basically different in their distribution of traffic among the airports. This is best seen in the percentages of passengers going to Newark Airport (57 percent of the passengers coming from the counties west of the Hudson River went to Newark Airport, while 10 percent of those from east of the river did so). Counties east of the Hudson River are similar in their distribution of passengers among airports, while the counties across the river show greater diversity. At one extreme, among the New Jersey counties, 82 percent of the total traffic from Bergen County is divided equally between Newark and La Guardia Airports, illustrating that Newark Airport does not have the great advantage for people in Bergen County that it does for those in other parts of Northern New Jersey. At the other extreme, 70 percent of the people leaving from Essex County used Newark Airport.

The data on which Table 7 is based are the same as those underlying Table 6, but rearranged to reflect the origin of all passengers who took flights from each airport. This table shows clearly that proximity and accessibility are strong factors in determining the areas from which each airport draws its patrons. La Guardia and New York International Airports draw overwhelmingly from the counties east of the Hudson River, while Newark draws from the two sides of the river about equally. The preponderant importance of Manhattan as a source of passengers is apparent for all airports, especially the two Long Island facilities.

Ground Transportation: The means of transportation by which air passengers get to the airports from the various counties is largely influenced by the distances, the transportation facilities and the time and expense involved in getting there. As each airport has a unique transportation situation, each is treated separately, in three parts of Table 8.

Table 8A distributes the major modes of ground transportation to La Guardia Airport-automobile, taxi and airport coach

for passengers coming from the entire Metropolitan Area and for some of the larger counties. The area west of the Hudson is treated as a unit since the data with respect to La Guardia Airport were too sparse to allow a breakdown by counties.

Manhattan exerts an extremely strong influence on the average distribution of modes of ground transportation to La Guardia Airport for the Metropolitan Area as a whole, since 58 percent of all La Guardia passengers came from this Borough. Manhattan's low percentage of car use to the airport probably results from the fact that a very large portion of the air passengers from Manhattan do not reside in the Metropolitan Area and therefore do not have the use of an automobile. As might be expected, the proportion of persons using airport coach is by far highest for

people coming from Manhattan, and is higher for those leaving Brooklyn than other counties. Over half of all the people going to La Guardia from Manhattan arrive at the airport by taxi, reflecting its relative inexpensiveness and convenience.

Table 8B which deals with New York International, shows that Manhattan provides almost the same proportion of the total traffic to this airport as for La Guardia. Here again, the percentage of auto use from Manhattan is the same as in Table 8A. However, a considerable shift has occurred with respect to the use of taxi and airport coach services. The percentage of airport coach users is twice that recorded at La Guardia, while the percentage of taxi users is only half that of La Guardia. Expense strongly influences the choice of ground transportation for those

not using a private automobile; airport coach fares are the same to both airports, while the taxi fare is more expensive to New York International because of its greater distance from Manhattan.

Table 8C concerns the use of ground transportation to Newark Airport. Not as many counties are listed individually as for the other airports, because of the smaller sample size. Manhattan, which contributed more than one-third of the traffic to Newark Airport during the survey period, distributed the ground transportation sharply in favor of airport coach. Essex County, where Newark Airport is situated, distributed the use of ground transportation mainly between automobile and taxi, with a small portion (5 percent) probably going by public buses.

# ORIGIN OF PASSENGERS DEPARTING FROM EACH AIRPORT AND GROUND TRANSPORTATION USED

FIGURE 9

No airport coach service to Newark Airport originates on the New Jersey side of the Hudson River. Though the sample size for Bergen and Union Counties is not large enough to interpret their results with certainty, the strength of the use of a private

## CROUND TRANSPORTATION TO EACH AIRPORT FOR RESIDENTS AND NON-RESIDENTS OF THE METROPOLITAN AREA (Excludes Transfer Passengers)

car is a probable measure of wide automobile ownership and excellent facilities provided by the New Jersey Turnpike and other roads.

Table 9 compares the mode of ground transportation to the airports used by residents and non-residents of the Metropolitan Area. This table illustrates that the use of a private car is mainly restricted to resident passengers, since fewer of the non-residents would be expected to have a private car available. For both residents and non-residents, relatively many more passengers used a car to get to Newark Airport than to the two New York Airports. This reflects the smaller proportion of persons coming from Manhattan, whence automobiles are relatively infrequently used.

Curiously, the greater rate of car usage at Newark compared with the other airports is primarily due to higher automobile use among non-resident air passengers. The high cost of trans-Hudson

# HOW RESIDENTS AND NON-RESIDENTS ARRIVE AT THE AIRPORTS

Source: Table 9

FIGURE 10

taxi service is reflected in the extensive use (44 percent) of the airport coach by non-residents in going to Newark Airport from Manhattan.

The Airport Used and Its Relationship to Residence: Table 10 distributes the 79,000 in-flight survey passengers who reside in

the Metropolitan Area, according to their county of residence, including a percentage distribution of the traffic that these counties provided to each of the airports. This table distinguishes itself from Tables 8A, 8B and 8C in that it deals with residents of the Metropolitan Area alone and in that the counties listed are not necessarily the point of origin for the air trip.

A notable point of information derived from Table 10 is the smaller importance of Manhattan as a source of travel, when con-

trasted with the percent of persons beginning their trip in the Borough. This is to be expected, since most of the people leaving from Manhattan either reside in other counties in the Metropolitan Area or reside outside the Metropolitan Area. Manhattan is the business and vacation center of the city, and its offices and hotels make it the major point from which people would be expected to depart for the airports.

The geographical differences between airports are highlighted in the case of Newark Airport where, except for Manhattan, traffic is primarily derived from the New Jersey counties. Essex County, which has the largest population and which embraces Newark Airport, quite naturally has the highest percent (23 percent) of the total traffic to that airport by *residents* of the

NOTE: Components add to less than totals because smaller counties were omitted.

Metropolitan Area. Essex County originates 34 percent of the total traffic to Newark provided by residents of the area west of the Hudson. Nassau County surprisingly accounted for 6 percent of Newark's passengers. It is quite possible that many of these people work in Manhattan, and began their trip from their office. The county distributions of La Guardia and New York International resident patronage show strong similarity.

Table 11 shows how the passengers residing in the Metropolitan Area in each of the principal counties were distributed among the three airports in the New York region.

The nearness of Westchester and Fairfield Counties to La Guardia Airport shows up in their preference for that airport. Bergen County residents indicate a preference for La Guardia Airport, despite the fact that Newark is at least equally as accessible as La Guardia Airport. The greater schedule frequency out of the New York Airport may influence the choice of the Bergen County residents. The question of location cannot be expected to influence greatly the choice between La Guardia and New York International by residents of Queens and Nassau Counties. La Guardia Airport's present superiority in convenience and frequency of flight accommodations make it the heavy choice over New York International. Residents of the other counties listed in the table apportion their traffic much along geographical lines.

### Characteristics of the Traveler

The preceding sections of this report discuss data concerning the destinations of the passengers, where they came from, what airports they used, how they got to the airport, and when they made their trips. This section will cover a series of tables about the passengers themselves. Data on their sex, age, occupation, industry and income will be examined to determine their relationship to the passengers' air travel.

Age and Sex, and Type of Ticket: Table 12 and Figure 11 distribute the passengers into four age groups, according to their sex and the type of ticket they purchased. Included for com-

parison is a distribution of the U. S. population, twelve years of age and over, into the same age and sex groups. Almost threefourths of the 194,000 domestic passengers who traveled on scheduled airlines during the survey period were men. The 25-44 group is clearly dominant, for both men and women, in all classes of tickets except the men with family plan tickets.

Male travelers accounted for 78 percent of all first-class ticket holders, reflecting the preponderance of business travel made by this group. Table 4 shows that 87 percent of all business travelers purchased first-class accommodations. The *proportion* of coach travel by women was considerably larger, although in actual *numbers*, more women traveled on first-class tickets. Relatively many more young people of both sexes traveled by coach than traveled first-class. The age distribution of coach passengers is similar to that of the U. S. population, in each category except the oldest; but the preponderance of men among coach travelers contrasts with the approximately equal distribution of sexes in

the population as a whole. The extremely high percentage of women who use the family plan results from the terms under which such tickets are sold.

Frequency of Travel: Table 13 gives a frequency distribution of the number of trips that respondents indicated they had made during the last twelve months. Passengers were requested to "count round trips as two" trips. It is quite apparent that most of the trips reported were made by a very small percentage of the

### Table 13

80-99	2,000	1	166,600	4
100–149	5,100	3	532,300	14
150 and over	2,100	1	376,600	10
Total	194,100	100%	3,771,100	100%

travelers. Passengers making 150 trips or more in the twelve months preceding the survey accounted for 10 percent of all trips reported, while the group itself amounted to only 1 percent of all the passengers. Similarly, 12 percent of all the passengers accounted for half (49 percent) of all the trips reported taken during the last twelve months. The passengers in this group averaged fifty or more trips per year.

Caution must be exercised in interpreting data on the number of trips made by passengers. The qualifications attached to the data are discussed in Appendix IV. While these considerations

limit the usefulness of data on absolute numbers of trips, they do not detract from cumulative comparisons of numbers of trips and persons, such as the following:

1% of all passengers took	10% of all air trips in a year
5%	28%
15%	56%
30%	78%
45%	89%
90%	99%

Income: Income is so much the "symbol of success," and at the same time the object of taxation, that it is extremely difficult to know whether people are reporting it accurately. The in-flight survey questionnaire was purposely designed as a folder so that answers would be concealed, and since the questionnaire was anonymous, as great an inducement to honesty as possible was provided. In addition to deliberate misstatement, there is also the real possibility that many people do not know their family income. This may especially be true of wives and children. There is no alternative but to accept the responses made.

Table 14 and Figure 13 separate air passengers into five income groups and the three types of tickets purchased by these groups. It is quite clear that the ratio of first-class accommodations purchased is higher as the family income of the passengers is higher. Fifty percent of all the respondents to the survey reported a family income of \$10,000 or more per year. More than 80 percent of these people bought first-class tickets. The lower income groups show a marked tendency to travel on coach flights. More than 40 percent of the passengers whose reported family incomes were under \$6,000 purchased tourist tickets.

<sup>1</sup> Adapted from Bureau of the Census, Current Population Reports, Series P-60, No. 15, April 27, 1954, Table 3. Adjusted as described in Appendix II.

# INCOME OF PASSENGERS AND CLASS OF TICKET

# INCOME OF PASSENGERS AND INCOME OF POPULATION

The difference between family incomes reported on the survey and for the United States as a whole is striking. The half of the passengers reporting family incomes over \$10,000 contrasts with 5 percent of the population generally. About four-fifths of

the population have incomes below \$6,000, while only 18 percent of the respondents reported incomes in these groups. As income data are generally reported either as the number of families with a given family income or as the number of persons with a given personal income, the data in Table 14 had to be adapted from U. S. Census data in the manner described in Appendix II.

Table 15 presents passengers in the various family income brackets, and the frequency of their travel. The average number of trips made in the last twelve months is far greater for passengers with higher family incomes. This ranges from the low average of four trips per year for those whose family income is under \$3,000 to a high of about thirty-six trips per year for those with family incomes in excess of \$20,000 per year.

These averages cannot be interpreted as relating to air travel by the population generally, because persons who made no trips had no possibility of being surveyed. The average is therefore the number of trips for those making one or more trips. The overstatement discussed in Appendix IV also applies here. The passengers in the two highest income categories accounted for 50 percent of all the passengers during the survey period, showing the highest rate of purchase of first-class tickets, and the highest average number of trips per year.

### Table 15

NUMBER OF TRIPS PER YEAR FOR PASSENGERS IN EACH INCOME GROUP (Excludes Transfer Passengers)

() Measure is probably accurate, but based on too few cases to assure that it is within the prescribed range of reliability.

NOTE: Breakdown into business and personal made only for more populous occupation categories.

Occupation: Table 16 and Figure 14 relate the occupation of passengers to the average number of trips made during the twelve months preceding the survey period. In addition, the number of passengers making business and personal trips is shown for the larger occupation groups. The largest group, "Professional-Technical" accounted for 30 percent of the total number of passen-

# OCCUPATION OF PASSENGERS

gers, and 80 percent of this group indicated they were on a business trip. The "Manager-Official" category was almost the same size; 85 percent of the people in this group stated they were traveling on business.

The "Salesmen" category, though a low third in rank, rep-

resenting about 9 percent of the total traffic, showed the highest average number of trips (36) during the twelve-month period. About 90 percent of the salesmen in the survey were on business trips. The "Secretary-Clerk" group accounted for a fair share (5 percent) of all the passengers. The average number of trips per year taken by this group, about six, is low when compared with other groups already mentioned. As shown, only one out of five trips made by secretaries and clerks is for business.

Housewives account for a large portion (12 percent) of the total travel of all occupation groups. The trips made by these women were almost entirely for personal reasons.

Table 16 also relates the number of passengers in each occupation with the importance of the occupation in the population generally, through use of a ratio of passengers, separately for those on business and personal trips, per 10,000 population. In this measure, secretaries and clerks are seen to rank high in personal travel. The manager-officials, who take about eight times as many trips as the secretary-clerks per unit of 10,000 population, take only slightly more personal trips (15) relative to their population than the thirteen trips reported by the secretary-clerk group. Mechanics, craftsmen and factory workers, as a group, took only two trips per 10,000 population for business or personal reasons combined.

## Characteristics of the Resident Travel Market

*Purpose of Trip:* Table 17 shows that among passengers living in the Metropolitan Area, 67 percent were leaving the area on business trips. Among non-residents the proportion was smaller, but this is not necessarily an indication that New Yorkers do more business traveling in general, because the survey does not cover all trips of non-residents, just those from New York.

There is a considerable difference among regions in the purpose of their residents' travel from New York, varying from 64 percent of business travel for residents of the East North Central region to 34 percent for Canadians.

Just as the residents of various sections of the country differ

\* Based on too few cases to merit publication.

in the reported purposes of their travel, so do the residents of the several counties within the New York/New Jersey Metropolitan Area. Table 18 shows the number of passengers residing in each county in the Metropolitan Area as well as the ratio of business to personal travel for passengers who live in the larger counties. The preponderance of business travel is especially manifest for passengers resident in Nassau, Westchester and Bergen Counties.

Table 19 compares traffic and population in each of the counties. Outstanding is the fact that the share of the traffic provided by Nassau, Westchester and Bergen markets in the Metropolitan Area is much greater than their share of the local population. The table also shows, however, that if one excludes business traffic from the measure, the share provided by these counties is considerably smaller. But as their percents of personal trips are no

smaller than their share of the population, it is clear that these counties have a high amount of business travel rather than a small amount of personal travel.

This table gives the percentage ratio of the number of travelers residing in each of the counties to the total number of resident passengers in the Metropolitan Area. Similar distributions are shown for all passengers on business trips and all passengers on

# Residence of Passengers Living in Metropolitan Area (Excludes Transfer Passengers)

Population data from Regional Plan Association:

Population, 1954-1975 in The New Jersey-New York-Connecticut Metropolitan Region, RPA Bulletin No. 85, November, 1954, Table V.

personal trips. If, in the case of Nassau, Westchester, and Bergen Counties, the comparison is limited to personal travel, these counties correspond more closely to the rest of the area. Westchester and Nassau Counties provided a rather sizeable share of the personal passengers as compared with their population, although not nearly to the same degree as their contribution to total business travel.

FIGURE 15

Although the ratio of business to personal travel by Manhattan residents was lower than the average for the Metropolitan Area, a larger share of the Manhattan residents traveled than reported for the general local population. Brooklyn, the largest in population, with 18 percent of the area's total, had only 7 percent of the passengers. Its share of the business passengers was even lower, 5 percent, while its share of the personal passengers was 10 percent.

The Income Factor: An obvious explanation for differences in volume of air travel among residents of the various counties is the difference in the distribution of incomes among the counties. Because air travel is so highly correlated with income, a moderate difference in family incomes results in substantial differences in air travel frequency. The question remains, however, whether the income patterns of residents of each county fully explain the observed differences in travel volumes, or whether there are other important basic factors that influence travel differently among the various counties.

Tables 20 and 21 were prepared in an attempt to identify such "other" factors. Their purpose is to isolate the income factor, so that differences remaining among the counties become apparent. To this end, separate data for the population, number of passengers and number of trips, as well as ratios of passengers and trips per unit of population, are shown for each income bracket and for each county. Comparison within a single income bracket then becomes possible among counties; income "is held constant."

There are two major limitations to the success of Tables 20 and 21 in abstracting the influence of income. One is the necessarily crude nature of the adjustment in Census data (described in Appendix II) to produce estimates of the number of persons in each category of 1954 family income. The other is the broadness of the "\$10,000 and over" income category. It was seen in Tables 14 and 15 that people whose family incomes were \$10,000 and over accounted for 50 percent of all passengers, and that the average trips made were considerably different for those in the \$10,000-\$19,999 group from those in the over-\$20,000 group.

() Measure is probably accurate, but based on too few cases to assure that it is within the prescribed range of reliability.

Notes: Income refers to number of persons with designated family income. See Appendix II for source of income data for population.

But as Census data show only a single group over-\$10,000, no distinction is possible above this figure. These limitations restrain the conclusions to be drawn from the tables and preclude significance in small differences in the figures shown. There is good reason to believe, however, that *substantial* differences in the tables are due to *real* differences among the counties which income alone does not explain.

Table 20 shows the number of resident passengers and total population in each income group for the Metropolitan Area and for each of the larger counties, as well as the ratio of passengers to each unit of 1,000 population. The data in the "all incomes" column of this table strengthen the idea that counties having more high-income families provide a greater portion of the travel market from the Metropolitan Area. Nassau, Westchester and Bergen counties each has a population of which about 40 percent have family incomes of \$6,000 or more per year. Each of these counties has well over the average number of passengers for each unit of 1,000 population.

Bergen County, the lowest of the three, has one and a half times the average for the area as a whole. These results confirm the indications of Table 18 and 19 that Nassau, Westchester and Bergen Counties produce a high degree of business travel. Examination of some of the income groups reveals some differences in the amount of travel made by people residing in different counties who have the same family income. Manhattan, Nassau and Westchester counties have the highest number of passengers for each unit of 1,000 population in the \$10,000-per-year-andover family income group, for which Table 15 shows that the highest frequency of travel takes place. This is also reflected in the number of trips made in the last twelve months, relative to the population in the top income group, shown in Table 21.

The values for these three counties are a high of about 54 passengers and 1,400 trips per unit of 1,000 population in Westchester, 47 passengers and 1,300 trips recorded in Nassau County, while Bergen County is fairly high, with 38 passengers and 1,050 trips for each 1,000 persons in the group earning \$10,000 or more per year. Except for Essex County, which was about average, the

( ) Measure is probably accurate, but based on too few cases to assure that it is within the prescribed range of reliability. (571.9)

Notes: Income refers to number of persons with designated family income. See Appendix II for source of income data for population. remaining counties are all below the average for the Metropolitan Area with respect to proportion of people with family incomes of \$10,000 or more. Manhattan, with the highest number of resident passengers and trips per 1,000 population in the over-\$10,000 group, differs from Westchester and Nassau Counties in that business travel as a proportion to total travel of residents was below the average for the area.

In summary, it is evident that among people whose family incomes are over \$10,000 there is a substantial variation from county to county in amount of air travel. This may be due to differences not disclosed by the Census in average incomes above \$10,000, or to a faulty adjustment of the population data; but more likely it points to a real difference among travel characteristics among counties. This difference noted in the high incomes is also evident in the income groups below \$10,000. Whether number of passengers per 1,000 population, or number of trips in the last twelve months per 1,000 population is used as an index of inter-county differences, the range in frequency of travel is substantial. In the \$6,000-\$9,999 income bracket, passengers varied from 2.2 per 1,000 population in the Bronx to 11.4 in Nassau. In trips per 1,000 population for this income group, the range was 13.7 for the Bronx to 231.9 for Fairfield.

Similar differences can be found among other income groups, pointing to the conclusion that income differences alone do not explain the very different air travel frequencies among the counties. Nor do accessibility to airports or the adequacy of schedules at the nearer airport appear to account for the differences. At each income level Brooklynites appear to do little air traveling, although that borough is conveniently located to all airports, especially the two airports having the wider range of schedules.

On the other hand, Bergen County, with much less convenient access to the airports than Brooklyn, is at most income levels above the Metropolitan Area average in the frequency of its residents' travel. There are evidently subtler forces at work that account for these differences, perhaps related to social status or national origin, which have not been measured here. Bare income statistics do not, of course, reveal how families with the

# FAMILY INCOME AND NUMBER OF TRIPS IN LAST TWELVE MONTHS FOR RESIDENTS AND NON-RESIDENTS OF THE METROPOLITAN AREA (Excludes Transfer Passengers)

Number of Trips	2,147,100	1	5	15	31	43	5
Average Number of Trips	19	4	7	13	21	39	8

same income may spend their money very differently. Certainly it is reasonable to surmise that there is a fundamental difference in spending behavior between a suburban family whose head is a business executive earning \$12,000 per year, and a city family with two or three blue-collar earners whose combined income is \$12,000 per year. Different parts of the Metropolitan Area have different proportions of these two types of families, and the many types in between.

Table 22 deals with the family income and the number of trips made in the last twelve months by residents and non-residents of the Metropolitan Area and includes the average number of trips for each income group. Half of all the domestic scheduled passengers were in the \$10,000-and-over income group, and they accounted for 72 percent of the total number of trips made during the last year. An examination of the residents and non-residents shows a similar distribution of the passengers and trips made in each of the income groups. Residents in all income groups combined averaged about the same number of trips (20) per year as did non-residents who averaged 19 trips per year.

## What Industries Generate Business Air Travel?

For the 60 percent of passengers traveling for business, the characteristics of their firms are as significant as the characteristics of the traveler. The freedom of choice of the business traveler is considerably reduced as to the decision on when he will travel, where he will go, the means of transportation he will use, his type of ticket, and in fact, whether the trip will be made. Some business travelers may have a good deal to say about these particulars of their trips, while others may be sent on trips by their superiors with all details taken care of by different persons.

There might be a maximum of flexibility in the case of an independent professional man, who has the choice of accepting or rejecting a commission in another city. Economic necessity may curb even his freedom as to whether or not to travel. In other cases, the decision that the businessman will make a trip is determined by someone other than the traveler, but the choice of the particular time and means of transportation may be left to the traveler.

In the United States: Table 23 and Figure 16 show that the industrial composition of business travelers leaving New York is dominated by manufacturing. Thirty-nine percent of the business travelers were in manufacturing, while in the working population as a whole, manufacturing accounts for 26 percent of the people. While the wholesale-retail segment of industry is well represented with 15 percent of the travelers, this is less than the 19 percent in the working population generally. No other industry group accounts for as much as 10 percent of the business travelers.

Although it is an insignificant part of the total air travel represented by the survey, the entertainment industry accounted for the highest number of business travelers compared to the number of persons in that industry throughout the country. Finance, insurance, and real estate contributed a large number of travelers in relation to the working population in this industry.

It is not possible to know whether the difference among industries in their air travel per 10,000 population is due to the extent of travel generally by persons in the industries, or whether it is due to the fact that the New York area specializes in some industrial functions. The high levels for entertainment and for finance indicate that for these industries, at least, it probably is New York's specialization that accounts for the high proportion of travel of persons within these industries.

Among passengers in each industry who were traveling during the survey period, there was a considerable variation in the average number of trips made in the last twelve months. These averages were computed for all passengers who reported an industry, whether they were on a business trip or a personal trip, since the number of trips in the past year as reported covered all purposes. The highest average is seen to be the fifty-seven trips for persons in the construction industry. As this industry did not have many passengers in comparison with its national population, it appears that not many people in the construction industry

travel to New York, but those who travel at all travel a great deal. This conforms to the general impression that it is an industry with many local workers and a relatively few highly mobile engi-

## INDUSTRY OF PASSENGERS

neers. People in finance, on the other hand, individually make fewer trips per year than the average traveler, although we have seen that the number of passengers during the survey period was high in relation to their national numbers. In the New York-New Jersey Metropolitan Area: Table 24 relates the industry of passengers residing in the Metropolitan Area to the local population in each industry. Therefore it describes the industry of passengers whose business takes them out of the area. It is not surprising, consequently, that wholesale and retail trade has one of the lowest ratios, as this industry probably attracts out-of-towners rather than sending out local residents. The high value for mining is reasonable; headquarters personnel of mining companies would inevitably travel to their operating locations.

### **Transfer Passengers**

In addition to the questionnaires representing passengers who originated their trip at La Guardia, New York International, or Newark Airports, there were 1,282 questionnaires representing some 44,000 transfer passengers. As previously stated, a transfer passenger is one whose air trip originated at some point outside the New York Area and who changed planes in New York to continue to his ultimate destination. Some of these passengers shuttled from one airport to another; others changed planes at the same airport. Passengers who stayed on a through-flight were not given questionnaires, and are not represented in the survey. Tables 25 and 26, which deal with transfer passengers, are confined solely to the origin and destination of the trips made by them.

Destination: Table 25 deals with the destination of the transfer passengers for the various regions of the United States. Their destinations were considerably different from those in Table 1 for originating passengers. New England, which was the destination of only 13 percent of originating passengers, is the area to which over a third of the transfer passengers were going. Most of the traffic to New England was destined for Boston, Providence, and Hartford-Springfield, with more than half of these passengers going to Boston. The Middle Atlantic states accounted for 17 percent of the total transfer traffic and almost half of this went to Philadelphia.

The other two large regions, the South Atlantic and the East North Central, each had about 15 percent of the total traffic with a third of the traffic for each region going to Washington and Chicago, respectively. The transfer traffic to remaining areas of the United States is small. Canada had a 4 percent share of the transfer passengers, and 75 percent of this traffic went to Montreal.

Origin: Table 26 concerns itself with the originating points of transfer passengers for the various regions and for some of the country's principal cities. It also includes those passengers who originated their trips at overseas points and are continuing their trip on domestic flights. The same regions that shared most of the traffic as destination points in Table 25 accounted for most of the traffic as points of origin in Table 26. New England, the South and Middle Atlantic states, and the East North Central states were the points of origin for two-thirds of the transfer passengers. Boston alone was the origin of 14 percent of these people. Overseas points accounted for origins of 11 percent of the total transfer passengers.

Transfer passengers whose point of origin was unknown accounted for 10 percent of all the origins. This figure is attributable more to confusion on the part of transfer passengers in responding to the question on the origin of their trip, rather than to a failure to answer the question at all.

It is clear from these tables that a major part of the transferring involves people going either to or from New England. Sixty-five
percent of the trips have either their origin or destination in New England, 30 percent in Boston alone.

### APPENDIX I

#### Survey Methodology

Selecting the Sample of Flights: The decision to have a survey supervisor on hand at the airport shortly before flight time of each sample flight largely dictated the structure of the sample. The three-week survey period had to be partitioned into uniform working shifts. Forty-two shifts were defined at each airport, by having two shifts per day; one from 6 A.M. to 4 P.M., the other from 4 P.M. to 2 A.M.—a total of 126 shifts for the three airports. It was assumed that the period from 2 A.M. to 6 A.M. was insignificant, and could be disregarded without distorting survey findings.

The number of shifts to be selected from these 126 was set at 23, or enough to yield at least 5,000 questionnaires. These shifts were allocated among airports as follows: 9 at La Guardia, 7 at New York International, and 7 at Newark, to achieve the most efficient distribution of the sampling effort.

The choice of shifts at each airport was made so as to assure representation of daytime and nighttime flights, and also weekend and weekday flights. These parts of the week constituted strata from which selections were made at random, the probability of selection being proportional to estimated variability in each stratum.

The next stage of sampling was the selection of flights within each selected shift at each airport. The number of flights to be chosen for each airline was determined before the selection according to the share of airport activity accounted for by the airline. These numbers established the proportions among airlines which were used in selecting flights in all shifts, with the result that the number of flights selected for any particular airline is approximately constant from shift to shift at any airport.

To make the flight selections within a shift, a sequence of airlines was pre-listed. A starting time and starting airline were randomly selected, and the nearest flight for the first airline was selected. The next time was about forty-five minutes later (to give the supervisor time to see the flight attendant before flight time), when the nearest flight of the second airline was chosen. If the specified airline did not have a flight within a reasonable interval of the selected time, the next airline was selected and the order interchanged for the two selections.

If a selected flight was missed in the field because of cancellations, delays of over an hour, or diversions, the same or a similar flight number was taken one or more weeks later.

Computation of Estimates in Tables of the Report: In using the sample to make estimates of the number of persons who have a certain characteristic out of the total number of passengers during the survey period, as much use as possible was made of control data. These control figures, obtained from airline operating records, were the number of passengers on flights during each period of the week, on first-class compared with coach flights, from each airport and for each airline. To illustrate the tie-in with these operating data (which are free from sampling error) the estimation of the number of passengers who reside in the Metropolitan Area is described below.

Questionnaires from flights in the sample showed that 45 percent of the passengers on the first-class flights of a particular airline departing from La Guardia Airport during a weekday evening were residents of the New York-New Jersey Metropolitan Area. As the total number of first-class passengers departing from La Guardia Airport on this airline during weekday evenings of the survey period is available from the operating records, the survey ratio can be applied to this known datum, and an estimate formed of the number of Metropolitan Area residents in this segment of the passenger population.

This estimate is therefore grounded in part on operating records and in part on the survey. An estimate is formed in a similar way for passengers of other airlines, other airports, other periods of the week, and on coach flights, and the results totaled to form an aggregate estimate of the number of Metropolitan Area residents departing from the three airports on all domestic flights of the thirteen airlines throughout the survey period. Although this is an accurate description of the result of the method used in producing the estimates appearing in the report, a number of computational short-cuts were used which allowed combining some of these steps without any sacrifice in accuracy.

Reliability of Data: The virtue of probability sampling is that it makes possible the estimation of degree to which the sample estimates can depart from the values that would have been obtained if all passengers had been included in the survey. Because the estimates of sampling variability are based on the dispersion of observations in the sample, they are different for each datum obtained on the survey. That is, the sampling variability is much less for information which shows great uniformity among respondents, than for questions to which people tend to report a wide variety of answers. But because the computation of these individual variability estimates is a highly involved mathematical procedure, an estimate of sampling variability was computed only for place of residence. This estimate serves to illustrate the principle, and also serves as an approximation of similar estimates of variance for other measures made from the sample.

The sampling variability is not only different for each datum being measured, but it increases only fractionally as compared with the reduction in size of the subsample upon which the datum is based. In other words, the distribution of the means of ground transportation used by persons starting their trip in Manhattan is more reliable than the distribution of those starting their trip in one of the smaller counties. Figure 17 describes this relationship. Although it was computed for residence only, it can serve as an approximation for other measures as well. This graph tells, for each number of interviews on which the measure is based, the coefficient of variation associated with the measure.

For example, a datum based on the full 6,500 non-transfer passenger interviews—such as the fact that 29 percent of passengers were traveling to the East North Central states—has a coefficient of variation of 2.5 percent. This can be interpreted to mean that it is "almost" certain that the percent of all passengers traveling during the survey period who were going to this region was between 27.5 per cent and 30.5 percent. These limits were computed by adding two coefficients of variation (5 percent) to the measure of 29 percent, and by substracting the same amount

# RELATIONSHIP OF CARD COUNT TO COEFFICIENT OF VARIATION

77

(note that the "5 percent" means 5 percent of 29 percent, not 5 percentage points). By using two coefficients of variation, the term "almost" used above means a confidence of 95 percent that the percent of travelers in the "universe" of 194,100 who traveled to the East North Central states was between 27.5 percent and 30.5 percent.

Assuming arbitrarily that a coefficient of variation of 20 percent was the maximum that should be allowed in the data, this chart shows that no data should be presented which constitute a breakdown of fewer than about 145 interviews. Consequently, the tables present without qualification only data based on 145 or more interviews. But because the computations of the coefficient of variation were believed to be rather conservative, the tables also show, between parentheses to designate the doubtfulness of their validity, figures which appear reasonable but are derived from only 75 through 144 interviews.

The tendency of samples to vary from the universe from which they are drawn is not the only source of possible error in the survey. Precautions were taken, however, through the use of a sizable program of checking, to keep to a minimum errors in coding the questionnaires, transcribing the codes to punched cards, tabulating and preparing tables for the text of the report.

One source of error, important in many surveys, is negligible in this survey: the error of non-response. Approximately 95 percent of all adult passengers on the selected flights completed a usable questionnaire. Consequently, even if the non-respondents differed considerably from those who completed questionnaires, their absence could not have made any appreciable distortion in the results.

### APPENDIX II

# Computation of Estimated 1954 Population of New York Metropolitan Area by County According to Estimated 1954 Family Income Levels

Family income was requested of each respondent to the in-flight survey. As the survey was conducted in September, 1954, the respondent probably answered in terms of his income for that calendar year. Therefore, to compare the income reported during the survey with income for the population in general, an estimate of the family income of people during 1954 was required. Inasmuch as the comparison was to be made for residents of each county of the New York-New Jersey Metropolitan Area, these estimates were needed for each county.

Data in just that form do not exist. The most nearly applicable are from the Census of Population of 1950, which reports the income of families in each county for 1949. These data do not conform to requirements in the three following respects: first, incomes changed between 1949 and 1954; second, populations have increased since 1949; and third, the number of *families* in each bracket of family income is not the same as the number of *persons* in each bracket of family income. The first two inadequacies are obvious, but the third is somewhat more subtle and merits clarification.

There is a tendency for higher-income families to be larger than lower-income families, a fact that may be due to the greater opportunity of larger families to have several earners. Therefore the likelihood of finding air passengers whose family incomes are high is greater than that of finding air passengers whose family incomes are low. The number of *families* in each bracket of family income had to be converted into the number of *persons* in each bracket of family income in order to compare the population at large with air passengers.

To convert the number of families in various family income brackets into the number of people in the same income groups, we had to assume, in the absence of more precise data, that the characteristics of the New York Metropolitan Area, as concerns family size for each income group, conformed to those for the United States as a whole. Table 3 of the "Current Population Reports," Bureau of the Census, dated April 1954, Series P-60, Number 15, shows the distribution of families and unrelated individuals by total money income for the United States as a whole, urban and rural for 1952.

The table shows a percentage distribution by income of the total number of families in each family size up to and including all those whose family size is seven or more persons. For the purposes of computing the average family size for each income group, we used the data as presented except that for the relatively few families consisting of seven or more persons, we arbitrarily assumed that eight persons would be the average family size for that group. This yielded the average family size for the total United States for each broad income group as follows:

- a) Under \$3,000-2.5 persons
- b) \$3,000-\$5,999-3.4 persons
- c) \$6,000-\$9,999-3.6 persons
- d) \$10,000 and over-3.8 persons

This relationship was applied to the New York Metropolitan Area through Table 45 of the U. S. Census of Population: 1950, Volume II, *Characteristics of the Population*, Part 32, New York; Part 30, New Jersey; and Part 7, Connecticut: Chapter B. This table contains a distribution of the number of families and unrelated individuals for each county in various income groups. It was assumed that family size is a stable phenomenon over a short period, and that it is justified to use the 1952 data as though they described 1949. Multiplying the average family size for the broad income groups by the number of families in Table 45 yields a distribution of the number of people in each family income group.

The next step was the adjustment of these 1949 data to reflect 1954 incomes. Using data from the Survey of Current Business and from the Statistical Abstract of the United States for 1954, it was determined that the average income had increased about 23 percent from 1949 to 1954. The Survey of Current Business, after taking seasonal adjustments into account, indicates that in 1949 the total personal income of the United States was 209.8 billions, which increased to 286.5 billions as of September, 1954. The Statistical Abstract gives the estimated number of families in 1949 as 37,750,000, which increased to 41,900,000 in 1954. The average family income derived in these two years from the above data was \$5,560 in 1949 and \$6,849 in 1954, representing an increase of 23 percent.

Knowing that the average income increased by 23 percent does not readily provide a basis for computing the change in the number of people in each bracket of family income. The reasoning used to bridge this gap is speculative. If we assume that there has been no change in the relative distribution of incomes, the increase in the average would mean that everyone's income increased by 23 percent. If we assume further that people are evenly distributed within each bracket of family income, 23 percent of the people in each bracket will move into the next higher bracket.

This shift in the income level was applied to the broad income groups for each county by subtracting 23 percent of the people from each income group and adding it to the next higher income group. It is not certain that the application of this 23 percent shift to each county in the New York Metropolitan Area reflects the actual distribution of the population by income. However, on the theory that the area conforms to the United States as a whole, there is evidence in support of this shift.

The Census Bureau's Current Population Survey yields an annual measure of the distribution of incomes for the United States as a whole. Application of the procedure used for the individual counties to this nationwide distribution for 1949, yields a distribution very similar to that found in the Population Survey for 1952, the latest year for which the data are available. As incomes have risen more slowly since that year, the procedure would probably yield a good approximation to the 1954 national income distribution, as well.

After adjusting for this shift in income levels from 1949, it was

then necessary to distribute the population by county to reflect the population increases from 1949 to 1954. This was done by applying a percentage distribution of the 1949 population by county to the similar data for 1954 as contained in Bulletin No. 85 dated November 1954, of the Regional Plan Association.

## APPENDIX III

## Comparison of Survey Data with External Information

The following is a comparison of the distribution of destinations for the in-flight survey with data supplied by the September 17– 30, 1953, Civil Aeronautics Board Origin and Destination Survey. This comparison is divided into two parts: a. for the regions of the United States and Canada, and b. for some of the principal cities to which air passengers traveled.

a. Region as a percent of total departures from New York:

Region	C.A.B. September, 1953	In-flight Survey September, 1954
All Regions	100%	100%
New England	13	13
Middle Atlantic	14	11
South Atlantic	21	20
East North Central	24	29
East South Central	3	3
West North Central	4	4
West South Central	5	5
Mountain	1	2
Pacific	8	6
Canada	7	5
Other	0	2

There is a great similarity between the two columns although the C.A.B. Survey covers traffic that took place a year earlier. As stated in the report, there is no reason to expect any radical change in the destinations of air passengers over a comparatively short period of time.

b. City as a percent of total departures from New York:

City	C.A.B. September, 1953	In-flight Survey September, 1954
1. Chicago	10.0%	11.3%
2. Boston	7.9	7.5
3. Washington, D.C.	7.1	7.2
4. Miami	5.9	4.7
5. Cleveland	3.1	4.3

City	C. A. B. September, 1953	In-flight Survey September, 1954
6. Pittsburgh	2.8	3.7
7. Detroit	4.0	3.1
8. Montreal	4.2	3.1
9. Los Angeles	3.9	2.4
10. San Francisco	2.7	2.1
11. Cincinnati	1.2	1.7
12. Milwaukee	1.0	1.6
13. Dallas	1.0	1.6
14. St. Louis	1.5	1.5
15. Denver	0.5	1.5

### Comparison of Survey Data with External Information

The cities listed above were the fifteen most frequent destinations to which respondents to the in-flight survey were traveling. The general similarity in the two surveys is particularly noteworthy in view of the fact that while controls were introduced into the selection of flights on the in-flight survey for such factors as airport, airline, day of week, and class of flight, destinations entered through chance alone. The September 1954, C.A.B. Study was not available at the time this report was prepared.

In-flight survey results that deal with local origins of the respondents are very similar to the Origin and Destination Survey conducted by the Port Authority in 1951. The earlier survey had more than 36,000 interviews compared with 6,500 for the inflight survey. The following table compares the local origins and destinations of the 1951 survey with the local origins of the inflight survey.

> Counties of Origin and Destination in 1951 Survey and Counties of Origin in 1954 In-Flight Survey

1951 O. & D. Survey	1954 In-flight Survey
100%	100%
87	84
56	54
3	2
6	5
9	8
	1951 O. & D. Survey 100% 87 56 3 6 9

County or Borough	1951 O. & D. Survey	1954 In-flight Survey
Nassau	5	7
Suffolk	1	1
Westchester	5	5
Fairfield	2	2
West of Hudson	13	16
Bergen, Rockland	3	4
Hudson	1	1
Passaic, Morris	1	2
Essex	5	5
Somerset, Middlesex	1	1
Union, Richmond	2	2
Monmouth	0	1

#### **Comparison of Survey Data with External Information**

The two columns are not entirely comparable, because the 1951 survey includes both overseas and domestic traffic and also gives combined data on the local origins and destinations of both inbound and outbound passengers. However, overseas traffic was a small part (10 percent) of the total traffic in 1951. The fact that the 1951 O & D survey combines local origins and destinations would not cause much change in the distribution among the various counties, on the assumption that most of the departing passengers would return to the same points. Notwithstanding these basic differences, the two surveys show a markedly similar distribution of the traffic for the counties of the Metropolitan Area.

The percentage of domestic passengers who reside in the Metropolitan Area remained virtually unchanged in both surveys. The 1951 O & D survey indicated that resident domestic passengers accounted for 43 percent of total domestic passengers compared with 41 percent for the 1954 in-flight survey.

### APPENDIX IV

## Qualifications on the Use of Data for the More Frequent Traveler

The in-flight survey was a probability sample, in essence, of all occupied plane seats on flights leaving the airports for domestic points during a three-week period. Undoubtedly, during the three-week period some individual persons occupied a seat on more than one flight. It is not therefore precisely a sample of all persons who made a flight at any time during the survey period. A person who made two flights from New York had double the chance of being included in the sample and is, therefore, represented twice in the results. It is not known whether anyone was actually *in* the sample twice; this is less important than their being *represented* by the sample twice.

People who made, for example, fifty air trips in a year from New York to a domestic point probably made, on the average, three trips during the survey period. They are therefore represented three times by the sample. There is no information on how many of the trips reported by passengers were, in fact, made from New York on domestic flights. At most, it would be onehalf, as the questionnaire asked that round trips be reported as two trips. It is probably considerably below this, however, since certainly some of the frequent travelers who are represented by the survey made their trips from points other than New York and may have made overseas trips. The result is that the true number of individuals who made a large number of trips is almost certainly somewhat smaller than indicated in Table 13.

Although there is no way of knowing the extent of this overrepresentation, a maximum can be assigned to it. It would be largest if all outbound trips were in fact made from New York to domestic points. On this assumption, the number of passengers making 100 or more trips drops from 4 percent to 1 percent, and their trips decrease from 24 percent of the total to 9 percent. Similarly, the number of passengers making fifty or more trips would be 6 percent of the total instead of 12 percent shown in Table 13, and their trips would be 28 percent instead of 49-percent.

As adjusting for multiple trips during the survey period reduces both the number of passengers and the number of trips, the cumulative percentages are essentially unaffected. Consequently, these cumulative percentages are approximately correct, regardless of how many trips were made by some passengers during the survey period. THE PORT OF NEW YORK AUTHORITY is the self-supporting corporate agency of the States of New Jersey and New York. Operating without burden to the taxpayer, it was created in 1921 by treaty between the two States to deal with the planning and development of terminal and transportation facilities, and to improve and protect the commerce of the Port District.

Port Authority Commissioners, six from each State, are appointed by the Governors of New Jersey and New York. They serve without pay for terms of six years.

The Authority's Lincoln and Holland Tunnels and George Washington Bridge spanning the Hudson River, and its Bayonne and Goethals Bridge and Outerbridge Crossing connecting Staten Island and New Jersey, join the States into one vast industrial, residential and recreational area.

The bi-state agency's terminal facilities include the Port Authority Bus Terminal, the Port Authority Building, housing the Union Railroad Freight Terminal, and the New York Union Motor Truck Terminal, in Manhattan; the Port Authority Grain Terminal at Gowanus Bay, Brooklyn; La Guardia Airport and New York International Airport in New York City; Newark Airport, Teterboro Airport, Port Newark, Hoboken-Port Authority Piers, and the Newark Union Motor Truck Terminal in New Jersey.

Charged by statute with the protection of port commerce, the Port Authority appears before such regulatory bodies as the Interstate Commerce Commission, the Civil Aeronautics Board and the Federal Maritime Board in the interest of the welfare of the unified Port Area. It maintains branch offices in Washington, D.C., Chicago, Cleveland and Rio de Janeiro, Brazil in the interest of promoting the movement of commerce through the Port of New York.
