

# Overview

- At October 2016 Workshop, the following relationship was derived between adjacent band transmitter tolerable effective isotropic radiated power (EIRP) and ITM. At a particular center frequency, and for the case of a single transmitter this relationship is:

$$EIRP_{Tol}(\vec{r}_T, \vec{r}) = \frac{PL(\vec{r}_T, \vec{r})}{g_T(\theta(\vec{r} - \vec{r}_T)) \cdot g_R(\theta(\vec{r}_T - \vec{r}))} \cdot ITM$$

propagation loss

normalized transmitter and  
GNSS receiver gains,  
respectively, with respect to  
linear polarization

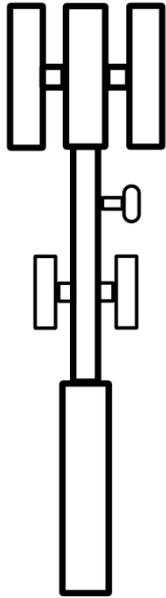

- This presentation:
  - Provides models for adjacent band transmitters (base stations and handsets), and GNSS receiver antenna patterns
  - Provides C/A results for: (1) impacted regions for adjacent band transmitters of various types, (2) maximum EIRPs as a function of “standoff” distances

# Adjacent Band Transmitter Models

# Base Station Modeling

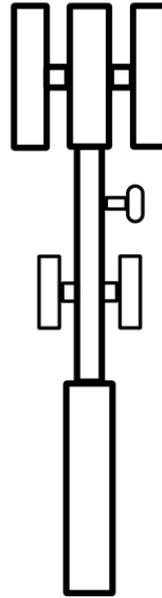

- ❑ Models from International Telecommunication Union Radiocommunication Sector (ITU-R) utilized:
  - Report ITU-R M.2292 – provides characteristics of 4G networks
  - Recommendation ITU-R F.1336 – invoked in M.2292; provides base station antenna gain pattern models
- ❑ M.2292 addresses five network deployment types for 1-3 GHz:
  1. Macro rural
  2. Macro suburban
  3. Macro urban
  4. Small cell outdoor/Micro urban
  5. Small cell indoor/Indoor urban
- ❑ Following charts provide a summary of their base station characteristics

# ITU-R M.2292 Macro Base Stations

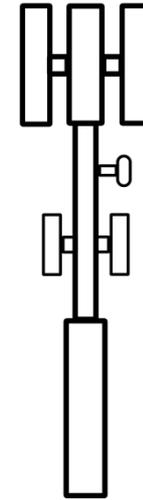

## Macro Rural

- 18 dBi antenna gain
- +/-45° polarization
- 3 sectors
- EIRP: 58/61/61 dBm
- 30 m height
- 3 deg downtilt
- > 3 km cell radius

## Macro Suburban

- 16 dBi antenna gain
- +/-45° polarization
- 3 sectors
- EIRP: 56/59/59 dBm
- 30 m height
- 6 deg downtilt
- 0.5 – 3 km cell radius

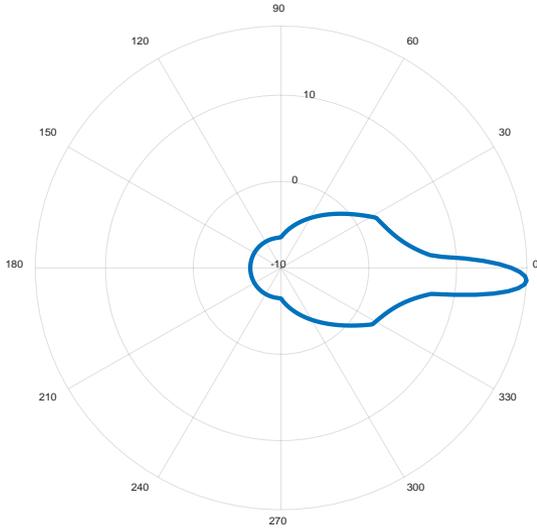

## Macro Urban

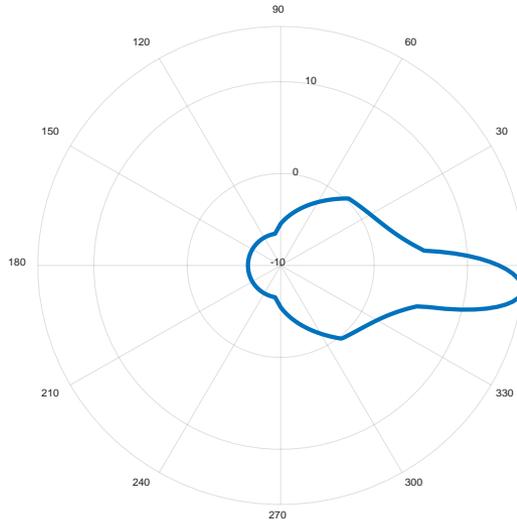

- 16 dBi antenna gain
- +/-45° polarization
- 3 sectors
- EIRP: 56/59/59 dBm
- 25 m height
- 10 deg downtilt
- 0.25 – 1 km cell radius

# Macro Base Station Antenna Gain Patterns

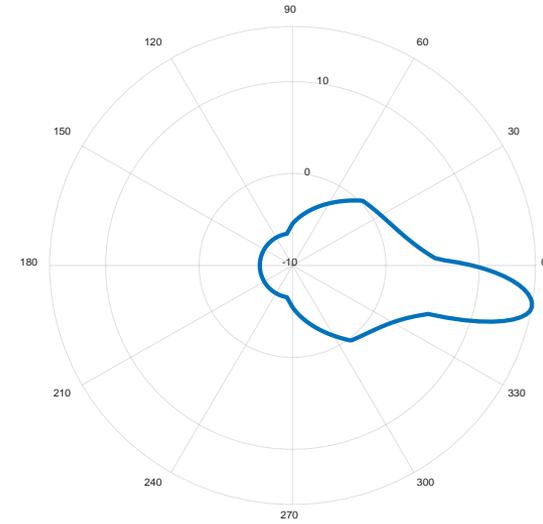

ELEVATION

Rural

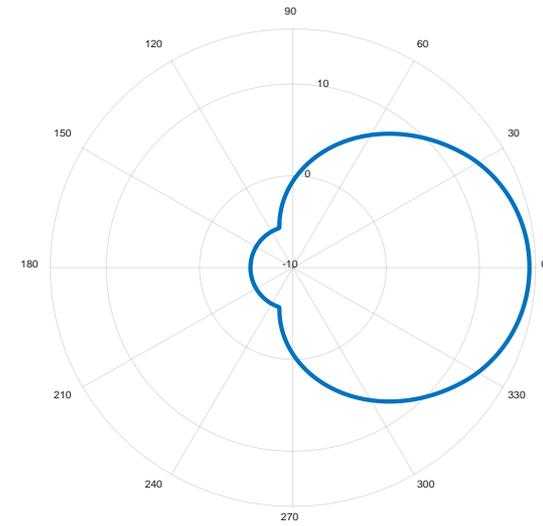

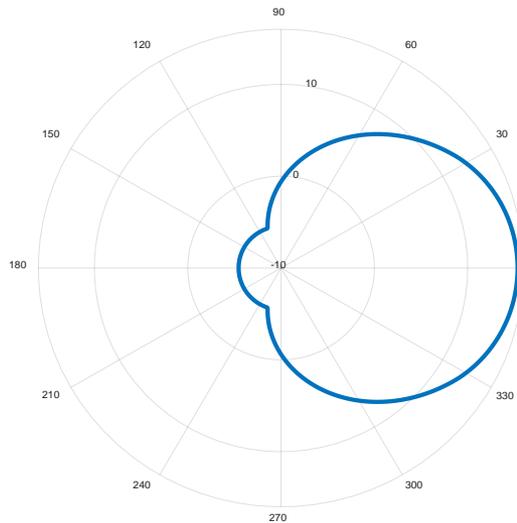

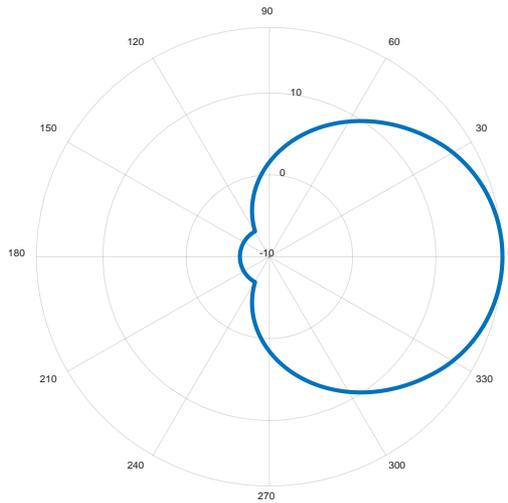

Suburban

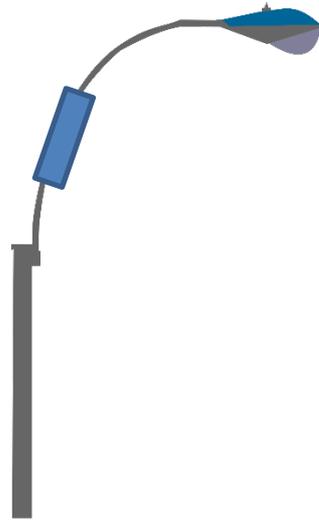

Urban

AZIMUTH

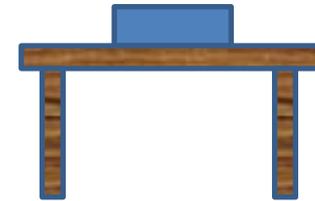

# ITU-R M.2292 Small Cell Base Stations

## Small cell outdoor/ Micro urban

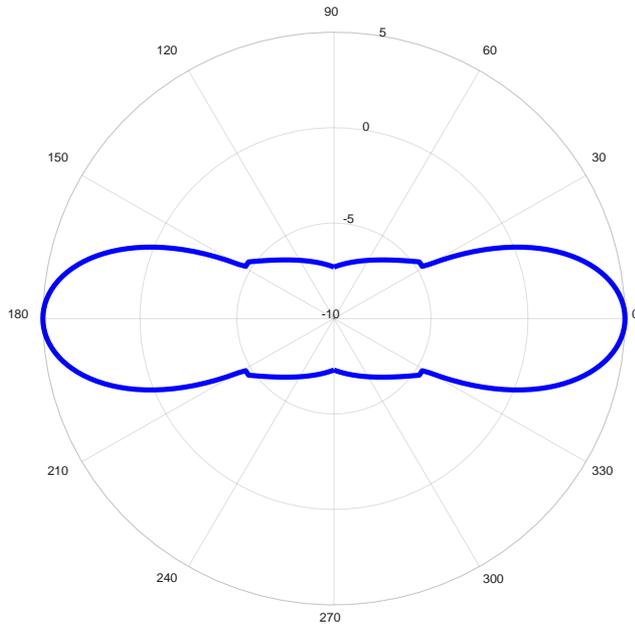

- 5 dBi antenna gain
- Linear polarization
- Single sector
- No downtilt
- EIRP: 40 dBm
- 6 m height
- 1 – 3 per Urban macro cell

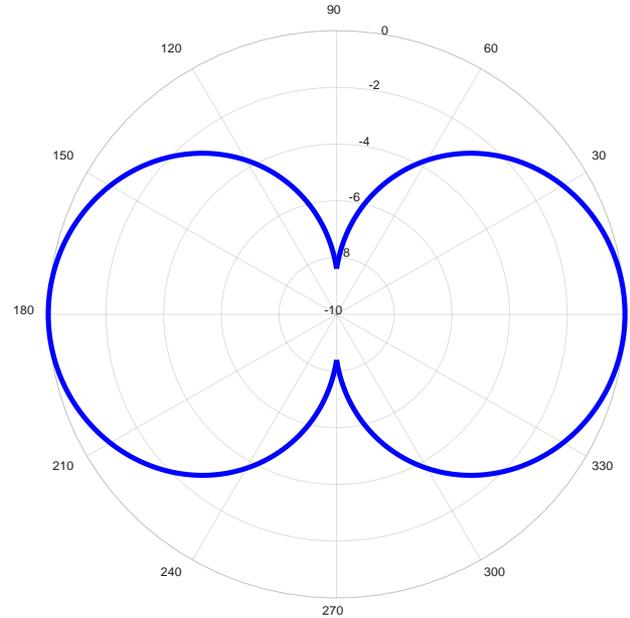

## Small cell indoor/ Indoor urban

- 0 dBi antenna gain
- Linear polarization
- Single sector
- No downtilt
- EIRP: 24 dBm
- 3 m height

# Small Cell Antenna Gain Patterns

**Small cell outdoor/Micro urban**

**Small cell indoor/Indoor urban**

Both patterns are omnidirectional. Plots above are elevation cuts.

# Handset/Mobile Device Modeling

- ❑ 23 dBm EIRP
- ❑ Isotropic transmit antenna gain
- ❑ Vertical polarization
- ❑ Assumed to be at 2 m height above ground

# GNSS Receiver Antenna Models

# GNSS Receiver Antenna Pattern Models

## □ GLN, GAV, HPR, TIM

- Measured horizontal and vertical (HPOL/VPOL) antenna patterns from 14 antennas were grouped by category of receivers and averaged

- A second order parametric fit:

$$(normalized\ gain) = -\alpha \times (off-boresight\ angle)^2$$

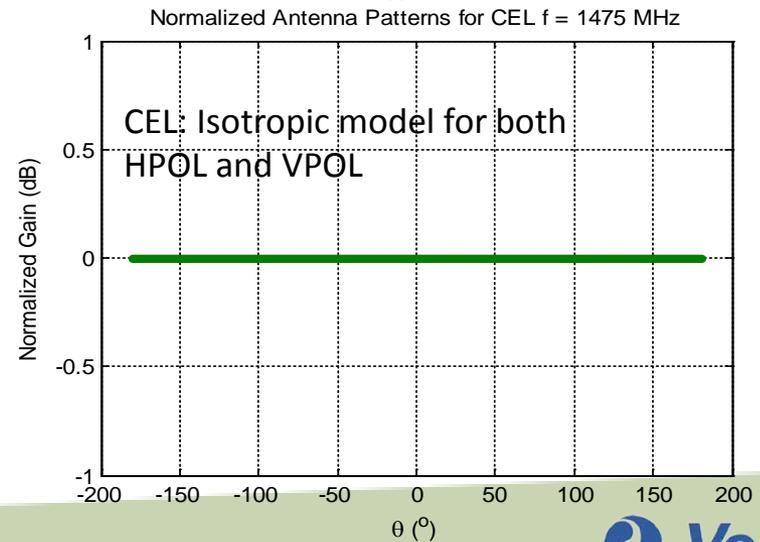

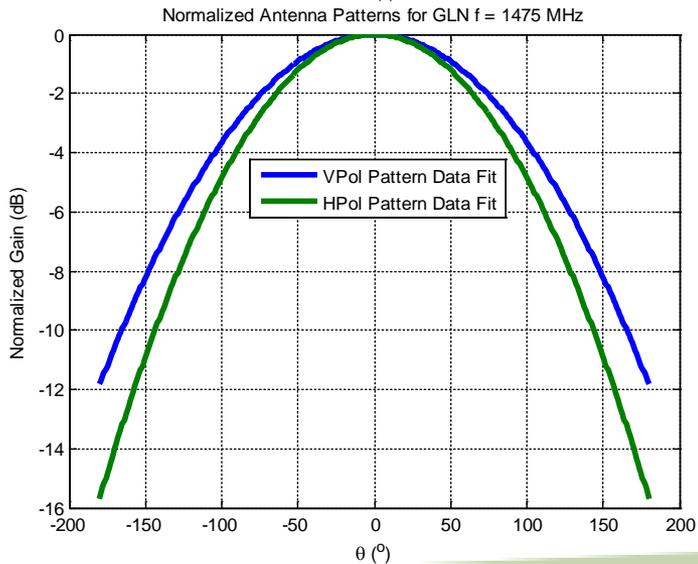

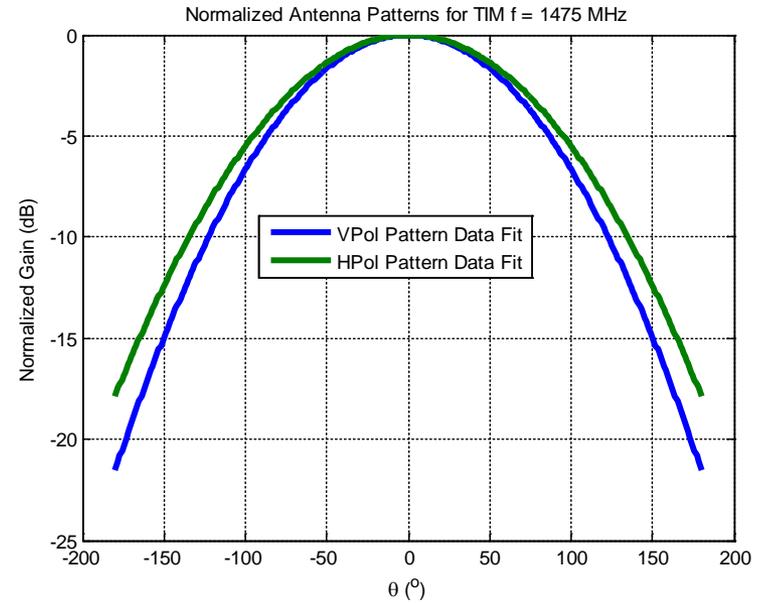

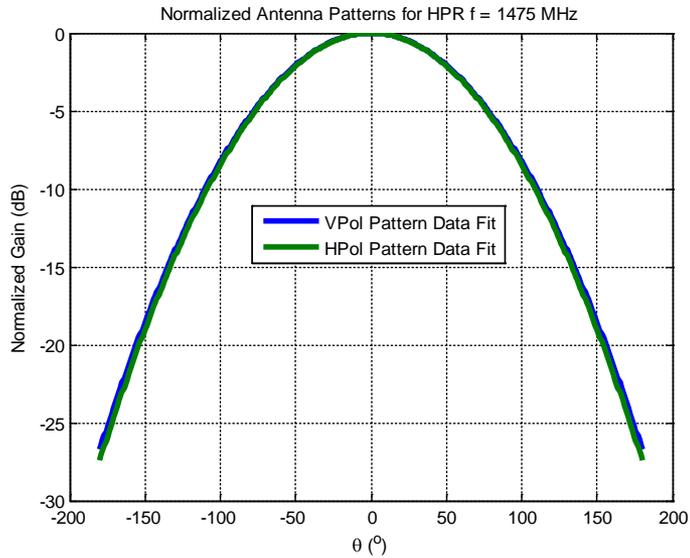

to the average pattern within each category was performed to capture the frequency dependent patterns for each of the H and V polarizations in the analysis

Function of receiver category, frequency, V/H

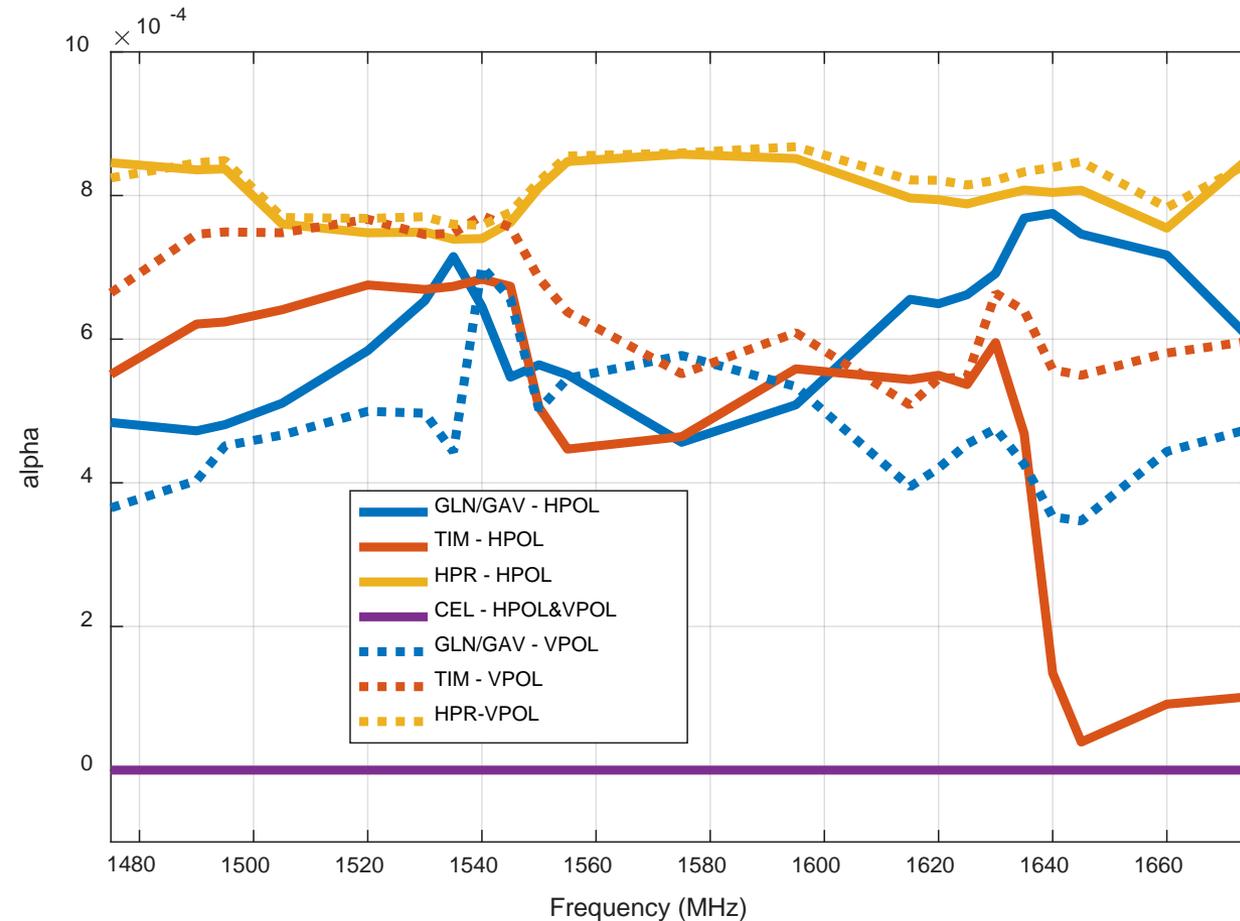

## □ CEL

- Normalized pattern modeled as isotropic with equal HPOL/VPOL

# Example of VPOL and HPOL Patterns

# Parametric Fit Parameters

- Normalized gain,  $G = -\alpha\theta^2$  where  $\theta$  is off-boresight angle (deg)
- Higher  $\alpha$  means gain falls off faster with decreasing elevation angle
- Note that HPR antennas had most rapid gain fall-off and retained RHCP at low elevation angles
- GLN/GAV antennas exhibited faster fall-off of HPOL gain with decreasing elevation angle (as expected)

# Propagation Loss Models

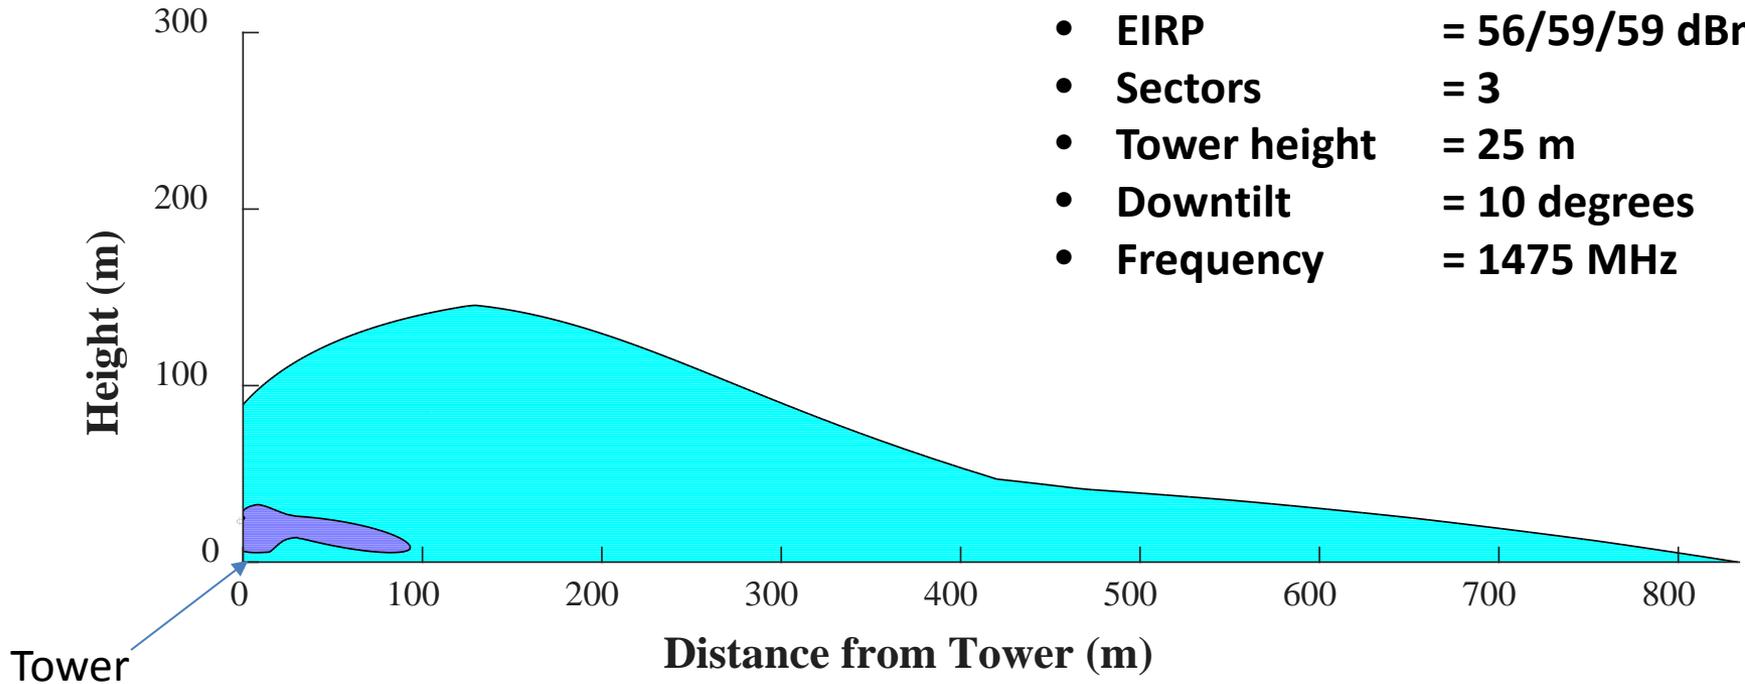

# Propagation Loss Modeling

- ❑ The primary propagation model used in this presentation is the free-space path loss
- ❑ Two-ray path loss model is expected to show larger impact regions (A GLN use case is discussed later in this brief)
- ❑ Irregular Terrain Model ( an improved version of the Longley-Rice Model ) will be considered in the final report

# **Impacted Area Results: Single Macro-Urban Base Station**

# Macro Urban, GLN, 1475 MHz

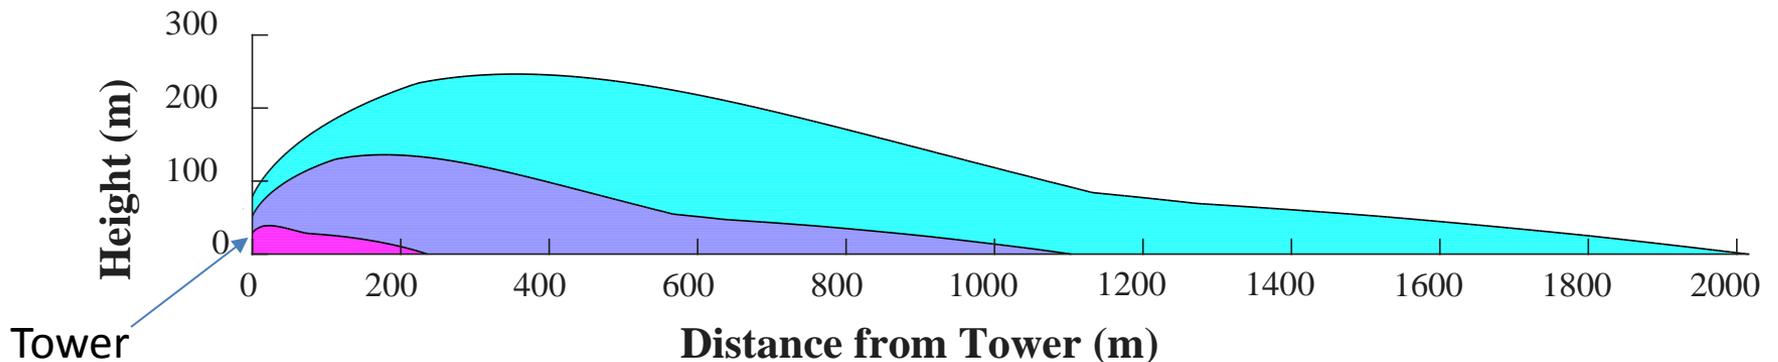

- EIRP = 56/59/59 dBm
- Sectors = 3
- Tower height = 25 m
- Downtilt = 10 degrees
- Frequency = 1475 MHz

-   $\geq 1$  dB  $C/N_0$  degradation
-  Loss of lock of low elevation satellites with clear sky visibility
-  Loss of lock of all satellites with clear sky visibility

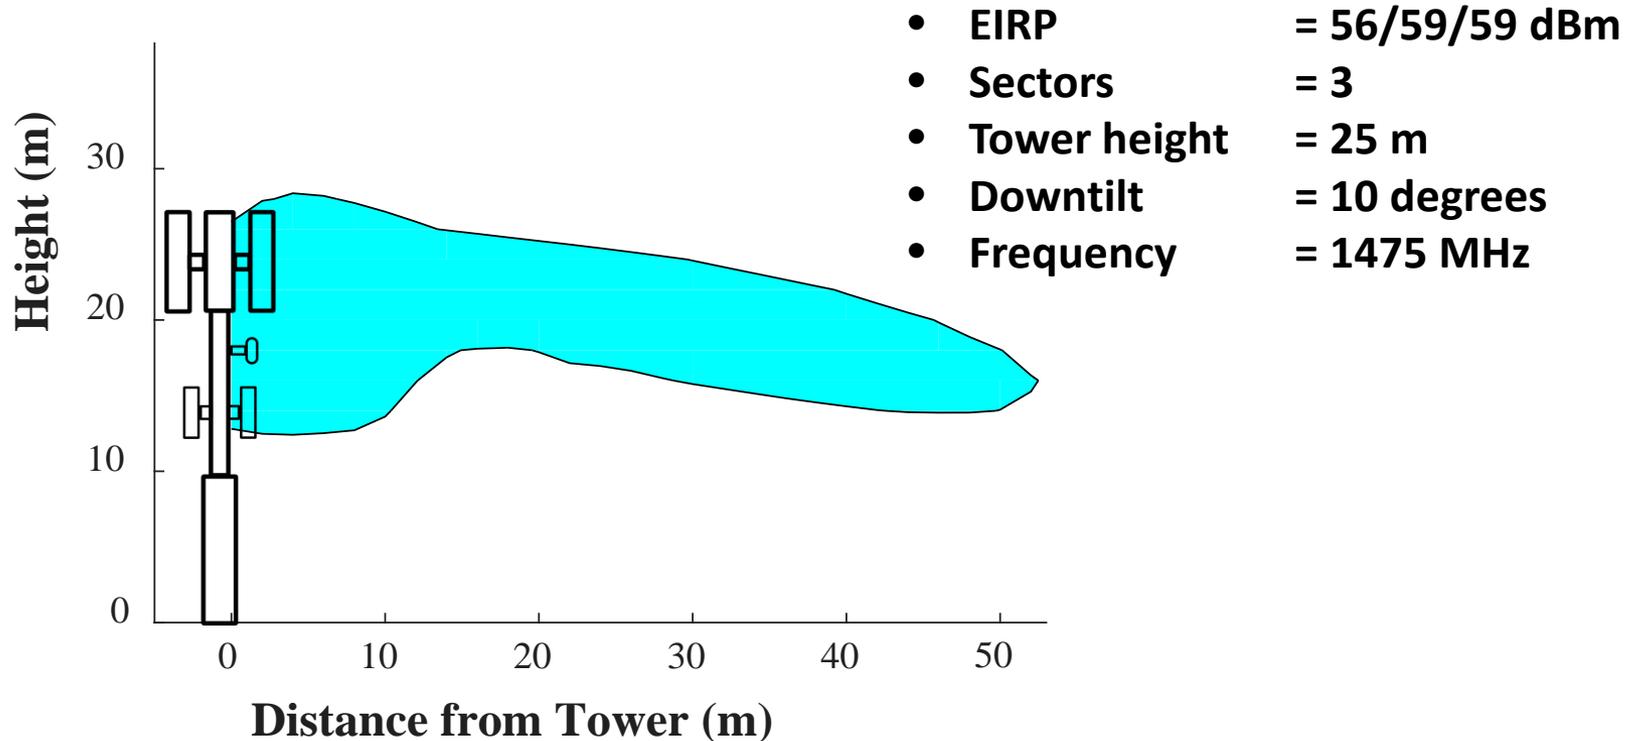

# Macro Urban, HPR, 1475 MHz

- EIRP = 56/59/59 dBm
- Sectors = 3
- Tower height = 25 m
- Downtilt = 10 degrees
- Frequency = 1475 MHz

-   $\geq 1$  dB  $C/N_0$  degradation
-  Loss of lock of low elevation satellites with clear sky visibility
-  Loss of lock of all satellites with clear sky visibility

# Macro Urban, TIM, 1475 MHz

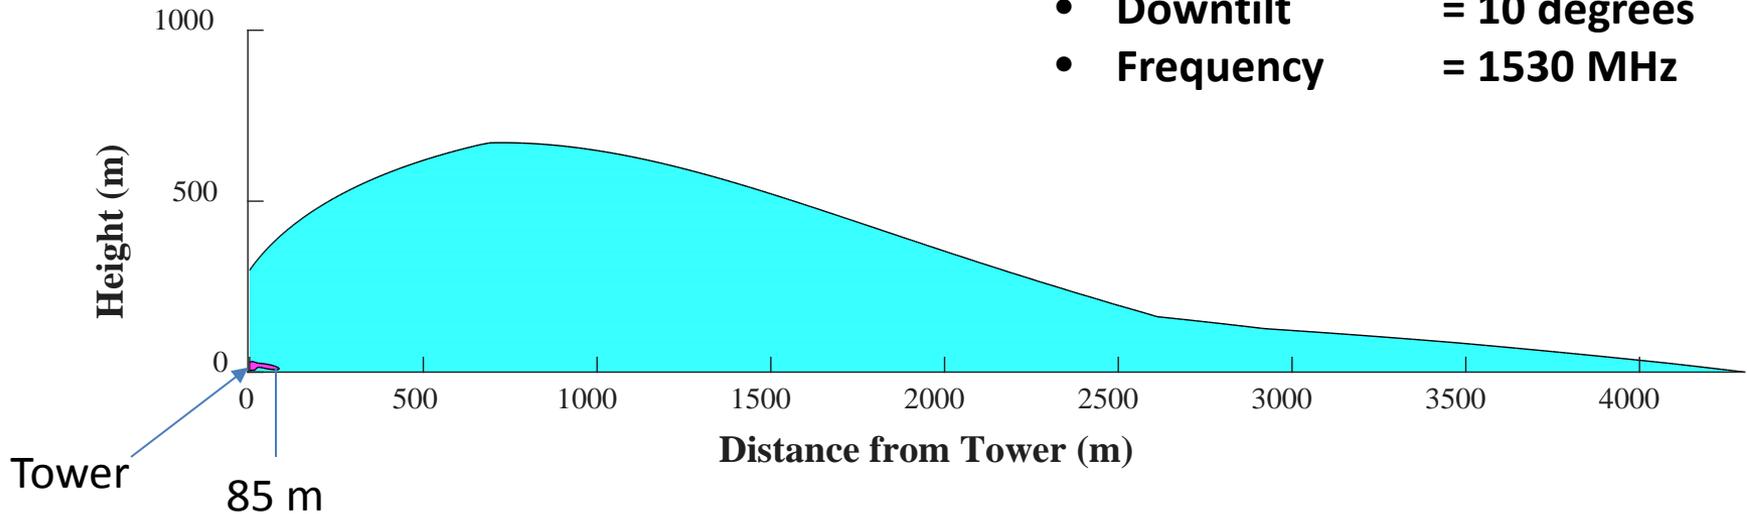

-   $\geq 1$  dB  $C/N_0$  degradation
-  Loss of lock of low elevation satellites with clear sky visibility
-  Loss of lock of all satellites with clear sky visibility

# Macro Urban, CEL, 1475 MHz

No impact up to maximum power tested at WSMR.

# Macro Urban, GLN, 1530 MHz

- EIRP = 56/59/59 dBm
- Sectors = 3
- Tower height = 25 m
- Downtilt = 10 degrees
- Frequency = 1530 MHz

$\geq 1$  dB  $C/N_0$  degradation

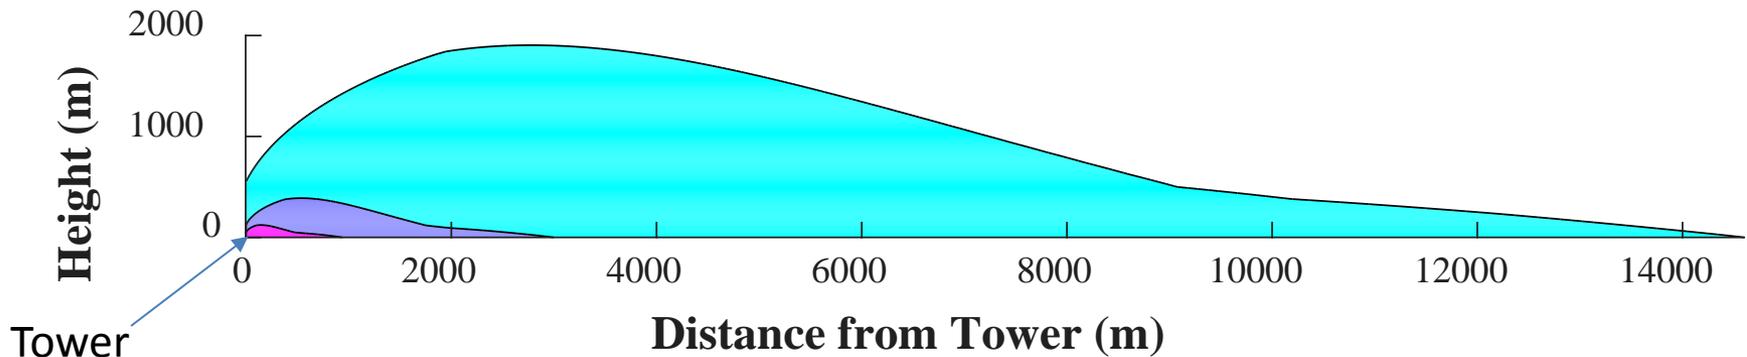

Loss of lock of low elevation satellites with clear sky visibility

Loss of lock of all satellites with clear sky visibility

# Macro Urban, HPR, 1530 MHz

- EIRP = 56/59/59 dBm
- Sectors = 3
- Tower height = 25 m (82')
- Downtilt = 10 degrees
- Frequency = 1530 MHz

$\geq 1$  dB  $C/N_0$  degradation

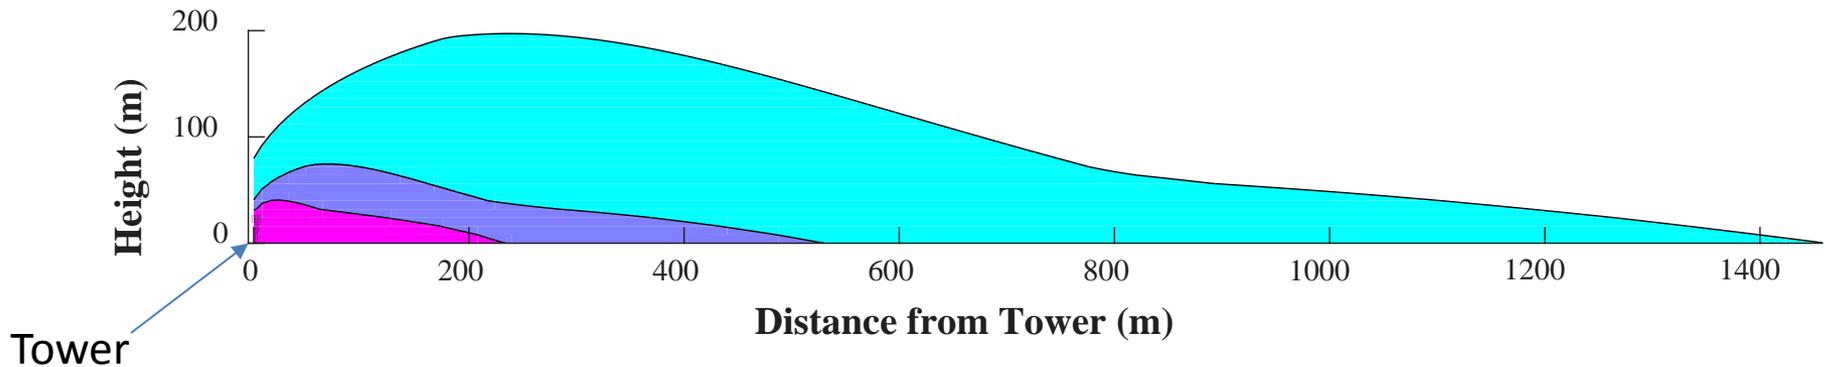

Loss of lock of low elevation satellites with clear sky visibility

Loss of lock of all satellites with clear sky visibility

# Macro Urban, TIM, 1530 MHz

- EIRP = 56/59/59 dBm
- Sectors = 3
- Tower height = 25 m (82')
- Downtilt = 10 degrees
- Frequency = 1530 MHz

$\geq 1$  dB  $C/N_0$  degradation

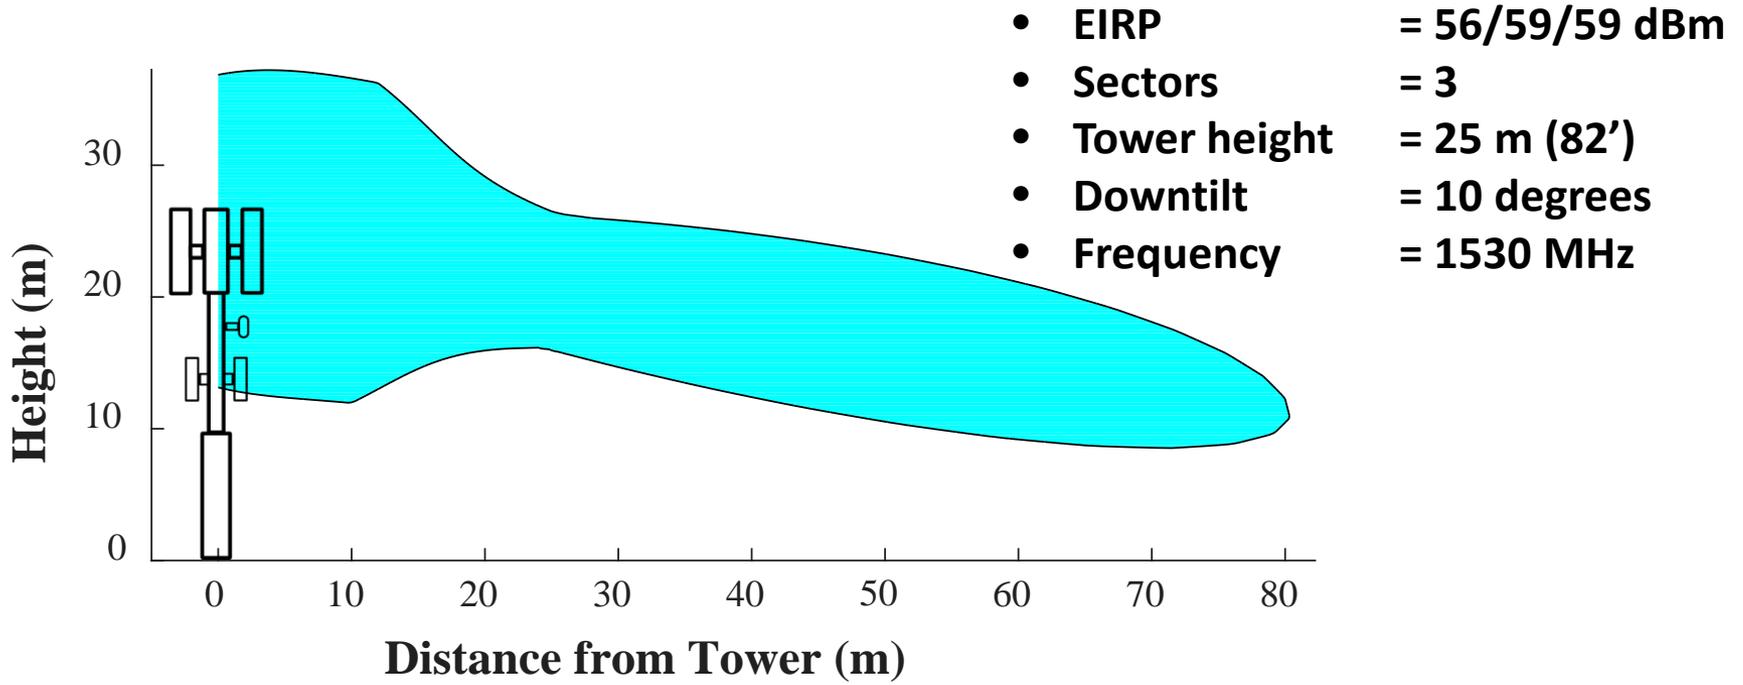

Loss of lock of low elevation satellites with clear sky visibility

Loss of lock of all satellites with clear sky visibility

# Macro Urban, CEL, 1530 MHz

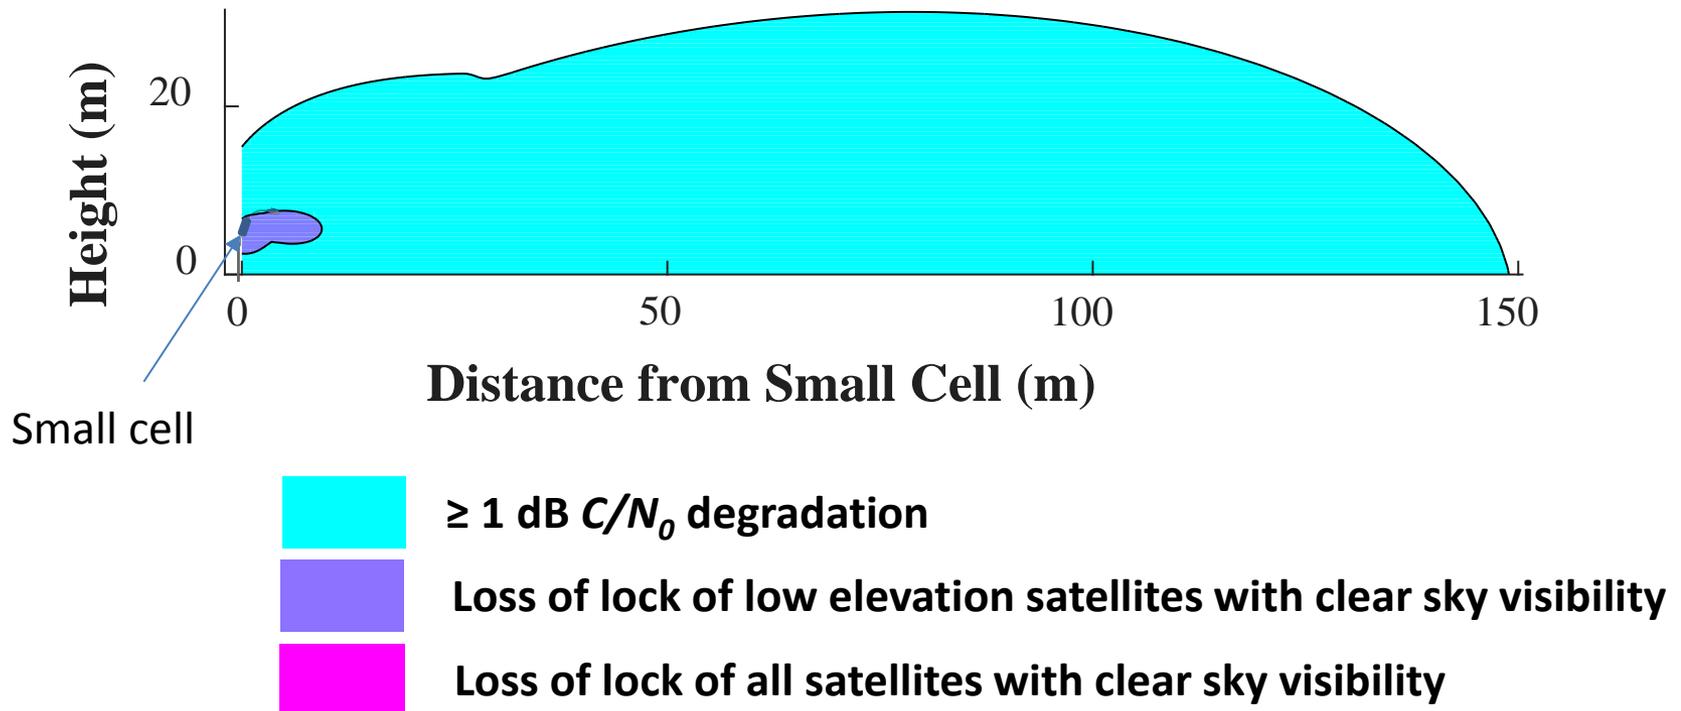

-   $\geq 1$  dB  $C/N_0$  degradation
-  Loss of lock of low elevation satellites with clear sky visibility
-  Loss of lock of all satellites with clear sky visibility

# Impacted Area Results: Single Small Cell Outdoor

$\geq 1$  dB  $C/N_0$  degradation

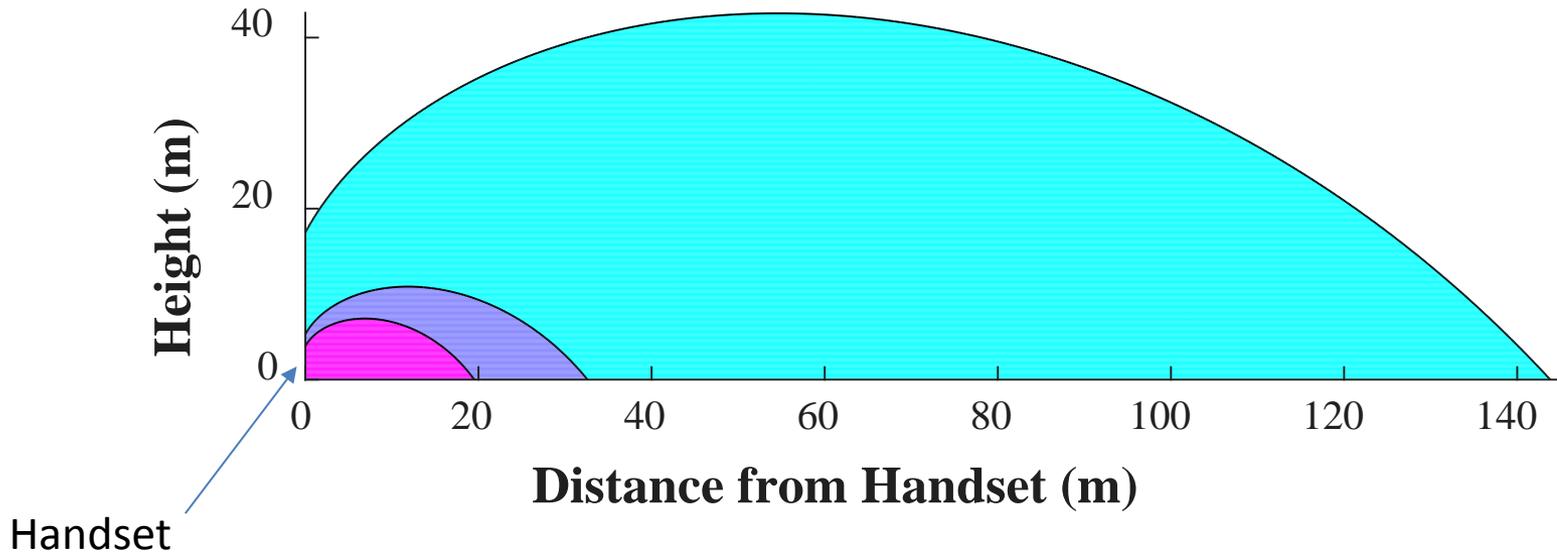

Loss of lock of satellites with 10 dB attenuation

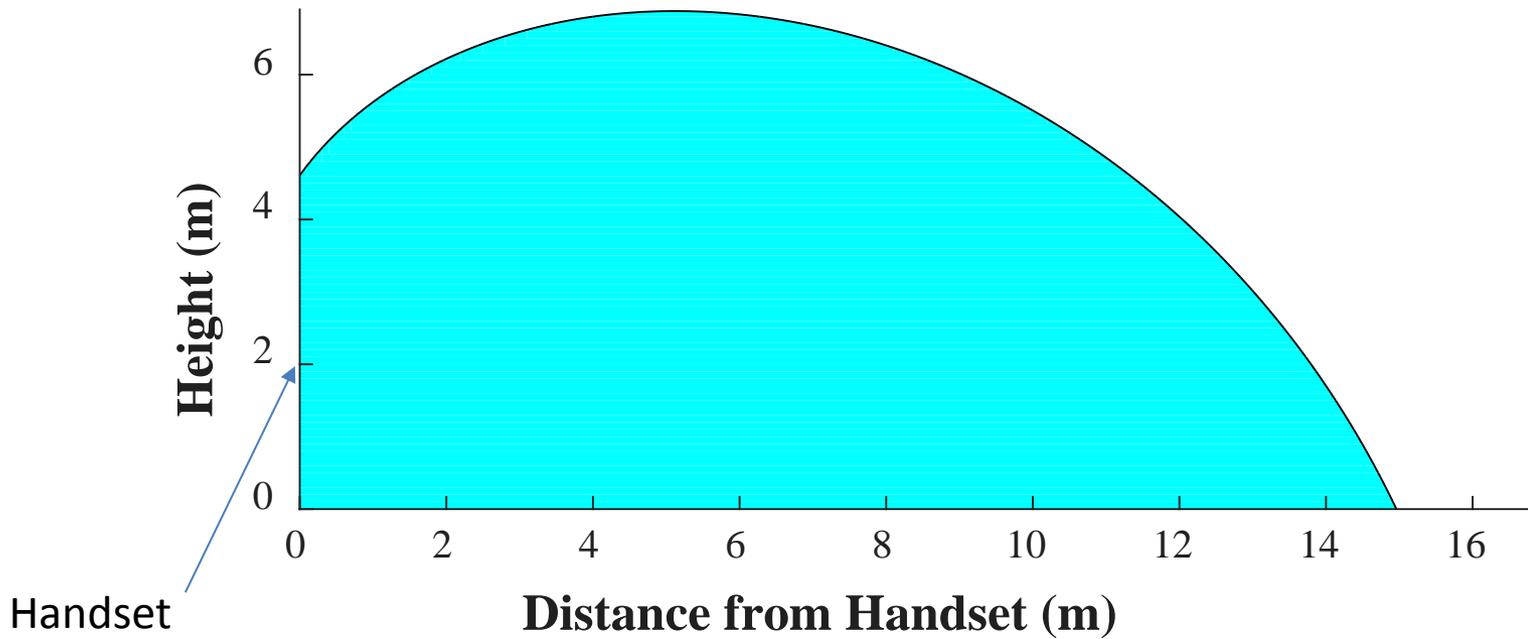

Loss of lock of all satellites with clear sky visibility

# Inverse Modeling Results: Single Macro-Urban Base Station

# Inverse Modeling Analysis

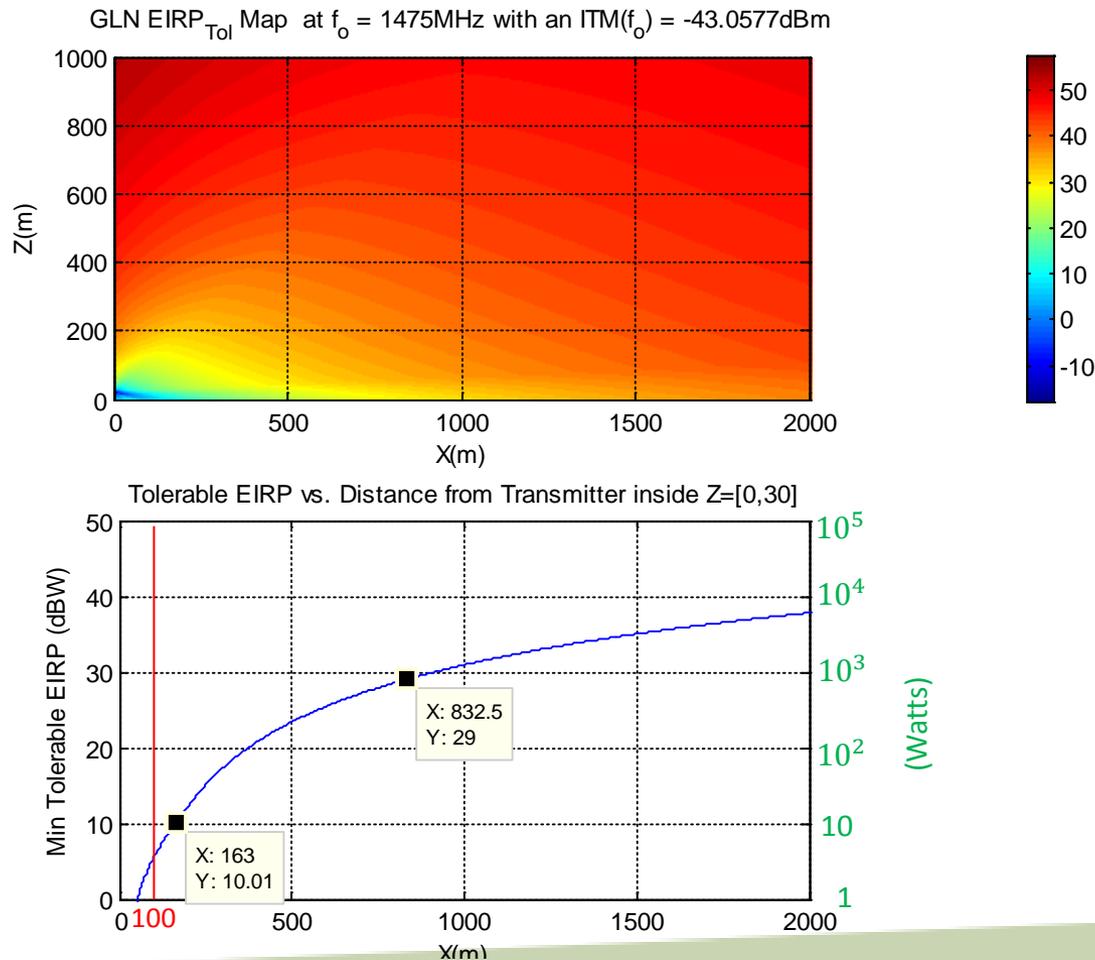

- ❑ The inverse modeling analysis calculates the maximum tolerable EIRP levels as a function of standoff distance
- ❑ Inverse modeling is a design tool to determine the maximum EIRP value that can be tolerated for the case of either single transmitter or a network transmitters

# Inverse Modeling: CEL, 1475 MHz

- ❑ No detectable impact up to -10 dBm receive power => No inverse EIRP calculated

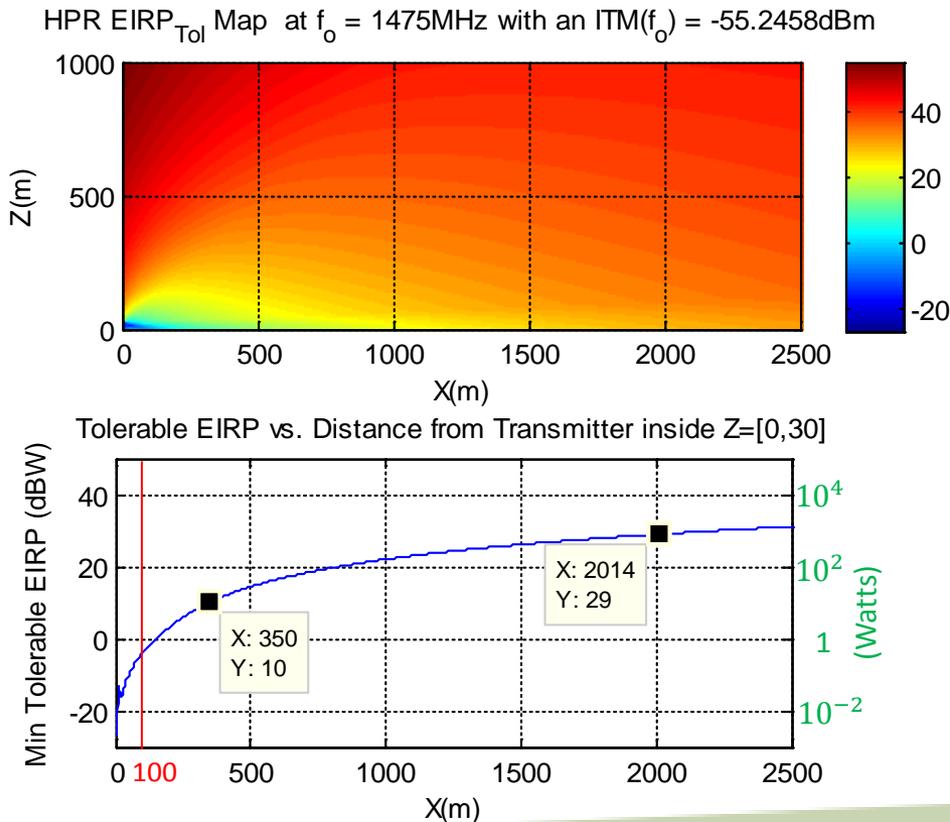

# Inverse Modeling: GLN, 1475 MHz

- Extent of the impact region: 800 to 850 m from transmitter for EIRP of 29 dBW  
160 to 165 m for EIRP of 10 dBW

# Inverse Modeling: HPR, 1475 MHz

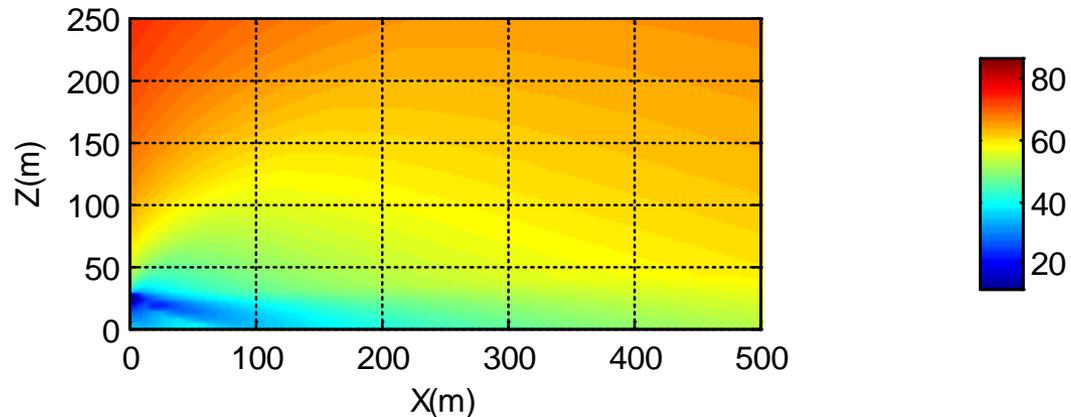

- Extent of the impact region: 2 km from transmitter for EIRP of 29 dBW  
350m for EIRP of 10 dBW

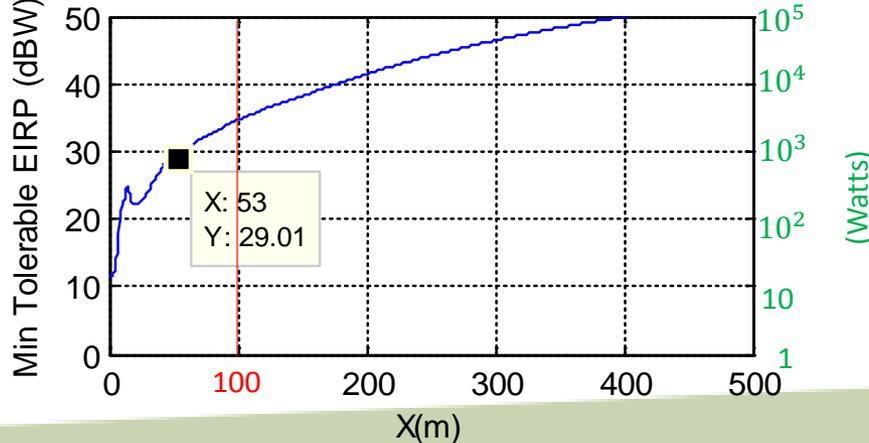

# Inverse Modeling: TIM, 1475 MHz

- Extent of the impact region: 50 to 60 m from transmitter for EIRP of 29 dBW  
No detectable impact for EIRP of 10 dBW

TIM EIRP<sub>Tol</sub> Map at  $f_o = 1475\text{MHz}$  with an  $\text{ITM}(f_o) = -15.2559\text{dBm}$

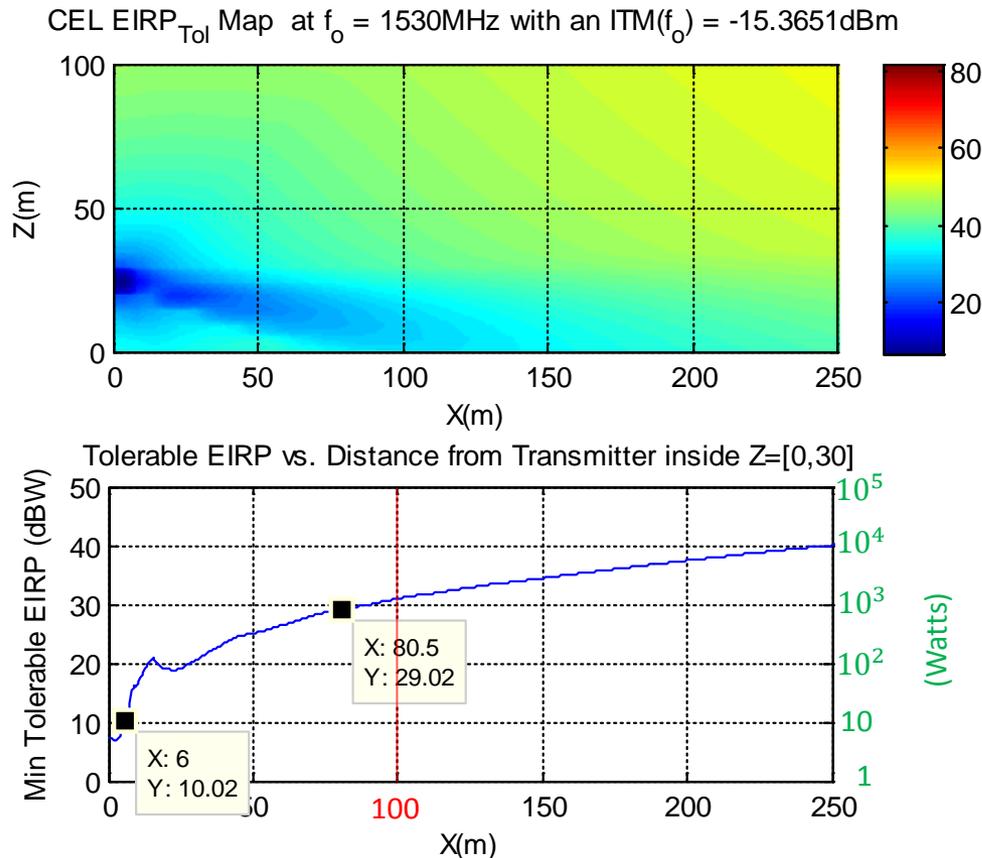

Tolerable EIRP vs. Distance from Transmitter inside  $Z=[0,30]$

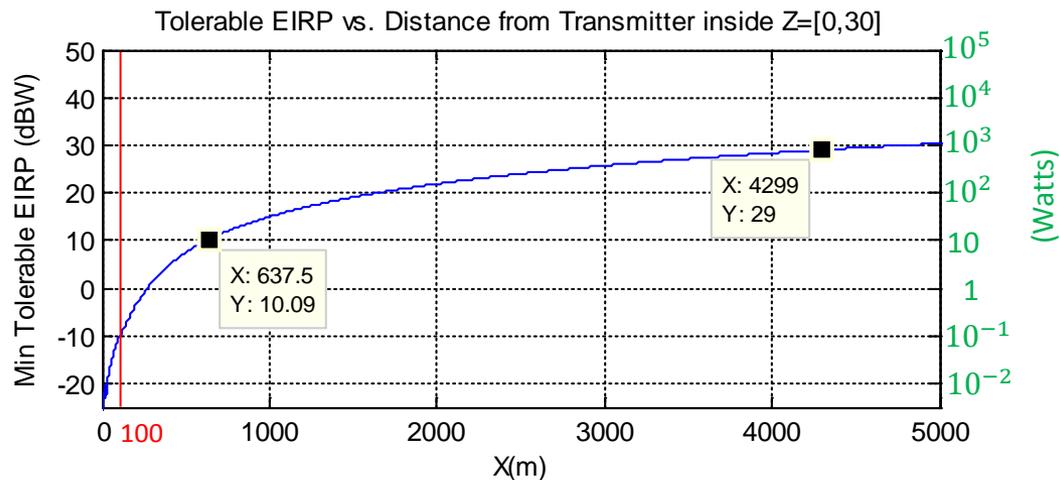

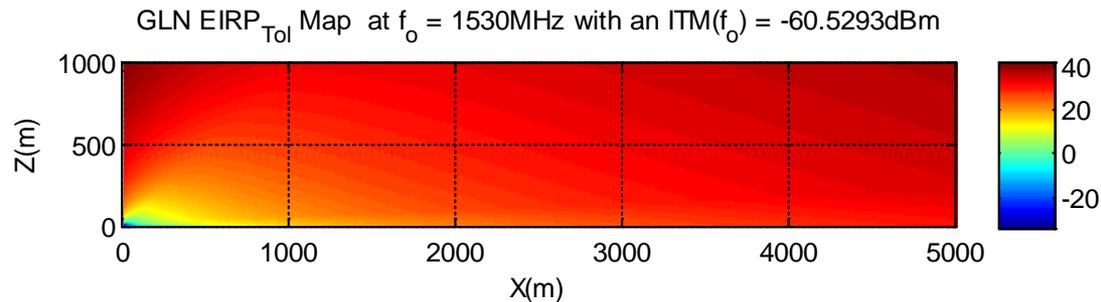

# Inverse Modeling: CEL, 1530 MHz

- Extent of the impact region: 80 m from Transmitter for EIRP of 29 dBW  
6 m for EIRP of 10 dBW

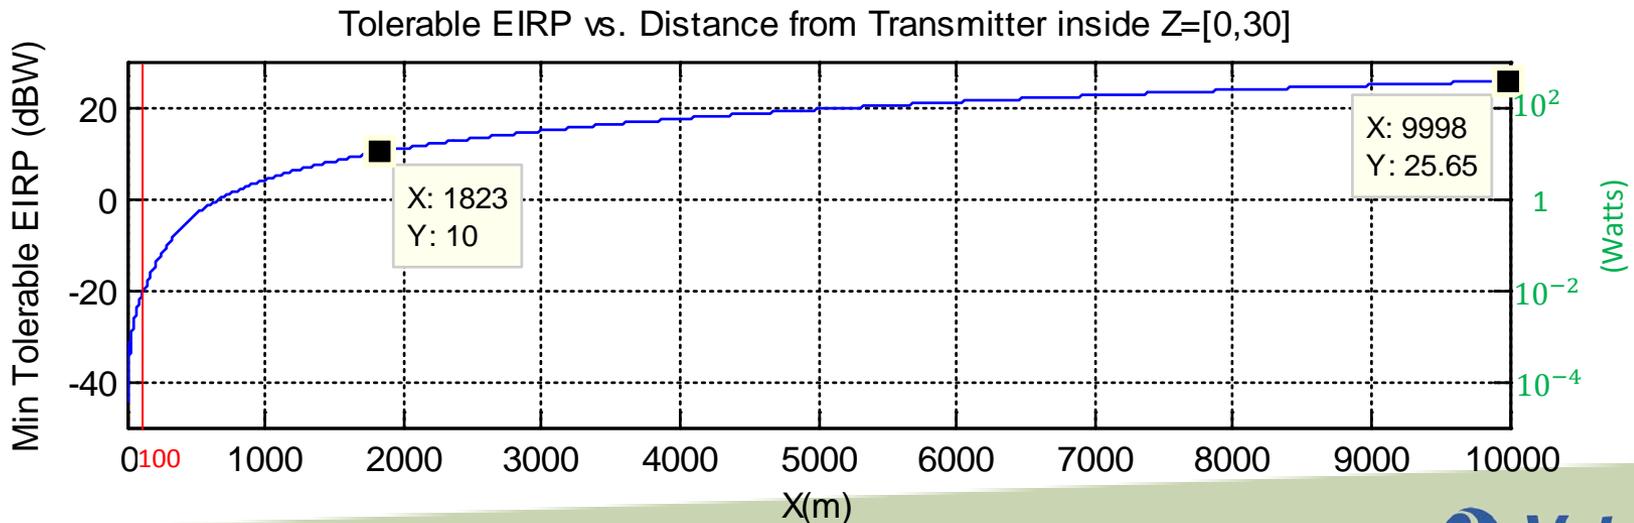

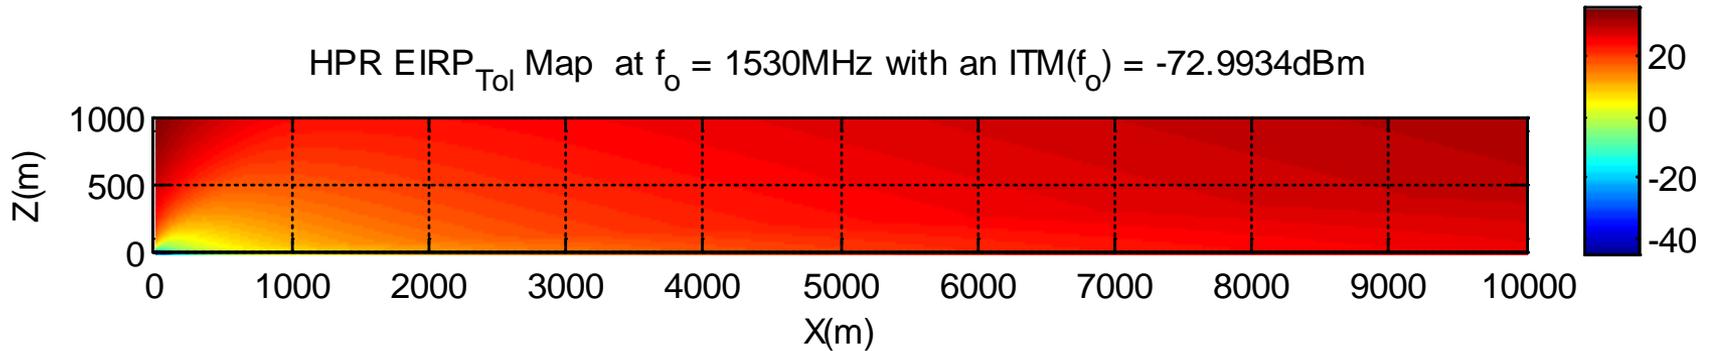

# Inverse Modeling: GLN, 1530 MHz

- Extent of the impact region: 4 to 4.5 km from Transmitter for EIRP of 29 dBW  
600 to 650 m for EIRP of 10 dBW

# Inverse Modeling: HPR, 1530 MHz

- Extent of the impact region: >10 km from Transmitter for EIRP of 29 dBW  
1.5 to 2 km for EIRP of 10 dBW

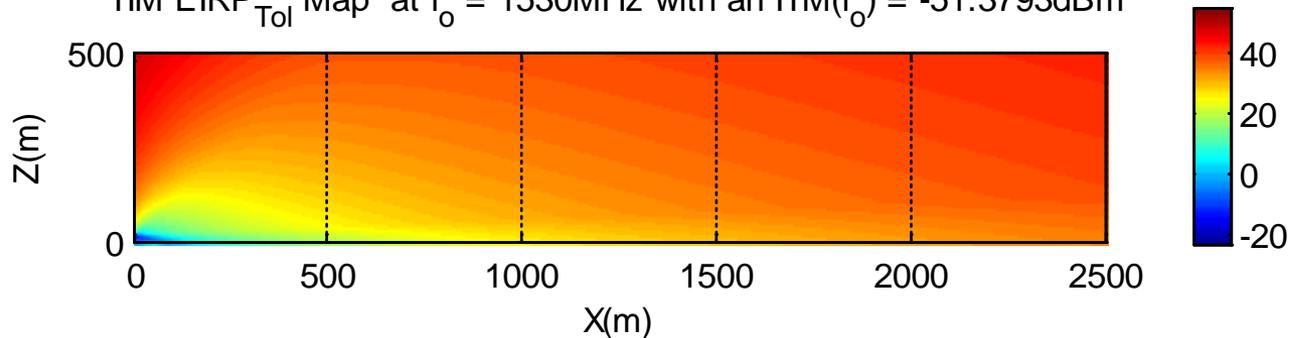

# Inverse Modeling: TIM, 1530 MHz

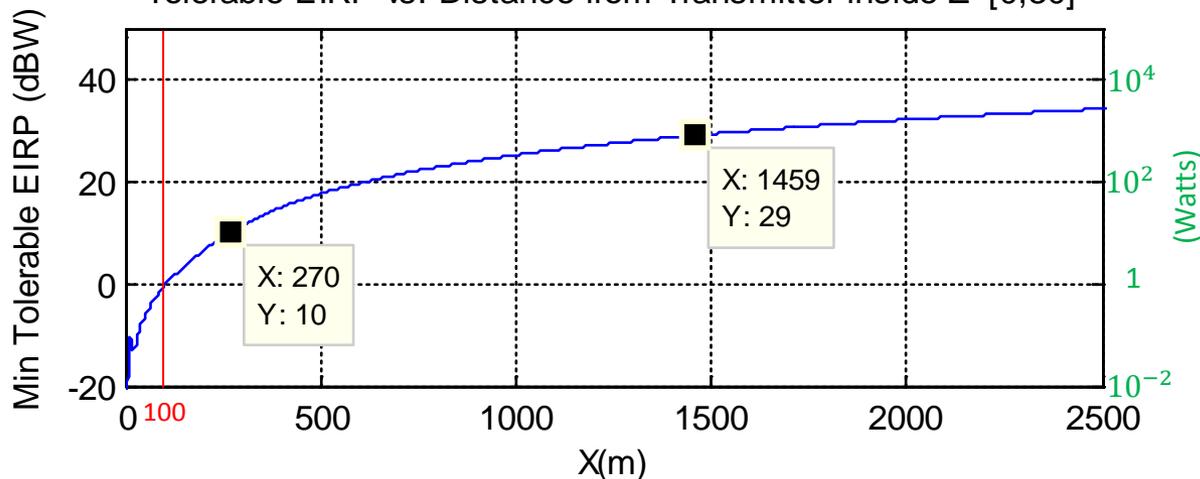

- Extent of the impact region: 1.5 km from transmitter for EIRP of 29 dBW

270 m for EIRP of 10 dBW

TIM EIRP<sub>Tol</sub> Map at  $f_o = 1530\text{MHz}$  with an  $\text{ITM}(f_o) = -51.3793\text{dBm}$

Tolerable EIRP vs. Distance from Transmitter inside  $Z=[0,30]$

# **Inverse Modeling Results: Single Micro-Urban Base Station**

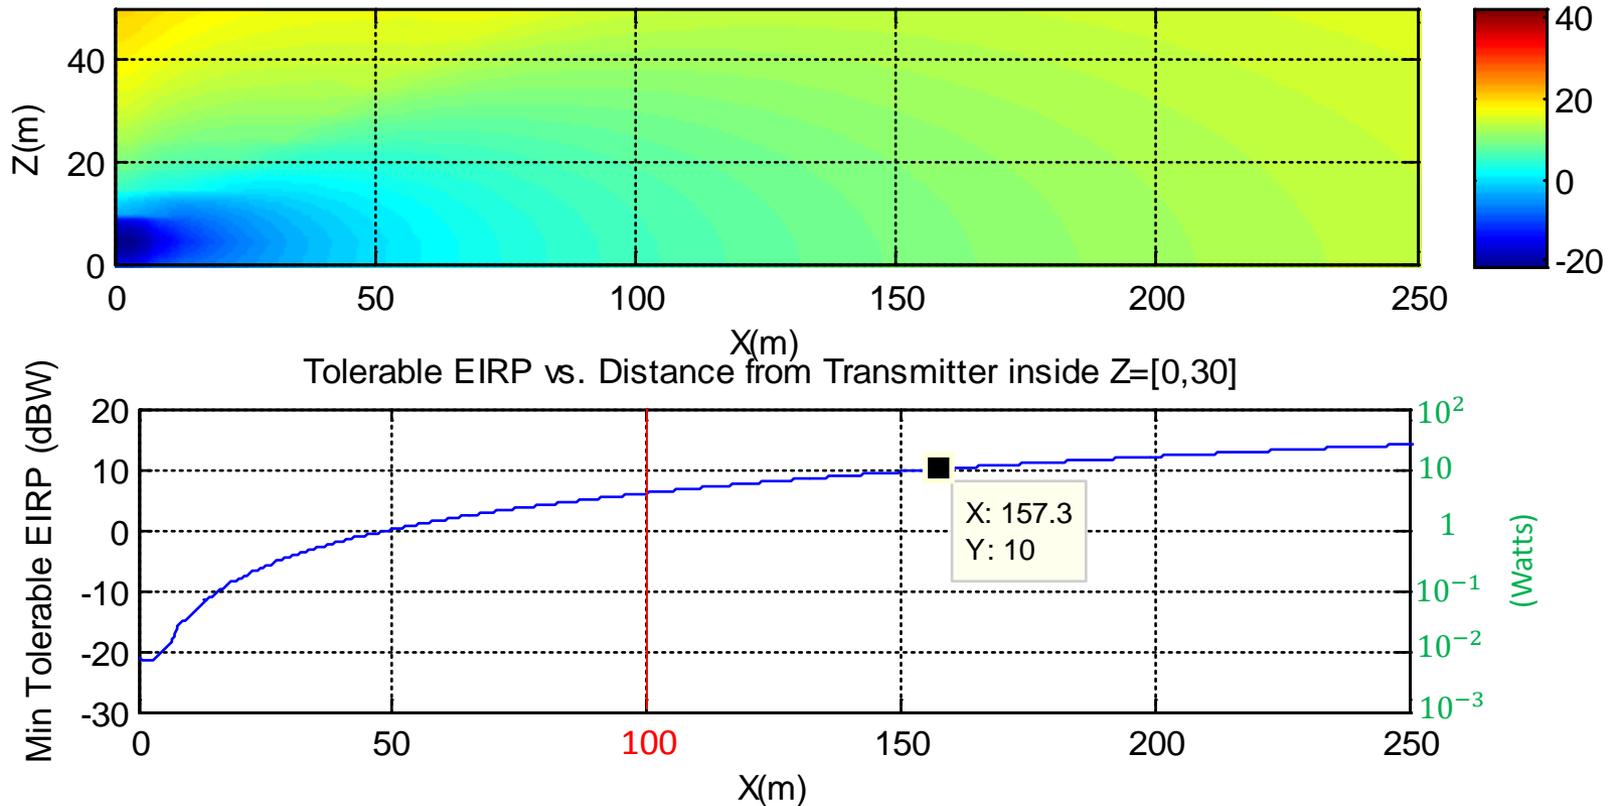

# Inverse Modeling: CEL, 1475 MHz

- ❑ No detectable impact up to -10 dBm receive power => No inverse EIRP calculated

# Inverse Modeling: GLN, 1475 MHz

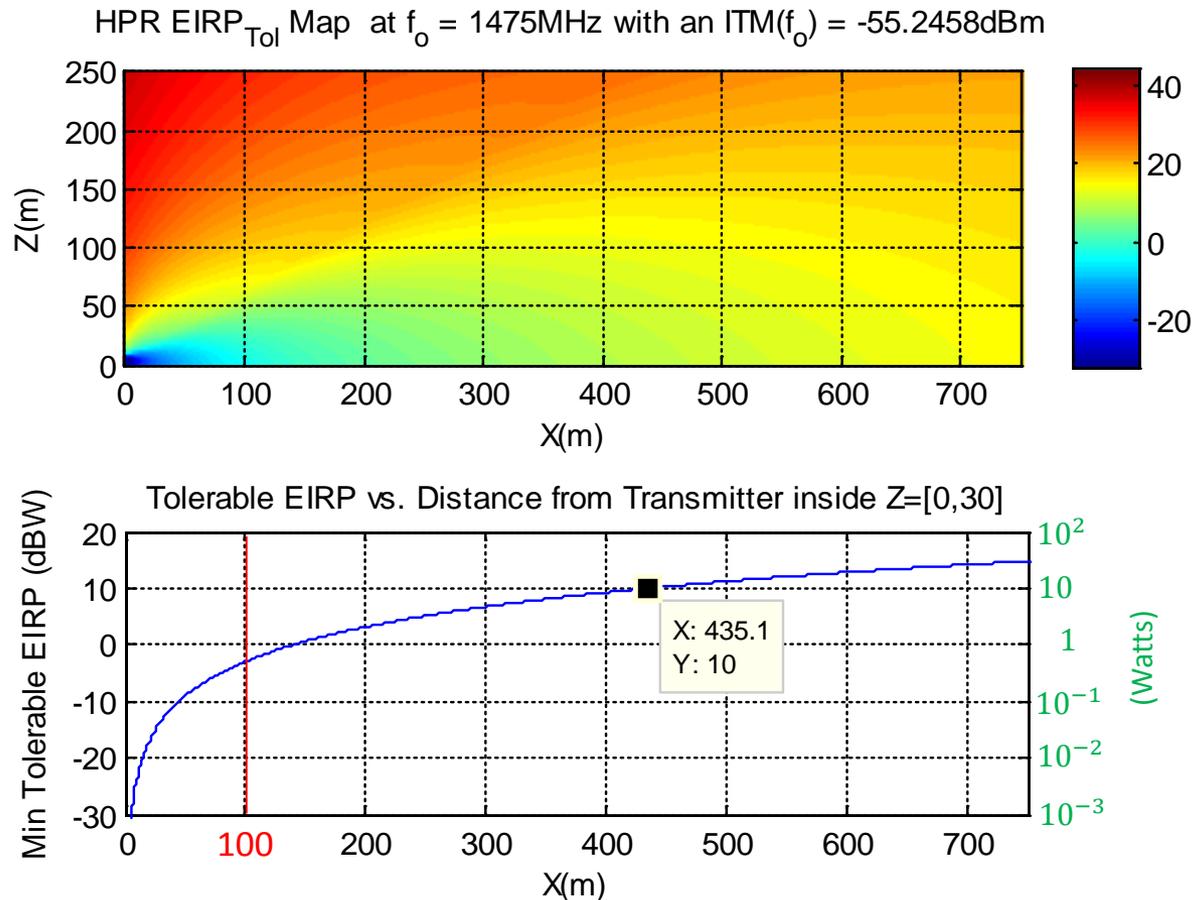

- Extent of the impact region: 150 to 160 m from transmitter for EIRP of 10 dBW

GLN EIRP<sub>Tol</sub> Map at  $f_o = 1475\text{MHz}$  with an  $\text{ITM}(f_o) = -43.0577\text{dBm}$

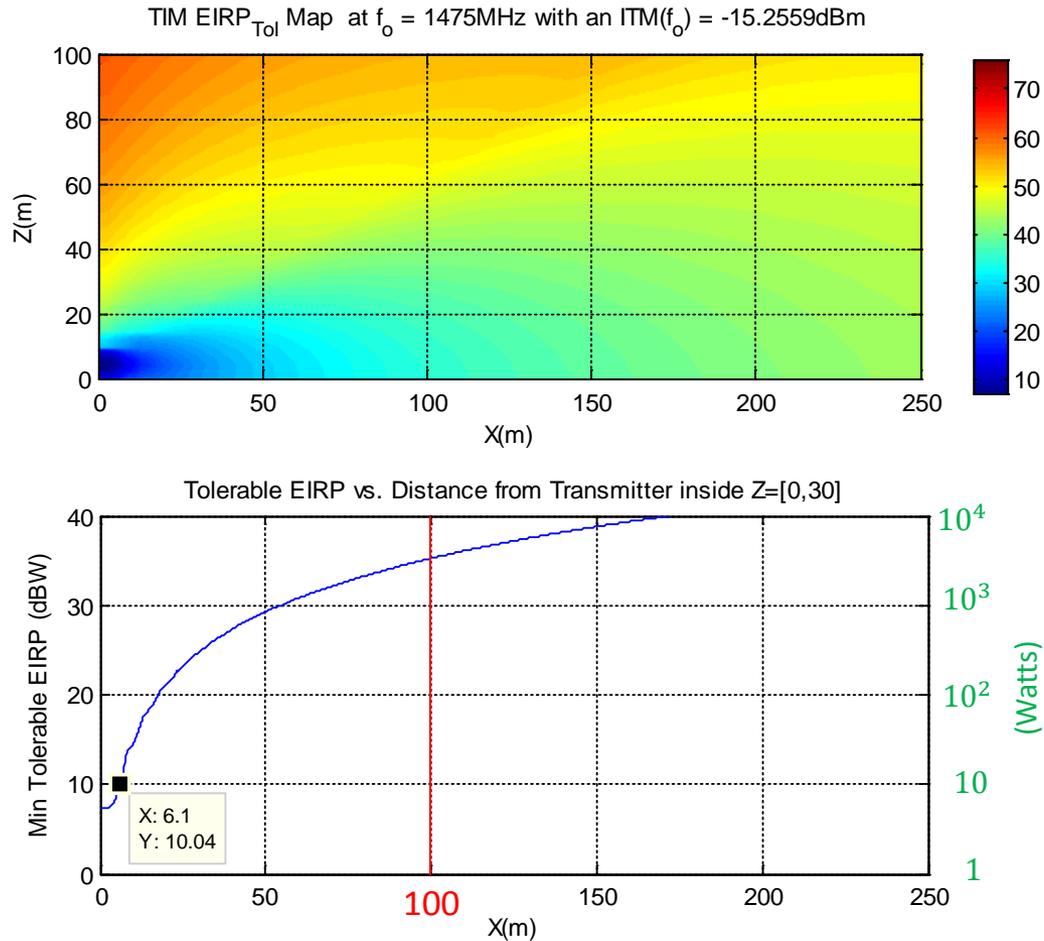

# Inverse Modeling: HPR, 1475 MHz

- Extent of the impact region: 400 to 450 m from transmitter for EIRP of 10 dBW

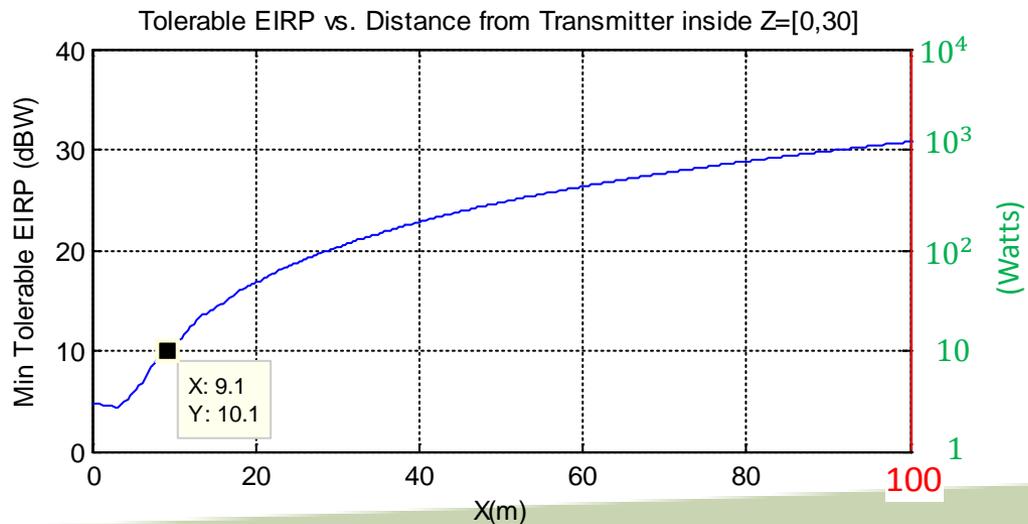

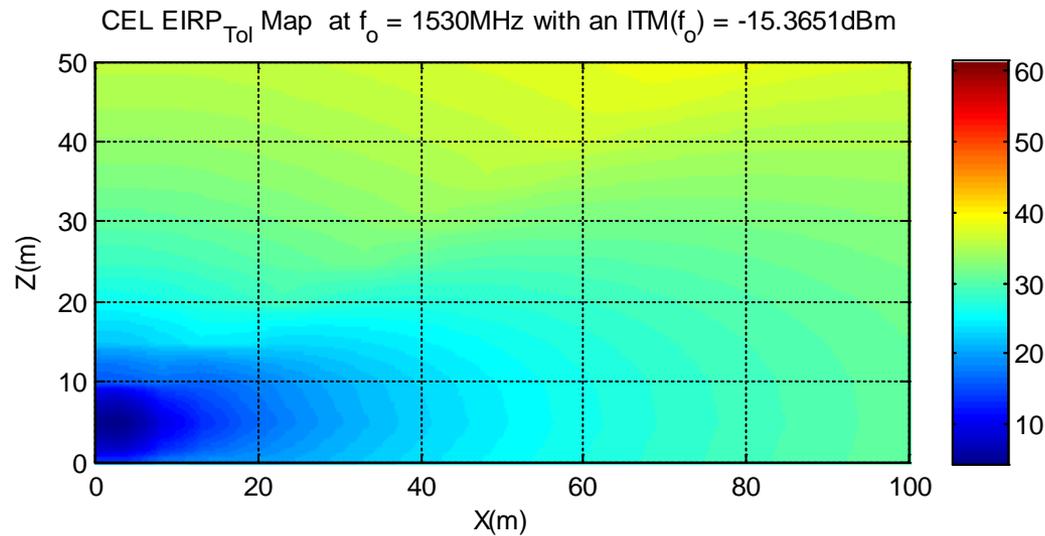

# Inverse Modeling: TIM, 1475 MHz

- Extent of the impact region: < 10 m from transmitter for EIRP of 10 dBW

# Inverse Modeling: CEL, 1530 MHz

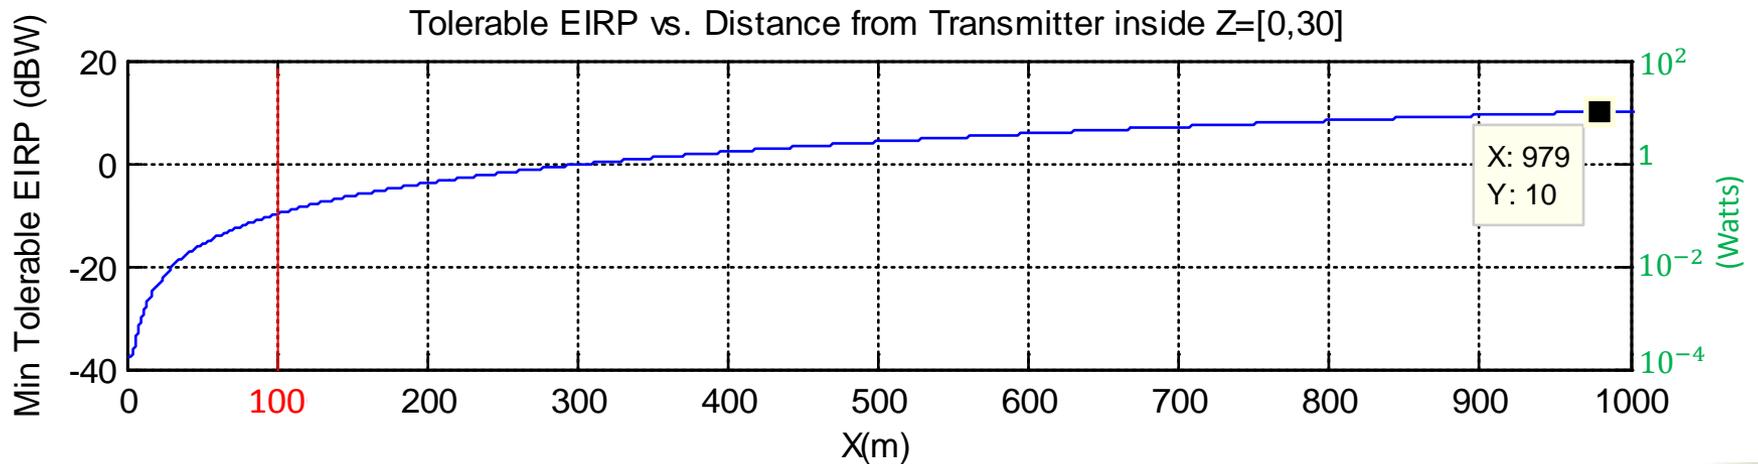

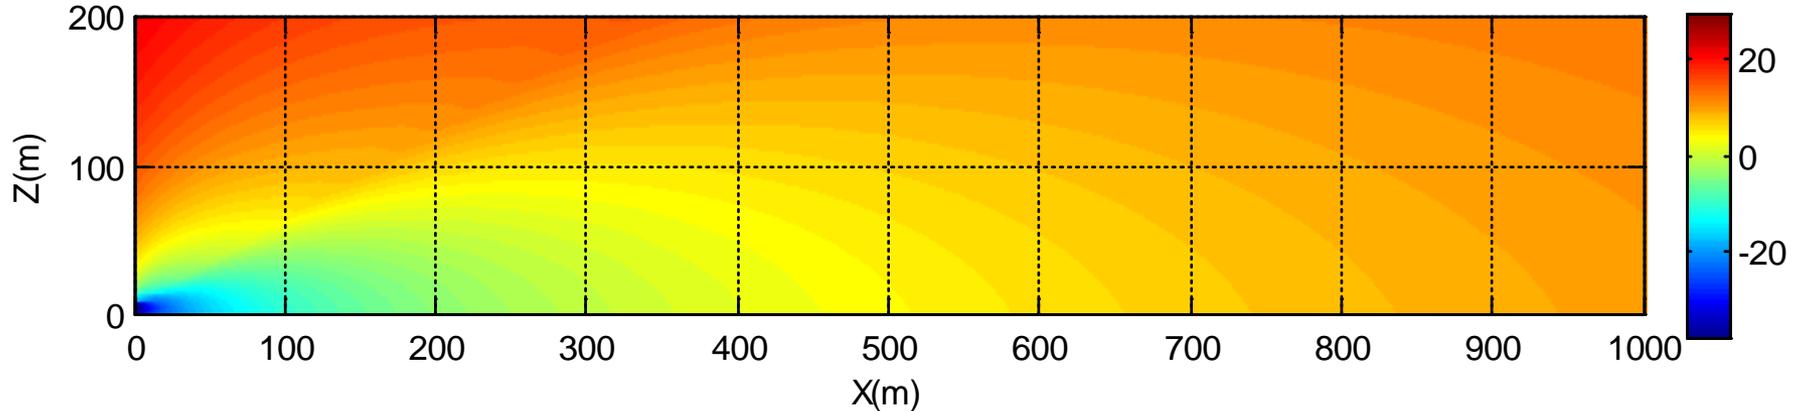

- Extent of the impact region: < 10 m from transmitter for EIRP of 10 dBW

# Inverse Modeling: GLN, 1530 MHz

- Extent of the impact region: 900m to 1 km from transmitter for EIRP of 10 dBW

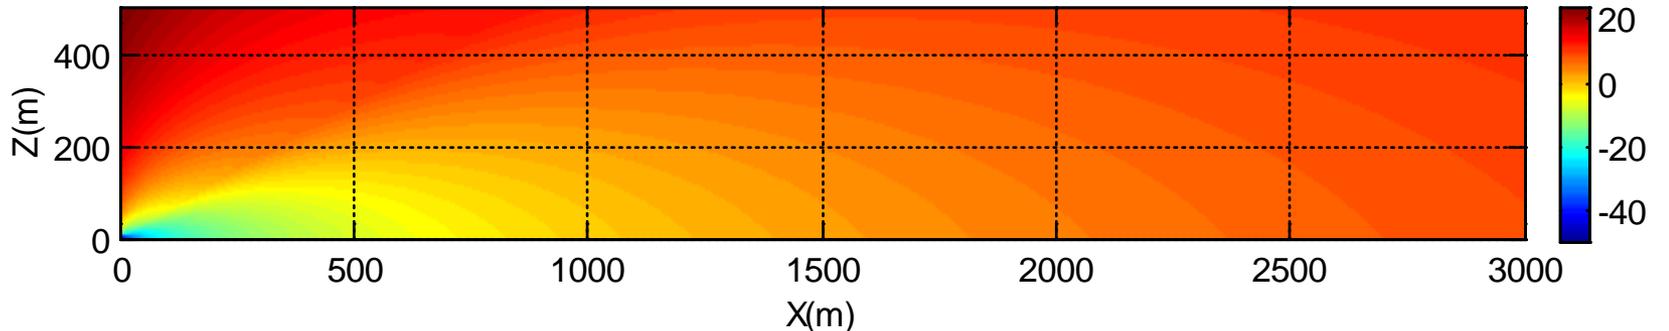

GLN EIRP<sub>Tol</sub> Map at  $f_o = 1530\text{MHz}$  with an  $\text{ITM}(f_o) = -60.5293\text{dBm}$

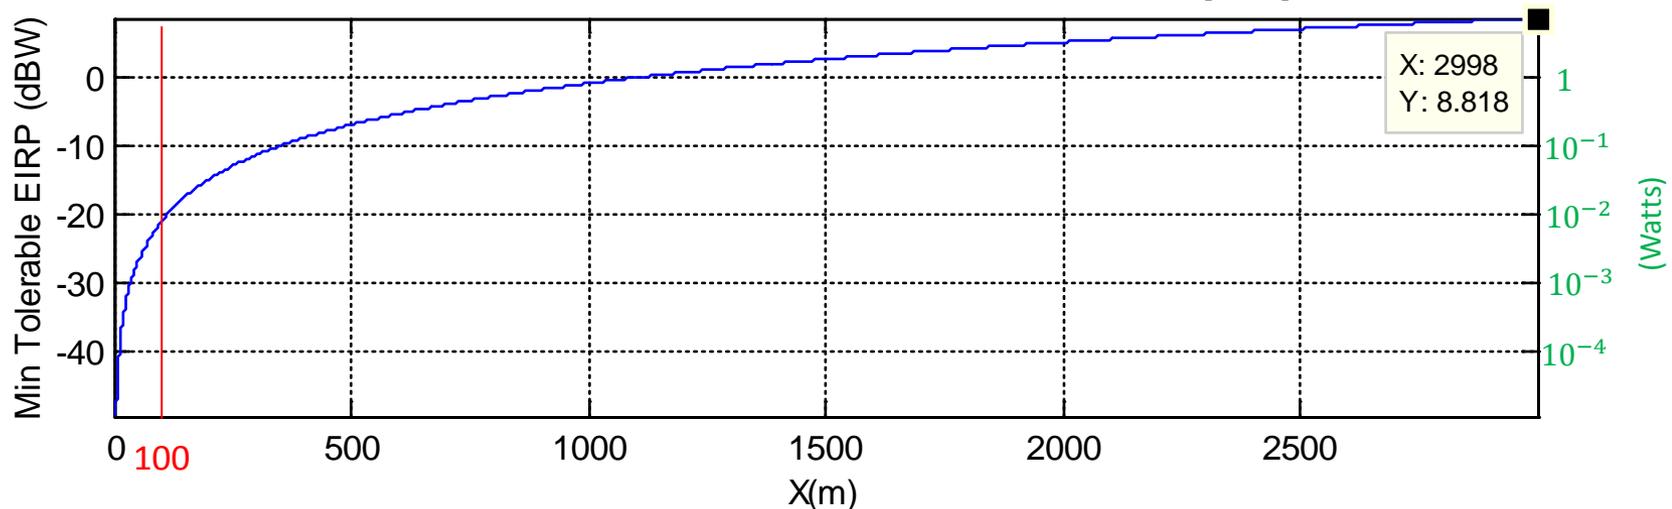

# Inverse Modeling: HPR, 1530 MHz

- Extent of the impact region: > 3km from Transmitter for EIRP of 10 dBW

HPR EIRP<sub>Tol</sub> Map at  $f_o = 1530\text{MHz}$  with an  $\text{ITM}(f_o) = -72.9934\text{dBm}$

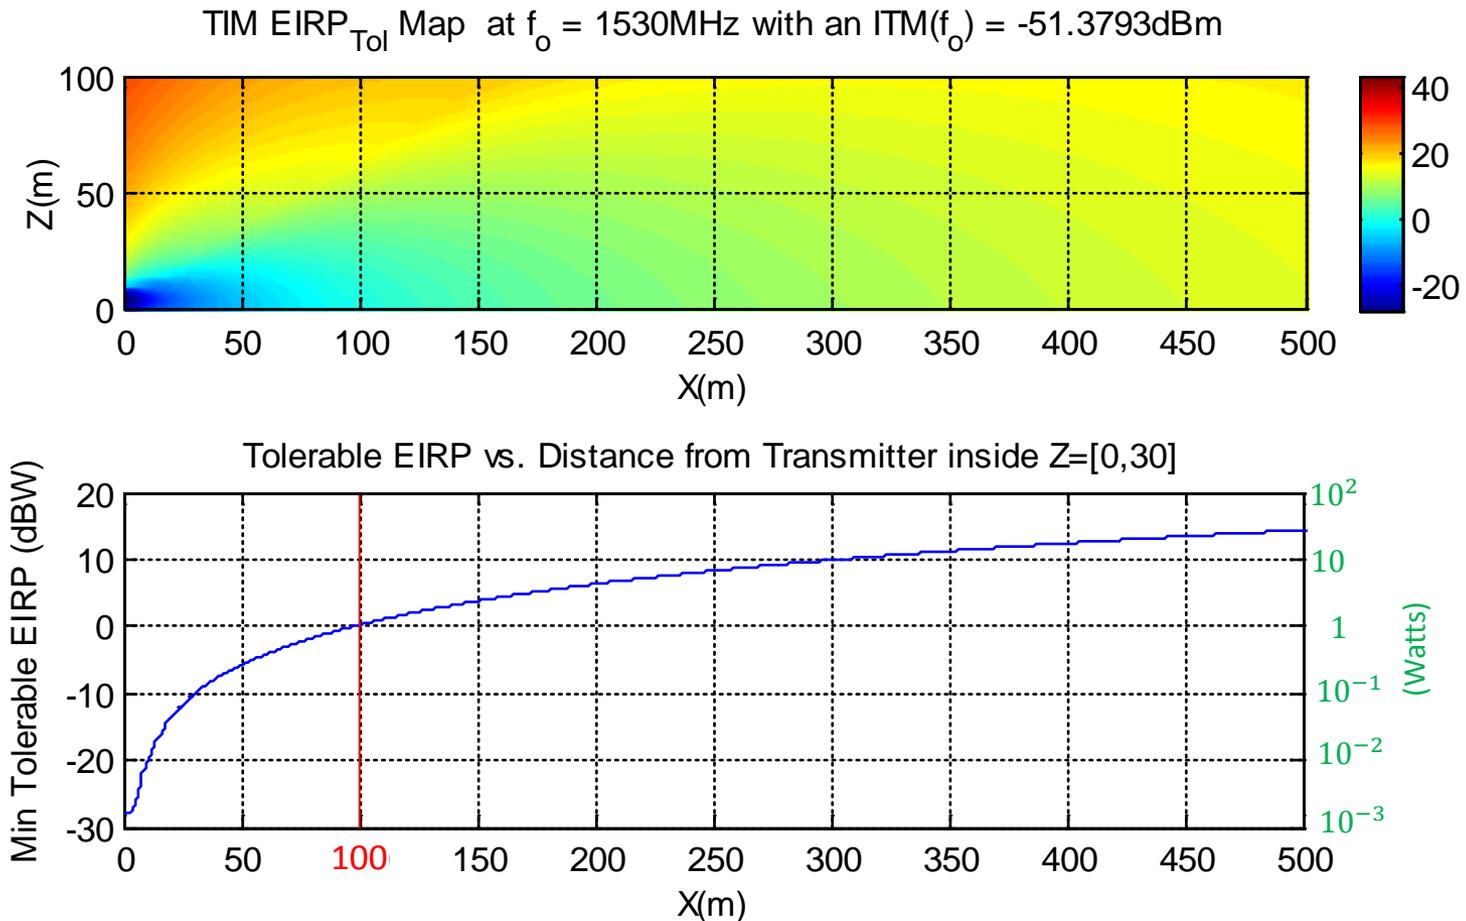

Tolerable EIRP vs. Distance from Transmitter inside Z=[0,30]

# Inverse Modeling: TIM, 1530 MHz

- Extent of the impact region: 300 m from Transmitter for EIRP of 10 dBW

# Summary Inverse Modeling Results (Single Base Station) in dBW

1475 MHz

Deployment	Stand off distance (m)	Max Tolerable EIRP (dBW)			
		GLN	HPR	TIM	CEL
Macro Urban	10	-14.4	-24.0	14.6	N/A*
	100	5.6	-4.0	34.6	N/A*

		GLN	HPR	TIM	CEL
Macro Urban	10	0.8 mW	64 $\mu$ W	8.7 mW	12.3 W
	100	79.4 mW	6.5 mW	0.9 W	1.26 kW
Micro Urban	10	1 mW	76 $\mu$ W	9.8 mW	11.7 W
	100	104 mW	7.8 mW	1 W	1.2 kW

\*N/A = not applicable; no degradation at maximum power at WSMR.

# Inverse Modeling Results: Base Station Network

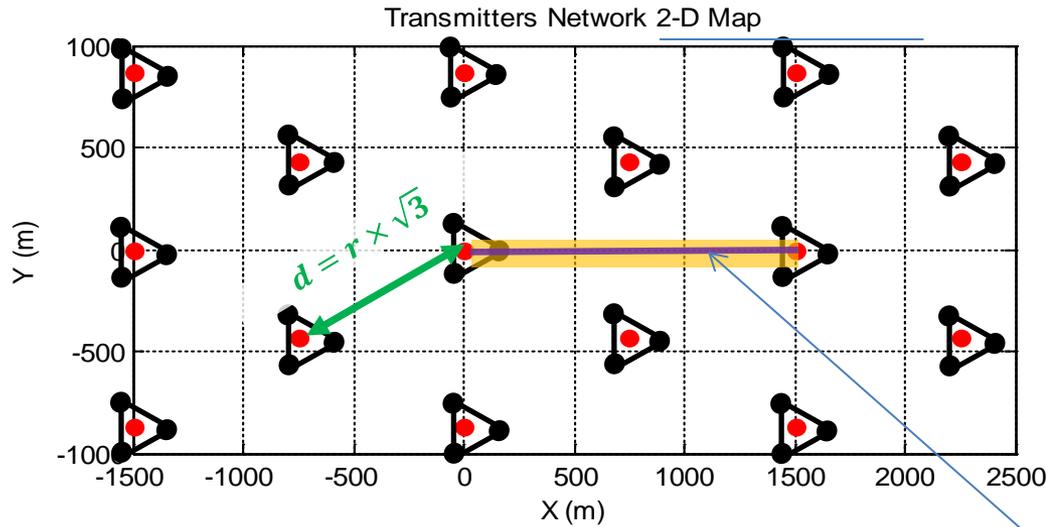

# Aggregation Effect

- The analysis so far considered the impact of a single transmitter on the degradation of the L1 C/A signal received by GNSS receivers
  
- The following analysis will look at the aggregate effect of a macro urban IMT network deployment with a transmitter at the center of each cell by receiver category
  - Performed for a user at 5 m above ground level (20 m below the base station transmitter)
  - Network parameters are: Cell radius  $A = 2 \cdot r = 500m^*$ , resulting in an tower interspacing distance of  $d = \sqrt{3} \cdot r = \sqrt{3} \times 250 = 433 m$

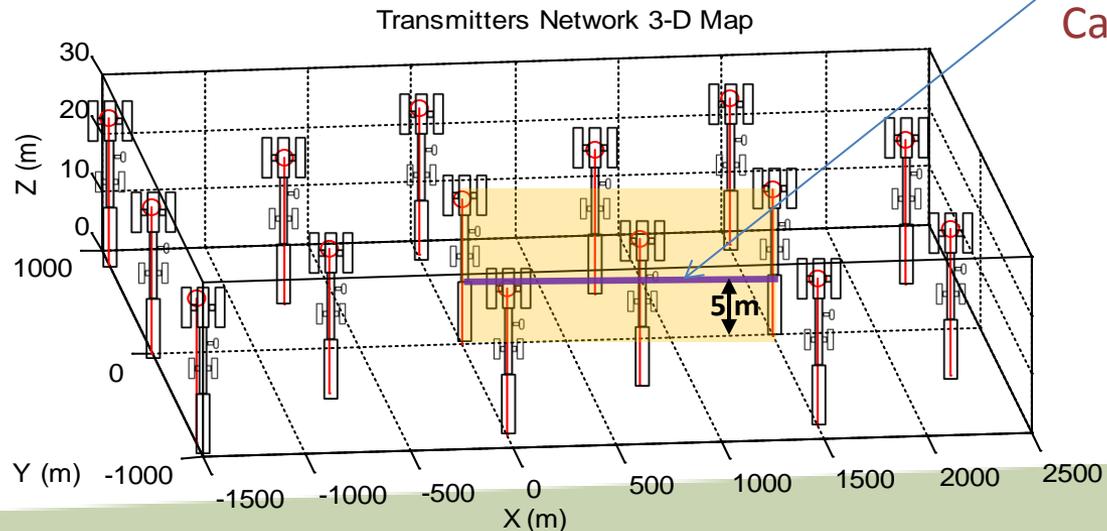

\* See ITU-R M.2292 TABLE-3 typical cell radius to be used in sharing studies

# Single Transmitter vs. Network Results for GLN Category

GLN,  $EIRP_{Tot}$  vs. Distance to Receiver at Frq = 1530MHz with an  $ITM(f_o) = -60.5293dBm$

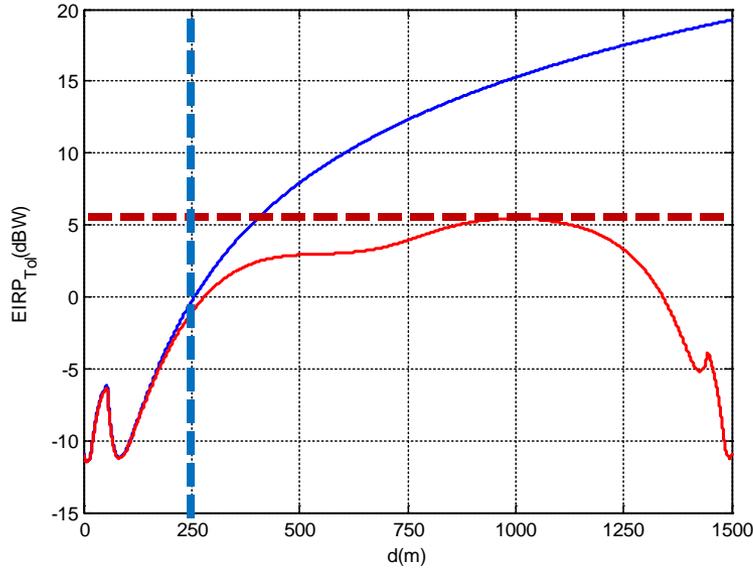

EIRP Level where GLN Receivers are impacted everywhere inside a network

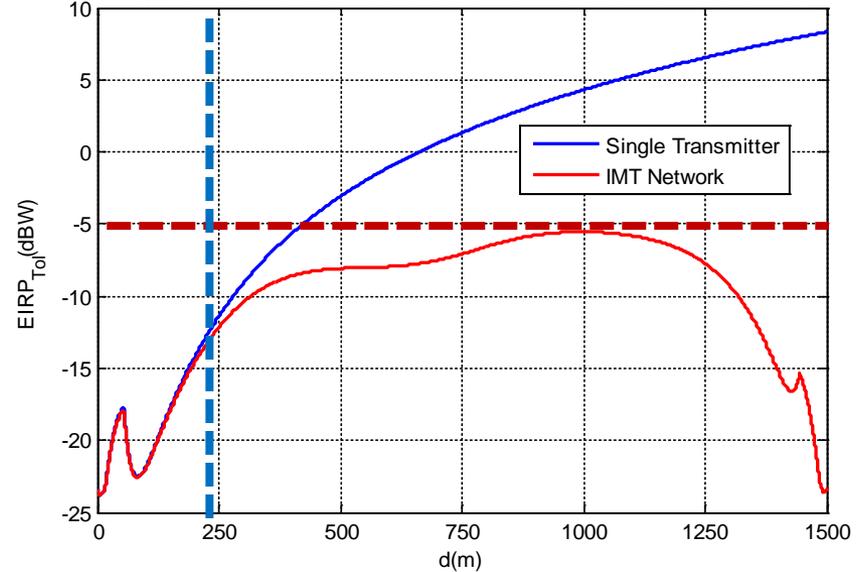

Distance beyond which Network Effects become significant

# Single vs. Aggregate Modeling Results for 1530 MHz

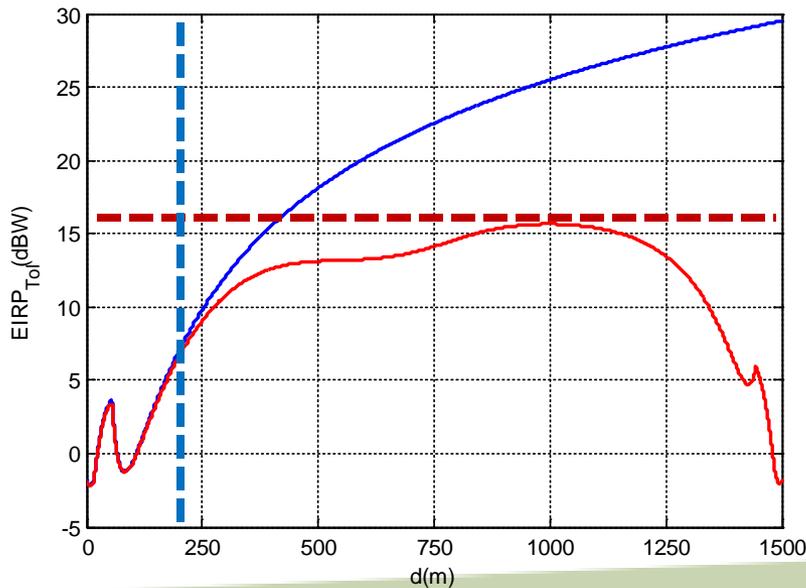

GLN,  $EIRP_{Tot}$  vs. Distance to Receiver at Frq = 1530MHz with an  $ITM(f_o) = -60.5293dBm$

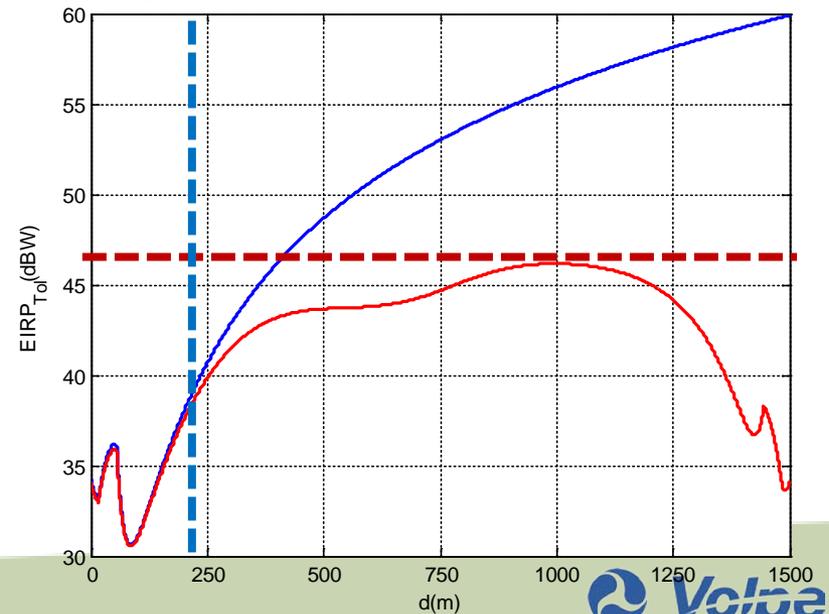

HPR,  $EIRP_{Tot}$  vs. Distance to Receiver at Frq = 1530MHz with an  $ITM(f_o) = -72.9934dBm$

TIM,  $EIRP_{Tot}$  vs. Distance to Receiver at Frq = 1530MHz with an  $ITM(f_o) = -51.3793dBm$

CEL,  $EIRP_{Tot}$  vs. Distance to Receiver at Frq = 1530MHz with an  $ITM(f_o) = -15.3651dBm$

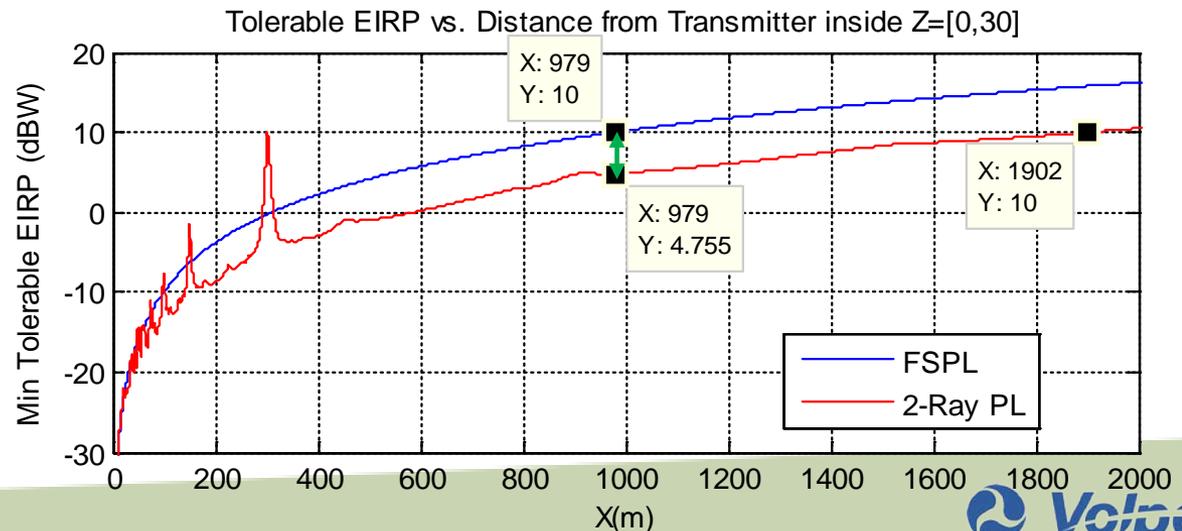

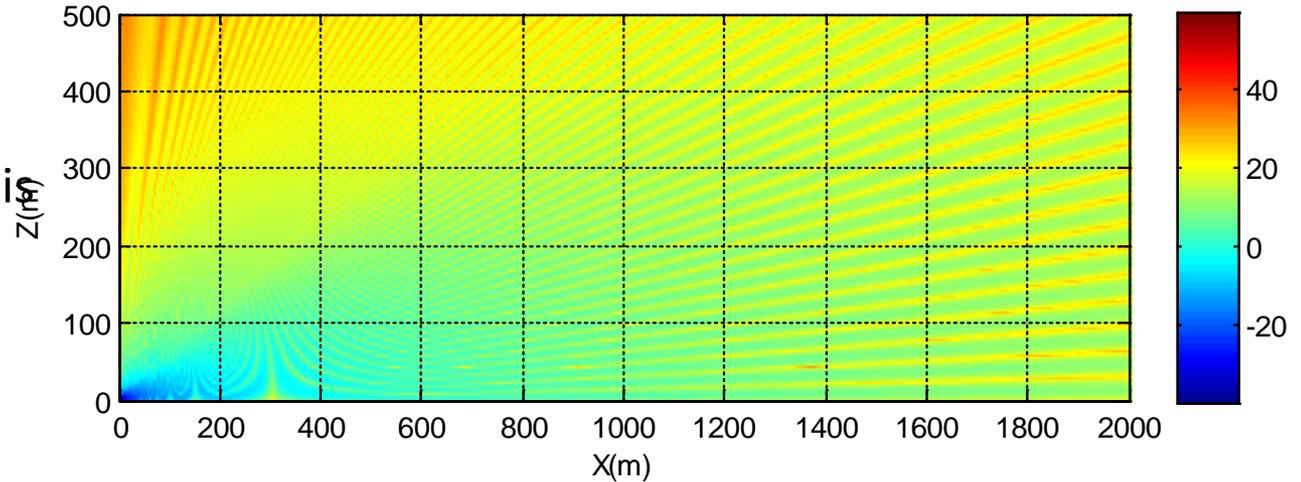

# Sensitivity to Propagation Models

FSPL vs. 2-Ray PL

# Sensitivity to Propagation models, GLN Case, Micro Urban

GLN EIRP<sub>Tol</sub> Map at  $f_o = 1530\text{MHz}$  with an  $\text{ITM}(f_o) = -60.5293\text{dBm}$

- 2-Ray PL reduces the maximum tolerable EIRP when protection is considered over a reasonable range of heights

# Summary

- Models to determine tolerable transmit power levels have been developed
  - These models incorporate transmitter and polarization dependent receivers gain patterns
  - These models are capable of looking at different network characteristics and deployment types such as the ITU-R M.2292
  
- Results with two deployment types and using L1 C/A ITMs were presented
  - Single Macro Urban base station at 29 dBW resulted in standoff distances > 2 km for 1475 MHz and > 14 km for 1530 MHz
  - Single Micro Urban base station at 10 dBW resulted in standoff distances > 400 m for 1475 MHz and > 3 km for 1530 MHz
  - Single Handset at -7 dBW resulted in standoff distances > 140 m for 1630 MHz
  
- Inverse modeling yields tolerable EIRP levels for given standoff distance. Key results are:
  - At 1475 MHz, the tolerable EIRP values for standoff distances of 10 m and 100 m are -24 dBW and -4 dBW respectively
  - At 1530 MHz, the tolerable EIRP values for standoff distances of 10 m and 100 m are -42 dBW and -22 dBW respectively
  - Results are similar for the single base station corresponding to either deployment type as expected
  
- Aggregation effects and 2-Ray propagation effects were shown to further reduce the tolerable EIRP levels
  
- This analysis will be applied to the remaining tested frequencies and the other GNSS signals with sensitivity analysis to additional propagation models (such as the Irregular Terrain Model)
