| 16. Abstract <br> The report presents the details of a study carried out to test and implement a dilemma zone protection technique at three highspeed closely-spaced intersections on Roosevelt Blvd in Middletown, Ohio. Several factors that affect the testing and implementation of the dilemma zone reduction technique were considered as follows: (a) length of dilemma zone, which allowed for vehicular speeds ranging from $45 \mathrm{mph}(72.41 \mathrm{kmph})$ to $60 \mathrm{mph}(96.54 \mathrm{kmph})$ since speeds on these roadways are not uniform and tend to vary within a wide range; (b) detectors, which takes into account the varying speeds that exists on these roadways were located at $300 \mathrm{ft}(91.44 \mathrm{~m})$ or $600 \mathrm{ft}(182.88 \mathrm{~m})$, but not both; (c) green extensions, which varied from 1 sec to 5 sec in increments of 1 sec , with the "no green extension" being used as the base case; and (d) vehicle conflicts caused by (i) running red light (ii) stopping abruptly or (iii) accelerating through yellow representing the dilemma zone problem. The traffic data was collected during off peak hours in the morning ( $9 \mathrm{am}-11 \mathrm{am}$ ) and at night ( $8 \mathrm{pm}-10 \mathrm{pm}$ ). In all, 288 hours of data were collected on the six intersection approaches. The analysis revealed that that accelerating through yellow was the major conflict for all intersections, followed by running red and stopping abruptly respectively. The study indicated that the three types of conflicts namely, running red light, stopping abruptly and accelerating through yellow can be successfully used to identify vehicles that experience dilemma zone problems at signalized intersections. Overall, this study has shown that, for the roadway segment of Roosevelt Blvd between Highland and Armco, which has a speed limit of $45 \mathrm{mph}(72.41 \mathrm{kmph})$, dilemma zone protection can be effective by placing detectors at $300 \mathrm{ft}(91.44 \mathrm{~m})$ and providing a green extension of 3 sec on most, but not all, approaches. The effectiveness was more evident during the morning period than during the night period indicating that drivers' speed behavior may be different during daylight and night conditions. The study shows that there is no one "universal" rule for dilemma zone protection that would apply equally to all intersections because each intersection is unique in its geometric and operational characteristics and vehicular speeds on any intersection varies within a wide range. Recommendations for implementing the technique for future improvements of intersections identified with dilemma zone problems were made. |  |  |

## FIELD TESTING AND IMPLEMENTATION OF DILEMMA ZONE PROTECTION AND SIGNAL COORDINATION AT CLOSLEY-SPACED HIGHSPEED INTERSECTIONS

## 1 INTRODUCTION

Historically, high speed signalized intersections have reported many crashes and have always posed a challenge to traffic engineers for enhancing safety at these intersections. The area close to the intersection, called the dilemma zone, poses a high accident potential for the driver in stopping safely during the yellow interval or in proceeding through the intersection before the beginning of red. The driver is in a potentially hazardous situation whereby, if he tries to cross the intersection at the onset of red interval, he may end up in an angle accident with the cross street traffic or if he accelerates through yellow, he may end up in a rear-end collision. The uncertain situation in a dilemma zone can potentially lead to rear-end or right angle collisions.

Generally, the location of the driver on the intersection approach and the speed of the vehicle influence the driver's decision to stop or proceed when he sees the green signal changing to yellow. The minimum distance the driver requires to stop depends upon the speed of the vehicle, the driver's reaction time, and the deceleration rate. The clearing distance is the distance the vehicle travels between the times the signal changes to yellow to the time the signal changes to red. The stopping distance is the distance traveled by the vehicle between the times the signal changes to yellow to the time when the vehicle actually comes to rest. In Figure 1 the stopping distance is referred to as $\mathrm{X}_{\mathrm{s}}$ and the clearing distance as $X_{c}$. If $X_{s}$ is greater than $X_{c}$, and the vehicle is placed in

Figure 1. Dilemma Zone

between them, a dilemma zone is formed. In this situation, neither the distance to the intersection is adequate for stopping nor is the signal interval adequate for clearing the intersection. An example of clearing distance for a yellow interval of 4 sec is shown in Table 1. The stopping sight distances as suggested by AASHTO are shown in Table 2.

Table 1. Clearing Distance for 4 Sec Yellow Intervals

| Speed | Clearing <br> Distance, ft <br> $(\mathbf{m})$ |
| :---: | :---: |
| $\mathbf{m p h}(\mathbf{k m p h})$ | (Computed) |
| $35(56.32)$ | $204(62.18)$ |
| $40(64.36)$ | $236(71.93)$ |
| $45(72.41)$ | $264(80.47)$ |
| $50(80.45)$ | $292(89.00)$ |
| $55(88.50)$ | $320(97.54)$ |
| $60(96.54)$ | $352(107.29)$ |

Some researchers define the dilemma zone as the area on a high speed approach within which $10 \%$ of the drivers stop and $90 \%$ of the drivers proceed, when they see the signal changing to yellow. It occurs at the end of green phase, which is often associated with rear end and right-angle collisions [2]

In general, a high speed intersection consists of an intersection approach with vehicular speeds of 35 mph ( 56.32 kmph ) or higher. When signalized intersections are located adjacent to each other, then it is always advantageous to coordinate them. It helps to reduce the number of stops, maintain optimum travel speeds, reduce delay and reduce accident potential on roadways. Further, proper coordination can help in reducing vehicle emissions. Signal coordination depends upon the prevailing speed on the main street, spacing of signals, traffic volumes on major and side streets, and number of nonsignalized intersections. Among these factors, the traffic engineer can only exert control over the signal timing, at least in the short term. The traffic speed is not constant and varies with the time of day and motorists are heavily constrained in their choice of speeds during congested traffic conditions. Similarly, the traffic volumes are not constant and may be heavy inbound in the mornings and outbound in the evenings. Signal spacing is fixed for all existing systems. The signal timing parameters that are very important in the design of a coordinated system are:
a) Cycle length
b) Offsets
c) Green splits and
d) Phase sequence.

The speed of the vehicles at an intersection is not constant and drivers tend to vary their speeds according to the geometry of the intersection, existence of advance warning signs (if any), signal indicators, and the distance to the stop line. The $85^{\text {th }}$ percentile speed or any variation of the prevailing speeds is normally a basis for fixing the length of the intervals, or the timings for the dynamic signs with flashers, but neither the slow moving vehicles nor other variations are considered in the design. Researchers

have shown that a large number of drivers on high speed signalized intersections increase their speeds when they see yellow light or, even worse, go through red light without stopping. Hence, a large number of vehicles continue to experience dilemma zone problems at high speed signalized intersections. Most of the computer programs used for coordinating signals consider the movement of platoon of vehicles, not of individual vehicles, for optimization of stop, delay, or green bandwidth and hence the measures of effectiveness or performance are given on an aggregate basis. Those programs do not provide any clue whatsoever if an individual vehicle might experience dilemma zone at the intersections. Experiences have shown that, when adjacent intersections are closely spaced (1000 ft (304.8 m)-2000 ft (609.6 m) ) it is difficult to achieve the twin operational goals of dilemma zone protection and efficiency maximization (signal coordination) at high speed signalized intersections.

In the past, the researchers at University of Cincinnati developed a method by modifying the NETSIM code to calculate the dilemma zone for each vehicle. They computed optimal signal timings using PASSER II and TRANSYT -7F, and using the modified code they conducted simulation studies and found that the number of vehicles experiencing the dilemma zone can be significantly reduced by providing a green extension of 1 or 2 seconds. This report describes a testing and implementation of the technique, which was performed at several high speed signalized intersections in the City of Middletown, Ohio.

## 2 OBJECTIVES

The objective of this study is:
a) To field test and implement a dilemma zone protection technique at a high-speed signalized corridor with closely-spaced intersections.
b) To recommend a method for reducing dilemma zone problems that can be implemented by ODOT and cities/municipalities in Ohio.

## 3 BACKGROUND AND SIGNIFICANCE OF WORK

The problem of dilemma zone has been around for a long time, perhaps as long as traffic signals have existed at high speed intersections. The adequacy of signal change interval has been extensively examined ever since it was formulated by Gazis et al in the early 1960s [1]. It has been shown that dilemma zone protection can help reduce crashes at high speed intersections. Reports have noted a $54 \%$ reduction in crash frequency after installation of dilemma zone protection at high speed signalized intersections. Studies have shown an $8 \%$ reduction in crashes after installation of dilemma zone protection, and the low percentage was attributed to the poor design of protection [2].

Some of the methods that have been used to address dilemma zone problems are summarized below.

### 3.1.Adjustment of phase-change interval:

Adjusting the yellow time and "all-red" time has been shown to have reduced crashes at intersections. An onsite field observation of vehicles entering the intersection after the onset of yellow signal conducted in New York, showed that red light violations have been reduced drastically when the yellow signal was increased according to ITE's recommendations. A study conducted in Detroit, Michigan, comparing red light violations at an intersection with all-red time and an intersection without all-red time showed that there was drastic reduction of running red lights at the intersection with allred time [3].;

The following equation may be used to calculate the duration of the yellow interval [4]:

$$
\begin{equation*}
y=t+\frac{V}{2 a} \tag{1}
\end{equation*}
$$

where,

$$
\begin{aligned}
& \mathrm{y}=\text { length of the yellow interval, seconds } \\
& \mathrm{t}=\text { perception reaction time (usually } 1 \mathrm{sec} \text { ) } \\
& \mathrm{V}=\text { approach speed, } \mathrm{ft} / \mathrm{s} \\
& \mathrm{a}=\text { deceleration rate } \mathrm{ft} / \mathrm{s}^{2}
\end{aligned}
$$

If it is desired to provide an additional all-red clearance at the intersection, it may be calculated as follows:
$r=\frac{(W+L)}{V}$.
where,

$$
r=\text { length of all-red clearance, seconds }
$$

$\mathrm{W}=$ width of intersection, ft
$\mathrm{L}=$ length of the vehicle, ft
$\mathrm{V}=$ approach speed, $\mathrm{ft} / \mathrm{s}$

Hence, the total phase-change period is the sum of equations (1) and (2). Table 3 presents some theoretical minimum clearance intervals for various approach speeds and cross street widths [4].

| Table 3. Theoretical Minimum Clearance Intervals |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Approach Speeds | Yellow Interval | Total Clearance Intervals |  |  |  |  |
| $\mathbf{M p h}(\mathbf{k m p h})$ | (Sec) | (Yellow plus al-red clearance for crossing street widths, feet (m)) |  |  |  |  |
|  |  | $\mathbf{3 0 ( 9 . 1 4 )}$ | $\mathbf{5 0}(\mathbf{1 5 . 2 4})$ | $\mathbf{7 0}(\mathbf{2 1 . 3 4 )}$ | $\mathbf{9 0}(\mathbf{2 7 . 4 3})$ | $\mathbf{1 1 0}(\mathbf{3 3 . 5 3})$ |
| $20(32.19)$ | 3.0 | 4.2 | 4.9 | 5.5 | 6.2 | 6.9 |
| $25(40.23)$ | 3.0 | 4.2 | 4.7 | 5.3 | 5.8 | 6.4 |
| $30(48.28)$ | 3.2 | 4.3 | 4.8 | 5.2 | 5.7 | 6.2 |
| $35(56.33)$ | 3.6 | 4.5 | 4.9 | 5.3 | 5.7 | 6.1 |
| $40(64.37)$ | 3.9 | 4.8 | 5.1 | 5.5 | 5.8 | 6.1 |
| $45(72.42)$ | 4.5 | 5.1 | 5.4 | 5.7 | 6.0 | 6.3 |
| $50(80.47)$ | 4.7 | 5.3 | 5.6 | 5.9 | 6.2 | 6.4 |
| $55(88.51)$ | 5.0 | 5.7 | 5.9 | 6.2 | 6.4 | 6.7 |

However, increased yellow time can pose problems by increasing cycle lengths and delays. When there are closely spaced signalized intersections this may reduce the coordination among the signals.

### 3.2. Advanced Warning Signs

There are two broad classes of advance warning signs.
3.2.1.) Passive advance warning signs: These are passive signs just like many other traffic signs and they indicate the presence of an intersection ahead, and alert the drivers.
3.2.2.) Dynamic advance warning signs: These kinds of signs have flashers which start flashing a few seconds before the onset of the yellow interval and continue to flash until the end of the red interval. The most common sign used by the Ohio Department of Transportation (ODOT) is "Prepare to Stop When Flashing" (PTSWF) sign. ODOT also uses a Continuously Flashing Symbolic Signal Ahead (CFSSA) sign at high-speed intersections. The CFFSA sign, as the name suggests, has green, red, and yellow circles and flashers that flash all the time. The flashers are not connected to the signal controller and hence detectors, if any, have no effect on the flashing of the CFSSA sign. An additional sign that has been used by ODOT is the Flashing Symbolic Signal Ahead (FSSA) sign, which is similar to the PTSWF sign except that the texts are replaced by the green, yellow, and red circles. The flashers operate in the same way as the PTSWF sign. The signs are shown in figure 2.
Figure 2 Advance Warning Signs

(C) CFSSA \& FSSA signs
(b) PTSWF sign

(a) PSSA sign

### 3.3. Advanced Detection

In this system, loop detectors are used to detect approaching vehicles and the green time is extended. The detectors are placed close to the stop line and upstream of the intersection. The detectors are separated with a distance depending upon the location of the dilemma zone. When a vehicle is detected, a signal is sent to the signal controller and the green time is extended by a few seconds to accommodate the vehicle before the signal changes to red. The green time cannot be extended forever, and so the controller shifts the signal when the maximum green time is reached. The shift is abrupt and does not give enough warning to the drivers in the dilemma zone. When the detectors do not detect the vehicle on the major road, the right of way may shift to the minor road. In places of heavy traffic there are high chances for frequent maxouts, and reduce the level of protection of dilemma zone. In places where there are frequent maxouts, advanced warning signs are used in combination with advanced detectors. When the green time reaches a maximum, the controller starts a count down to the yellow signal, and the advanced warning signs are actuated. These help to increase the protection of dilemma zone.

### 3.4. Dynamic Dilemma Zone Protection

These systems attempt to allocate dilemma zone protection intelligently on the basis of vehicle needs at a particular time rather than as a result of fixed detection scheme. They do not make use of fixed detection near intersections, except for the stop line detection. The speed of each vehicle is measured well ahead of the intersection, and its travel time to the beginning and end of its individual dilemma zone is predicted. Then the green phase is ended when the number of vehicles is at a minimum. Examples of these systems are European systems like MOVA, LHOVRA, [5], SOS or D-CS developed by Texas Transportation Institute [6].

In- vehicle Detection Systems are new advancements in the area of dilemma zone protection. But they provide aid to individual vehicles. Young-Jun Moon et. al developed a system and field tested it and found that it could help eliminate dilemma zone, reduce red light violations and intersection collision. In order to determine whether a vehicle is in dilemma zone, the researchers, installed an antenna near the intersection, which reports number of seconds the light will remain green before the onset of yellow. The onboard device, which receives this information, estimates if the vehicle is in dilemma zone using the warning algorithm developed by the researchers and if so, it activates the visual and audible signs [7].

### 3.5. Simulation Study by the University of Cincinnati

The literature review has shown that the previous studies were mostly concentrated on determining the extent of dilemma zone, the driver behavior during the signal change interval, the placement of detectors to detect a vehicle in the dilemma zone, and the use of dynamic signs. Most of them were carried out from the point of view of an isolated intersection, and hence the results were not always applicable to a system of coordinated signals on an arterial corridor. Many arterials have several signals that are
closely spaced (1000 ft ( 304.8 m ) - $2000 \mathrm{ft}(609.6 \mathrm{~m})$ ). The researchers at the University of Cincinnati conducted simulated studies for signal systems that consisted of several signalized high-speed intersections. First, the researchers conducted a study of dilemma zone problems by collecting and analyzing traffic flow data at a high-speed intersection using five video cameras covering a stretch of $1400 \mathrm{ft}(426.72 \mathrm{~m})$. By figuring out the speeds and locations of the vehicles, when the signal turns yellow, they were able to determine whether a vehicle was in a dilemma zone or not. Their analysis showed that a maximum of green extension or cutback needed to get a vehicle out of the dilemma zone is generally no more than 2 seconds. Next, the researchers modified the NETSIM code, to calculate the dilemma zone for each vehicle. They performed a simulation study using the modified NETSIM code, on five signalized intersections on US 33 in Columbus, Ohio. Using PASSER and TRANSYT-7F programs, they found that if the green time was extended by one second, there would be a decrease of 33 percent for the vehicles experiencing dilemma zone, and by $94 \%$ if a maximum extension of five seconds was allowed. They concluded that by implementing a signal timing strategy for green extension, the number of vehicles experiencing dilemma zone could be significantly reduced.

Extending or cutting back green interval may be helpful to keep some vehicles away from the dilemma zone but may affect the following vehicles. Keeping this in mind, the extension (or cutback) must be done with the following vehicles also in mind, and also delay time for the cross traffic. Theoretically, one can keep on extending the green time, but it would affect the delay for cross traffic and the overall speed in the arterial Hence, it calls for an upper limit for the green extension or cutback, and the overall cycle length must be maintained in order to preserve the coordination of the series of traffic signals. To compensate the extension (or cutback), one can always reduce (or increase) the next green interval on the cross street or the main street.

## 4 TESTING AND IMPLEMENTATION OF DILEMMA ZONE TECHNIQUE AT CLOSELY-SPACED HIGH-SPEED SIGNAIZED INTERSECTION

### 4.1. Site Selection, Equipment Installation and Design of Experiment

In consultation with ODOT officials, it was decided to test and implement the technique at three signalized intersections on SR 122 Roosevelt Blvd in the City of Middletown, Ohio. The City had offered to install and maintain the equipment at its own cost if ODOT would allow it to keep the equipment upon the completion of this research project. Upon approval by ODOT, the University of Cincinnati purchased and delivered the equipment to the City for installation at Roosevelt Blvd. and the intersections of Highland, Wicoff, and Armco.

Roosevelt Blvd. is an urban divided highway with a number of closely-spaced signalized intersections and a speed limit of $45 \mathrm{mph}(72.42 \mathrm{kmph})$. The three intersections are closely spaced within a distance of $1 / 2$ mile. The distance from Highland to Wicoff is about 0.3 miles and the distance from Wicoff to Armco is about 0.2 miles. The equipment installed at the three intersections consisted of video cameras (Iteris) that allowed the setting up of two detectors at $300 \mathrm{ft}(91.44 \mathrm{~m})$ and $600 \mathrm{ft}(182.88 \mathrm{~m})$ on each intersection approach, thus eliminating the need for permanent installation of loop detectors in the pavement. At each intersection, one camera was installed on Roosevelt Blvd. in each direction, and one camera was installed on each direction of the side street resulting in a total of 12 cameras at the three selected intersections. Necessary cables and wires were provided to carry the signals from the detectors to the 170 E type controllers (Safetran) located at the intersections.

The intersection of Roosevelt and Highland is a four-legged intersection with two through lanes and one right turning lane in each direction. The eastbound approach has an exclusive left turn lane. However, left turns are prohibited in the westbound direction.

The intersection of Roosevelt and Wicoff is four-legged intersection with two through lanes, one left turning lane and one right turning lane in each direction.

The intersection of Roosevelt and Armco is a three-legged T-intersection with an opening in the median that allows westbound traffic and northbound traffic to make left turns.

A few photographs of the intersections and the cameras are provided in Figures 37. The layouts of the intersections are shown in Figures 1, 2, 3 of the Appendix.

Figure 7. Controller - Roosevelt Blvd at Wicoff

## Design of experiment:

The following factors were considered for the testing and implementation of the dilemma zone technique:

## (1) Length of dilemma zone

For a yellow time of 3 sec and a vehicle traveling at $45 \mathrm{mph}(72.42 \mathrm{kmph}$ ), we can calculate the clearing distance as follows:

$$
\text { Distance covered in } 3 \mathrm{sec}(\text { clearing distance })=\frac{45^{*} 5280}{3600} \times 3=198 \mathrm{ft}(60.35 \mathrm{~m}) .
$$

Similarly, distance traveled at other speeds can be calculated. Referring to Table 1, the stopping sight distances and clearing distances at different speeds are shown in Table 4.

Table 4. Calculating the stopping and clearing distances

| Speed <br> mph <br> $(\mathbf{k m p h})$ | Stopping sight <br> distances <br> $\left(\mathbf{X}_{\mathbf{s}}\right) \mathbf{f t}(\mathbf{m})$ | Clearing <br> Distance |
| :---: | :---: | :---: |
| $45(72.41)$ | $319(97.23)-383(116.74)$ | $198(60.35)$ |
| $50(80.45)$ | $376(114.6)-461(140.51)$ | $219(66.75$ |
| $55(88.50)$ | $432(131.67)-537(163.68)$ | $240(73.15)$ |
| $60(96.54)$ | $501(152.70)-633(192.94)$ | $264(80.47)$ |

Since vehicular speeds vary within a wide range, it was decided to allow for operating speeds between 45 mph ( 72.42 kmph ) and 60 mph ( 96.54 ).

Hence, the length of dilemma zone $=(501-198)=303 \mathrm{ft}(92.35 \mathrm{~m})$.

## (2) Locations of detectors

In order to allow for the time lag that occurs while detecting vehicles and actually displaying greens, we added $100 \mathrm{ft}(30.48 \mathrm{~m})$ to the above distance of $198 \mathrm{ft}(60.35 \mathrm{~m})$. Hence it was decided that the first detector would be placed at a distance of 300 ft $(91.44 \mathrm{~m})$ from the stop line and the second detector would be placed at $(300+300)=600$ $\mathrm{ft}(182.88 \mathrm{~m})$.

## (3) Green extensions

It was decided that all testing would be conducted in reference to the "base case", which consisted of no extension of green interval. Tests would be performed by providing green extensions of $1 \mathrm{sec}, 2 \mathrm{sec}, 3 \mathrm{sec}, 4 \mathrm{sec}$ and 5 sec . at the end of current green interval.
(4) Vehicular conflicts

The following vehicular conflicts were observed to determine if a vehicle experienced dilemma zone problem on the intersection approach [4]:
a) Ran red light
b) Stopped abruptly
c) Accelerated through yellow light.

## (5) Data collection periods

During peak hours, when traffic volume on the roadway is heavy, vehicular speed tends to be low; motorists tend to travel in platoons and are less likely to experience dilemma zone problems. Hence, the data needed to be collected during off peak hours when speed tended to be high and drivers had the maximum opportunity to experience dilemma zone problems. It was also important to collect data during both daylight and nighttime conditions. Based on a sample of 24 -hour volume data provided by the City, it was determined that the hours between 9:00am and 11:00am in the morning had low traffic volumes during daylight hours and hence it was decided to collect data during these hours. Similarly, $\mathbf{t}$ was determined that the hours between 8:00pm and 10:00pm at night during the winter months had sufficiently low traffic volumes to allow the researchers collect data for nighttime conditions.

## (6) Signal coordination

The signals were coordinated by the City of Middletown, which also developed and implemented the signal timings for the intersections under study. All three intersections had semi-actuated signals. Since the side street traffic volumes were quite low at these intersections, the frequency of vehicles on the side streets activating the
detectors and receiving green light was quite low. Hence, the City decided to set the signals on "recall" during the data collection periods so that the yellow interval would repeat itself during each cycle. Due to the "recall" effects, it was determined that any attempt to conduct delay data would not be meaningful and hence a delay study was not conducted.

The data were collected on weekdays by six graduate students, with each student counting the vehicular conflicts and other traffic counts on each approach. A sample data collection form is shown in the Appendix.

The data was simultaneously collected on all major approaches of the three intersections by six graduate students. At any one time, either the detector at 300 ft ( 91.44 $\mathrm{m})$ or at $600 \mathrm{ft}(182.88 \mathrm{~m})$, but not both, was activated. For the "base case", data was collected for 2 hours in the morning and 2 hours at night without providing any extension of the green time. Then, for each 2 -hour period in the morning and at night, data was collected by providing the green extensions of $1,2,3,4$, and 5 sec respectively. A pilot study was conducted on the first day to familiarize every one with the data collection method. Based on the experience on the first day, the data collection form was slightly modified. The following is a summary of the number of hours for which data were collected for this project.

Table 5. Total Hours of Data Collection

| Intersection | Number of hours of data <br> collected |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | Daylight <br> Conditions | Evening <br> Conditions |  |  |  |
| Roosevelt Blvd at Highland (Eastbound Approach) | 24 | 24 |  |  |  |
| Roosevelt Blvd at Highland (Westbound Approach) | 24 | 24 |  |  |  |
| Roosevelt Blvd at Wicoff (Eastbound Approach) | 24 | 24 |  |  |  |
| Roosevelt Blvd at Wicoff (Westbound Approach) | 24 | 24 |  |  |  |
| Roosevelt Blvd at Armco (Eastbound Approach) | 24 | 24 |  |  |  |
| Roosevelt Blvd at Armco (Westbound Approach) | 24 | 24 |  |  |  |
| Total |  |  |  | $\mathbf{1 4 4}$ | $\mathbf{1 4 4}$ |
| Total hours of observations $=\mathbf{2 8 8}$ |  |  |  |  |  |

The collected data for 288 hours were tabulated in Excel spreadsheets. The number of right turning vehicles, left turning vehicles, through vehicles and the number of vehicles stopping at red, running through red, passing through green, stopping abruptly on red, and accelerating through yellow were recorded into the spreadsheets. The "total traffic volume" was calculated as the sum of left turning, right turning and through vehicles. The number of vehicles running red, stopping abruptly at red, and accelerating through yellow was summed as "conflict volume". Since the traffic count varied from day to day and according to the time of day, "conflict percentage" was considered a good measure of effectiveness for dilemma zone protection. The "conflict percentage" was calculated as the "total conflict volume" over "total volume" as follows:

Conflict Percentage $=\frac{\text { Conflict Volume }}{\text { Total Volume }} * 100$
Hence the percent reduction in conflicts were calculated as
Percentage reduction of conflict percentage $=$
$\underline{\text { (conflict percentage at no green extension - conflict percentage at given green extension) }} * 100$
conflict percentage at no green extension

The results of the data analysis for each approach are discussed in the following sections.

### 4.2. Analysis of individual approaches

The data collected was tabulated in Excel spreadsheet. The traffic counts included right turning vehicles; left turning vehicles; through vehicles, vehicles running red, abruptly stopping at red, accelerating through yellow, and vehicles that stopped at red. The 'total volume" is the sum of left turning, right turning and through vehicles. The "conflict volume" comprised of vehicles that an red, abruptly stopped at red, and accelerated through yellow. The "total volume" during the morning period ranged from 800 vehicles to 1650 vehicles for two hours of observations, while the "conflict volume" ranged from 8 to 69 vehicles. The "total volume" during the night period ranged from 650 to 1200 vehicles, while the "conflict volume" ranged from 1 to 80 . The volume counts for all approaches are tabulated in Tables 6-11.

### 4.2.1. Roosevelt Blvd at Highland Street (Eastbound Approach)

The analysis for green extension at the intersection of Roosevelt Blvd and Highland (eastbound approach) provided insights into the operation of the traffic signal in relation to dilemma zone problem. The increase or decrease in dilemma zone conflicts was compared with the "base case" where no green extension was provided. During the morning period, when the detector was placed at $300 \mathrm{ft}(91.44 \mathrm{~m})$, the green extension of 3 sec reduced dilemma zone conflicts by $94 \%$. In contrast, the dilemma zone conflicts increased by almost $150 \%$ with the green extension of 1 sec , by $20 \%$ with the green extension of $2 \mathrm{sec}, 15 \%$ with the green extension of 4 sec and $100 \%$ with the green extension of 5 sec . Thus, the green extension of 3 sec gave the best results for reducing dilemma zone conflicts. During the evening period, with detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$, there were reductions of dilemma zone conflicts for all green extensions except for the extension of 4 sec . However, the highest reduction in dilemma zone conflicts was seen at 3 sec extension, which provided a reduction of $84 \%$.

During the morning period, with the detector active at $600 \mathrm{ft}(182.88 \mathrm{~m})$, the data showed that there were reductions in dilemma zone conflicts when the green extensions were 2 $\mathrm{sec}, 3 \mathrm{sec}$, and 4 sec respectively. But the extensions of 1 sec and 5 sec showed increases in dilemma zone conflicts. The 3 sec extension reduced the dilemma zone conflicts by $17 \%$. During the evening period, the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$ showed similar results, with the dilemma zone conflicts reducing for green extensions of $1 \mathrm{sec}, 3 \mathrm{sec}$ and 5 sec . An increase in dilemma zone conflicts was noted when the green time was extended by 2 sec and 4 sec . The highest reduction of $91 \%$ occurred when the green extension of 3 sec was provided.

Based on the above results, one could conclude that the green extension of 3 sec was most effective in reducing dilemma zone conflicts on the eastbound approach of Roosevelt Blvd. at Highland Street. The results are presented in the tables and figures below.

Note: In these tables, the positive sign (+) indicates a reduction in dilemma zone conflicts and the negative sign (-) indicates an increase.

Figure 11. Conflict percentages for $600 \mathrm{ft}(\mathbf{1 8 2 . 8 8 m})$ evening - Roosevelt Blvd at Highland (East Bound)

Further, an analysis was conducted by excluding the right and left turning traffic and considering the through traffic only (stopping at red, passing through green, running red, accelerating through yellow, abruptly stopping) as the "total volume". The analysis was done for the data collected with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$. It was found that though there was an increase in conflicts for most green extensions, a decrease was observed when the extension of 3 sec was provided during the morning period. The evening period had a different trend; there were reductions in dilemma zone conflicts observed, when the green extensions were provided, except for the 4 sec extension. The highest reduction was obtained when the green extension of 3 sec was provided. The results are shown in the following tables and figures.

Table 13. Conflict analysis (excluding left and right turning traffic) -Roosevelt at Highland (Eastbound approach)

### 4.2.2. Roosevelt Blvd at Highland Street (Westbound Approach)

The extension of green time at Roosevelt Blvd at Highland Street (westbound approach) showed that, with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ during the morning period, there was a reduction in dilemma zone conflicts when the green time extension was $2 \mathrm{sec}, 3 \mathrm{sec}, 4 \mathrm{sec}$ respectively. However, the highest reduction in dilemma zone conflicts ( $47 \%$ ) occurred when the green extension of 3 sec was provided. The data for the evening period showed that though there was an increase in dilemma zone conflicts when the green extensions of 1 sec and 2 sec were provided, and there were reductions in dilemma zone conflicts when the green extensions of $3 \mathrm{sec}, 4 \mathrm{sec}$ and 5 sec were provided. There was a reduction of $10 \%$ when the extension of 3 sec was provided.

The data collected with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$ showed similar patterns for the morning period. There was a reduction of dilemma zone conflicts when the green times were extended except that a marginal increase was observed when the 4 sec extension was provided. There was a decrease of $30 \%$ in dilemma zone conflicts when the 3 sec green extension was provided. For the evening period, with the detector at 600 ft ( 182.88 m ), the percentage conflicts increased when the green extensions were provided, unlike the other cases. It was observed that there was an increase of almost $90 \%$ for each extension.

Table 14. Conflict Analysis - Roosevelt at Highland (Westbound Approach)

| Detector <br> Position | Time of Day | Green <br> Extension | Percentage Conflict | Percentage reduction in percentage conflict |

|  |  |  |  |  |

Figure 15. Conflict percentages for $\mathbf{3 0 0 f t}(\mathbf{9 1 . 4 4 m})$ morning - Roosevelt Blvd at Highland (West Bound)

Figure 16. Conflict percentages for 300ft ( $\mathbf{9 1 . 4 4 m}$ ) evening - Roosevelt Blvd at Highland (West Bound)

Figure 17. Conflict percentages for $600 f \mathrm{f}$ ( $\mathbf{1 8 2 . 8 8 m}$ ) morning - Roosevelt Blvd at Highland (West Bound)

Further analysis was undertaken with the data collected with the detector at 300 ft (91.44 $\mathrm{m})$, as the data with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$ did not show consistent results. In this case, the left turning and right turning traffic was excluded from the total volume. The total volume included vehicles passing through green, stopping at red, abruptly stopping on red, accelerating through yellow and running through red. The conflict volume included those vehicles which ran red, stopped abruptly at red or accelerated through yellow. The analysis showed that there was a decrease in dilemma zone conflicts when the green extensions were provided, but the increase was marginal for the green time extensions of 1 sec and 5 sec extension during the morning period. The highest reduction occurred when the green extension of 3 sec was provided. During the evening period, except for the green extensions of 1 sec and 2 sec , there was a reduction in dilemma zone conflicts when the green extension of $3 \mathrm{sec}, 4 \mathrm{sec}$ and 5 sec were provided. The highest reduction in dilemma zone conflicts occurred when the 3 sec green extension was provided.

Evening

In summary, the study showed that the 3 sec green extension resulted in the highest reduction of dilemma zone conflicts for this intersection approach.

### 4.2.3.Roosevelt Blvd at Wicoff (Eastbound Approach)

On analyzing the data collected at the intersection of Roosevelt and Wicoff, with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ during the morning period, the researchers found that there was a reduction in dilemma zone conflicts when the green time extensions were provided. A decrease of $59 \%$ relative to the base case (with no extension) was observed when the 3 sec extension was provided, and $97 \%$ when the extension of 5 sec was provided. During the evening period, with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$, the collected data showed increase in dilemma zone conflicts when compared to the base case, for all the green extensions. During the morning period, with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$, the analysis showed that there was reduction of dilemma zone conflicts when green extensions were provided, except for the extension of 1 sec where a small increase was noted. Like in the previous intersection, it was observed that the extension of 3 sec produced the highest reduction of dilemma zone conflicts, where there was a reduction of $70 \%$ compared to the base case. On the other hand, with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$, the evening period did not show such a pattern; instead it recorded an increase in the dilemma zone conflicts when green extensions were provided. The percentages and the relative reduction in conflict percentages are shown in following tables and figures.

Table 16. Conflict analysis - Roosevelt at Wicoff (Eastbound approach)

| Detector Position | Time of Day | $\begin{gathered} \text { Green } \\ \text { extension } \end{gathered}$ | Conflict Percentage | Reduction in percentage conflicts |

Figure 25. Conflict percentages for $\mathbf{6 0 0 f t} \mathbf{( 1 8 2 . 8 8 m})$ evening - Roosevelt Blvd at Wicoff (East Bound)

An analysis was further carried out by excluding the right turning and left turning vehicles from the "total volume". Further, as the data with the detector at $600 \mathrm{ft}(182.88$ m ) did not show consistent results, the researchers only carried the analysis with the data obtained with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$. The results showed that there was a reduction of conflict percentages observed, and highest reduction of $58 \%$ in dilemma zone conflicts was observed when the 3 sec green extension was provided, which was a pattern similar to that observed in previous approaches. However, during the evening period, the data showed a different trend, there was an increase in dilemma zone conflicts observed with all green time extensions.

### 4.2.4. Roosevelt Blvd at Wicoff (Westbound Approach)

The dilemma zone conflicts observed at the intersection of Roosevelt at Wicoff (westbound approach), for the morning period with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$, showed an increase for all green extensions when green times were extended. But the observations for the evening period with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ showed that there was a decrease in dilemma zone conflicts of $30 \%$ except for 3 sec extension that showed a slight increase of $4 \%$. The conflict volumes observed during the morning period with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$ showed that there was a reduction of dilemma zone conflicts except for a marginal increase for 2 sec green extension. It was noted that there was a $60 \%$ decrease of observed dilemma zone conflicts for the green extension of 3 sec . During the evening period, with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$, it was observed that there was a decrease in dilemma zone conflicts except for the green extensions of 2 sec and 3 sec , where an increase of $5 \%$ and $42 \%$ were recorded. The observations are tabulated below.

Table 18. Conflict analysis - Roosevelt at Wicoff (Westbound Approach)

Figure 32. Conflict percentages for $600 \mathrm{ft}(\mathbf{1 8 2 . 8 8 m})$ evening - Roosevelt Blvd at Wicoff (West Bound)

A further analysis was performed excluding the left and right turning traffic in the calculation of the total volume. It was observed that there was an increase in conflicts for all green extensions during the morning period. In the case of the evening period, it was observed that there was a decrease in dilemma zone conflicts with the detector at 300 ft $(91.44 \mathrm{~m})$, except for the extension of 3 sec .

### 4.2.5. Roosevelt Blvd at Armco (East Bound Approach)

In the base case (where there was no green extension), the dilemma zone conflict was quite low at $0.678 \%$ during the morning period, and $2.817 \%$ during the evening period. Comparing the morning period, it was noted that the conflicts increased when
different green extensions were provided, for the detector at both $300 \mathrm{ft}(91.44 \mathrm{~m})$ and $600 \mathrm{ft}(182.88 \mathrm{~m})$. The conflicts were much higher than the base cases when the 2 sec green extension was provided. During the morning period, the dilemma zone conflict was very high ( $706 \%$ ) when the 3 sec green extension was provided with the detector at 300 ft ( 91.44 m ). Such an steep increase in conflict cannot be explained and one can only speculate if it was caused by human error on the part of the data collectors or any unusual circumstances on this day. At night, however, the dilemma zone conflicts for 3 sec extension decreased by $44 \%$ over the base case.

In general, it was observed that the dilemma zone conflicts during the evening period were lower when compared to the morning period. On the whole, it was observed that the evening conflicts decreased when the detector was placed at $300 \mathrm{ft}(91.44 \mathrm{~m})$ and $600 \mathrm{ft}(182.88 \mathrm{~m})$ respectively. Further it was noted that by providing a green extension of 3 sec , the conflict rate reduced by $44 \%$ and $42 \%$ when the detectors were placed at 300 $\mathrm{ft}(91.44 \mathrm{~m})$ and $600 \mathrm{ft}(182.88 \mathrm{~m})$ respectively.

Green Time Extension (Sec)

An analysis was carried out by excluding left and right turning vehicles with the detector placed at $300 \mathrm{ft}(91.44 \mathrm{~m})$. The analysis showed that an increase in conflicts was observed when the green extensions were provided. As in the previous analysis, there was a very high increase in the percentage of conflict when the green time was extended by 3 sec . The nighttime data showed a different pattern, in contrast to morning data. There was a decrease in dilemma zone conflicts for green extensions of 1 sec and 3 sec . The 3 sec extension had the highest decrease of $46 \%$. There was a marginal increase of $1.3 \%$ for the extension of 2 sec . When the green time was extended by 4 sec and 5 sec , there were increases in observed dilemma zone conflicts by $129 \%$ and $26 \%$ respectively.

Figure 42 Conflict percentages (excluding left and right turning traffic) $\mathbf{3 0 0} \mathbf{f t}$ ( 91.44 m ) evening -Roosevelt at Armco (Eastbound approach)

### 4.2.6.Roosevelt Blvd at Armco (Westbound Approach)

An analysis of dilemma zone conflicts at the intersection of Roosevelt Blvd. and Armco showed that there was reduction in dilemma zone conflicts when green extensions were provided during the morning period with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$, except for 1 sec
extension when an increase in dilemma zone conflicts was recorded. The highest reduction of $58 \%$ was recorded for the green extension of 3 sec . During the morning period, with the detector at $600 \mathrm{ft}(182.88 \mathrm{~m})$, it was observed that there was a decrease in dilemma zone conflicts for green extensions of $1 \mathrm{sec}, 2 \mathrm{sec}$ and 4 sec . But it increased by $99 \%$ when 3 sec extension was provided and by $88 \%$ when 5 sec extension was provided. Analyzing the night period, it was seen that the conflicts were reduced when the detector was placed at $600 \mathrm{ft}(182.88 \mathrm{~m})$; there was a decrease of $49 \%$ when the green extension of 1 sec was provided and a decrease of $58 \%$ when the green time was extended by 2 sec . But an increase of around $41 \%$ and $23 \%$ were observed for the extensions of 3 sec and 5 sec respectively.

Figure 44. Conflict percentages for 300ft ( $\mathbf{9 1 . 4 4 m}$ ) evening - Roosevelt Blvd at Armco (Westbound approach)

Figure 46. Conflict percentages for $\mathbf{6 0 0 f t} \mathbf{( 1 8 2 . 8 8 m})$ evening - Roosevelt Blvd at Armco ( Westbound approach)

Further analysis was carried out by excluding the right turns and left turns, and just considering the through traffic (vehicles running through green, stopping on red, running red, stopping abruptly, accelerating through yellow) as the total volume. The conflict volume was calculated by account ing for those vehicles which ran red, stopped abruptly, or accelerated through yellow. Considering all the intersections, results were more consistent when the detector was present at $300 \mathrm{ft}(91.44 \mathrm{~m})$ rather than at 600 ft . So the analysis excluding right turning and left turning vehicles were carried only for the observations with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$. The results are tabulated below.

Table 23. Conflict Analysis (excluding left and right turning traffic) -Roosevelt at Armco (Westbound approach)

| Detector <br> Position | Time of <br> Day | Green <br> Extension | Conflict <br> Percentage | Percentage <br> reduction <br> in conflict <br> percentages |
| :---: | :---: | :---: | :---: | ---: |
| 300 ft | Morning | 0 sec | 3.7529 |  |
| 300 ft | Morning | 1 sec | 4.4221 | -17.832 |
| 300 ft | Morning | 2 sec | 3.645 | 2.875 |
| 300 ft | Morning | 3 sec | 1.572 | 58.112 |
| 300 ft | Morning | 4 sec | 1.8993 | 49.391 |
| 300 ft | Morning | 5 sec | 1.8213 | 51.470 |
|  |  |  |  |  |
| 300 ft | Evening | 0 sec | 1.2732 |  |
| 300 ft | Evening | 1 sec | 1.3144 | -3.236 |
| 300 ft | Evening | 2 sec | 1.7793 | -39.750 |
| 300 ft | Evening | 3 sec | 1.3253 | -4.092 |
| 300 ft | Evening | 4 sec | 1.6928 | -32.956 |
| 300 ft | Evening | 5 sec | 2.2962 | -80.349 |

It was observed that there was a reduction of dilemma zone conflicts for the morning period, except for 1 sec green extension. Also, the highest reduction of $58 \%$ was seen when the green extension of 3 sec was provided. Considering the night period, there was not much reduction in conflicts, and in fact a small rise in conflicts, when green extension was provided, the highest being $80 \%$ compared to the base case, when the green extension of 5 sec was provided.

### 4.3. Analysis of Individual Conflicts

In an attempt to find out which, if any, of the conflicts contributed more significantly then the other conflicts, an analysis was carried out to calculate the individual conflicts (running red light, abruptly stopping, or accelerating through yellow). The individual percentages were found by dividing the volume for the particular conflict by the total volume. The analysis was carried out using the total volumes excluding left and right turning vehicles, and the data collected with the detector active at $300 \mathrm{ft}(91.44$ $\mathrm{m})$. The results are tabulated below.

An average of all the percentages were taken at each approach for both the morning and evening periods, and the pattern for each conflict (running red, abruptly stopping on red, and accelerating through yellow) was plotted as shown below.

Figure 50. Individual Conflicts for Running Red Light

Figure 51. Individual Conflicts for Stopping Abruptly at Red.

Intersection

Figure 52 Individual Conflict Percentage for accelerating through yellow

The results show that accelerating through yellow was most common followed by running through red and abruptly stopping during the change interval.

Figure 53.Summary of Individual Conflicts

## 5. CONCLUSIONS AND RECOMMENDATIONS

The report presents the details of a study carried out to develop a technique for the field evaluation of dilemma zones at high speed intersections in Ohio.

The objective of this study was fulfilled by testing and implementing a dilemma zone protection technique at three high-speed closely-spaced intersections on Roosevelt Blvd in Middletown, Ohio. Several factors that affect the testing and implementation of the dilemma zone reduction technique were considered:
(a) Length of dilemma zone, which allowed for vehicular speeds ranging from $45 \mathrm{mph}(72.41 \mathrm{kmph})$ to $60 \mathrm{mph}(96.54 \mathrm{kmph})$ since speeds on these roadways are not uniform and tend to vary within a wide range;
(b) Location of detectors, which takes into account the varying speeds that exists on these roadways;
(c) Green extensions, which varied from 1 sec to 5 sec in increments of 1 sec , with the "no green extension" being used as the base case;
(d) Vehicle conflicts caused by (i) running red light (ii) stopping abruptly or (iii) accelerating through yellow representing the dilemma zone problem.
(e) Data collection during the hours when traffic volume on the roadway was low and speed tended to be high both during daylight and nighttime conditions;
(f) Signal coordination at semi actuated signals, which required the signals to be set on "recall" for availing the yellow interval during each cycle for maximization of the data collection efforts.

The data was collected at the intersection of Roosevelt Blvd and Highland, Wicoff, and Armco. Two camera detectors (at 300ft (91.44m) and $600 \mathrm{ft}(182.88 \mathrm{~m})$ ) were placed on both approaches of each intersection at Roosevelt Blvd. The number of vehicles in dilemma zone was determined by counting the number of vehicles that ran red, abruptly stopped at red, and accelerated through yellow. The base case consisted of observations where no green extension was provided when the signal changed to yellow. The test cases consisted of green extensions of $1 \mathrm{sec}, 2 \mathrm{sec}, 3 \mathrm{sec}, 4 \mathrm{sec}$ and 5 sec when the vehicles were detected at $300 \mathrm{ft}(91.44 \mathrm{~m})$ or $600 \mathrm{ft}(182.88 \mathrm{~m})$, but not both. The traffic data was collected during off peak hours in the morning ( $9 \mathrm{am}-11 \mathrm{am}$ ) and at night ( $8 \mathrm{pm}-10 \mathrm{pm}$ ). In all, 288 hours of data were collected on the six intersection approaches. Conflict volumes (vehicles running red, abruptly stopping at red, and accelerating through yellow) were determined and conflict percentages were calculated for all cases of green extensions and detector locations. The analysis revealed that that accelerating through yellow was the major conflict for all intersections, followed by running red and stopping abruptly respectively.

The analysis showed that for both the eastbound and westbound approaches of Highland Street, the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ and the green time extension of 3 sec provided the maximum reduction in dilemma zone conflicts during both morning and night periods. Further analysis was carried out by excluding the left and right turning vehicles from the analysis; however, the dilemma zone reduction pattern did not change.

For the eastbound approach of Roosevelt Blvd at Wicoff, the extension of 3 sec provided a significant reduction in dilemma zone conflicts, except for the night
observations. If the left and right turning traffic was excluded, the results showed that the 3 sec green extension with detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ was effective during the morning period, while an increase in conflicts was noted for the night period. On the westbound approach of Roosevelt Blvd at Wicoff, a small increase in conflicts was noted for green extensions in many cases. But the morning period with detection at 600 ft ( 182.88 m ) showed a decrease in conflicts with a green extension of 3 sec .

On the westbound approach of Roosevelt Blvd at Armco, the 3 sec green extension with the detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ showed a reduction in conflicts for the morning period and an increase in conflicts for the night period. On the eastbound approach, the 3 sec green extension with detector at $300 \mathrm{ft}(91.44 \mathrm{~m})$ showed an increase in conflicts during the morning period, and a decrease during the night period.

The study indicated that the three types of conflicts namely, running red light, stopping abruptly and accelerating through yellow can be successfully used to identify vehicles that experience dilemma zone problems at signalized intersections. The use of these measures in implementing dilemma zone protection techniques in the future is important since currently no other direct measures are available for identifying dilemma zone problems at signalized intersections. Overall, this study has shown that, for the roadway segment of Roosevelt Blvd between Highland and Armco, which has a speed limit of $45 \mathrm{mph}(72.41 \mathrm{kmph})$, dilemma zone protection can be effective by placing detectors at $300 \mathrm{ft}(91.44 \mathrm{~m})$ and providing a green extension of 3 sec on most, but not all, approaches. The effectiveness was more evident during the morning period than during the night period indicating that drivers' speed behavior may be different during daylight and night conditions. The study shows that there is no one "universal" rule for dilemma zone protection that would apply equally to all intersections because each intersection is unique in its geometric and operational characteristics and vehicular speeds on any intersection varies within a wide range.

The technique used in the present study is simple to implement, and can be used at most of the intersections requiring the use of a detector. Vehicle detection can be provided by using loop detectors, if necessary, instead of video detectors as was done in this study. If the base conflict rate is relatively high, this technique has the potential of reducing dilemma zone problems if it is judiciously implemented.

## Recommendations

Improvements to intersections identified with dilemma zone problems may include the following tasks:
(a) Determine the speed limits and location of the detector: Since vehicular speeds on any roadway normally vary within a wide range, it is important for the traffic engineer to decide the speed limits for which dilemma zone protection would be maximized. Once this decision is made, the length of dilemma zone can be calculated and the location of the detector can be determined as shown in Section 4.1 (design of experiments).
(b) Collect sample data for base case: Before implementing the green extension, it is suggested that the traffic engineer collect 2-hour sample data during offpeak hours by counting vehicles that (a) run red light, (b) stop abruptly and (c) accelerate through yellow during the base case, that is, with no green extension.
(c) Implement the green extension: Once the green extension has been implemented, it is important to keep an eye on any abnormalities that might show up during the initial period.
(d) Fine tune the green extension: After allowing a familiarization period of a few weeks, repeat step (b) above for the green extension and make adjustments to the green extension as necessary.
