## EXECUTIVE SUMMARY

The Highway Safety Manual (HSM) provides comprehensive screening methodologies for microscopic entities such as segments, intersections, or corridors (AASHTO, 2010). While microscopic screening analysis can identify specific locations with high traffic crash risk, macroscopic screening investigation can consider an overall zonal level risk. In Phase I of the project, we followed the HSM screening procedure and extended it to the macroscopic level. Thus, our vision is to provide more practical and useful safety screening methodologies with comprehensive and balanced perspectives, macro- and micro-levels.

TAZs (Traffic analysis zones) have been most widely used as a spatial unit for macroscopic analysis; however, TAZs have two disadvantages: small size in urban areas and high percentage of zonal boundary crashes. Thus, in this study we have suggested two ways to overcome this issue. The first way is to develop a new study unit - Traffic safety analysis zones (TSAZs) by aggregating existing TAZs with similar crash rates. The second way is to apply a larger geographic unit such as TADs (Traffic analysis districts) or counties. We explored traffic safety not only at TAZs but also at TSAZs, TADs, and counties.

The research team developed Florida-specific SPFs (Safety performance functions) both at the macro-level and micro-level for 17 crash types. At the macro-level, overall, 204 SPFs were developed based on SWTAZs (Statewide TAZs), TSAZs, TADs, and counties. The research team has found various contributing factors for each traffic crash type at the macro-level. At the micro-level, overall, 404 SPFs were estimated for 13 segments and 16 intersection facility types.

Before the research team proceeded to the screening analysis, we performed a grid structure analysis to identify the best geographic units. The results showed that SWTAZs are the optimal zone system for screening non-motorized crashes such as pedestrian and bicycle crashes. On the other hand, TADs are found to be the best geographic unit for all other crash types.

Subsequently, screening analysis was conducted at the two-levels using PSI (Potential for Safety Improvement) and ranked. The screening results from the two levels were integrated, and all the results were provided in Excel spreadsheets for the convenient application for practitioners.

In summary, this project developed numerous Florida-specific SPFs both at macro-level and micro-level using statewide data. The research team explored 17 major crash types. The research team suggests using TADs as a geographic unit along with SWTAZs, TSAZs, and counties. Moreover, this project presents a separate and an integrated screening method that can be used to overcome the shortcomings of macro- and micro-level approaches by integrating the two levels. A reasonable approach is two steps: first identify the problematic areas; second zoom in with micro-screening to identify the specific problems and locations. It is intended that the results of the project would provide a comprehensive perspective on appropriate traffic safety plans and help practitioners screen and rank any area, segment, or intersection in the state.

## 1 INTRODUCTION

In Phase I of the project, we extended the screening procedure in Part B of the Highway Safety Manual from microscopic to macroscopic safety analysis. A regionalization method was used to develop a new study unit - Traffic safety analysis zones (TSAZs) - in order to overcome the limitations of the current Traffic analysis zones (TAZs) such as small unit sizes in the urban areas and a high percentage of zonal boundary crashes. The newly developed TSAZs were used as a basic geographic unit for the analysis. We selected three counties of Central Florida to apply the new screening process, and we have for the first time integrated both micro-level screening (i.e., identifying high risk locations such as intersections and roadway segments) with the newly developed macrolevel screening based on the zonal level. The procedure would help safety professionals and engineers to identify the locations and zones simultaneously that are in urgent need of safety treatments. The innovation is the combined screening and prioritization approach, which extends the current HSM approach to incorporate micro and macro levels. It is expected that this integrated screening approach can provide a comprehensive perspective by balancing two aspects: macroscopic and microscopic approaches.

Our novel integrated screening method overcame the shortcomings of the current macroand micro-level approaches and provided a comprehensive perspective on appropriate safety treatments by balancing the accuracy and efficiency of screening in Phase I. However, Phase I research illustrated that there are five main issues that need to be addressed before finalizing this work.

First, from a developmental point of view, the results must be inclusive and useful to the whole state. Currently we have used Orange, Seminole, and Osceola Counties as the study area. This area is part of FDOT District 5 and MetroPlan Orlando. Our current results are area specific at this stage, particularly because the research team has integrated TAZs to develop new zonal system: TSAZs. Thus, there is a need to make this system more general to the whole state so any district or MPO can effectively use the method. This project can be considered part of the "Big data" initiatives, as the data requirements are extensive and include complete planning, census, roadway, crash and other data to be integrated. There is a need to collect data from at least one or more districts (e.g., Tampa) and validate and refine our results to reach a common methodology for the 2-level screening across the state. By doing so, we can also examine the transferability of the SPFs to other regions.

Second, practitioners and policy makers may want to define zones with high crash risks at different macroscopic levels in Florida. Although TSAZs were developed and suggested for the macro-level screening in Phase I, larger geographic units such as statewide traffic analysis zones (SWTAZ), traffic analysis districts (TADs) and counties may be also useful from a practical perspective.

Third, from an applications point of view, we have already developed simple spreadsheets to implement the results that were delivered with the final report of Phase I. However, these spreadsheets can be enhanced to be more user-friendly and applicable to all regions in Florida. Also, the ideal spreadsheet should have the ability not only to
implement the results of phase I, but also to use the TSAZs, which are key to this work. Since the development of TSAZs is very complex and would not be easy for practitioners, the research team will either develop the TSAZ map for the whole state to facilitate the integration with the new spreadsheets or develop a mapping procedure to convert the TAZs into TSAZs. Another alternative approach would be to explore the applicability of existing geographical units for safety analysis such as SWTAZ, TAD and County.

Fourth, while this work is very useful from a safety perspective, accommodating the relationship with transportation demand will allow us to integrate safety and transportation planning process for better planning and safety prediction. We expect that there will be an opportunity for proactive safety management application in both long and short-range transportation plans.

Fifth, it would be desirable to extend the methodology to different injury levels, collision types (such as Pedestrians), times, and other conditions. For example implementation of screening by peak/off-peak or night/day, etc. The analysis would help produce well defined safety treatments for target crashes. Also, the latest 3-years of crash data (from 2010 to 2012) will be included, and the new analysis results will be compared to our current crash patterns in Phase I.

In summary, our vision is to provide more practical and useful safety screening methodologies and results for various crash types to FDOT and its districts. Based on the
above discussion, the main objectives of this second phase of the project are summarized as follows:

1. Develop TSAZs for other areas in Florida
2. Develop SPFs for 17 crash types based on micro-level (i.e., intersection and segment) and macro-level (i.e., SWTAZs, TSAZs, TADs, counties),
3. Identify hot zones at different spatial scales, such as SWTAZ, TAD and county,
4. Identify hot intersections and sections,
5. Use and adapt the HSM screening procedures,
6. Develop practical and user-friendly spreadsheets for the integrated screening,
7. Provide a stepwise procedure for integrating micro and macro screening results with transportation planning, and
8. Analyze hot sites/zones by various crash types, times, and conditions.

Chapters by each task in this research project are as follows:

- Chapter 1: Introduction
- Chapter 2: Data Collection (Task 1)
- Chapter 3: Data Preparation and Explanatory Analysis (Task 2)
- Chapter 4: Development of TSAZs (Task 3)
- Chapter 5: Development of Various SPFs at Macro-level (Tasks 4-6)
- Chapter 6: Macro-level Screening (Task 7)
- Chapter 7: Development of Various SPFs at Micro-level (Task 8)
- Chapter 8: Micro-level Screening (Task 8)
- Chapter 9: Integration of Macro-Level and Micro-level Screening Results (Task 9)
- Chapter 10: Integration Results (Task 9)
- Chapter 11: Development of Spreadsheets (Task 10)
- Chapter 12: Summary and Conclusion

## 2 DATA COLLECTION

In order to achieve the objectives as described in the previous chapter, the research team has collected crash, geographic boundary maps, demographic, socio-economic, facility, roadway, and traffic data from multiple sources. The crash data were obtained from FDOT (Florida Department of Transportation) CARS (Crash Analysis Reporting System) database and Signal Four Analytics (S4A). The geographic units such as TAZ, TAD, and county boundary maps were collected from FDOT District Offices/MPOs (or FDOT Central Office), U.S. Census Bureau, and Florida Geographic Data Library (FGDL), respectively. The demographic data and socioeconomic data were obtained from the U.S. Census Bureau and FDOT District Offices/MPOs (or FDOT Central Office). Lastly, the roadway and traffic data were collected from FDOT Transportation Statistics Office (TRANSTAT).

### 2.1 Crash Data

Figure 2-1 presents the overall process of the crash data collection from the two sources: FDOT CARS and S4A.Two forms of crash report are used in Florida. They are short form and long form crash reports. Crashes reported on the long forms involve either higher injury severity level or criminal activities such as hit-and-run or DUI. Since only long form crashes have been coded and archived in FDOT's CARS database. The research team has collected short form crashes from S4A. Therefore, the research team is able to use more complete crash data in this research project.

Figure 2-1 Crash data collection process

The number of crashes by severity levels, form types, and years is shown in Table 2-1. The number of injury and fatal crashes are stable across 3 years. However, it is evident that many PDO (Property Damage Only) crashes in 2010-2011 are under-reported compared to the number of PDO crashes in 2012. The possible reasons for the underreporting of PDO crashes are as follows: First, S4A started to collected short form crash data from all counties in Florida from 2010 onward. However, very few short form crash data were collected in 2010 except for select counties. The number of reported short form crashes has significantly increased since 2011. Second, the crash report form has been changed in 2011, and thus it is thought that there was confusion in submitting
crash reports. Third, The Florida Statutes regarding the crash reporting rules (F.S. 316.066) have been amended, and the number of reportable long form crashes has increased since 2012. The amended Florida Statutes regulate that traffic crashes should be reported by long form if a crash: 1) resulted in death of, personal injury to, or any indication of complaints of pain or discomfort by any of the parties or passenger involved in the crash; 2) involves DUI (Driving Under the Influence of alcohol or drugs) or hit-and-run (F.S. 316.061(1) and 316.193); 3) rendered a vehicle inoperable to a degree that required a wrecker to remove it from the scene of the crash; or 4) involved a commercial motor vehicle. These possible reasons may increase the number of PDO reported long crashes in 2012. The State is moving in the right direction and the data appear to be more complete. More PDO crashes are captured by both long and short forms. There is an indication that the percent of PDO crashes reported on Long forms is increasing. In July 2010 agencies were no longer required to submit short forms; this led to some agencies to change to all long forms. We are trying to use as much complete crash database as possible, while maintaining consistency. This is difficult as it is apparent that the changes in 2010 and 2011 are impacting the number of reported crashes. Up to the time of writing this report, the 2013 geocoded crash data were not available from FDOT.

Table 2-1 The number of crashes by severity levels, form types, and years

| Year | Severity levels |  |  | Source |  | Sum |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | PDO | Injury | Fatal | S4A | CARS |  |
| 2010 | 147,872 | 122,288 | 2,183 | 15,370 | 256,973 | 272,343 |
| 2011 | 169,484 | 102,398 | 2,103 | 53,343 | 220,642 | 273,985 |
| 2012 | 241,321 | 111,450 | 2,136 | 99,885 | 255,022 | 354,907 |
| Sum | 558,677 | 336,136 | 6,422 | 168,598 | 732,637 | 901,235 |

Figure 2-2 Comparison of the proportion of crashes by severity levels between long form only (left) and complete data (right)

As shown in Figure 2-2, crash data without short form reports (long form only data) have $45.9 \%$ of injury crashes and $53.2 \%$ PDO crashes. On the other hand, the percentage of injury crashes was dropped to $37.3 \%$ whereas PDO crashes were $62.0 \%$, which is obviously more reasonable. Using data with many missing PDO crashes may result in biased model estimation, particularly for total and PDO SPFs (no effect for injury and fatal SPFs). Therefore, the complete data including both short and long form data were used in this research project.

Each yellow point in Figure 2-3 represents the location of a traffic crash. Figure 2-4 shows the result of Kernel Density Estimation (KDE) of crashes, which defines the spread of risk as an area around a defined cluster in which there is an increased likelihood
of a traffic crash to occur based on spatial dependency. As seen in Figure 2-4, the largest cluster is located in Miami-Dade County, and Hillsborough and Pinellas Counties and Orange County have the second and third largest clusters, respectively. Also, Duval and Escambia Counties show the relatively high concentration of traffic crashes.

Figure 2-3 Crash locations (2010-2012)

Figure 2-4 Kernel density estimation of traffic crashes

### 2.2 Geographic Boundary Maps

Four types of geographic boundary maps were collected: regional TAZ (RTAZ), statewide TAZ (SWTAZ), TAD, and county maps. RTAZs are used by FDOT district offices and MPOs for regional transportation plans whereas the SWTAZ is used by FDOT Central Office for statewide transportation plans.

Moreover, SWTAZ needs to be explored to be determined if it is suitable for the traffic crash analysis. TAD is a new and highly aggregated geographic unit for traffic analysis. TAD may be useful if practitioners want to define crash patterns at a higher aggregate level. Lastly, Florida county maps will be used for the highest aggregation level screening analysis in this study.

Table 2-2 summarizes the collected RTAZ systems by districts. Overall, nine RTAZ systems were collected from seven FDOT districts/MPOs. Some areas located in the rural area have very large average TAZ areas, such as District $1\left(2.447 \mathrm{mi}^{2}\right)$. In contrast, some TAZs in the urban area have relatively small average TAZ areas, for example, the average area in District 6 is $0.431 \mathrm{mi}^{2}$. Figure $2-5$ exhibits the collected TAZ maps.

Table 2-2 Summary of RTAZ systems by districts

| District | Covered counties (No of counties) | $\begin{aligned} & \hline \text { Area } \\ & \left(\mathbf{m i}^{2}\right) \end{aligned}$ | $\begin{aligned} & \text { No of } \\ & \text { TAZs } \end{aligned}$ | Avg. area per TAZ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Collier, Charlotte, DeSoto, Glades, Hardee, Hendry, Highlands, Lee, Manatee, Okeechobee Polk, and Sarasota (12) | 11,977 | 4894 | 2.447 |
| $2{ }^{2-1}$ | Duval, Baker, Clay, Putnam, Nassau, and St. Johns | 4,117 | 1862 | 2.213 |
| 2-2 | Alachua (1) | 969 | 560 | 1.730 |
| 3-1 | Leon, Gadsden, Wakulla, and Jefferson (4) | 2,456 | 1309 | 1.877 |
| 3 3-2 | Bay, Calhoun, Escambia, Franklin, Gulf, Holmes, Jackson, Okaloosa, Santa Rosa, Walton, and Washington (11) | 8,214 | 1359 | 6.044 |
| 4 | Brevard, Indian River, St. Lucie, Martin, and Palm Beach (5) | 4,377 | 2454 | 1.784 |
| 5 | Orange, Seminole, Osceola, Lake, and Volusia (5) | 4,667 | 2028 | 2.301 |
| 6 | Broward and Miami-Dade (2) | 1,061 | 2459 | 0.431 |
| 7 | Pinellas, Hillsborough, Pasco, Hernando, and Citrus (5) | 3,275 | 2370 | 1.382 |
| Total | 51 Counties | 41,113 | 19,295 | 2.131 |

Figure 2-5 Collected RTAZ maps by district

SWTAZ, TAD, and county maps are summarized in Table 2-3. Considering the overall average regional TAZ area is $1.9 \mathrm{mi}^{2}$, SWTAZs are approximately 3.5 times larger (6.472 $\mathrm{mi}^{2}$ ) compared to regional TAZs. In case of TADs and counties, their areas are 50 and 450 times greater than those of the regional TAZs, respectively. Figures 2-6 to 2-8 depict the SWTAZ, TAD, and county map in Florida, respectively.

Figure 2-9 compares the regional TAZ, SWTAZ, and TAD in Leon County. RTAZ, SWTAZ and TAD have $1,309,353$, and 22 zones in the area, respectively. All these three zonal systems have tendency that their zones are smaller in the urban area whereas they are relatively bigger in the rural area. It is observed that zones are extremely small in case of the regional TAZ, especially in the urban area.

Table 2-3 Summary of SWTAZ, TAD and county maps

| Geographic Units | County (No of counties) | $\begin{aligned} & \text { Area } \\ & \left(\mathbf{m i}^{2}\right) \end{aligned}$ | $\begin{gathered} \text { No of } \\ \text { SWTAZs } \end{gathered}$ | Avg. area/SWTAZ |
| :---: | :---: | :---: | :---: | :---: |
| SWTAZ | All counties (67) | 55,127 | 8,518 | 6.472 |
| TAD |  | 61,368 | 594 | 103.314 |
| County |  | 56,695 | 67 | 846.194 |

### 2.3 Demographic and Socioeconomic Data

Demographic and socioeconomic data, which can serve as surrogate for traffic volumes that affect crash occurrence, are collected (Table 2-4). The demographic data such as population, population by race/ethnicity, and population by age group based on the census block were acquired from the U.S. Census Bureau. TAZ-based data were provided by FDOT District Offices/MPOs, which are called Zone Data (ZDATA). Single Family Units (SFU), MFU (Multi Family Units), and HMT (Hotel, Motel, and Timeshare) data were acquired, which are very closely related to trip generation. Furthermore, trip attraction factors such as employments and school enrollments are obtained based on TAZ maps.

Table 2-4 Summary of demographic and socioeconomic data

| Category | Variables | Base units | Sources |
| :---: | :---: | :---: | :---: |
|  | Population <br> Population by race/ethnicity <br> Population by age group | Census <br> block | U.S. Census Bureau |
| Demographic | Number of SFU <br> Percentage of the nonpermanent vacant in SFU <br> Percentage of the single family vacant <br> Population of SFU in residential area <br> Number of MFU <br> Percentage of the nonpermanent vacant in MFU <br> Percentage of the multiple family vacant <br> Population of MFU in residential area | TAZ | FDOT District Offices/MPOs or FDOT Central Office |
| Socioeconomic | Percentage of SFU owns no vehicle <br> Percentage of SFU owns one vehicle <br> Percentage of SFU owns two or more vehicles <br> Percentage of MFU owns no vehicle <br> Percentage of MFU owns one vehicle <br> Percentage of MFU owns two or more vehicles |  |  |
|  | Number of HMT rooms <br> Percentage of HMT occupancy <br> Number of HMT occupants |  |  |
|  | Industrial Employment Commercial Employment Service Employment Total Employment School Enrollment |  |  |
|  | Urban boundaries | Polygon | FGDL |
|  | Median household income | Block Group | U.S. Census Bureau |

### 2.4 Roadway and Traffic Data

Roadway/traffic data were collected from FDOT TRANSTAT and FDOT UBR (Unified Basemap Repository) (Table 2-5). The roadway data includes the location of intersections and traffic signals, total roadway length, and roadways by speed limits. Traffic data contain AADT (Annual Average Daily Traffic) and truck traffic volume. Roadway and traffic data are expected to be important contributing factors for the crash occurrence.

Table 2-5 Summary of roadway and traffic data

| Category | Variables | Base <br> units | Sources |
| :--- | :--- | :--- | :--- |
| Roadway | Intersection <br> Traffic signal locations | Point | FDOT <br> TRANSTAT |
|  | Total roadway length <br> Roadway by speed limits | Polyline | FDOT UBR |
| Traffic | AADT <br> Truck traffic volume | Polyline | FDOT <br> TRANSTAT |

## 3 DATA PREPARATION AND EXPLORATORY ANALYSIS

The newly collected data has been processed for developing various SPFs (Safety performance functions) in this chapter. This chapter summarizes descriptive statistics and several spatial distributions of the collected data by different geographic units. The geographic units include nine RTAZs, SWTAZs, TADs, and counties.

### 3.1 Regional Traffic Analysis Zone (RTAZ)

There are nine RTAZ systems in Florida. In general, each district has one RTAZ system. However, In the case of Districts 2 and 3, they have two RTAZ systems each. RTAZs do not cover all areas in Florida. For instance, some rural areas in Districts 2 and 3 are not covered by RTAZs.

### 3.1. 1 Regional traffic analysis zone 1

RTAZ 1 is located in Southwestern Florida. RTAZ 1 includes 12 counties in District 1: Collier, Charlotte, DeSoto, Glades, Hardee, Hendry, Highlands, Lee, Manatee, Okeechobee Polk, and Sarasota counties as shown in Figure 3-1. Descriptive statistics for roadway and crash variables are summarized in Tables 3-1 and 3-2, respectively. Moreover, Figures 3-2 and 2-3 display roadways by functional classifications and spatial distribution of total crashes in RTAZ 1.

Figure 3-1 Location of RTAZ 1

Table 3-1 Descriptive statistics for roadway variables in RTAZ 1

| Variables | Mean | Stdev | Min | Max |
| :---: | :---: | :---: | :---: | :---: |
| Area (mi ${ }^{2}$ ) | 2.447 | 13.020 | 0 | 602.794 |
| Total road length (mi) | 6.469 | 20.183 | 0 | 1233.702 |
| Road density ( $\mathrm{mi} / \mathrm{mi}^{2}$ ) | 12.936 | 11.795 | 0 | 424.666 |

Figure 3-2 Roadways by functional classifications in RTAZ 1

Figure 3-3 Spatial distributions of total crashes in RTAZ 1

### 3.1.2 Regional traffic analysis zone 2-1

District 2 has two RTAZ systems: RTAZ 2-1 (Jacksonville metropolitan area) and RTAZ 2-2 (Alachua County). RTAZ 2-1 covers 6 counties including Duval, Baker, Clay, Putnam, Nassau, and St. Johns. RTAZ 2-1 is located in the northeastern Florida as shown in Figure 3-4. Descriptive statistics for roadway and crash variables are presented in Tables 3-3 and 3-4, respectively. Furthermore, Figures 3-5 and 3-6 exhibit roadways by functional classifications and spatial distribution of total crashes in RTAZ 2-1.

### 3.1.3 Regional traffic analysis zone 2-2

RTAZ 2-2 only contains Alachua County. The location of RTAZ 2-2 is shown in Figure 3-7. Descriptive statistics for roadway and crash variables are presented in Tables 3-5 and 3-6, respectively. Furthermore, Figures 3-8 and 3-9 exhibit roadways by functional classifications and spatial distribution of total crashes in RTAZ 2-2.

### 3.1.4 Regional traffic analysis zone 3-1

RTAZ 3-1 covers 4 counties in the Capital region in District 3: Leon, Gadsden, Wakulla, and Jefferson counties. The location of RTAZ 3-1 is presented in Figure 3-10. Descriptive statistics for roadway and crash variables are presented in Tables 3-7 and 3-8, respectively. In addition, Figures 3-11 and 3-12 display roadways by functional classifications and spatial distribution of total crashes in RTAZ 3-1.

### 3.1.5 Regional traffic analysis zone 3-2

RTAZ 3-2 contains 11 counties in the northwestern area in District 3: Bay, Calhoun, Escambia, Franklin, Gulf, Holmes, Jackson, Okaloosa, Santa Rosa, Walton, and Washington counties. The location of RTAZ 3-2 is presented in Figure 3-13. Descriptive statistics for roadway and crash variables are presented in Tables 3-9 and 3-10, respectively. In addition, Figures 3-14 and 3-15 demonstrate roadways by functional classifications and spatial distribution of total crashes in RTAZ 3-2.

Figure 3-13 Location of RTAZ 3-2

Table 3-9 Descriptive statistics for roadway variables in RTAZ 3-2

| Variables | Mean | Stdev | Min | Max |
| :---: | :---: | :---: | :---: | :---: |
| Area (mi ${ }^{2}$ ) | 6.044 | 16.882 | 0.007 | 349.303 |
| Total road length (mi) | 15.988 | 28.492 | 0 | 485.286 |
| Road density ( $\mathrm{mi} / \mathrm{mi}^{2}$ ) | 10.925 | 8.628 | 0 | 50.648 |

### 3.1.6 Regional traffic analysis zone 4

RTAZ 4 is located in the Southeastern Florida in District 4. RTAZ 4 includes 5 counties in District 4: Brevard, Indian River, St. Lucie, Martin, and Palm Beach counties as shown in Figure 3-16. Descriptive statistics for roadway and crash variables are summarized in Tables 3-11 and 3-12, respectively. Besides, Figures 3-17 and 3-18 present roadways by functional classifications and spatial distribution of total crashes in RTAZ 4.

Figure 3-16 Location of RTAZ 4

Table 3-11 Descriptive statistics for roadway variables in RTAZ 4

| Variables | Mean | Stdev | Min | Max |

### 3.1.7 Regional traffic analysis zone 5

RTAZ 5 covers 4 counties in the Central Florida region, including Orange, Seminole, Osceola, Lake, and Volusia counties in District 5. The location of RTAZ 5 is presented in Figure 3-19. Descriptive statistics for roadway and crash variables are presented in Tables 3-13 and 3-14, respectively. In addition, Figures 3-20 and 3-21 display roadways by functional classifications and spatial distribution of total crashes in RTAZ 5.

### 3.2 Statewide TAZ (SWTAZ)

There are 8,518 SWTAZs in the Florida (Figure 3-28). SWTAZs cover the whole state and are used by FDOT Central Office for statewide long-term transportation plans. The collected data were processed based on SWTAZs and socio-demographic, roadway, and crash variables are summarized in Tables 3-19 to 3-21, respectively. Also, roadways by functional classifications and spatial distribution of total crashes are shown in Figures 329 and 3-30, correspondingly. SWTAZs will be used for developing Traffic safety analysis zones (TSAZs) in the following chapter.

Figure 3-30 Spatial distributions of total crashes in SWTAZ

### 3.3 TAD

Similar to TSAZ, TADs (Traffic analysis districts) cover the whole state (Figure 3-31). However, TAD is a much more highly aggregated geographic unit compared to TSAZ. TADs may be useful if practitioners want to define crash patterns at a higher aggregate level. The collected data were prepared based on TAD, and processed socio-demographic, roadway, and crash variables are summarized in Tables 3-22 to 3-24, correspondingly. Moreover, population density, roadways by functional classifications, and total crash maps are displayed in Figures 3-32 to 3-34, respectively.

### 3.4 County

Florida has 67 counties as presented in Figure 3-35. The counties will be used for the highest aggregation level traffic safety analysis. The collected data were also processed based on counties. Tables 3-25 to 3-27 show the summary of socio-demographic, roadway, and crash variables, correspondingly. Furthermore, population density, roadways by functional classifications, and total crash maps are exhibited in Figures 3-36 to 3-38, respectively.

## 4 DEVELOPMENT OF TRAFFIC SAFETY ANALYSIS ZONES

### 4.1 Overview

Many researchers have used TAZs as a spatial unit for their macroscopic traffic safety analysis (Ng et al., 2002; Hadayeghi et al., 2003, 2006, 2010a, 2010b; De Guevara et al., 2004; Naderan and Shahi, 2010; Abdel-Aty et al., 2011; Siddiqui et al., 2012; Siddiqui and Abdel-Aty; Abdel-Aty et al., 2013). Using TAZs in the macroscopic safety analysis is reasonable because they are transportation/traffic related zone system. However, Lee et al. (2014) pointed out that TAZs may have several limitations due to the following general zoning criteria for TAZs (Baass, 1980; Meyer and Miller, 2001):

- Minimizing the number of intra-zonal trips
- Recognizing physical, political, and historical boundaries

Basically TAZs are designed to analyze origin-destination pairs of trips generated from each zone. Thus, transportation planners need to minimize trips which start and end in the same zone. It is inferred that minimizing intra-zonal trips end up with the small size of TAZs. On the other hand, traffic safety analysts need to consider traffic crashes that occur inside zones. So they can be related to zonal characteristics with traffic safety of the zones. Therefore, it is possible that TAZs are too small to analyze traffic safety at the macroscopic level. Moreover, the small size of zones makes many zones with zero crash counts, especially for rarely occurring crashes such as fatal crashes. The second criterion abovementioned indicates that TAZs are usually divided by physical boundaries, mostly arterial roadways. Considering that many crashes occur on arterial roads, between zones, inaccurate results will be made from relating traffic crashes on the boundary of the zone
to only the characteristics of that zone (Siddiqui and Abdel-Aty, 2012). A simple way to overcome these two issues while using TAZs for safety analysis is to aggregate TAZs into sufficiently large and homogenous traffic crash patterns.

### 4.2 Regionalization

The research team decided to use SWTAZs (Statewide traffic analysis zones), instead of RTAZs (Regional traffic analysis zones). Although RTAZs are smaller and they have more detailed information, some regions especially in the rural area are not covered by RTAZs. Therefore the research chose SWTAZs as a base geographic unit for the regionalization. The existing SWTAZs were aggregated if they meet the following conditions:

- Zones are spatially contiguous; and
- Zones have same crash rate levels.

All SWTAZs were classified into several categories based on their crash rates (crashes per $\mathrm{mi}^{2}$ ) as shown in Table 4-1.

Subsequently, the neighboring zones with same categories are combined and new five zone systems were created (TSAZ1-5). The optimal zone scale for TSAZs was determined using Brown-Forsythe $\left(F_{B F}\right)$ test. $F_{B F}$ test evaluates whether the variance of variables of interests (i.e. crash rates) is equal when the scales of zone systems change. The underlying assumption of $F_{B F}$ is that there is greater variance in crash rates among smaller zones and a lower variance among larger zones. A high variance value means that the crash risks are local, whereas a low variance means that more global crash patterns
can be captured. The optimal zone scale ensures that the variance of crash rates is somewhere in between. Root et al. (2011), Root (2012) applied $F_{B F}$ tests to determine the optimal scale for their medical studies. Lee et al. (2014) used $F_{B F}$ test in determine the optimal scale for the new zone system for the traffic safety analysis.

Table 4-1 Classification of SWTAZs by crash rates

| No | Number of classifications | Classifications (based on percentile crash rate) | $\begin{gathered} \text { Range } \\ \text { (crash per mile) } \end{gathered}$ |
| :---: | :---: | :---: | :---: |
| 1 | 2 | Class 1: 50-100\% | 20000-8.122 |
|  |  | Class 2: 0-50\% | 8.120-0.000 |
| 2 | 3 | Class 1: 66-100\% | 20000-15.614 |
|  |  | Class 2: 33-66\% | 15.609-3.751 |
|  |  | Class 3: 0-33\% | 3.744-0.000 |
| 3 | 5 | Class 1: 80-100\% | 20000-30.249 |
|  |  | Class 2: 60-80\% | 30.229-11.978 |
|  |  | Class 3: 40-60\% | 11.975-5.260 |
|  |  | Class 4: 20-40\% | 5.258-1.616 |
|  |  | Class 5: 0-20\% | 1.615-0.000 |
| 4 | 7 | Class 1: 86-100\% | 20000-44.702 |
|  |  | Class 2: 71-86\% | 44.690-19.305 |
|  |  | Class 3: 57-71\% | 19.296-10.660 |
|  |  | Class 4: 43-57\% | 10.658-6.058 |
|  |  | Class 5: 29-43\% | 6.056-2.879 |
|  |  | Class 6: 14-29\% | 2.878-0.952 |
|  |  | Class 7: 0-14\% | 0.951-0.000 |
| 5 | 10 | Class 1: 90-100\% | 20000-66.773 |
|  |  | Class 2: 80-90\% | 66.681-30.249 |
|  |  | Class 3: 70-80\% | 30.229-18.126 |
|  |  | Class 4: 60-70\% | 18.102-11.978 |
|  |  | Class 5: 50-60\% | 11.975-8.122 |
|  |  | Class 6: 40-50\% | 8.120-5.260 |
|  |  | Class 7: 30-40\% | 5.258-3.118 |
|  |  | Class 8: 20-30\% | 3.116-1.616 |
|  |  | Class 9: 10-20\% | 1.615-0.548 |
|  |  | Class 10: 0-10\% | 0.546-0.000 |

$F_{B F}$ statistics are calculated using the following formula:
$F_{B F}=\left[\sum_{i=1}^{t}\left(\bar{D}_{i}-\bar{D}\right)^{2} /(t-1)\right] /\left[\sum_{i=1}^{t} \sum_{j=1}^{n_{1}}\left(\bar{D}_{i j}-\bar{D}_{1}\right)^{2} /(N-t)\right]$
where, $n_{i}$ is the number of samples in the $i$ th zone system, $N$ is the total number of samples for all zone systems, $t$ is the number of neighborhood groups $y_{i j}$ is the crash rates of the $j$ th sample from the $i$ th zone system, $\bar{y}_{i}$ is the median of crash rate from the $i$ th zone system, and $D_{i j}=\left|y_{i j}-\bar{y}_{i}\right|$ is the absolute deviation of the $j$ th observation from the $i$ th zone system median, $\bar{D}_{i}$ is the mean of $D_{i j}$ for zone system $i$, and $\bar{D}$ is the mean of all $D_{i j}$. The test assumes that the variances of different zones are equal under the null hypothesis. The calculated value was obtained using an $F$ distribution and $\alpha=0.1$ was used to test for statistical significance.

There are two steps involved in the $F_{B F}$ test. First, the variance between each zone system from TSAZ5 $(\mathrm{N}=4,907)$ to TSAZ1 $(\mathrm{N}=1,064)$ (Table 4-2). The largest zone system (TSAZ1) is compared for a total of four separate calculations of $F_{B F}$, as shown in the $F_{B F I}$ column of Table 4-2. Second, the variance between each neighborhood group from TSAZ1 to TSAZ4 and the smallest zone system (TSAZ5) is compared ( $F_{B F 2}$ ). TSAZ5 was used as the smallest zone system instead of SWTAZ $(N=8,518)$ since the variance of crash rates based on SWTAZs is very large (standard deviation=3,035.39), which shows the crash rates are not relevant to SWTAZs. A significant value of $F_{B F I}$ implies that the zone system does not reflect the global pattern of crash data; in essence, each zone is so small that it only captures local crash patterns. On the contrary, the significant value of $F_{B F 2}$ indicates that the zone data are not local; they are so large that local level crash
patterns are undetectable. The zone systems between lower and upper limits identify a spatial scale at which local level variation is still detectable but also captures larger zonal level crash characteristics.

Table 4-2 Brown-Forsythe test for determining optimal zone scale

| Zone <br> system | No of zones | Crashes per miles |  |  | Brown-Forsythe test |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | Stdev | $\mathrm{F}_{\text {BF1 }}$ | p-value | $\mathrm{F}_{\text {BF2 }}$ | p-value |  |
| SWTAZ | 8,518 | 144.5877 | 3035.39 | - | - | - | - |  |
| TSAZ5 | 4,907 | 14.614 | 53.510 | 3.630 | 0.0567 | - | - |  |
| TSAZ4 | 3,920 | 14.678 | 59.152 | 2.810 | 0.0936 | $\mathbf{0 . 0 1 0}$ | $\mathbf{0 . 9 4 3 6}$ |  |
| TSAZ3 | $\mathbf{3 , 0 4 1}$ | $\mathbf{1 4 . 9 4 7}$ | $\mathbf{6 6 . 5 5 7}$ | $\mathbf{1 . 9 6 0}$ | $\mathbf{0 . 1 6 1 7}$ | $\mathbf{0 . 0 6 0}$ | $\mathbf{0 . 8 1 3 4}$ |  |
| TSAZ2 | $\mathbf{1 , 7 5 4}$ | $\mathbf{1 5 . 6 3 4}$ | $\mathbf{8 6 . 8 4 3}$ | $\mathbf{0 . 4 4 0}$ | $\mathbf{0 . 5 0 8 1}$ | $\mathbf{1 . 0 7 0}$ | $\mathbf{0 . 3 0 0 2}$ |  |
| TSAZ1 | 1,064 | 18.036 | 110.703 | - | - | 3.630 | 0.0567 |  |

### 4.3 Traffic Safety Analysis Zones

The $F_{B F}$ test results for homogeneity of variance for crash rates under various zone scales are presented in Table 4-2. The $F_{B F I}$ test statistics shows that zone systems smaller than TSAZ3 (i.e., TSAZ4 and TSAZ5) have significantly different variance from that of TSAZ1. Thus, zone systems smaller than TSAZ3 are too small to capture global crash patterns. On the other hand, $F_{B F 2}$ test statistics indicates that the zone system larger than TSAZ2 (i.e., TSAZ1) is so large that it cannot capture local crash characteristics. Given the result, systems with TSAZ2 and TSAZ3 are considered optimal for macro-level crash
analysis. In conclusion, TSAZ2 was chosen as the final TSAZ since it can minimize boundary crashes and zones without certain types of crashes.

Table 4-3 contrasts the areas in SWTAZ and TAZ. As shown in the table, the number of zones in TSAZ $(\mathrm{N}=1,754)$ is one-fifth of $\operatorname{SWTAZ}(\mathrm{N}=8,518)$, and the average area in SWTAZ is $18.061 \mathrm{mi}^{2}$ whereas that in SWTAZ is $6.472 \mathrm{mi}^{2}$.

Table 4-3 Area in SWTAZ and TSAZ

| Zone system | No of zones | Average (mi ${ }^{2}$ ) | Stdev | Min | Max |
| :---: | :---: | :---: | :---: | :---: | :---: |
| SWTAZ | 8,518 | 6.472 | 24.803 | 0.000 | 885.322 |
| TSAZ | 1,754 | 18.061 | 226.645 | 0.000001 | 9395.0400 |

Table 4-4 compares the crash rates in SWTAZ and TSAZ. The mean crash rate in SWTAZ is 144.588 crashes per mile while that in TSAZ is almost one-tenth, 15.634 crashes per mile. Moreover, the standard deviation of crash rate in SWTAZ is very large, it is 3035.390 . After the regionalization, the standard deviation of crash rate in TSAZ became 86.843. It may imply that the new zone system, TSAZ have more homogenous crash rates compare to SWTAZ.

Table 4-4 Crash rates in SWTAZ and TSAZ

| Zone system | Average (crash per mi) | Stdev | Min | Max |
| :---: | :---: | :---: | :---: | :---: |
| SWTAZ | 144.588 | 3035.390 | 0.000 | 2517.986 |
| TSAZ | 15.634 | 86.843 | 0.000 | 20000 |

Table 4-5 contrasts the numbers and percentages of zones without crashes in SWTAZ and TSAZ. There is no big difference in the percentage of zones without total crashes before and after the regionalization. However, when it comes to fatal crashes, the percentage of zones without fatal crashes in SWTAZ is $63.0 \%$ while it is smaller in TSAZ (54.1\%).

Table 4-5 Zones without crashes in SWTAZ and TSAZ

| Zone system | Zones without total crashes |  | Zones without fatal crashes |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Zones | Percentage | Zones | Percentage |
| SWTAZ | 291 | $3.4 \%$ | 5363 | $63.0 \%$ |
| TSAZ | 90 | $3.0 \%$ | 1664 | $54.1 \%$ |

Table 4-6 compares the numbers and percentages of boundary crashes in SWTAZ and TSAZ. There are $68.2 \%$ boundary crashes in SWTAZ whereas there are $47.0 \%$ boundary crashes in TSAZ. In other words, more than $20 \%$ of boundary crashes has been reduced after the regionalization.

Table 4-6 Boundary crashes in SWTAZ and TSAZ

| Zone system | Boundary crashes | Total crashes | Percentage |
| :---: | :---: | :---: | :---: |
| SWTAZ | 614,671 | 901,235 | $68.2 \%$ |
|  |  |  | $47.0 \%$ |
| TSAZ | 423,275 |  |  |

Figures 4-1 to 4-4 compare SWTAZ and TSAZ maps in Districts 7 (Tampa and St.
Petersburg area), 6 (Miami-Dade and Broward area), 2 (Jacksonville area), and 5
(Orlando area), respectively. As presented in the Figures, the zones, especially in the urban area, are highly aggregated.

Figure 4-1 SWTAZ (upper) and TSAZ (lower) in District 7 - Tampa and St. Petersburg area

Figure 4-2 SWTAZ (upper) and TSAZ (lower) in District 6 - Miami-Dade and Broward area

Figure 4-3 SWTAZ (upper) and TSAZ (lower) in District 2 - Jacksonville area

Figure 4-4 SWTAZ (upper) and TSAZ (lower) in District 5 - Orlando metropolitan area

### 4.4 Suggestions for Using TSAZs

As described in the Phase I report and Lee et al. (2014), TSAZs based SPFs outperform SWTAZ based SPFs. The previous studies pointed out that TAZs have two disadvantages in exploring traffic safety: 1) small size in urban areas and 2) boundary crashes. Regionalization of TAZs by aggregating zones with similar crash rates can alleviate these weaknesses. In rural areas, however, the regionalization may excessively aggregate the existing TAZs because traffic crash rates are generally quite low. Also, the regionalization is not very essential in rural areas as rural TAZs are large in most of cases, different from urban TAZs. Therefore, it is recommended using TSAZs in large metropolitan areas. The research team summarized TSAZ-SWTAZ tables for the following urbanized areas in Appendix A.

- Miami-Dade MPO
- Broward MPO
- Palm Beach MPO
- Hillsborough MPO
- Pinellas MPO
- Pasco MPO
- MetroPlan Orlando (Orange, Seminole, and Osceola Counties)
- North Florida TPOs (Duval, Nassau, Clay, and St. Johns Counties)
- Sarasota-Manatee MPO
- Alachua County
- Leon County

## 5 DEVELOPMENT OF VARIOUS SPFS AT THE MACRO-

## LEVEL

In sections 5-1 to 5-4, the research team built various SPFs for four geographic units (i.e., SWTAZs, TSAZs, TADs, and counties). TAZs are the only traffic related zone system which delineated by state and local transportation officials. For this reason, TAZs have been widely adopted for macroscopic traffic safety analysis. However, TAZs have two possible limitations: boundary crash problem and small size. TSAZs were developed by aggregating current SWTAZs to alleviate the possible limitations while keeping advantages of the SWTAZs. TADs are new, higher-level geographic entities for traffic analysis. TADs can be useful if practitioners want to examine traffic crashes at a more aggregate level. Counties are the highest aggregation level of existing geographic units at the state-wide level. County-level analysis will allow practitioners to analyze counties with high traffic crash risks at the highest aggregation level.

The research team has developed many crash types in this research project. First, the research team developed SPFs by severity levels such as KABCO (total), KABC (fatal-and-injury crashes), KAB (fatal-and-injury crashes without possible injury) and KA (fatal-and-severe injury crashes). Second, the research team has built SPFs by time periods. The research team divided crashes into weekday and weekend crashes. The weekday crashes were classified into morning peak (07:00-08:59), off-peak (09:0015:59), evening peak (16:00-17:59), and nighttime (18:00-06:59). In case of the weekend crashes, since it is known that there is no significant variation in traffic volume during the
daytime as during weekdays, only daytime (07:00-17:59) and nighttime (18:00-06:59) were considered. Moreover, SPFs for four major collision types (i.e., single-vehicle, multiple-vehicle, pedestrian-involved, and bicycle-involved collision) were estimated. Lastly, SPFs for special crash types: adverse weather conditions (rain and fog) and DUI (Driving under the influence of alcohol or drugs) were developed.

Three types of SPFs by explanatory variable types were estimated: base, semi-fully specified, and fully specified SPFs. Base SPFs only have the exposure variable, VMT (vehicle miles traveled) in their models. VMT is essential to undertake meaningful and statistically sound traffic safety analyses (AASHTO, 2010) and is easy to collect and process. The semi-fully specified SPFs have both traffic (i.e., VMT, the proportion of heavy vehicles, etc.) and roadway variables (i.e., proportions of arterial/collectors/local roads, signal density, etc.). The variables used in the semi-fully specified SPFs are directly related to traffic or roadway characteristics. It is expected that the semi-fully specified SPFs have better predictability than the base SPFs. The fully specified SPFs have all the variables in their models, including not only traffic- or roadway-related variables but also demographic, socio-economic, and geographic variables. Several demographic, socio-economic, and geographic variables have been found to be key factors for traffic crashes at the macroscopic level (Abdel-Aty et al., 2013; Lee et al., 2014).

A negative binomial (NB) model was used to be consistent with the current Highway Safety Manual (AASHTO, 2010). The number of crashes is a non-negative integer,
which is not normally distributed. Poisson or NB models have the ability to develop the crash frequencies with explanatory variables; however, The Poisson model has been criticized because of its implicit assumption that the variance equals the mean. This assumption is often violated in the crash data in particular. Most of crash data have a greater variance than their mean and therefore the data is over-dispersed. NB models can relax the over-dispersion issue. The mean-variance relationship in NB distribution is as follows:

$$
\begin{equation*}
\operatorname{Var}(Y)=\mu+k \mu^{2} \tag{1}
\end{equation*}
$$

where, $Y$ is response variable, $\mu$ is mean response of the observation, and $k$ is dispersion parameter. Thus, if the dispersion parameter $k$ is close to zero, the variance is also near to the mean, which is the basic assumption of Poisson distribution. The existence of overdispersion is adjusted by the log-linear relationship between the expected number of crashes and covariates.

$$
\begin{equation*}
\log \left(\mu_{i}\right)=\beta_{0}+\sum \beta X_{i}+\varepsilon_{i} \tag{2}
\end{equation*}
$$

where, $i$ is an observation unit, $\mu_{i}$ is the expected number of crashes per year at $i$, $X_{i}$ is covariates, $\beta_{0}$ is the intercept, $\beta$ is the estimated coefficient vector and $\varepsilon_{i}$ is the random error term. The following function is the probability of mass function of the negative binomial distribution, where $\Gamma(x)$ is gamma function and over-dispersion parameter $\alpha$ should be greater than 0 .

$$
\begin{equation*}
\operatorname{Pr}\left(Y=y_{i}\right)=\frac{\Gamma\left(y_{i}+\frac{1}{k}\right)}{\Gamma\left(\frac{1}{k}\right) \Gamma\left(y_{i}+1\right)}\left(\frac{k \mu_{i}}{1+k \mu_{i}}\right)^{y_{i}}\left(\frac{1}{1+k \mu_{i}}\right)^{\frac{1}{k}} \tag{3}
\end{equation*}
$$

The abbreviations used in the modeling results were described in Table 5-1.

Table 5-1 Abbreviations used in the modeling results

| Category | Abbreviations | Meaning |
| :---: | :---: | :---: |
| Crash types <br> (Target <br> variables) | K | Fatal crash |
|  | A | Incapacitating injury crash |
|  | B | Non-incapacitating injury crash |
|  | C | Possible injury crash |
|  | O | Property damage only crash |
|  | WD_AMPEAK | Crash occurred during weekday AM Peak (07:00-08:59) |
|  | WD_OFFPEAK | Crash occurred during weekday off-peak (09:00-15:59) |
|  | WD_PMPEAK | Crash occurred during weekday PM Peak (16:00-17:59) |
|  | WD_NIGHT | Crash occurred during weekday nighttime (18:00-06:59) |
|  | WE_DAY | Crash occurred during weekend daytime (07:00-17:59) |
|  | WE_NIGHT | Crash occurred during weekend daytime (18:00-06:59) |
|  | SV | Single-vehicle collision |
|  | MV | Multiple-vehicle collision |
|  | PED | Pedestrian-involved collision |
|  | BIKE | Bicycle-involved collision |
|  | RAIN | Crash under rainy condition |
|  | FOG | Crash under foggy condition |
|  | DUI | Crash due to driving under the influence of alcohol or drugs |
| Explanatory variables | LN_HMTS_DENS | Natural log of hotel, motel, timeshare room density |
|  | LN_TOT_EMP | Natural log of total employment |
|  | LN_SCH_DENS | Natural Log of school enrollment density |
|  | P_FREEWAY | Proportion of freeway/expressway |
|  | P_ARTERIAL | Proportion of arterial roads |
|  | P_COLLECTOR | Proportion of collectors |
|  | P_LOCALROAD | Proportion of local roads |
|  | P_HIGHPSL | Proportion of roadway length with Posted Speed Limit higher than 55 mph |

Table 5-1, continued.

| Explanatory variables | LN_ROAD_DEN | Natural log of roadway density |
| :---: | :---: | :---: |
|  | P_AGE1524 | Proportion of residents between 15 and 24 years old |
|  | LN_SIGNAL_MI | Natural log of signals per mile |
|  | LN_INTER_MI | Natural log of intersections per mile |
|  | LN_VMT | Natural Log of VMT |
|  | P_HEAVY_VMT | Proportion of heavy vehicle in VMT |
|  | LN_BIKELANE | Natural log of bike lane length |
|  | LN_SIDEWALK | Natural log of sidewalk length |
|  | LN_TOT_COM | Natural log of number of total commuters |
|  | P_COM_PUB | Proportion of commuters using public transportation |

### 5.1 Development of Various SPFs for SWTAZs

There are 8,518 SWTAZs in Florida (Figure 5-1). SWTAZs are used by FDOT Central Office for statewide long-term transportation plans. SWTAZs have been widely adopted for macroscopic traffic safety analysis since they are the only spatial unit related transportation. One of the advantages of using SWTAZs is that we can directly use transportation planning data based on SWTAZs for traffic safety analysis. Moreover, SWTAZ based SPFs enable transportation planners to take traffic safety into consideration in the long-term transportation planning.

Figure 5-1 Statewide traffic analysis zones (SWTAZs)

Tables 5-2 to 5-4 present the base SPFs by severity levels, time periods, and collision types or special events, respectively. The coefficients of the natural $\log$ of VMT (LN_VMT) have a positive sign in all the base SPFs as expected. The values in parentheses indicate p -values for estimated coefficients.

Table 5-2 Base SPFs by severity levels based on SWTAZs

Tables 5-5 to 5-7 present the semi-fully specified SPFs by severity levels, time periods, and collision types or special events, correspondingly. The proportion of arterials (P_ARTERIAL) is not significant in any semi-fully specified SPFs based on SWTAZs whereas the proportion of collectors (P_COLLECTOR) is significant in many semi-fully specified SPFs and it is negatively related to crash counts in most of SPFs except for crash occurred in weekend daytime (WE_NIGHT), pedestrian-involved crash (PED), bicycle-involved crash (BIKE), fog-related crash (FOG) and DUI-related crash (DUI). On the other hand, the proportion of local roads (P_LOCALROAD) is significant in all crash types and it has a positive relationship with the crash counts. It was shown that the natural $\log$ of signals per mile (LN_SIGNAL_MI) is significant in SPFs of total crash (KABCO), crash during weekday off-peak (WD_OFFPEAK), crash during weekday nighttime (WD_NIGHT), crash during weekend nighttime (WE_NIGHT), single-vehicleinvolved crash (SV), multiple-vehicle-involved crash (MV), pedestrian-involved crash (PED), bicycle-involved crash (BIKE), and fog-related crash (FOG). It is interesting that effect of the signal density is not always consistent. In SPFs of total crash (KABCO), crash during weekday off-peak (WD_OFFPEAK), crash during weekday nighttime (WD_NIGHT), crash during weekend nighttime (WE_NIGHT), multiple-vehicleinvolved crash (MV), pedestrian-involved crash (PED) and bicycle-involved crash (BIKE), the coefficient of signal density has a positive sign while it has a negative sign in single-vehicle-involved crash (SV) and fog-related crash (FOG) SPFs. It is possible that the natural log of signals per mile (LN_SIGNAL_MI) shows the degree of urbanization. Then it may imply that total crashes, crashes occurring in non-peak hours, multiple-
vehicle, pedestrian, and crashes are more likely to occur in the urban area. In contrast, single-vehicle and fog-related crashes are more likely to happen in the rural area. It was revealed that the proportion of heavy vehicle in VMT (P_HEAVY_VMT) is consistently negatively associated to the majority of crash types; except for single-vehicle-involved crash (SV). It was shown that the proportion of heavy vehicle in VMT (P_HEAVY_VMT) is not significant in the SPF of single-vehicle-involved crash (SV).

Tables 5-8 to 5-10 present the fully specified SPFs by severity levels, time periods, and collision types or special events. It was uncovered that the natural log of hotel, motel, timeshare room density (LN_HMTS_DENS) is significant in many SPFs. The coefficient of the natural $\log$ of hotel, motel, timeshare room density (LN_HMTS_DENS) has a positive sign in SPFs of total crash (KABCO), crash during weekday off-peak (WD_OFFPEAK), crash during weekday PM peak (WD_PMPEAK), crash during weekday nighttime (WD_NIGHT), crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), multiple-vehicle-involved crash (MV), pedestrian-involved crash (PED), bicycle-involved crash (BIKE), and DUI-related crash (DUI) while it has a negative sign in SPFs of fatal and incapacitating injury crash (KA), crash during weekday AM peak (WD_AMPEAK), single vehicle-involved crash (SV), and fog-related crash (FOG). The natural log of total employment (LN_TOT_EMP) is positively related to crash counts in most of SPFs; however, it is not significant in the DUI-related crash (DUI) SPF. It was also shown that the natural log of school enrollment density (LN_SCH_DENS) is significant in all SPFs. In most of cases, its coefficient has a positive sign whereas its coefficient has a negative sign only in the fog-related crash (FOG) SPF.

The natural log of bike lane length (LN_BIKELANE) is found significant in SPFs of fatal and incapacitating injury crash (KA), crash during weekday PM peak (WD_PMPEAK), single-vehicle-involved crash (SV), pedestrian-involved crash (PED), fog-related crash (FOG), and DUI-related crash (DUI). Its effectiveness on crash frequency is positive in fatal and incapacitating injury crash (KA), crash during weekday

PM peak (WD_PMPEAK), single-vehicle-involved crash (SV), fog-related crash (FOG), and DUI-related crash (DUI) whereas it is negative in pedestrian-involved crash (PED). Moreover, the natural $\log$ of sidewalk length (LN_SIDEWALK) is significant in many SPFs. It is positively related to crash counts in most of SPFs; however, it was not significant in SPF of crash during weekday PM peak (WD_PMPEAK) and fog-related crash (FOG).

It was found that the proportion of commuters using public transportation (P_COM_PUB) is significant in the most of SPFs except for single-vehicle-involved crash (SV). Its coefficient has a positive sign in most of cases but it has a negative sign in SPF of fogrelated crash (FOG) and DUI-related crash (DUI). Positive relationships between the proportion of commuters using bicycle (P_COM_BIKE) and crash frequency were shown in SPFs of pedestrian-involved crash (PED), bicycle-involved crash (BIKE), and DUI-related crash (DUI). On the contrary, negative relationships between the proportion of commuters using bicycle (P_COM_BIKE) and crash counts were found in SPFs of total crash (KABCO), fatal and incapacitating injury crash (KA), crash during weekday AM peak (WD_AMPEAK), crash during weekday nighttime (WD_NIGHT), crash during weekday daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), single-vehicle-involved crash (SV), rain-related crash (RAIN), and fog-related crash (FOG). It was discovered that the proportion of commuters by walking (P_COM_WALK) is positively related to crash counts only in pedestrian-involved crash (PED) and bicycleinvolved crash (BIKE) while it is negatively related with crash frequency in total crash
(KABCO), fatal and injury crash (KABC), fatal and severe injury crash (KAB), fatal and incapacitating injury crash (KA), crash during weekday AM peak (WD_AMPEAK), crash during weekday off-peak (WD_OFFPEAK), crash during weekday PM peak (WD_PMPEAK), crash during nighttime (WD_NIGHT), crash during daytime (WE_DAY), single-vehicle-involved crash (SV), multiple-vehicle-involved crash (MV), rain-related crash (RAIN), and fog-related crash (FOG). Distance to the nearest urban area (DIST_TO_URBAN) has a positive sign in the almost all SPFs except for fogrelated crash (FOG). In the fog-related crash (FOG) SPF, it has a negative sign, which implies that fog crashes are more frequent in the rural area. Lastly, it is noteworthy to mention that the natural $\log$ of lake or pond area in square mile (LN_LAKE_AREA) is only significant in the fog-related crash (FOG) SPF and it was positively related to fog crashes.

Table 5-11 compares AIC, BIC, MAD and adjusted $R^{2}$ in base, semi-fully specified, and fully specified SPFs. It is evident that the models are significantly improved if more explanatory variables are included. Nevertheless, it needs much time and efforts to collect and process demographic, socio-economic, and other geographic data for estimating fully specified SPFs. Thus, it is a trade-off between model complexity and accuracy. Types of SPFs should be chosen considering data availability and required prediction accuracy. For example, if practitioners want to compute the most accurate and reliable predicted number of crashes, fully specified SPFs are recommended to use. On the other hand, in case practitioners need a simpler model with the limited number of variables despite of lower predictability, base or semi-fully specified SPFs can be considered.

### 5.2 Development of Various SPFs for TSAZs

Basically TAZs are designed to find out origin-destination pairs of trips generated from each zone. Thus, transportation planners need to minimize trips which start and end in the same zone. It is inferred that minimizing intra-zonal trips ends up with the small size of TAZs. On the other hand, traffic safety analysts need to consider traffic crashes that occur inside zones so they can be related to zonal characteristics with traffic safety of the zones. Therefore, it is possible that TAZs are too small to analyze traffic safety at the macroscopic level. Moreover, TAZs are usually divided by physical boundaries, mostly arterial roadways. Considering that many crashes occur on arterial roads, between zones, inaccurate results will be made from relating traffic crashes on the boundary of the zone to only the characteristics of that zone (Siddiqui and AbdelAty, 2012). A simple way to overcome these two issues while using TAZs for safety analysis is to aggregate TAZs into sufficiently large and homogenous traffic crash patterns. The existing zones were aggregated based on the following conditions (Lee et al. 2014):

- Zones are spatially contiguous; and
- Zones have same crash rate levels.

Table 5-12 contrasts the areas in statewide TAZ (SWTAZ) and TSAZ. As shown in the table, the number of zones in TSAZ $(\mathrm{N}=1,754)$ is one-fifth of SWTAZ $(\mathrm{N}=8,518)$, and the average area in TSAZ is $18.061 \mathrm{mi}^{2}$ whereas that in SWTAZ is $6.472 \mathrm{mi}^{2}$.

Table 5-12 Area in SWTAZs and TSAZs

| Zone system | No of zones | Average (mi $\left.{ }^{\mathbf{2}}\right)$ | Stdev |
| :---: | :---: | :---: | :---: |
| SWTAZs | 8,518 | 6.472 | 24.803 |
| TSAZs | 1,754 | 18.061 | 226.645 |

Table 5-13 compares the numbers and percentages of boundary crashes in SWTAZ and TSAZ. There are $68.2 \%$ boundary crashes in SWTAZ whereas there are $47.0 \%$ boundary crashes in TSAZ. In other words, more than $20 \%$ of boundary crashes has been reduced after the regionalization.

Table 5-13 Boundary crashes in SWTAZs and TSAZs

| Zone system | Boundary crashes | Total crashes | Percentage |
| :---: | :---: | :---: | :---: |
| SWTAZs | 614,671 | 901,235 | $68.2 \%$ |
| TSAZs | 423,275 |  | $47.0 \%$ |
|  |  |  |  |

Figure 5-2 compares SWTAZ and TSAZ maps in Districts 6 (Miami-Dade and Broward area). As presented in the figures, the zones are highly aggregated especially in the urban area.

Figure 5-2 TAZs (upper) and TSAZs (lower) in District 6 - Miami-Dade and Broward area

Table 5-14 to 5-16 show the base SPFs based on TSAZs by severity levels, time periods, and collision types or special events, respectively. The natural Log of VMT (LN_VMT) has a positive relationship with crash counts in all SPFs.

Table 5-17 to 5-19 display the semi-fully specified SPFs based on TSAZs by severity levels, time periods, and collision or special events, correspondingly. It was discovered that the proportion of arterial roads ( P _ARTERIAL) is negatively related to crash frequency when it is significant whereas the proportion of local roads (P_LOCALROAD) is always significant and it is positively associated with crash frequency. Furthermore, the natural $\log$ of signals per mile (LN_SIGNAL_MI) is also significant in most SPFs. It has a positive sign in the majority of cases; nevertheless, it has a negative sign only in SPF of single-vehicle-involved crash (SV). It may indicate single-vehicle-involved crash (SV) are more frequent in the areas with less signal density. It was exposed that the proportion of heavy vehicle in VMT (P_HEAVY_VMT) is negatively associated to most of crash types. Nevertheless, it is not significant in SPFs of fatal and incapacitating injury crash (KA) and fog-related crash (FOG).

Table 5-20 to 5-22 show the fully specified SPFs based on TSAZs by severity levels, time periods, and collision types or special events, respectively. Different from the fully specified SPFs based on TAZs, only a few additional socio-demographic variables were included in the TSAZ-based SPFs because many variables are highly correlated each other in TSAZs.

The natural Log of school enrollment density (LN_SCH_DENS) has a positive coefficient sign in the most of SPFs although it is not significant in fatal and incapacitating injury crash (KA) and fog-related crash (FOG) SPFs. It was shown that the proportion of urban area (P_URBAN) is
negatively associated with crash counts in severe injury crash (KAB), fatal and incapacitating injury crash (KA), crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), single-vehicle-involved crash (SV), fog-related crash (FOG), and DUI-related crash (DUI). In contrast, it is positively related to crash frequency only in bicycle-involved crash (BIKE). Moreover, the natural log of bike lane length (LN_BIKELANE) is significant in the most SPFs except for fog-related crash (FOG). It has a positive coefficient when it is significant.

It was uncovered that the proportion of commuters using public transportation (P_COM_PUB) has a positive coefficient in the majority of cases. The only exception is the fog-related crash (FOG), in which the proportion of commuters using public transportation (P_COM_PUB) is not significant. Furthermore, the proportion of commuters using bicycle (P_COM_BIKE) has a negative effect on crash counts in general (i.e., total crash (KABCO), fatal and injury crash (KABC), crash during weekday AM peak (WD_AMPEAK), crash during weekday off-peak (WD_OFFPEAK), crash during weekday PM peak (WD_PMPEAK), crash during weekday nighttime (WD_NIGHT), crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), single-vehicle-involved crash (SV), multiple-vehicle-involved crash (MV), and rain-related crash (RAIN)); however, it has a positive effect only on bicycle-involved crashes (BIKE). In case of the proportion of commuters by walking (P_COM_WALK), it has a negative sign in the many SPFs; nevertheless, it is not significant in fatal and incapacitating injury crash (KA), pedestrian-involved crash (PED), bicycle-involved crash (BIKE), fog-related crash (FOG), and DUI-related crash (DUI). As in the fog-related crash (FOG) SPF based on TAZs, the natural $\log$ of lake or pond area in square mile (LN_LAKE_AREA) has a positive effect on fog crashes based on TSAZs.

### 5.3 Development of Various SPFs for TADs

TADs (Traffic analysis districts) are newly developed geographic units for transportation plans. Compared to SWTAZs and TSAZs, TADs are a much more highly aggregated geographic unit. TADs can be useful if practitioners want to analyze crash patterns at a higher aggregate level than SWTAZs or TSAZs (Figure 5-3).

Figure 5-3 Traffic analysis districts (TADs)
Tables 5-24 to 5-26 show the base SPFs based on TADs by severity levels, time periods, and collision types or special events, respectively. The natural $\log$ of VMT (LN_VMT) has a positive relationship with crash counts in all SPFs.

Table 5-24 Base SPFs by severity levels based on TADs

Table 5-27 to 5-29 display the semi-fully specified SPFs based on TADs by severity levels, time periods, and collision or special events, correspondingly. The natural $\log$ of intersections per mile (LN_INTER_MI) is significant in many semi-fully specified SPFs while it is positively related with crash counts in most SPFs except for fog-related crash (FOG). The natural log of roadway density (LN_ROAD_DEN) is significant in all crash types and it has a positive relationship with the crash counts other than the single-vehicle-involved crash (SV) and fogrelated crash (FOG). It was shown that the natural $\log$ of sidewalk length (LN_SIDEWALK) is significant in SPFs of total crash (KABCO), fatal and injury crash (KABC), fatal and severe injury crash (KAB), fatal and incapacitating injury crash (KA), crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), single-vehicle-involved crash (SV), multiple-vehicle-involved crash (MV), and pedestrian-involved crash (PED) and all the coefficient of the sidewalk is positive. However, the natural $\log$ of bike lane length (LN_BIKELANE) is only significant in bicycle-involved crash (BIKE) and has positive relationship with crash counts. It was revealed that the proportion of freeway/expressway (P_FREEWAY) is only significant in crash during weekday off-peak (WD_OFFPEAK) and bicycle-involved crash (BIKE SPFs) whereas the proportion of local roads (P_LOCALROAD) in only significant in the SPFs of crash during weekday PM peak (WD_PMPEAK) and crash during weekday nighttime (WD_NIGHT). The proportion of roadway length with Posted Speed Limit higher than 55 mph (P_HIGHPSL) is significant in fog-related crash (FOG) and DUIrelated crash (DUI) SPFs. It is interesting that the effect of the proportion of roadway length with Posted Speed Limit higher than 55 mph (P_HIGHPSL) for the two crash types is different. In fog-related crash (FOG) SPF, the coefficient of the proportion of roadway length with Posted

Speed Limit higher than 55 mph (P_HIGHPSL) is positive while it has negative sign in DUIrelated crash (DUI) SPF. It implies that areas with more high-speed roads are vulnerable to fog crashes whereas those with less high-speed roads are more exposed to DUI-related crashes.

Table 5-30 to 5-32 present the fully specified SPFs by severity levels, time periods, and collision types or special events. It was disclosed that the natural $\log$ of hotel, motel, timeshare room density (LN_HMTS_DENS) is significant in the SPFs of total crash (KABCO), fatal and injury crash (KABC), crash during weekday off-peak (WD_OFFPEAK), crash during weekday
nighttime (WD_NIGHT), crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), crash for all collision types, rain-related crash (RAIN), and fog-related crash (FOG). The coefficient of the natural $\log$ of hotel, motel, timeshare room density (LN_HMTS_DENS) has a positive sign in most crash types except for fog-related crash (FOG). The proportion of families with 2 vehicles ( P _2AUTO) is significant and has a positive relationship to crash during weekday nighttime (WD_NIGHT) and multiple-vehicle-involved crash (MV) SPFs while the proportion of families with 0 vehicle (P_0AUTO) is only significant in DUI-related crash (DUI) SPFs and positively related to the crash counts. The proportion of urban area ( $\mathrm{P}_{-}$URBAN) is found significant in many SPFs. The coefficient of the proportion of urban area (P_URBAN) is positive in total crash (KABCO), fatal and injury crash (KABC), fatal and severe injury crash (KAB), crash during weekday AM peak (WD_AMPEAK), crash during weekday off-peak (WD_OFFPEAK), crash during weekday PM peak (WD_PMPEAK), crash during weekday nighttime (WD_NIGHT), multiple-vehicle-involved crash (MV), bicycleinvolved crash (BIKE), and rain-related crash (RAIN) while it is negative in fatal and incapacitating injury crash (KA), crash during weekend nighttime (WE_NIGHT), single-vehicleinvolved crash (SV), and DUI-related crash (DUI).

It was found that the natural log of number of total commuters (LN_TOT_COM) is significant in most crash types except for crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), pedestrian-involved crash (PED), bicycle-involved crash (BIKE) and fog-related crash (FOG) and the coefficient of the natural log of number of total commuters (LN_TOT_COM) has a positive sign in all SPFs. It was uncovered that the proportion of
commuters using public transportation (P_COM_PUB) has positive relationship with pedestrianinvolved crash (PED) and bicycle-involved crash (BIKE). The proportion of commuters by walking (P_COM_WALK) and the proportion of commuters using bicycle (P_COM_BIKE) is positively associated with pedestrian-involved crash (PED) and bicycle-involved crash (BIKE) separately. It is worthy to note that the natural $\log$ of lake or pond area in square mile (LN_LAKE_AREA) is only significant in the fog-related crash (FOG) SPF and it has positive relationship with fog crashes.

### 5.4 Development of Various SPFs for Counties

Florida has 67 counties as presented in Figure 5-4. Counties are the highest aggregation level of existing geographic units at the state-wide level. County-level analysis will allow practitioners to determine which counties have high traffic crash risks.

Figure 5-4 Counties in Florida

5-34 to 5-36 show the base SPFs based on counties by severity levels, time periods, and collision types or special events, respectively. The natural Log of VMT (LN_VMT) has a positive relationship with crash counts in all SPFs as expected.

Tables 5-37 to 5-39 exhibit the semi-fully specified SPFs based on counties by severity levels, time periods, and collision or special events, correspondingly. Only few variables were significant in the semi-fully specified SPFs. It was discovered that the proportion of freeway/expressway (P_FREEWAY) is significant in many SPFs except for rain-related crash (RAIN) and fog-related crash (FOG) while the coefficient of the proportion of freeway/expressway (P_FREEWAY) has a negative sign all SPFs. The proportion of roadway length with Posted Speed Limit higher than 55 mph (P_HIGHPSL) was found only significant in fog-related crash (FOG) SPF and its coefficient has a negative sign.

Tables 5-40 to 5-42 present the fully specified SPFs based on counties by severity levels, time periods, and collision types or special events, respectively. Different from the fully specified SPFs based on other geographic units, trip production and attraction data were attempted in the SPFs. It was shown that the proportion of home-based shopping trip production (P_HBSHP) is significant in fatal and injury crash (KABC) and DUI-related crash (DUI) SPFs, and the proportion of home-based social and recreational trip production (P_HBSRP) is only significant in fatal and severe injury crash (KAB) SPF. The proportion of home-based social and recreational trip attraction (P_HBSRA) was found to be positively related to fatal and incapacitating injury crash (KA) while the proportion of home-based working trip attraction (P_HBWA) is positively associated with single-vehicle-involved crash (SV). Beside trip generation factors, only a few additional socio-demographic variables were included in the county-based SPFs since many variables highly correlated with each other at the county level.

The proportion of residents between 15 and 24 years old (P_AGE1524) is significant in total crash (KABCO), crash during weekday PM peak (WD_PMPEAK), crash during weekday nighttime (WD_NIGHT), crash during weekend daytime (WE_DAY), crash during weekend nighttime (WE_NIGHT), multiple-vehicle-involved crash (MV), pedestrian-involved crash (PED), rain-related crash (RAIN) and fog-related crash (FOG) and has positive relationship with the crash counts. The proportion of families with 2 vehicles ( $\mathrm{P} \_2$ AUTO) is only significant in fatal and incapacitating injury crash (KA) while the proportion of families with 0 vehicle (P_0AUTO) is significant in crash during weekday morning peak (WD_AMPEAK), crash during weekday off-peak (WD_OFFPEAK), crash during weekday nighttime (WE_NIGHT), single-vehicle-involved crash (SV), bicycle-involved crash (BIKE) and rain-related crash (RAIN).

Distance to the nearest urban area (DIST_TO_URBAN) is negatively related to the counts of crash during weekday AM peak (WD_AMPEAK) and weekday off-peak (WD_OFFPEAK). The proportion of commuters using bicycle (P_COM_BIKE) is only significant in bicycle-involved crash (BIKE) SPF and its coefficient has a positive sign. Unlike the previous three geographic units, the natural log of lake or pond area in square mile (LN_LAKE_AREA) is not significant in fog-related crash (FOG) SPF based on counties.

Table 5-43 shows the AIC, BIC, MAD, and adjusted $R^{2}$ in base, semi-fully specified, and fully specified SPFs. As shown in the table, County-based SPFs have good performance regarding adjusted $R^{2}$ and SPFs have larger $\mathrm{R}^{2}$ value if more explanatory variables are contained in most of
cases. However, MAD of the fully specified SPFs is smaller than that of the other two types of SPFs except for DUI-related crash (DUI) while MAD of the semi-fully specified SPFs is smaller than that of the base SPFs for fatal and severe injury crash (KAB), fatal and incapacitating injury crash (KA), crash during weekday off-peak (WD_OFFPEAK), crash during weekday nighttime (WD_NIGHT), single-vehicle-involved crash (SV), fog-related crash (FOG).

### 5.5 Summary of Macroscopic Safety Modeling Results

The research team has completed developing SPFs by severity levels, time periods, collision types, and special events based on different geographic units (TAZs, TSAZs, TADs, and counties). TAZs have been widely adopted for traffic safety analysis. However, TAZs have two possible limitations as previously mentioned. In order to overcome the limitations, the research team has developed TSAZs by combining current TAZs with comparable traffic crash rates into larger geographic units. In recent, TADs were developed for the large scale planning. Thus, it is believed that TADs are useful if practitioners wish to analyze crash patterns at the higher aggregate level. County is the highest aggregation level of existing geographic units at the statewide level. County-level analysis will allow practitioners to determine which counties have high traffic crash risks.

Three types of SPFs by explanatory variables were estimated: base, semi-fully specified, and fully-Specified SPFs. Base SPFs only have the exposure variable: VMT (vehicle miles traveled). The base SPFs are easy to estimate since it has only one variable; however, their model performance is not good as other two types of SPFs. In the semi-fully specified SPFs, both traffic and roadway characteristic variables were used, it was shown that, in most of cases, semifully specified SPFs considerably perform better than base SPFs. Lastly, the fully specified SPFs have not only roadway and traffic variables but also socio-demographic and geography variables, which perform the best among the three types of SPFs. However, the fully specified SPFs need extensive data from multiple sources and require time and efforts to process the collected data. When very accurate predicted crash counts are required or have enough time and resources, fully
specified SPFs are recommended to use. On the contrary, base SPFs or semi-fully specified SPFs can be used when time and resources are limited or only rough crash trends are required.

## 6 MACRO-LEVEL SCREENING

The main objective of Chapter 6 is to identify hot zones using the SPFs estimated in the previous Chapter 5. In order to achieve the objective, the optimal zone systems for selected crash type were determined. Potential for Safety Improvements (PSIs) were computed based on the best zone systems and zonal-level screening for each crash type were conducted. The comparative analysis of geographic units for macro-level analysis is described in section 6.1. In section 6.2, the PSIs were computed for different crash types and an example of zonal-level screening results was suggested. Lastly, the spatial distributions of hotspots for all crash types were presented in section 6.3.

### 6.1 Comparative Analysis of Geographic Units for Macro-level Screening

Among various geographic units, only SWTAZs and TADs are delineated for the purpose of transportation planning. Thus, SWTAZs and TADs have several advantages for crash modeling: first, the transportation planning related data (such as trip production/attraction, employments, car-ownership, households, etc.); second, it is easier to be integrated with the transportation planning process. There are 8,518 SWTAZs, and 594 TADs in Florida. Between the two geographic units, a TAD is considerably larger than a SWTAZ as shown in Figure 6-1. The average area of SWTAZs and TADs are 6.472 and 103.314 square miles, respectively, which indicates that a TAD is 16 times larger than a TAZ on average. As Lee et al. (2014) pointed out TAZs may have two limitations for safety analysis: 1) A TAZ is possibly too small for safety analysis; and 2) A TAZ may have a boundary crash issue. The authors cautiously concluded that a larger zone system can overcome these two limitations. Nevertheless, it is still necessary to
compare the two geographic units because the data currently used are different from what Lee et al. (2014) used, and also the optimal zone system may be different by crash type.

In this Chapter 6, three most widely used crash types including total, severe, and non-motorized mode crashes are selected for the comparative analysis. A severe crash (KA) is defined as a combination of fatal and incapacitating injury crashes. A non-motorized mode crash refers to pedestrian or bicycle-involved crashes. In 2010-2012, a total of 901,235 crashes were recorded in Florida among which 50,039 (5.6\%) were severe crashes and 31,547 (3.5\%) were non-motorized mode crashes. Three fully specified SPFs for total, severe, and non-motorized mode crashes were estimated based on both SWTAZs and TADs. The fully specified SPFs have all the variables in their models including not only traffic and roadway related variables but also demographic, socio-economic, and geographic variables.

Figure 6-1 Comparison of SWTAZs and TADs

### 6.1.1 Statistical methodology

A Negative Binomial (NB) model was used for the SPFs in order to keep consistent with the current Highway Safety Manual (AASHTO, 2010). The number of crashes is non-negative integers, which are not normally distributed. Both Poisson and NB models can be used for crash frequency analysis. Nevertheless, Poisson model is based on the assumption that the mean is equal to the variance of distribution. The assumption of equal mean-variance is often violated when the variance is larger than mean, which is commonly observed in crash data. NB models relax the variance assumption by adding an independently distributed error term to the mean of the Poisson model. The mean-variance relationship in NB distribution is as follows:

$$
\begin{equation*}
\operatorname{Var}(Y)=\mu+\alpha \mu^{2} \tag{1}
\end{equation*}
$$

where, $Y$ is response variable, $\mu$ is mean response of the observation, and $\alpha$ is dispersion parameter. The existence of over-dispersion is adjusted by the log-linear relationship between the expected number of crashes and covariates.

$$
\begin{equation*}
\ln \left(\mu_{i}\right)=\beta_{0}+\sum \beta X_{i}+\varepsilon_{i} \tag{2}
\end{equation*}
$$

where, $i$ is an observation unit, $\mu_{i}$ is the expected number of crashes per year at site $i, X_{i}$ is covariates, $\beta_{0}$ is the intercept, $\beta$ is the estimated coefficient vector and $\varepsilon_{i}$ is the random error term. $\exp \left(\varepsilon_{i}\right)$ is assumed to be gamma-distributed with mean 1 and variance $\alpha$ so that the variance of the crash frequency distribution becomes $\mu_{i}\left(1+\alpha \mu_{i}\right)$ and different from the mean $\mu_{i}$. The NB model for the crash count $y_{i}$ of entity $i$ is given by

$$
\begin{equation*}
P\left(y_{i}\right)=\frac{\Gamma\left(y_{i}+\frac{1}{\alpha}\right)}{\Gamma\left(y_{i}+1\right) \Gamma\left(\frac{1}{\alpha}\right)}\left(\frac{\alpha \mu_{i}}{1+\alpha \mu_{i}}\right)^{y_{i}}\left(\frac{1}{1+\alpha \mu_{i}}\right)^{\frac{1}{\alpha}} \tag{3}
\end{equation*}
$$

where $y_{i}$ is the number of crashes in zone $i$ and $\Gamma(\cdot)$ refers to the gamma function.

The SPFs of the three crash types (i.e., total, severe, and non-motorized mode crashes) were developed by employing NB model based on SWTAZs and TADs. Generally, one simple method to compare the SPFs based on SWTAZs and TADs is to analyze the difference directly between the observed and predicted crash counts of each geographic unit. However, this method may result in biased conclusion since the geographic units have different sample sizes. Thus, a new method using a grid structure as surrogate geographic unit was proposed in this task to compare the SPFs based on different geographic units.

### 6.1.2 Grids for comparing different geographic units

As shown in Figure 6-2, the grid structure, unlike the SWTAZ and TAD, is a neutral geographic unit that evenly overlay the whole state. Hence, it should be more reasonable if the comparison can be conducted based on the same grid structure. The observed crash counts in each grid can be determined directly by using Geographic Information System (GIS). The predicted crash counts of SPFs based on SWTAZs and TADs can be transformed to the same grid structure by the method as introduced in the following part.

Figure 6-2 Grid structure of Florida ( $\mathbf{1 0 \times 1 0}$ mile $^{\mathbf{2}}$ )
The method of transforming predicted crashes into grid is introduced by taking Grid $10 \times 10$ mile $^{2}$ as an example. As shown in Figure 6-3, the red square is one grid (named as Grid A) which intersects with four SWTAZ/TAD units (named as SWTAZ/TAD 1, 2, 3, and 4) with four regions (named as Region 1, 2, 3, and 4). For each SWTAZ/TAD, it is assumed that the crashes are evenly distributed so that the predicted crash counts for each region can be determined by:

$$
\begin{equation*}
y_{R i}^{\prime}=y_{T i}^{\prime} * P_{R i}^{\prime} \tag{4}
\end{equation*}
$$

where $y_{R i}^{\prime}$ and $y_{T i}^{\prime}$ are the predicted crash counts in Region $i$ and SWTAZ/TAD $i, P_{R i}^{\prime}$ is the proportion of Region $i$ 's area by SWTAZ/TAD $i$ 's area.

Obviously, the crashes happened in Grid A should be equal to the sum of crashes happed in the four intersected regions. Then the predicted crash counts of the four SWTAZs/TADs can be partly transformed into Grid A by adding the predicted crash counts of all the four intersected regions. Based on this method, the predicted crash counts of SWTAZs and TADs can be transformed into the same grids. For each grid, one observed crash number and two different values of the transformed predicted crash counts can be obtained. The difference between observed and transformed predicted crash numbers of the grid structure will be analyzed. Finally, by comparing the difference of SWTAZs and TADs, the superior geographic unit can be obliquely identified for crash analysis.

Figure 6-3 Method to transform predicted crash counts

Additionally, the comparison results should be more reasonable if grids of different sizes are employed since the areas of SWTAZs and TADs are quite different. In consideration of the average area of the two geographic units, ten levels of grid structures with side length from 1 to 10 miles were created. Table 6-1 summarizes average areas and observed crash counts of SWTAZs, TADs, and different grid structures. The Grid $\mathrm{L} \times \mathrm{L}$ means the grid structure with side length of $L$ miles. Based on the average area and crash counts, it can be concluded that the SWTAZs and TADs are separately comparable with Grid $3 \times 3$, and Grid $10 \times 10$.

Three types of measures, Mean Absolute Error (MAE), Root Mean Squared Errors (RMSE), and $R^{2}$ were employed to compare the difference of observed and transformed predicted crash values based on SWTAZs and TADs. The three measures can be computed by:

$$
\begin{gather*}
M A E=\frac{1}{N} \sum_{i=1}^{N}\left|y_{i}-y_{i}^{\prime}\right|  \tag{5}\\
R M S E=\sqrt{\frac{1}{N} \sum_{i=1}^{N}\left(y_{i}-y_{i}^{\prime}\right)^{2}}  \tag{6}\\
R^{2}=1-\frac{\sum_{i=1}^{N}\left(y_{i}-y_{i}^{\prime}\right)^{2}}{\sum_{i=1}^{N}\left(y_{i}-\bar{y}\right)^{2}} \tag{7}
\end{gather*}
$$

where $N$ is the number of observations, $y_{i}$ and $y_{i}^{\prime}$ are the observed and transformed predicted values of crashes for entity $i$, and $\bar{y}$ is the average of the observed values of crashes.

The MAE and RMSE with smaller values reveal better performance while larger $R^{2}$ value corresponds to superior result. In comparison of MAE and RMSE, RMSE is sometimes more preferred because RMSE is more sensitive to larger errors.

| Geographic units | $\begin{aligned} & \hline \text { Area } \\ & \left(\text { mile }^{2}\right) \end{aligned}$ | Number of zones | Total crash |  |  |  | Severe crash |  |  |  | Non-motorized mode crash |  |  |  |

### 6.1.3 Results and discussion

The modeling results of the three crash types based on SWTAZs and TADs have been presented in the previous report. Based on the results, the predicted crash counts for each crash types of the three geographic units can be computed and then transformed into the correspondingly intersected grids. MAE, RMSE and $R^{2}$ for each grid structure were calculated with the observed crash counts and different transformed predicted crash counts based on different geographic units. As shown in Table 6-2, it can be seen that: (1) in total and severe crash models, for most grid structures, the MAE indicates SWTAZs based models perform better than the models based on TADs while the $R M S E$ and $R^{2}$ show the opposite results. With the defined square term, RMSE as well as $R^{2}$ should be more sensitive with larger difference than MAE. Hence, SWTAZs based models for total and severe crashes are more likely to offer predicted results with larger errors. Therefore, TADs seems to provide better models than SWTAZs for total and severe crashes. (2) in non-motorized mode crash model, the results of all the grid structures indicate that SWTAZs based models can offer better results than models based on TADs. The result is not surprising since the non-motorists should have much shorter trip distance, leading that non-motorized mode crashes area more likely to be located quite close to the non-motorists' residence area (Lee et al., 2015).

In summary, TADs based models for total and severe crashes performed better than the models based on SWTAZs. On the other hand, SWTAZs can provide better model for non-motorized mode-involved crashes compared with TADs. In Florida, most crash types except non-motorized mode crashes should be more likely to involve motors. Considering this, SWTAZs are suggested
for non-motorized mode (i.e., pedestrian and bicycle) crash modeling while TADs are recommended for other crash types analysis.

Table 6-2 Comparison results based on grids

### 6.2 Identification of Hot Zones

PSI (Potential for Safety Improvements), or excess crash frequency using SPF (Safety performance function), was applied as the performance measure in the study to define a hot zone. The PSI refers to the difference between the expected crash count and the predicted crash count of each zone. The expected number of crashes is the estimate of long-term average crash frequency of an area based on a given set of characteristics of zones in a specific time period. Since a traffic crash is a random event, the observed crash frequency at an area will naturally fluctuate over time and cannot be a reliable indicator of what crash frequency is expected under the same condition over a long time period (AASHTO, 2010). In contrast, the expected number of crashes accounting for the regression-to-the-mean problem can provide more dependable expected number of crash. Meanwhile, the predicted number of crashes is the average number of crashes in the area with similar characteristics. Thus, the PSI can be an effective performance measure to identify those zones experiencing more crashes than others with similar characteristics. The zone with positive PSI is regarded as hazardous since it has more crashes than others with similar characteristics. Also, a zone is considered safe if its PSI is smaller than zero, indicating it has less crashes compared with other zones have.

The calculation of the expected number of crashes using Empirical Bayes (HSM 2010; Girasek \& Taylor, 2010) method is as follows:

$$
\begin{equation*}
N_{\text {expected }}=W \times N_{\text {predicted }}+(1-W) \times N_{\text {observed }} \tag{1}
\end{equation*}
$$

where $N_{\text {expected }}$ is the expected number of crash, $W$ is the EB weight, $N_{\text {predicted }}$ is the predicted number of crash, and $N_{\text {observed }}$ is the observed crash counts. The predicted number of crash can
be obtained from the SPF while the weighted adjustment are calculated using the following equation.

$$
\begin{equation*}
W=\frac{1}{1+k \times N_{\text {predicted }}} \tag{1}
\end{equation*}
$$

where $k$ is the over-dispersion parameter of the SPF.

All zones in this study area were classified into two categories based on their PSIs: hot and normal zones. The hot zones are defined as zones with a top $10 \%$ PSI while normal zones are the other zones. Table 6-3 exhibits a part of the screening results of total crashes based on TADs. In cased of TAD with ID number 486, its PSI is 6273.586 which is in the top $0.17 \%$. Thus, the TAD was categorized as "Hot" zone, indicating that the zone had serious traffic safety problems compared with other similar TADs. The PSI of TAD with ID number 261 is 681.824 and it is in the top $10.10 \%$ PSI. The TAD was categorized as "Normal" zone, which has a traffic safety problem not as severe as "Hot" zone.

Table 6-3 Example of the screening results: total crashes based on TADs

| Rank | ID | Observed Number | Predicted Number | Expected Number | PSI | Percentile | Category |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 486 | 14648 | 8369 | 14628 | 6259 | $0.17 \%$ | HOT |
| 2 | 484 | 13288 | 7303 | 13253 | 5950 | $0.34 \%$ | HOT |
| $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ |
| 60 | 261 | 2872 | 2188 | 2868 | 680 | $10.10 \%$ | NORMAL |
| $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ |
| 594 | 142 | 3873 | 6404 | 3886 | -2518 | $100.00 \%$ | NORMAL |

### 6.3 Macro-level Screening for Various Crash Types

Using the method above, the PSI by each crash type were calculated based on selected analysis zone and categorized based on the PSI value. In research, SWTAZs were selected for screening analysis of non-motorized mode (i.e., pedestrian and bicycle) crashes while TADs were adopted for other crash types screening. The screening results of different crash types are shown as follows.

### 6.3.1 Screening results by severity levels based on TADs

Figure 6-4 exhibits the screening results of total (KABCO), fatal-and-injury (KABC) crashes, fatal-and-injury crashes without possible injury (KAB), and fatal-and-severe injury (KA) crashes based on TADs. It was revealed that the spatial distribution of hot zones of different crash severities is different. The hot zones of total and fatal-and-injury crashes are concentrated in urban area in which has higher traffic exposure and population. In contrast, fatal-and-severe injury crash hot zones are more often observed in rural areas. This was also confirmed in the SPF for fatal-and-severe injury crash (KA), as it was found that the proportion of urban area is negatively associated with fatal-and-severe crash occurrence.

Figure 6-4 Hot zone identification by severity levels using PSI based on TADs

### 6.3.2 Screening results by time period based on TADs

The screening results by time period on weekdays are presented in Figure 6-5. Most hot zones of crash during different time period on weekdays are found in urban area. However, the hot zones disseminate in different pattern by time period. It was shown that most hot zones of crash during weekday AM peak are concentrated in east and middle parts of Florida. The hot zones of crash during weekday off-peak and PM peak have similar spatial distribution, locating at the peripheral areas. Moreover, the hot zones of crashes during weekday nighttime are located in middle-east and southeast areas.

Figure 6-5 Hot zone identification by time period on weekday using PSI based on TADs

The spatial distribution pattern can be found in Figure 6-6. It is revealed that hot zones of crashes during daytime and nighttime on weekend are in similar areas. Most zones are found in urban areas which attract more recreational activities on weekend. However, compared with total crashes and crashes during weekday AM peak, the crashes on weekend are more likely to have hot zones in rural areas.

Figure 6-6 Hot zone identification by time period on weekend using PSI based on TADs

### 6.3.3 Screening results by special events based on TADs

The hot zones of special event (i.e., adverse weather and DUI) crashes together with total crashes (KABCO) are exhibited in Figure 6-7. It was revealed that the distribution of hot zones for the four crash types is not similar. It is also noteworthy to mention that crashes related to the two different adverse weather types (rain and fog) have different hot zone distribution. The crashes related to fog have more hot zones in rural area compared with rain-related crashes. The rural area should have more lakes and forests and may result in high fog occurrence. Lastly, it was found that the hot zones of DUI-related crashes are mainly in rural area which is also consistent with the SPF estimation result.

Figure 6-7 Hot zone identification by special events together with using PSI based on TADs

### 6.3.4 Screening results by collision types based on TADs/SWTAZs

Figure 6-8 summarizes the hot zones of single-vehicle and multiple-vehicle crashes based on TADs. It indicates that the hot zones of the two collision types have quite different spatial distribution. For the single-vehicle crashes, the hot zones more easily to be observed in rural areas since the driving speeds in this area are higher. Unlike single-vehicle crashes, the multiplevehicle crashes hot zones are more likely to be placed in urban areas where traffic exposure is higher and vehicle-to-vehicle conflicts are more frequent.

Figure 6-8 Hot zone identification for vehicles involved only using PSI based on TADs

The hot zones of non-motorized mode (i.e., pedestrian and bicycle) crashes are displayed in Figure 6-9 and the detailed spatial distribution for each district is shown in Figure 6-10. For the two crash types, they have similar spatial distributions of the hot zones. Districts 2, 4-7 have more hot zones of the non-motorized mode crashes. Moreover, the hot zones in these areas always are located in urban areas because pedestrians as well as bicyclists are prevalent mostly in urban areas.

Figure 6-9 Hot zone identification for non-motorized mode-involved crashes using PSI based on SWTAZs

Figure 6-10 Hot zone identification for pedestrian/bicycle-involved crashes (PED/BIKE) using PSI based on SWTAZs in each District

(PED/BIKE) using PSI based on SWTAZs in each District

Figure 6-10, continued. Hot zone identification for pedestrian/bicycle-involved crashes (PED/BIKE) using PSI based on SWTAZs in each District

### 6.4 Summary of Macroscopic Screening Results

The research team has completed macro-level crash screening by severity levels, time periods, collision types, and special events. A comparative analysis between SWTAZs and TADs was conducted to determine the best zone system for different crash types. The comparison results showed that the SWTAZs-based models perform better for non-motorized mode-involved crashes whereas the TADs-based models provide better performance for total and severe crashes. Therefore, SWTAZs and TADs are selected for screening of non-motorized mode crashes and other crash types, respectively. Then Potential for Safety Improvements (PSIs) were applied as a performance measure to identify hot zones. It was revealed that the hot zones of different crash types have diverse spatial distribution. It is expected that the macroscopic screening results are useful for policy-makers and practitioners understand hot zones of specific crash types in a broad perspective. Once they realize a particular zone has a specific safety problem, they can zoom in the problematic zones and find out individual hotspot intersections or segments with safety issues.

## 7 DEVELOPMENT OF VARIOUS SPFS AT THE MICRO-LEVEL

### 7.1 Segment and Intersection Facility and Crash Types

In Chapter 6, the research team developed a wide array of the SPFs for different types of segments and intersections. As shown in Table 7-1, Segments were categorized into 13 facility types based on the locations (i.e., urban or rural), number of lanes, access controls (i.e., full or no access control), and median division. In case of intersections, they were classified into 16 facility types based on the location, number of legs, and control types (i.e., stop or signal).

Initially, the research team developed SPFs by severity level such as KABCO (total), KABC (fatal-and-injury crashes), KAB (fatal-and-injury crashes without possible injury) and KA (fatal-and-severe injury crashes). Secondly, the research team has built SPFs by time period. The research team divided crashes into weekday and weekend crashes. The weekday crashes were classified into morning peak (07:00-08:59), off-peak (09:00-15:59), evening peak (16:00-17:59), and nighttime (18:00-06:59). In case of the weekend crashes, since it is known that there is no significant variation in traffic volume during the daytime as during weekdays, only daytime (07:00-17:59) and nighttime (18:00-06:59) were considered. Four major collision types: singlevehicle, multiple-vehicle, pedestrian involved, and bicycle-involved collision SPFs were estimated. Lastly, SPFs for special crash events including adverse weather conditions (i.e., rain and fog) and DUI (Driving under the influence of alcohol or drugs) were built. The abbreviations of the variables used in the modeling results are described in Table 7-2.

These SPFs enable practitioners to calculate the predicted and expected number of crashes by each specific facility type. Thus, practitioners can identify intersections and segments with high crash risks based on the SPFs. In Chapter 10, micro-level network screening for each crash type will be conducted using the developed SPFs.

Table 7-1 Abbreviations of types of segments and intersections

| Category | Abbreviations | Meaning |
| :---: | :---: | :---: |
| Segment | R2U | Rural 2-lane undivided |
|  | R2D | Rural 2-lane divided |
|  | RMU | Rural multi-lane undivided |
|  | RMD | Rural multi-lane divided |
|  | U2U | Urban 2-lane undivided |
|  | U2D | Urban 2-lane divided |
|  | UMU | Urban multi-lane undivided |
|  | UMD | Urban multi-lane divided |
|  | 3TL | 3-lane two-way left-turn lane |
|  | 5TL | 5 -lane two-way left-turn lane |
|  | 4FR | 4-lane full access control |
|  | 6FR | 6-lane full access control |
|  | 8FR | 8-lane full access control |
| Intersections | U_3SG | Urban 3-leg signalized |
|  | U_4SG | Urban 4-leg signalized |
|  | U_4SG_1OW | Urban 4-leg signalized: one of the road is one-way |
|  | U_4SG_2OW | Urban 4-leg signalized: both roads are one-way |
|  | U_5_6SG | Urban 5or 6 leg signalized |
|  | U_3ST_1S | Urban 3-leg stop controlled: 1-way stop |
|  | U_3ST_1SD | Urban 3-leg stop controlled: 1-way stop- divided |
|  | U_3ST_3S | Urban 3-leg stop controlled: 3-way stop |
|  | U_4ST_2S | Urban 4-leg stop controlled: 2-way stop |
|  | U_4ST_2S_1OW | Urban 4-leg stop controlled: 2-way stop: one of the road is oneway |
|  | U_4ST_4S | Urban 4-leg stop controlled: 4-way stop |
|  | R_4SG | Rural 4-leg signalized |
|  | R_3ST_1S | Rural 3-leg stop controlled: 1-way stop |
|  | R_4ST_2S | Rural 4-leg stop controlled: 2-way stop |
|  | R_4ST_4S | Rural 4-leg stop controlled: 4-way stop |
|  | ROUNDABOUT | Roundabouts |

Table 7-2 Abbreviations used in model estimation

| Category | Abbreviations | Meaning |
| :---: | :---: | :---: |
| Crash types <br> (Target <br> variables) | K | Fatal crash |
|  | A | Incapacitating injury crash |
|  | B | Non-incapacitating injury crash |
|  | C | Possible injury crash |
|  | O | Property damage only crash |
|  | WD_AMPEAK | Crash occurred during weekday AM Peak (07:00-08:59) |
|  | WD_OFFPEAK | Crash occurred during weekday off-peak (09:00-15:59) |
|  | WD_PMPEAK | Crash occurred during weekday PM Peak (16:00-17:59) |
|  | WD_NIGHT | Crash occurred during weekday nighttime (18:00-06:59) |
|  | WE_DAY | Crash occurred during weekend daytime (07:00-17:59) |
|  | WE_NIGHT | Crash occurred during weekend daytime (18:00-06:59) |
|  | SV | Single-vehicle collision |
|  | MV | Multiple-vehicle collision |
|  | PED | Pedestrian-involved collision |
|  | BIKE | Bicycle-involved collision |
|  | RAIN | Crash under rainy condition |
|  | FOG | Crash under foggy condition |
|  | DUI | Crash due to driving under the influence of alcohol or drugs |
| Explanatory variables | $\ln (\mathrm{AADT})$ | Natural Log of AADT of segments |
|  | $\ln (\mathrm{MJ}$ _AADT) | Natural Log of AADT of major road of intersections |
|  | $\ln (\mathrm{MN}$ _AADT) | Natural Log of AADT of minor road of intersections |
|  | $\ln$ (TEV) | Natural Log of total entering vehicles of intersections |

Micro-level facility types used in the analysis are classified as in Figure 7-1.

Figure 7-1 Micro-level facility types

### 7.2 Statistical Modeling Methodology

A negative binomial (NB) model was used to be consistent with the current Highway Safety Manual (AASHTO, 2010). The number of crashes is non-negative integers, which are not normally distributed. Poisson or NB models have the abilities to develop the crash frequencies with explanatory variables; however, Poisson model has been criticized because of its implicit assumption that the variance equals mean. This assumption is often violated especially in the
crash data. Most of crash data have a greater variance than their mean and therefore the data is over-dispersed. NB models can relax the over-dispersion issue. The mean-variance relationship in NB distribution is as follows:

$$
\begin{equation*}
\operatorname{Var}(Y)=\mu+\alpha \mu^{2} \tag{1}
\end{equation*}
$$

where, $Y$ is response variable, $\mu$ is mean response of the observation, and $\alpha$ is over-dispersion parameter. Thus, if the dispersion parameter $\alpha$ is zero, the variance is also equal to the mean, which is the basic assumption of Poisson distribution. The existence of over-dispersion is adjusted by the log-linear relationship between the expected number of crashes and covariates.

The formula showing the relationship between expected number of crashes and variables (i.e., AADT, segment length) for segment SPFs is as follows:

$$
\begin{equation*}
\log \left(\mu_{i}\right)=\beta_{0}+\beta_{1} \ln (A A D T)+\ln (\text { length })+\varepsilon_{i} \tag{2}
\end{equation*}
$$

where, $i$ is an observation unit, $\mu_{i}$ is the expected number of crashes per mile per year on segment $i, \beta_{0}$ is the intercept, $\beta_{1}$ is the estimated coefficient and $\varepsilon_{i}$ is the random error term.

Over-dispersion parameter in segment SPFs is a function of segment length. It can be calculated using the following equation:

$$
\begin{equation*}
\alpha=1 / \exp (c+\ln (\text { length })) \tag{3}
\end{equation*}
$$

where, $\alpha=$ over-dispersion parameter, and $\mathrm{c}=$ a regression coefficient used to compute the overdispersion parameter.

Furthermore, the equations showing the relationship between expected number of crashes and variables (i.e., major/minor AADT, TEV) for intersection SPFs are as follows:

$$
\begin{equation*}
\log \left(\mu_{i}\right)=\beta_{0}+\beta_{1} \ln \left(M J_{-} A A D T+\beta_{2} \ln \left(M N_{-} A A D T\right)+\varepsilon_{i}\right. \tag{4}
\end{equation*}
$$

or

$$
\begin{equation*}
\log \left(\mu_{i}\right)=\beta_{0}+\beta_{3} \ln (T E V)+\varepsilon_{i} \tag{5}
\end{equation*}
$$

where, $i$ is an observation unit, $\mu_{i}$ is the expected number of crashes per year on intersection/roundabout $i, \beta_{0}$ is the intercept, $\beta_{1}, \beta_{2}$ and $\beta_{3}$ are the estimated coefficients and $\varepsilon_{i}$ is the random error term. Equation (7) was used if either the natural $\log$ of AADT of major road of intersections: $\ln \left(\mathrm{MJ} \_A A D T\right)$ or the natural $\log$ of AADT of minor road of intersections: $\ln \left(\mathrm{MN} \_\mathrm{AADT}\right)$ is not significant in Equation (6).

### 7.3 Explanatory Analysis of the Prepared Data

The collected data were processed for segments and intersections. A descriptive statistics of the processed segments and intersection data are summarized in Tables 7-3 to 7-6 and Tables 7-7 to 7-10, accordingly.

Table 7-3 Descriptive statistics of rural area segment data

| Segment Types | Variables | Mean | Stdev | Min | Max | Total Crash Counts |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| R2U: Rural 2-lane undivided ( $\mathrm{N}=4145$ ) | Length | 2.505 | 2.934 | 0.1 | 28.919 | - |

### 7.4 Development of Various SPFs for Roadway Segments

Tables 7-11 to 7-23 present the SPFs by severity levels, time periods, collision types, and special events for different types of segments in rural/urban area. The coefficients of the natural log of AADT ( $\ln (\mathrm{AADT})$ ) have a positive sign in all the SPFs.

Table 7-11 SPFs for rural two-lane undivided segments (R2U)

| Crash Type |  | Intercept | $\boldsymbol{\operatorname { l n }}(\mathrm{AADT})$ | c | LL |

### 7.5 Development of Various SPFs for Intersections and Roundabouts

Tables 7-24 to 7-39 exhibit the SPFs by severity levels, time periods, collision types, and special events for 15 types of intersections and roundabouts. It was revealed that both the natural log of AADT of major road of intersections ( $\ln \left(\mathrm{MJ} \_\mathrm{AADT}\right)$ ) and the natural $\log$ of AADT of minor road of intersections (ln(MN_AADT)) are significant in all SPFs for urban 4-legged signalized intersections (i.e., U_4SG), and these exposure variables are significant in most SPFs such as urban 3-legged signalized intersections (U_3SG), urban 3-legged stop controlled intersections: 1way stop (U_3ST_1S), urban 4-legged signalized intersections: one of the road is one-way (U_4SG_1OW), urban/rural 4-legged stop controlled intersections: 2-way stop (U_4ST_2S/R_4ST_2S), and rural 3-legged stop intersections 1-way stop (R_3ST_1S).

On the other hand, sometimes, $\ln \left(M N \_A A D T\right)$ is not significant in several SPFs for rural 4-leg stop controlled intersections such as 4-way stop (R_4ST_4ST) and urban 4-leg stop controlled intersections including 2 -way stop: one of the road is one-way (U_4ST_2S_1OW). For these intersection types, the natural $\log$ of total entering vehicles of intersections $(\ln (\mathrm{TEV}))$, was applied $s$ an exposure variable. However, there are a few crash types neither $\ln \left(\mathrm{MJ} \_\right.$AADT $)$nor $\ln$ (TEV) was significant in the models, or the models are not converged. These crash types were marked with shaded gray in the following tables.

### 7.6 Summary of Microscopic Safety Modeling Results

The research team has completed developing SPFs by severity level, time period, collision type, and special event at the microscopic level. Various SPFs were estimated for each type of microlevel facility. The research team adopted a negative binomial (NB) model to be consistent with the current Highway Safety Manual (HSM). In case the number of crash cases is extremely small, the exposure variable is not significant or the model was not converged. Other than these cases, all the SPFs were developed and summarized in Chapter 7.

With the developed SPFs in Chapter 7 will be used to compute the predicted and expected number of crashes, which will be utilized to calculate a screening performance measure, PSI (Potential for Safety Improvements). In the following Chapter 8, the research team will conduct a micro-level screening for all crash types based on PSI using the developed SPFs.

## 8 MICRO-LEVEL NETWORK SCREENING

### 8.1 Identification of Hot Sites

PSI (Potential for Safety Improvements), or excess crash frequency using SPF (Safety performance function), was applied as a performance measure in the study to identify a hotspot. The PSI is the difference between the expected crash count and the predicted crash counts of each site. The PSI is an effective performance measure to identify those sites experiencing more crashes than others with similar characteristics. PSIs were calculated for each facility type and crash type and all the segments and intersections were ranked based on the computed PSI. A site is considered safe if its PSI is smaller than zero, indicating it has less crashes compared with other sites with comparable features. In contrast, a site is considered dangerous if the PSI value is greater than zero since it has more crashes than other sites with similar characteristics.

The formula for PSI is as follows:

$$
\begin{equation*}
\text { PSI }=N_{\text {expected }}-N_{\text {predicted }} \tag{1}
\end{equation*}
$$

where $N_{\text {expected }}$ is the expected number of crashes and $N_{\text {predicted }}$ is the predicted number of crashes. The predicted number of crash can be obtained from SPFs.

The calculation of the expected number of crashes using Empirical Bayes (Girasek and Taylor, 2010) method is as follows:

$$
\begin{equation*}
N_{\text {expected }}=W \times N_{\text {predicted }}+(1-W) \times N_{\text {observed }} \tag{2}
\end{equation*}
$$

where, $W$ is the Empirical Bayes weight and $N_{\text {observed }}$ is the observed crash counts. The weighted adjustments are calculated using the following equation:

$$
\begin{equation*}
W=\frac{1}{1+\alpha \times N_{\text {predicted }}} \tag{3}
\end{equation*}
$$

where $\alpha$ is the over-dispersion parameter of the SPF.

The sites with PSI greater than 10 percentile are defined as hotspots while the other sites are considered normal spots. Tables 1 and 2 show examples of hotspots for segments and intersections, respectively.

In Table 8-1, the six-lane freeway segment located at Roadway 87200000 between 4.653 and 5.441 mileposts has the PSI of 335.760 , which is the segment with the largest PSI. As shown in Table 8-2, the urban signalized 4-legged intersection located at Roadway 86000078 with milepost 1.681 has the PSI of 194.913, which is the one with the highest PSI. As mentioned earlier, a site with PSI greater than 10 percentile was identified as a "Hot" spot. On the other hand, a site having PSI smaller than 10 percentile was categorized as a "Normal" site.

### 8.2 Micro-level Screening for Various Crash Types based on Segments

ESRI ArcMap® was used to visualize the crash risks of each segment based on the category results. In the following sections, segments in Leon County were chosen as an example to show the screening results for selected crash types. Figure 1 depicts the statewide spatial distribution of hotspot segments for total crashes (KABCO). The most of hot segments are clustered in metropolitan areas such as Miami, Orlando, Tampa-St. Petersburg, Jacksonville, and so forth, as expected. Nonetheless, at a statewide level it is not able to specifically find hotspot segments. So it is necessary to zoom in to an area of interest in order to take a look at particular segments with problems.

Figure 8-1 Statewide spatial distribution of hotspot segments for total crashes (KABCO)

Figures 8-2 and 8-3 present the screening results of total (KABCO) and fatal-and-severe injury (KA) crashes based on all segments in Leon County, respectively. It was revealed that the spatial distribution pattern of hot segments for the two types is quite different. Total crashes (KABCO) hotspot segments are more collected in the center of Leon County and also some major arterials in rural areas are identified as a hotspot segment. On the contrary, fatal-and-severe crashes (KA) are spread out to rural areas and mostly on major arterials with high speed limit.

Figure 8-2 Hotspot segments in Leon county for total crashes (KABCO)

Figure 8-3 Hotspot segments in Leon County for severe crashes (KA)

Figures 8-4 exhibits hotspot segments in Leon County for pedestrian-involved crashes.
As shown in Figure 8-4, a majority of pedestrian crash hotspot segments are collected in the center of Tallahassee, and there are no hotspots for pedestrian crashes in rural areas. It is as expected because pedestrian activities usually very high in the urban areas.

Figure 8-4 Hotspot segments in Leon County for pedestrian crashes (PED)

### 8.3 Micro-level Screening for Various Crash Types based on Intersections

Figure 8-6 shows the statewide distribution of hotspot intersections for total crashes (KABCO). The screening result is very comparable with segment hotspot identification for total crashes. Most of hotspot intersections are located in large urban areas: Miami, Jacksonville, Tampa-St. Petersburg, Orlando, et cetera.

Figure 8-5 Statewide spatial distribution of hotspot intersections for total crashes (KABCO)

Figure 8-7 displays the hotspot intersections in Leon County for total crashes (KABCO). There are many hotspot intersections for total crashes in the urban area and several hotspot intersections are placed in rural areas. Nevertheless, only few hotspot intersections for severe crashes were observed in Leon County and most of them are located in the center of Tallahassee (Figure 8-8).

Figure 8-6 Hotspot intersections in Leon County for total Crashes (KABCO)

Figure 8-7 Hotspot intersections in Leon County for severe crashes (KA)

Figure 8-10 shows that the pedestrian crash hotspot intersections were mostly found in the center of Tallahassee.

Figure 8-8 Hotspot intersections in Leon County for pedestrian crashes (PED)

### 8.4 Summary of Microscopic Screening Results

The research team has completed calculation of the PSIs of all segments and intersections based on the SPFs by crash type. All the segments and intersections are screened as a hot or normal site by the ranking them based on the PSIs. Some examples of the screening results were provided for several crash types for a statewide level and Leon County. The results indicated that there is a significant difference in hotspot distribution by crash type. With the screening results, it is expected that policy makers and practitioners can understand the sites with safety problems by crash severity, time period, collision type, and special event, and also appropriate safety countermeasures to reduce such crash types can be provided to the hotspots with priority.

## 9 INTEGRATION OF MACRO-LEVEL AND MICRO-LEVEL SCREENING RESULTS

In Chapters 6 and 8, the research team identified hot zones and hotspots using PSIs in macroscopic and microscopic levels, respectively. As in Phase I of this project, it is expected that the two-level integration results can provide transportation planner and engineers a comprehensive perspective for traffic safety and then more strategic and efficient improvement can be planned and designed. In this chapter, an integration strategy is described in section 9.1. In section 9.2, the macro-level and micro-level based integration procedures are discussed, separately.

### 9.1 Integration Strategy

Various studies have been conducted to analyze transportation crashes for two levels: micro and macro-level. At micro-level, crashes on segments or intersections are investigated and locations with high traffic safety risk can be identified by screening with the objective of offering engineering solutions (such as installing sidewalk, bike lane, etc.). Meanwhile, the macro-level crashes from a spatial aggregation such as a TAZ or county are analyzed and the dangerous zones can be recognized based on screening results so as to provide countermeasures from a planning perspective. Since the micro and macro-level analysis and screening can reduce crashes with different solutions, the combination of screening results based on two levels can provide a comprehensive perspective and therefore develop more appropriate and efficient traffic safety treatments.

In Phase I of this project, the integration was conducted by combining micro-level results into macro-level and then classified zones into different categories based on both micro and macro-level. By this approach, safety issues at the macro- and/or microscopic levels for a zone can be simultaneously identified. However, the approach is limited since it is hard to identify safety issues by intersection or segment at microscopic level. Thus, a new integrated screening approach is required to overcome the shortcomings of the previous screening techniques, and to achieve a balance between details and efficiency.

In this chapter, the research team proposed two approaches for integration from both macroscopic and microscopic perspectives. The two integration approaches were conducted based on the macroscopic and microscopic screening results illustrated in the previous tasks (see Figure 9-1). In the previous tasks, the zones or sites are only classified into two categories: hot and normal. In the integration process, "cold" category was added for zones or sites with bottom $10 \%$ PSIs to offer better comparison and analysis for screening. At the macro-level, zones (Transportation Analysis District (TAD) and Statewide traffic analysis zone (STAZ)) were ranked by their zonal PSIs: zones with top $10 \%$ PSIs were classified as "Hot" zones; zones with bottom $10 \%$ PSIs were classified as "Cold" zones, and other zones were categorized as "Normal". It should be noted that these percentile can be changed as needed. At the microscopic level, sites (segment and intersection) were also ranked by their PSIs and classified into "Hot", "Normal", and "Cold" categories based on their ranking results. The integration process of two different levels is introduced in the following parts.

Figure 9-1 Results of macroscopic hot zone screening (left) and microscopic hotspot screening (right)

### 9.2 Integration Procedure

### 9.2.1 Macro-level based integration

The macro-level based integration procedure is summarized in Figure 9-2. Both macro-level zones and micro-level sites are classified into three categories: "Hot", "Normal", and "Cold". For each zone, the number of total segments and intersections can be determined by using GIS, and meanwhile the number of hot segments and intersections can be identified based on their category results. Thus, the proportion of hot segments and intersections can be determined for all zones. In order to identify whether a zone has safety issues and which site (segment or intersection) has high risk, all zones (TADs and STAZs) are classified in the form of "ZSI". The first character, "Z" of the classification illustrates the macroscopic safety risk which can be "H", " N ", or " C ". The " S " and " I " are numbers representing the proportion range of hot segments and intersections for each zone (Table 9-1). Thus, it is clear that which part should be paid attention based on the combination results. For example, a zone categorized as "H27" means the zone has crash issue at macroscopic level and most of intersections have safety problems.

Figure 9-2 Macro-based integration process

Table 9-1 Range of proportion for segments and intersections

| Segment / Intersection | Range of proportion |
| :---: | :---: |
| 0 | $>=0 \%,<=10 \%$ |
| 1 | $>10 \%,<=20 \%$ |
| 2 | $>20 \%,<=30 \%$ |
| 3 | $>30 \%,<=40 \%$ |
| 4 | $>40 \%,<=50 \%$ |
| 5 | $>50 \%,<=60 \%$ |
| 6 | $>60 \%,<=70 \%$ |
| 7 | $>70 \%,<=80 \%$ |
| 8 | $>80 \%,<=90 \%$ |
| 9 | $>90 \%,<=100 \%$ |

### 9.2.2 Micro-level based integration

The micro-level based integration is illustrated in Figure 9-3. In order to provide appropriate countermeasures to reduce crashes, all sites (segments and intersections) are classified into nine categories including two scale groups (micro and macro) and three safety levels (hot, normal, and cold). These categories are: $\mathrm{HH}, \mathrm{HN}, \mathrm{HC}, \mathrm{NH}, \mathrm{NN}, \mathrm{NC}, \mathrm{CH}, \mathrm{CN}$, and CC (see Table 9-2). Thus, HH indicates a site itself has safety problems and it locates in a zone with safety issues; HN means a site is risky and the risk of the zone where the site locates is moderate; HC illustrates a site faces high crash risk while it is in a safe zone; NH suggests that a site has moderate crash risk and the nearest zone are dangerous; NN represents that both the site and the zone it locates have moderate crash problems; NC specifies that a site has a moderate risk but the safety risk at the macro-level is low; CH indicates that the site is safe while it locates at a dangerous zone; CN means that a safe site locates in a zone with moderate crash problems; CC suggests that both the site itself and the zone is also safe.

Figure 9-3 Micro-based integration process

Table 9-2 Hot zone classifications (micro-based integration)

|  |  | Macro-level |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Hot | Normal | Cold |  |
| Micro-level | Hot | HH | HN | HC |
|  | Normal | NH | NN | NC |
|  | Cold | CH | CN | CC |

### 9.3 Summary

In this chapter, the research team suggested novel methodologies to combine macro-level and micro-level screening results. Two methodologies were proposed: macro-based and micro-based integrations. All crash types analyzed in the previous chapters can be consolidated with the proposed methods, which can provide comprehensive perspective to understand traffic safety issues.

## 10 INTEGRATION RESULTS

In this chapter, both macro-level and micro-level based integration screening results were computed based on the integration procedure introduced in Chapter 9. The integration results for total, severe, and pedestrian crashes in the selected five areas were illustrated and discussed. ESRI ArcMap® was used to visualize the macro and micro-level based combination results. In the following sections, Total (KABCO) and severe crashes (KA) were integrated based on TADs while Pedestrian crashes were combined based on SWTAZs. The total crash hot TADs screening results display the overall crash distribution in Florida, whereas the severe crash hot zone integration screening results exhibit the distribution of traffic crashes with severe injury or fatality. The pedestrian crash hot zone screening was also conducted since it is based on different zonal system. The macro-and micro-level based integration screening results are exhibited in Sections 10.1 and 10.2, respectively.

### 10.1 Macro-level Based Integration Screening Results

### 10.1.1 Total crashes (KABCO)

Figure 10-1 shows the spatial distribution of TADs by hot zone classification for total crashes in the whole state. The most of hot zones are clustered in metropolitan areas such as Tallahassee, Jacksonville, Tampa, Orlando, Miami, and so forth, as expected. Nonetheless, at a statewide level it is not able to specifically analyze the integration results. So it is necessary to zoom into several areas of interest in order to take a close look. Five areas in Florida (Leon County, Duval

County, Hillsborough County, Orange-Seminole-Osceola Counties, and Miami-Dade County) were chosen as examples to show our screening results.

Figure 10-1 Screening results for total crashes in Florida (TADs)

Figures 10-2 to 10-6 show the integration screening results for total crash based on TAD in five selected areas. In Leon and Duval Counties, only one or two TADs were identified as hot zones and the proportion of hot segments and intersection is not high, indicating that these hot zones had macro-level safety problems. In Hillsborough and Orange-Seminole-Osceola Counties, several TADs were classified as hot zones among which had high proportion of hot segments and intersections. For example, in Orange-Seminole-Osceola Counties, one TAD was labelled as "H51", indicating the zone was risky at macro-level and also has a lot of dangerous segments. Meanwhile, a close look for these segments is also needed. Moreover, half of zones in MiamiDade County were hot zones at macro-level. Meanwhile, most of the hot zones have high proportion of hot segments and intersections. Thus, in Miami-Dade County, both countermeasures from a planning perspective and engineering solutions should be provided to reduce crash risks.

Figure 10-2 Macro-level based integration results based on TADs for total crashes in Leon County

Figure 10-3 Macro-level based integration results based on TADs for total crashes in Duval County

Figure 10-4 Macro-level based integration results based on TADs for total crashes in Hillsborough County

Figure 10-5 Macro-level based integration results based on TADs for total crashes in Orange-Seminole-Osceola Counties

Figure 10-6 Macro-level based integration results based on TADs for total crashes in Miami-Dade County

### 10.1.2 Severe crashes (KA)

Figure 10-7 exhibits the spatial distribution of hot TADs for severe crashes in Florida. It was shown that severe crashes have the quite different distribution pattern from total crashes. Compared to the total crashes, the hot zones for severe crashes are spread out to more rural areas. In order to make a comparison with total crashes, the selected five regions were zoomed in to show the integrated screening results for severe crashes.

Figure 10-7 Screening results for severe crashes in Florida (TADs)

Figures 10-8 to 10-12 exhibit the integration screening results for severe crash based on TADs in the five selected areas. In Leon County, no hot zones were observed and all TADs have low proportion of hot segments and intersection. In Duval County, only one hot zone was identified and was labeled as "H00". Thus, this zone has only macro-level safety problem although no safety risks were observed at micro-level. On the other hand, there is a large cluster of severe crash hot zones in Hillsborough County. Some of the zones have only macro-level safety problems while some zones are risky at both levels. Moreover, the numbers of hot zones for severe crashes in Orange-Seminole-Osceola and Miami-Dade counties have reduced whereas more number of cold zones with a low proportion of hot segments and intersections are observed in the two areas.

Figure 10-8 Macro-level based integration results based on TADs for severe crashes in Leon County

Figure 10-9 Macro-level based Integration Results based on TADs for severe crashes in Duval County

Figure 10-10 Macro-level based integration results based on TADs for severe crashes in Hillsborough County

Figure 10-11 Macro-level based Integration Results based on TADs for severe crashes in Orange-Seminole-Osceola Counties

Figure 10-12 Macro-level based integration results based on TADs for severe crashes in miami-dade county

### 10.1.3 Pedestrian crashes (PED)

Figure 10-13 presents the spatial distribution of SWTAZs by hot zone classification for pedestrian crashes in Florida. Similar to total crashes, most of hot zones were concentrated in metropolitan areas. SWTAZs in Leon County, Duval County, Hillsborough County, Orange-Seminole-Osceola Counties, and Miami-Dade County were selected to provide an example of the integration screening results for pedestrian crashes.

Figure 10-13 Screening results for pedestrian crashes in Florida (SWTAZs)

Figures $10-14$ to $10-18$ show the integration screening results for pedestrian crash based on SWTAZs in the five selected areas. It should be noted that not all the zones can be labeled due to the scale of the report. For the detailed integration results of each zone, the readers are referred to the attached spreadsheets. It was indicated that most of the hot zones located in the center of the chosen urbanized areas. It was as expected because pedestrian activities usually take place in the urban areas. Most zones with moderate safety problem for pedestrians were observed in suburban areas. A majority of the zones have zero proportion of hot intersections and segments, especially in rural areas due to the very low pedestrian activities in the areas.

Figure 10-14 Macro-level based integration results based on SWTAZs for pedestrian crashes in Leon County

Figure 10-15 Macro-level based integration results based on SWTAZs for pedestrian crashes in Duval County

Figure 10-16 Macro-level based integration results based on SWTAZs for pedestrian crashes in Hillsborough County

Figure 10-17 Macro-level based integration results based on SWTAZs for pedestrian crashes in Orange-Seminole-Osceola Counties

Figure 10-18 Macro-level based integration results based on SWTAZs for pedestrian crashes in Miami-Dade County

### 10.2 Micro-level Based Integration Screening Results

In order to show examples of micro-level based integration screening results, one of the hot and cold zones (SWTAZ for pedestrian crashes and TAD for all other crash types) were chosen and zoomed in to display the location and screening results of segments and intersections.

### 10.2.1 Total crashes (KABCO)

Figures 10-19 to 10-23 exhibit the micro-level based integration results based on the chosen TAD (i.e., the zone with the highest PSI) for total crashes in the five areas. For the hot segment or intersection in these areas, safety should be improved by not only specific engineering solutions but also macro-level countermeasure such as education and enforcement.

In the selected hot TAD of Leon County, serval hot segments and intersection were found in the northwest part and also along the Apalachee Parkway (Figure 10-19). It is indicated that the TAD had micro-level safety problem not only for segment but also intersection. Figure 10-20 shows that the selected hot TAD in Duval County had segments with high risks on Interstate 95, State Road 115, and State Road 10 while only one dangerous intersection was found in this TAD.

In Hillsborough County (Figure 10-21), the hot TADs had several hot segments and intersection were observed on Interstate Road 275 and State Road 580. It was shown that multiple hot intersections and segments are on State Road 441 in the hot TAD in Orange-

Seminole-Osceola Counties (Figure 10-22). In Miami-Dade County, the selected hot TAD has several hot intersections and segments on State Road 441 and State Road 9.

Figure 10-19 Micro-level based integration results based on the selected hot TAD for total crashes in Leon County

Figure 10-20 Micro-level based integration results based on the selected hot TAD for total crashes in Duval County

Figure 10-21 Micro-level based integration results based on the selected hot TAD for total crashes in Hillsborough County

Figure 10-22 Micro-level based integration results based on the selected hot TAD for total crashes in Orange-Seminole-Osceola Counties

Figure 10-23 Micro-level based integration results based on the selected hot TAD for total crashes in Miami-Dade County

Figures 10-24 to 10-26 exhibit the micro-level based integration results based on the selected cold TAD for total crashes in Duval County, Hillsborough County, and Orange-Seminole-Osceola Counties. For Leon and Miami-Dade Counties, there is no "Cold" TAD for total crashes. In these TADs, several dangerous segments or intersections are observed. For these hot segments and intersection in cold TADs, only engineering solutions are needed to reduce crashes since all of them located in zones without traffic safety problems at macroscopic level.

Figure 10-24 Micro-level based integration results based on the selected cold TAD for total crashes in Duval County

Figure 10-25 Micro-level based integration results based on the selected cold TAD for total crashes in Hillsborough County

Figure 10-26 Micro-level based integration results based on the selected cold TAD
for total crashes in Orange-Seminole-Osceola Counties

### 10.2.2 Severe crashes (KA)

Figures 10-27 to10-30 exhibit the micro-level based integration results based on the selected hot TADs for severe crashes in the five selected areas except Leon County since no hot TAD was observed in this area. The TADs shown in the following figures are the same TADs for total crashes. It is noteworthy that these TADs have the same hot segments and intersections for total and severe crashes. Thus, as mentioned above, both macro-level and micro-level countermeasures should be simultaneously offered to reduce traffic crash risks in the areas.

Figure 10-27 Micro-level based integration results based on the selected hot TAD for severe crashes in Duval County

Figure 10-28 Micro-level based integration results based on the selected hot TAD for severe crashes in Hillsborough County

Figure 10-29 Micro-level based integration results based on the selected hot TAD for severe crashes in Orange-Seminole-Osceola Counties

Figure 10-30 Micro-level based integration results based on the selected hot TAD for severe crashes in Miami-Dade County

Figures $10-31$ to $10-35$ display the micro-level based integration results based on the selected cold TAD for severe crashes in the five areas. Except for the selected cold TAD in the Hillsborough County, the TADs in other areas have only one or two hot segments. However, in the selected cold TAD in the Hillsborough County, three hot intersections were revealed. It may be because other intersections or segments are exceptionally safe (in other words, very low PSIs) in the selected cold TAD for severe crash. Hence, special engineering countermeasures should be applied to solve the safety problems for these intersections.

Figure 10-31 Micro-level based integration results based on the selected cold TAD for severe crashes in Leon County

Figure 10-32 Micro-level based integration results based on the selected cold TAD for severe crashes in Duval County

Figure 10-33 Micro-level based integration results based on the selected cold TAD for severe crashes in Hillsborough County

Figure 10-34 Micro-level based integration results based on the selected cold TAD for severe crashes in Orange-Seminole-Osceola Counties

Figure 10-35 Micro-level based integration results based on the selected cold TAD for severe crashes in Miami-Dade County

### 10.2.3 Pedestrian crashes (PED)

The integration results for the selected hot SWTAZ in the five areas were shown in Figures 10-36 to 10-40. As shown in these figures, the SWTAZs have less segments and intersections inside compared with TADs since the area of SWTAZs is much smaller. Nevertheless, hot segments or intersections could be still found in these zones except for the SWTAZ in Orange-Seminole-Osceola Counties. That indicated that this SWTAZ has overrepresented pedestrian crash risks only at macro-level problem.

Figure 10-36 Micro-level based integration results based on the selected hot swtaz for pedestrian crashes in Leon County

Figure 10-37 Micro-level based integration results based on the selected hot SWTAZ for pedestrian crashes in Duval County

Figure 10-38 Micro-level based integration results based on the selected hot SWTAZ for pedestrian crashes in Hillsborough County

Figure 10-39 Micro-level based integration results based on the selected hot SWTAZ for pedestrian crashes in Orange-Seminole-Osceola Counties

Figure 10-40 Micro-level based integration results based on the selected hot SWTAZ for pedestrian crashes in Miami-Dade County

The integration results for the selected cold SWTAZ in the five areas were exhibited in Figures $10-41$ to $10-45$. The integration screening results indicated that the macro and micro-level results of pedestrian crashes are consistent based on cold SWTAZs. There was no hot segment and intersection in the cold TADs as shown in the following five figures.

Figure 10-41 Micro-level based integration results based on the selected cold SWTAZ for pedestrian crashes in Leon County

Figure 10-43 Micro-level based integration results based on the selected cold SWTAZ for pedestrian crashes in Hillsborough County

Figure 10-44 Micro-level based integration results based on the selected cold SWTAZ for pedestrian crashes in Orange-Seminole-Osceola Counties

Figure 10-45 Micro-level based integration results based on the selected cold SWTAZ for pedestrian crashes in Miami-Dade County

### 10.3 Summary

The research team has completed the combination of the two levels from both macroscopic and microscopic perspectives. All zones were integrated with the segments and intersections inside at macro-level while all segments and intersections were integrated with zones at micro-level. Some examples of the integration screening results were provided for several crash types for five selected metropolitan areas. With the twolevel screening results, it is expected that comprehensive understanding about transportation safety can be obtained so that the efficient safety planning as well as engineering countermeasures can be provided.

## 11 DEVELOPMENT OF SPREADSHEETS

Based on the integrated screening analysis in Chapter 9, six Excel spreadsheet files were prepared as follows:

- Macroscopic level based integrated screening:

1. SWTAZs: pedestrian and bicycle crashes
2. TADs: all other 15 crash types

- Microscopic level based integrated screening:

3. Segments combined with SWTAZs (for pedestrian and bicycle crashes)
4. Segments combined with TADs (all other 15 crash types)
5. Intersection combined with SWTAZs (for pedestrian and bicycle crashes)
6. Intersections combined with TADs (all other 15 crash types)

The macroscopic level based integrated screening results for several major crash types: total, severe, and pedestrian crashes were summarized in Appendices $\mathrm{B}, \mathrm{C}$, and D , respectively. The prepared spreadsheets will be sent along with the Final Deliverable.

Each spreadsheet is explained in sections 11.1 and 11.2.

### 11.1 Macroscopic Level Based Integrated Screening

### 11.1.1 SWTAZs based integration (for pedestrian and bicycle crashes)

As shown in Table 11-1, five columns were included in the spreadsheet of SWTAZs based integration: SWTAZ ID, number of segments in each SWTAZ, number of intersections in each SWTAZs, integration results for pedestrian and bicycle crashes. There were totally 8,518 SWTAZs in Florida employed for the integration. As for the integration for pedestrian and bicycle crashes, the results were shown in the form of "ZSI", the first character "Z" presents the safety risk SWTAZs which can be "H", "N", and "C"; the "S" and "I" are numbers representing the proportion range of hot segments and intersections for each zone (Table 11-2). For example, the pedestrian integration result for SWTAZ 1 was labeled as "H00", which means that this SWTAZ has hot safety risk for pedestrian crashes while the percentages of hot segments and intersections were between 0 to $10 \%$.

Table 11-3 Spreadsheet for SWTAZs based integration for pedestrian and bicycle crashes

| SWTAZ | No of Segments | No of Intersections | PED | BIKE |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 6 | 0 | H00 | N00 |
| $:$ | $:$ | $:$ | $:$ | $:$ |
| 109 | 8 | 3 | C00 | N10 |
| $:$ | $:$ | $:$ | $:$ | $:$ |
| 8518 | 0 | 0 | N00 | N00 |

Table 11-4 Range of proportion for segments and intersections

| Segment / Intersection | Range of proportion |
| :---: | :---: |
| 0 | $>=0 \%,<=10 \%$ |
| 1 | $>10 \%,<=20 \%$ |
| 2 | $>20 \%,<=30 \%$ |
| 3 | $>30 \%,<=40 \%$ |
| 4 | $>40 \%,<=50 \%$ |
| 5 | $>50 \%,<=60 \%$ |
| 6 | $>60 \%,<=70 \%$ |
| 7 | $>70 \%,<=80 \%$ |
| 8 | $>80 \%,<=90 \%$ |
| 9 | $>90 \%,<=100 \%$ |

### 11.1.2 TADs based integration (for other 15 crash types)

The integration results based on TADs for 15 other types of crashes such as KABCO (total crashes), KA (severe crashes) were as shown in Table 11-3. There are 594 TADs included for the integration. As shown in the following columns, the numbers of segments and intersections in each TAD are presented. Meanwhile, the integration screening index, "ZSI" was employed for the TADs based integration and the ranges for the "S" and "I" are same as SWTAZs based integration. For example, the first TAD in Table 3, TAD 0 is a "Normal" zone with hot segments and intersections for total crashes are less than or equal to $10 \%$. On the other hand, TAD 0 is a "Hot" zone for severe crashes with the hot segments are greater than $10 \%$ and less than or equal to $20 \%$; but no hot intersections.

Table 11-5 Spreadsheet for TADs based integration for 15 other types of crashes

| TAD | No of Segments | No of Intersections | KABCO | .. | KA | .. | DUI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 11.2 Microscopic Level Based Integrated Screening

As for the microscopic level based integrated screening, each segment and intersection is consolidated with macroscopic-level zone screening results.

### 11.2.1 Segments combined with SWTAZs (for pedestrian and bicycle crashes)

As shown in Table 11-4, six columns were included in the spreadsheet of segments combining with SWTAZ: ROADWAY (Roadway ID), BEGMP (Beginning milepost) ENDMP (ending milepost), SWTAZ a segment belongs to, categories of integrated screening results for pedestrian and bicycle crashes. Totally 29,011 segments in Florida were screened along with 8,518 SWTAZs. Nine categories were classified by considering two scale groups (micro and macro-levels) and three safety levels (hot, normal, and cold). These categories are: HH, HN, HC, NH, NN, NC, CH, CN, and CC (see Table 11-5). For example, the segment with Roadway ID 01000003 (MP: 0 to 0.17 ) was identified as "CN", indicating that the segment was very safe whereas it is located in a SWTAZ having a moderate risk for pedestrian crash.

Table 11-6 Spreadsheet for segments based integration for pedestrian and bicycle crashes

| ROADWAY | BEGMP | ENDMP | SWTAZ | PED | BIKE |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 01000003 | 0 | 0.17 | 789 | CN | CN |
| 01000003 | 1.26 | 2 | 152 | NC | NC |
| 01000010 | 0 | 0.47 | 3076 | HN | HH |
| 01000017 | 0.71 | 0.86 | 821 | CC | HC |
| 01000022 | 1.22 | 1.36 | 8283 | CH | CN |
| 01000024 | 0.09 | 0.4 | 4614 | NH | NH |

|  |  | Macro-level |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Hot | Normal | Cold |
| Micro-level | Hot | HH | HN | HC |
|  | Normal | NH | NN | NC |
|  | Cold | CH | CN | CC |

### 11.2.2 Segments combined with TADs (for other 15 crash types)

The integrated screening results based on segments consolidated with TADs for 15 crash types are shown in Table 11-6. All segments were combined with 594 TADs based on the locations. As shown in Table 6, Roadway ID, beginning milepost, ending milepost, TAD where a segment is located, and integration results for 15 other types of crashes were provided. The same integration method and nine categories were employed for the combination process. For example, the first segment (Roadway ID 01000003 / MP: 0 to
0.17 ) was classified as "NH" for total crashes, which means that this segment has a moderate crash risk for total crashes while it is located in a TAD with a high total crash risk for total crashes.

Table 11-8 Spreadsheet for segments based integration for 15 other types of crashes

| ROADWAY | BEGMP | ENDMP | TAD | KABCO | .. | KA | .. | DUI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 01000003 | 0 | 0.17 | 525 | NH | $:$ | CN | $:$ | NH |

| $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ | $:$ |
| 94819000 | 0.49 | 0.98 | 591 | NN | .. | NN | .. | NN |

### 11.2.3 Intersection combined with SWTAZs (for pedestrian and bicycle crashes)

The integrated screening results based on intersections combined with SWTAZs for pedestrian and bicycle crashes are presented in Table 11-7. Five columns were included in the table: Roadway ID, intersection milepost, SWTAZ, pedestrian and bicycle crash screening results. Totally 8,347 intersections in Florida were analyzed.

Table 11-9 Spreadsheet for intersections based integration for pedestrian and bicycle crashes

| ROADWAY | BEGMP | SWTAZ | PED | BIKE |

## 12 SUMMARY AND CONCLUSIONS

### 12.1 Summary

In this research project, there were eight major objectives. All the main objectives of this second phase of the project have been achieved as follows:

## 1. Develop TSAZs for other areas in Florida

TSAZs have been developed for the whole Florida. The developed TSAZs are recommended for metropolitan areas (Chapter 4).
2. Develop SPFs for 17 crash types based on micro-level (i.e., intersection and segment) and macro-level (i.e., SWTAZs, TSAZs, TADs, counties)

A series of SPFs for the following 17 crash types were developed at the micro-level and macro-level:

- Total crashes;
- Crashes by severity: KABC, KAB, and KA;
- Crashes by time period: weekday-morning peak, weekday-off peak, weekday-evening peak, weekday-nighttime, weekend-daytime, and weekend-nighttime;
- Crashes in adverse weather conditions: rainy, foggy conditions;
- Crash types: single-vehicle, multiple-vehicle, pedestrian, and bicycle involved; and
- DUI crashes

Overall 404 SPFs were estimated for 13 segments and 16 intersection facility types. Also, 204 SPFs were developed for SWTAZs, TSAZs, TADs, and county (Chapters 5 and 7).
3. Identify hot zones at different spatial scales, such as SWTAZ, TAD and county: The macroscopic screening analyses were conducted at different spatial scales (Chapter 6).

## 4. Identify hot intersections and sections

The microscopic screening investigations were performed for intersections and segments in Florida (Chapter 8).

## 5. Use and adapt the HSM screening procedures

All the screening procedure followed the HSM (Chapters 6 and 8).
6. Develop practical and user-friendly spreadsheets for the integrated screening

The integrated screening results were prepared in the form of spreadsheets (Chapter 11).
7. Provide a stepwise procedure for integrating micro and macro screening results with transportation planning

The stepwise procedures to consolidate micro and macro screening results were provided in Chapter 9.

## 8. Analyze hot sites/zones by various crash types, times, and conditions: The

 analysis results were provided in Chapters 5-11.
### 12.2 Conclusion

In recent, many studies have been conducted for traffic safety problems at both microscopic and macroscopic levels. Base on the HSM Part B (AASHTO, 2010), specific locations such as segments and intersections with high crash risks can be identified with a microscopic screening analysis and then proper engineering solutions (such as signalization, installing sidewalk, street lighting) are provided considering the sites' particular problems. In Phase I of the project, the research team followed the screening procedure in HSM and extended it to macroscopic level using Orange, Seminole, and Osceola Counties data. The research team extended these efforts to a statewide level. Thus, zones such as SWTAZs and TADs having particular transportation safety problems can be recognized by a macroscopic screening investigation and then countermeasures from a planning perspective such as educations, outreaches and enforcements can be suggested. The research team proposed a methodology to consolidate the screening results from the two levels.

In the macroscopic safety analysis, TAZs (Traffic analysis zones) have been most widely used as a spatial unit as they are directly related to transportation planning procedures. However, there are two major disadvantages for TAZs using in traffic safety analysis: 1) small size in urban area and 2) high percentages of boundary crashes. In order to
overcome these issues, the research team provided two solutions. The first way is to use regionalization to develop a new study unit TSAZs (Traffic safety analysis zones) for TAZs based on the crash rate. The other way is to apply larger geographic units such as TADs (Transportation Analysis Districts) and counties. In this study, statewide zonal systems: SWTAZs (Statewide TAZs), TSAZ, TADs, and counties were employed for macroscopic crash analysis. As for the TSAZs, the research team Brown-Forsythe test to select the optimal scale (one-fifth of number of SWTAZs), which reduces boundary crashes and zones without including rare types of crashes. The developed TSAZs are recommended applying in urban areas, which often have extremely small TAZs.

Overall, Florida-specific macro-level 204 SPFs were developed based on the four types of geographic units for 17 crash types by severity levels, time periods, collision types, and special events. We compared the predictability of SPFs of different zonal system for different crash types by employing neutral grid systems. Based on the comparison results, the best geographic units for screening analysis were determined: SWTAZs are the optimal zonal system for non-motorized mode crash (such as pedestrian and bicycle crashes) analysis while TADs were the most appropriate spatial unit for all other crash types.

Concerning microscopic crash analysis, one major challenge was that there are too many facility types of segments and intersections in the whole Florida. Basically, the research team used the facility types suggested in the HSM, and we have added more facility types
which were not covered by the HSM. Hence, segments were categorized into 13 facility types based on location (urban or rural), number of lanes, access control (full or no access control), and median division. Meanwhile intersection were classified into 16 facility types based on the location (urban or rural), number of legs ( $3,4,5$, or 6 ), control types (stop or signal controlled), and one-way roads. Totally 404 Florida-specific micro-level SPFs were estimated for 17 crash types based on each segment and intersection facility type.

Subsequently, a series of screening analyses were performed for the two levels by the ranking results based on the PSI (Potential for Safety Improvement). At the macroscopic level, a statewide screening analysis was conducted based on SWTAZs (for pedestrian and bicycle crashes) and TADs (for all other crash types). At the microscopic level, a statewide screening analysis was conducted for segments and intersections for various crash types. Both macro-level zones and micro-level sites are classified into three categories: "Hot", "Normal", and "Cold". Then, a two-stage integration of the screening results from macroscopic and microscopic perspectives was employed. As for the macrolevel based integration, the selected geographic units (i.e., SWTAZs and TADs) were labelled in the form of "ZSI". The first character "Z" of the classification illustrates the macroscopic safety risk which can be "H", "N", and "C". The subsequent categories: "S" and "I" are numbers representing the proportion range of hot segments and intersections for each zone, respectively. On the other hand, the micro-level based integration was developed to identify whether a segment or intersection has safety issues at micro- and/or
macroscopic levels. All segments and intersections were classified into nine categories that include two scale groups (micro and macro) and three safety levels (hot, normal, and cold) for 17 crash types. These categories are: HH, HN, HC, NH, NN, NC, CH, CN, and CC. The first character of the classification represents the microscopic safety risk, and the second character indicates the macroscopic safety levels.

Finally, five representative metropolitan areas in Florida were selected to show the integrated screening results for total, severe, and pedestrian crashes. The TAD-based total crash screening results display the overall crash distributions within the whole state and the selected five areas. The result indicated that the hot zones for total crashes are concentrated in metropolitan areas as expected. Meanwhile, the TAD-based severe crash screening result presents the distribution of dangerous areas for crashes with fatality or severe injuries. Compared to the total crash screening result, they have a tendency to be spread out to rural areas. Moreover, the integration screening results for pedestrian based on SWTAZs would show the spatial distribution of pedestrian-vehicle crashes. The hot zones for pedestrian crashes are mostly located in urban areas and also some suburban areas.

To sum up, the research team has proposed two approaches to combine the macro-level and micro-level screening results. In order to conduct a screening, we have developed 608 Florida-specific SPFs for various crash types by facility types and geographic units, which will be very useful for the Florida Department of Transportation, MPOs, and
regional governments. Furthermore, the integration results can provide a comprehensive perspective for the statewide transportation safety and then more appropriate and efficient treatment can be offered to reduce crash risks. Also, different macroscopic zonal systems are recommended for the integration for different crash types. SWTAZs are suggested to explore pedestrian and bicycle crashes and TADs are recommended for all other crash types. Based on the two integration results, distinct strategies should be adopted since different problems could be observed for different categories. In this report, a series of the spreadsheets also provided to help practitioners to employ the integrated screening results from this research.

Nevertheless, it is worth to note that there are several limitations to this study. First, the integration results were presented with maps which are hard to display result in detail for the whole Florida. It is suggested that an interactive GIS software application (e.g. ArcGIS Online) can be employed to better show the integration results for the whole state and the specified areas. Second, only an exposure variable (i.e., traffic) was used for the microscopic SPF estimation due to the complicacy of the categories of segments and intersections. The performance of the estimated SPFs and screening results can be improved if more detailed information can be added into models. Thus, more appropriate treatment can be proposed to specific zones and sites. Third, SPFs were developed for only segments and intersections with observed AADT. Thus, most local streets were not used to estimate SPFs. Lastly, the integration process was only conducted for the twolevel screening results in this research. It may be possible to have more reliable screening
results if the combination process can be accounted from the modeling perspectives. Thus, the effects of variables (such as traffic volume) can be also integrated for both macroscopic and microscopic levels.
