16. Abstract  The primary objective of this report is to document the effectiveness of low-cost treatments applied to low-volume roads (LVRs) in Colorado. By analyzing historical pavement performance data and treatment records, the effectiveness of each treatment type was determined. It was concluded that some surface maintenance strategies are effective long-term treatments for fatigue, longitudinal, and transverse cracking. However, the effectiveness of these treatments depends mainly on the initial condition index. An alternative maintenance strategy was proposed for CDOT considering a light rehabilitation technique with a surface treatment for poor roads. A long-term analysis of road maintenance and costs was conducted on a case study in Colorado. The results show the impact of both current and proposed maintenance strategies on the future of pavement condition. It was found that the proposed strategy would enhance the effectiveness of current policies followed by CDOT. This report also investigates the badly deteriorated LVRs in Colorado considering a specific characteristic of marginal pavement conditions. Different treatment strategies were evaluated to explore how reliable applying more pavement maintenance techniques is on these roads. The analysis of funding needs shows that marginal roads can be improved effectively within a maintenance capital improvement plan of five years from 2016 to 2020.  Implementation CDOT is advised to consider specific criteria while applying chip seals and thin overlays on roads. Chip seals shall be applied only while the pavement is still performing well. Pavement performance should be evaluated effectively considering the individual pavement condition indices rather than the overall drivability life value. Cold in-place recycling and full depth replacement are recommended to be integrated with the current applications of chip seals and thin overlays.

## **Executive Summary**

In the State of Colorado, low-volume paved roads are currently maintained with low-cost treatments to enhance the overall pavement condition represented by drivability life (DL). Colorado Department of Transportation (CDOT) assigns mainly two maintenance categories. The long-term effectiveness of such strategy at improving pavement performance is not well understood or documented. The primary objective of this report is to document the effectiveness of some in-practice treatments applied to low-volume roads (LVRs) in Colorado. By analyzing historical pavement performance data and treatment records, the effectiveness of each treatment type was determined using an evaluation methodology presented in this report. It was concluded that some surface maintenance strategies are effective long-term treatments for fatigue, longitudinal, and transverse cracking. However, the effectiveness of these treatments depends mainly on the initial condition index. An alternative maintenance strategy was proposed for CDOT considering a light rehabilitation technique with a surface treatment for poor roads. A long-term analysis of road maintenance and costs was conducted on a case study in Colorado. The results show the impact of both current and proposed maintenance strategies on the future of pavement condition. It was found that the proposed strategy would enhance the effectiveness of current policies followed by CDOT. This report also investigates the badly deteriorated LVRs in Colorado considering a specific characteristic of marginal pavement conditions. The different treatment strategies were evaluated to explore how reliable applying more pavement maintenance techniques is on these roads. The analysis of funding needs shows that marginal roads can be improved effectively within a maintenance capital improvement plan of five years from 2016 to 2020. Investing more effort in the marginal roads using only low-cost treatments is not recommended since the effectiveness of such treatments at this stage may not be reliable.

**Implementation:** The effectiveness of applying low-cost treatments on low-volume roads (LVRs) are dependent on the existing condition of pavement. Therefore, Colorado Department of Transportation (CDOT) is advised to consider specific criteria while applying chip seals and thin overlays on roads. Chip seals shall be applied only while the pavement is still performing well. Pavement performance should be evaluated effectively considering the individual pavement condition indices rather than the overall drivability life value. Accordingly, the pavement management engineers of the different CDOT regions are encouraged to apply chip seals and thin overlays using the threshold values of fatigue and transverse indices included in the proposed maintenance strategy.

The proposed strategy includes light rehabilitations with recycling techniques that can maintain low-volume roads to the desired performance target cost-effectively. Cold in-place recycling and full depth replacement are recommended to be integrated with the current applications of chip seals and thin overlays. Treatment options should be selected based on threshold values of fatigue and transverse indices. In addition, the strategy of maintaining roads by recycling treatments is more encouraging for LVRs with marginal conditions. These roads could be effectively maintained over a capital improvement plan of five years as shown in the report.

## List of Abbreviations

The following table describes the various abbreviations and acronyms used throughout the report:

Abbreviation	Description
AADT	Annual Average Daily Traffic
ACHP	Asphalt Chip Seal
ACIP	Asphalt Cold in Place Recycle
ADTT	Average Daily Truck Traffic
AHIP	Asphalt Hot in Place Recycling
AMDO	Asphalt Medium Overlay
AMFL	Asphalt Mill and Fill
AMJO	Asphalt Major Overlay
AREC	Asphalt Reconstruction
ATHO	Asphalt Thin Overlay
CDOT	Colorado Department of Transportation
CIR	Cold In-Place Recycling
CSU	Colorado State University
DL	Drivability Life
DN	Do Nothing
DOT	Department of Transportation
FDR	Full Depth Reclamation
IRI	International Roughness Index
LVR	Low-Volume Road
MR&R	Maintenance, Rehabilitation, and Repair
MUTCD	Manual on Uniform Traffic Control Devices
PMS	Pavement Management System
RSL	Remaining Service Life
WYT <sup>2</sup> /LTAP	Wyoming Technology Transfer Center/Local Technical Assistance Program

## **Chapter 1: Introduction**

A critical role of a pavement management system (PMS) is to provide useful and defensible programs of pavement management activities and resources (AASHTO, 1990). Over the last decade, significant progress has been made to customize the maintenance policies of low-volume roads (LVRs) to local needs and available resources. Because LVRs have relatively lower usage and occur in regions connecting remote areas with local access and collector roads, they are commonly constructed with low conventional design standards. When it comes to managing LVRs, state Departments of Transportation (DOTs) and local agencies are not supported with the appropriate funding levels for optimal serviceability when compared to higher volume roads. Transportation engineers and policy makers need to define effective pavement treatments and informed maintenance decisions to get the best value of the applied maintenance policies.

The strategy of low-cost treatments and light rehabilitation is extensively employed among local agencies and state DOTs on LVRs even if the pavement performance is poor. However, the effectiveness of the applied treatments at improving pavement performance is not well understood or documented. In the context of pavement preservation, low-cost and surface treatments should be applied to roads while the pavement is still performing well (Galehouse, 2004). When considering preventive maintenance as the only treatment for distressed low-volume paved roads, these applications have different effectiveness depending on the initial pavement performance and the surrounding environment. Some of the applied treatments may provide only short-term effectiveness and agencies make unnecessary expenditures when applying these strategies.

In the State of Colorado, LVRs are currently maintained with only low-cost treatments. The current policy of Colorado DOT (CDOT) includes two allowed categories of treatments which are “surface seals” and “thin overlays”. The surface seal treatment category is the lowest cost of treatment recommended by the PMS for treatment of LVR and can include any combination of treatments throughout the length of the project as long as the total cost does not exceed the lane-mile cost of the surface seal category. The ultra-thin overlay treatment category is the other low cost treatment recommended by the PMS for treatment of LVRs in worse pavement condition and can include any combination of treatments throughout the length of the project as long as the total cost does not exceed the lane-mile cost of the ultra-thin category of treatment cost. Chip sealing is one of the most common maintenance options applied to LVRs in Colorado for pavements in good condition (Galehouse, 2004). Overlay application is very limited and it is applied to LVRs only occasionally as funds are available (Hafez et al., 2017). Also, the lack of pre-overlay treatments affects the performance of overlays when they are placed directly on severely distressed pavements. As a result, poor roads that were applied with short-term improvements and no pre-overlay treatment of severely distressed areas display high post-treatment deterioration rates. This study investigates low-cost rehabilitation alternatives to help CDOT balance between pavement preservation and structural improvement on LVRs.

## **1.1 Objectives**

The primary objective of this report is to assist CDOT and other transportation agencies in determining the optimal allocation of available network budget, and the corresponding maintenance policy for LVRs. Considering different maintenance policy should be evaluated

by studying the benefit-cost impact of maintenance alternatives compared to the applied strategy. This report aims to achieve the following:

1. analyze the past performance of historical treatments applied to LVRs,
2. develop a methodology to identify the effectiveness of applied treatments in extending the service life of pavements on LVRs,
3. highlight maintenance activities that are successfully meeting agency needs,
4. establish an alternative maintenance strategy including effective treatments and informed maintenance decisions,
5. compare between the cost-effectiveness of different maintenance policies recommended for LVRs,
6. study the impact of current CDOT policy on future performance of LVRs in Colorado,
7. evaluate the effectiveness of maintenance strategies applied to poor roads with marginal conditions, and
8. identify capital improvement plans on LVRs with marginal conditions.

## **1.2 Study Background**

According to the Manual on Uniform Traffic Control Devices (MUTCD), a LVR is defined as a road carrying an Annual Average Daily Traffic (AADT) less than 400 vehicles per day (MUTCD, 2009). However, most DOTs consider state specific traffic ranges of high, medium, and low-volume roads to keep the road network of each type of manageable size (Hafez et al., 2017). According to CDOT, LVRs are defined as roads carrying ADT less than 2000 vehicles per day and average daily truck traffic (ADTT) less than 100 trucks per day - due to the high traffic volumes in Colorado (Redd, 2013). In recent years, state DOTs and transportation

agencies have focused on performing cost-effective pavement maintenance on LVRs. Agencies are establishing standards and practices for managing their LVRs. The objective is to customize current state and national standards to the available resources of local governments and municipalities. In 2015, Colorado State University (CSU) and the Wyoming Technology Transfer Center/Local Technical Assistance Program (WYT<sup>2</sup>/LTAP) started a research project to evaluate current national practices and recommend maintenance policies for managing low-volume paved roads in Colorado.

In order to document the most effective and recommended pavement management practices for LVRs, the study consists of two research phases. The first phase has been completed (*Best Practices to Support and Improve Pavement Management Systems for Low-Volume Paved Roads, 2017*) while the second phase is provided in this report. These research phases are described in the following sections.

### *1.2.1 Previous Study: Phase I*

The main objective of the first phase of this study was to investigate current national and local practices and recommended treatment policies that are in place on LVRs. A comprehensive literature review was conducted to highlight and discuss the most commonly applied treatment techniques and new technologies on LVRs. An independent review was introduced about the definitions of LVRs in addition to the key points of LVR pavement design, maintenance, and rehabilitation. Since recycling technologies are being integrated extensively in the maintenance of LVRs, detailed information was provided about the applications of cold in-place recycling (CIR) and full depth reclamation (FDR). The previous management efforts of different state DOTs and transportation agencies were presented showing specific maintenance policies for their LVRs. Most DOTs are combining recycling techniques with surface treatments and chip

seals. Strategies of CIR with chip seals or thin overlays were studied and they can improve the structural status of pavements with lower costs.

The WYT<sup>2</sup>/LTAP conducted online surveys as part of the research project conducted jointly with the CDOT. The objective of the surveys was to document what transportation agencies, including state DOTs, are doing to face the challenge of managing LVRs with limited resources. Four online surveys were sent to the TRB low-volume roads committee, eight state DOTs, local governments in Colorado, and the material advisory committee in the CDOT. These surveys have an average of 26 questions dealing with PMS specifications recommended for low-volume paved roads. Seventy-one transportation agencies and individuals responded to the survey. The findings of this study provide transportation agencies nationwide with comprehensive guidelines for managing LVRs. It also gives insight about the effectiveness of common treatment strategies applied to LVRs by different states at different management levels (Hafez et al., 2017).

### *1.2.2 Current Study: Phase II*

In today's global economy, some innovative pavement treatments have been developed to customize available resources to limited budgets. However, most of these strategies lack adequate justification or scrutiny to be applied on LVRs. In addition, proposed maintenance strategies are recommended to be optimized within the available budgets to preserve the LVRs network at an acceptable level of service. The second study performs a comprehensive analysis to demonstrate the optimal use of maintenance, rehabilitation, and repair (MR&R) strategies. In 2016, CSU and the WYT<sup>2</sup>/LTAP started the second research phase to investigate the cost-effectiveness of applied treatments in Colorado based on historical pavement condition data and treatment records so that recommendations can be developed for CDOT and other

transportation agencies. This study develops a treatment evaluation process and an optimization model to compare between the current CDOT maintenance policy and an alternative strategy recommended for LVRs in Colorado. The findings are summarized and documented in this report which focuses only on the management of low-volume paved roads. This approach is expected to increase understanding of selected maintenance policies for LVRs.

## **Chapter 2: Literature Review**

In 2013, CDOT began evaluating the condition of pavements using the Drivability Life (DL) metric. This process provides more reliable pavement performance criteria that reflects the actual driving condition compared to the regular Remaining Service Life (RSL) procedure. In the context of managing LVRs, the consequence of using DL evaluation process is that treatments focus more on enhancing drivability condition in pavement sections using low-cost surface treatments. This chapter provides detailed information about the pavement performance terminology of drivability life for paved roads in Colorado.

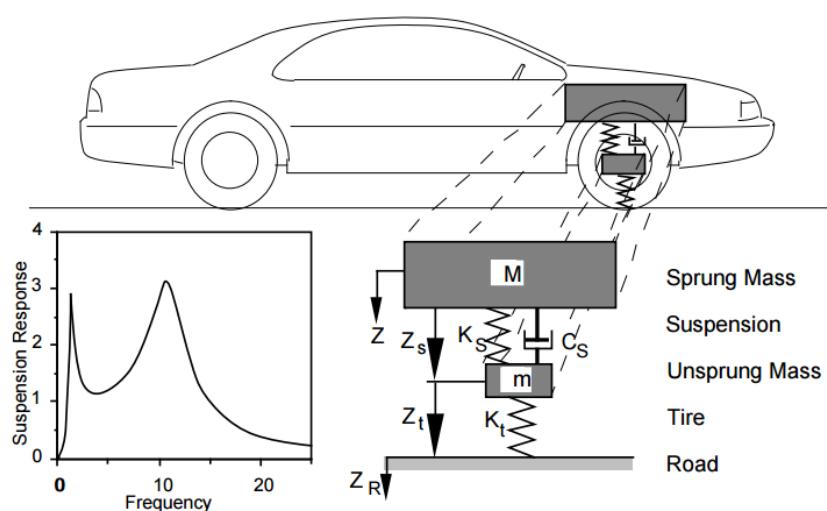

### **2.1 Drivability Life**

Drivability Life (DL) is pavement condition measure developed by CDOT to evaluate the overall condition and performance of pavements. DL is an indication of how long a road is anticipated to have acceptable driving conditions in years (Redd, 2013). DL is determined for asphalt pavement based on a trend analysis of five main distresses. As shown in Figure 2.1, three cracking types are considered in the evaluation process, including fatigue, longitudinal, and transverse cracking. These cracks have different severity levels depending on the size, width, and depth of each crack (Miller and Bellinger, 2003). The forth distress type is road roughness which is an indication of distortion of the road surface along a plane in the travel direction. The higher the road roughness is, the lower the ride quality. The most widely accepted index for measuring roughness is the International Roughness Index (IRI) (Sayers et al., 1986). IRI is represented by a ratio of accumulated suspension motions of a vehicle divided by the distance travelled by the vehicle (m/km or inches/mile). Higher IRI values represent more road roughness. The IRI is obtained by a quarter car model shown in Figure 2.2. The last distress is

pavement rutting. Rutting is a permanent deformation in the pavement surface along the wheel path, as shown in Figure 2.3.

**Figure 2.1: Pavement Cracking Indices for Paved Roads in Colorado**

**Figure 2.2 Quarter Car Model (Gillespie, 1992)**

**Figure 2.3: Shape of Rutting in a Pavement Surface (Miller and Bellinger, 2003)**

All of the previous distresses are normalized into condition indices on a scale from 0 (pavement's worst state) to 100 (excellent or brand new pavement). Consequently, five condition indices are considered while analyzing the pavement performance of LVRs in Colorado. They are described as follows:

- FATIG\_IDX: Fatigue Index
- LONG\_IDX: Longitudinal Index
- TRANSV\_IDX: Transverse Index
- RIDE\_IDX: Ride Index
- RUT\_IDX: Rut Index

As shown in Equation (1), the three cracking indices (e.g., fatigue, longitudinal, and transverse indices) are determined based on the relative quantity of cracking at each severity level (e.g., low, medium, and high) compared to the maximum possible amounts on pavements. These maximum values were developed by CDOT and they are listed in Table 2.1. Ride and rut indices are determined using Equations (2) and (3) respectively. Based on the value of each

distress index, the pavement performance can be classified into one of the five categories listed in Table 2.2.

$$Distress\ Index = 100 \left( 1 - \frac{Distress_{LOW}}{Max_{LOW}} - \frac{Distress_{MID}}{Max_{MID}} - \frac{Distress_{HIGH}}{Max_{HIGH}} \right) \quad (1)$$

$$RIDE\ Index = 100 * \left( 1 - \frac{IRI_{avg} - A_{min}}{B_{max}} \right) \quad (2)$$

$$Rut\ Index = 100 * \left( 1 - \frac{Rut_{avg} - B_{min}}{B_{max} - B_{min}} \right) \quad (3)$$

where,

- $Distress_{LOW}$ ,  $Distress_{MID}$ , and  $Distress_{HIGH}$ : Quantity of distress at each severity level (e.g., low, medium, and high) for Fatigue cracking (feet<sup>2</sup>), transverse cracking (feet), and longitudinal cracking (feet) respectively.
- $IRI_{avg}$  and  $Rut_{avg}$ : Average IRI (inch/mile) and rut depth (inch) respectively.
- The values of all other parameters of Equation (1) through Equation (3) are listed in Table 2.1.

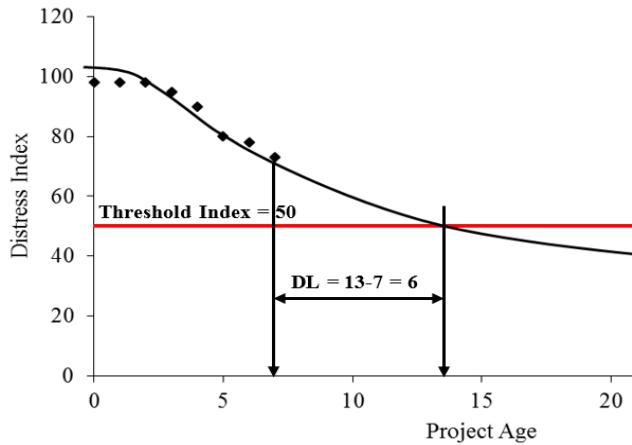

**Table 2.1: Values of Different Parameters for Asphalt Pavement**

Parameter	Fatigue Index	Transverse Index	Longitudinal Index	Ride Index	Rut Index
$Max_{LOW}$	6230	160	3802	-	-
$Max_{MID}$	3375	111	2492	-	-
$Max_{HIGH}$	2014	49	1478	-	-
$A_{min}$	-	-	-	0	-
$B_{min}$	-	-	-	-	0.15
$B_{max}$	-	-	-	26	0.95

**Table 2.2: Pavement Performance Category for Each Condition Index**

Index Range	Category
Greater than 90	Excellent
80 – 90	Good Condition
70 – 79	Fair Condition
60 – 69	Poor Condition
Less than 60	Very Poor Condition

According to CDOT, the pavement has a DL of 0 when any of the distress indices is less than 50. Each condition index has a specific performance curve as a function of pavement age. The overall DL value of a road is the minimum time remaining until any of the condition indices reaches a threshold value of 50. Figure 2.4 shows an example to determine DL of a road segment. Based on the historical values of distress indices, the pavement performance curve is fit with respect to the pavement age. From the existing value of the condition index, the pavement age can be projected (which is 7 years in the example). Based on the threshold of 50, the future pavement age can be estimated when the road becomes out of service (which is 13 years in the example). The DL value then can be determined which is the difference between the two ages (e.g., 6 years).

**Figure 2.4: An Example of Drivability Life Projection on a Pavement Performance Curve**

Three categories are considered to classify the overall DL value of a road. CDOT uses different standards for DL on different road classifications. The cutoff values of DL categories for LVRs are listed in Table 2.3.

**Table 2.3: Drivability Life Categories for Low-Volume Roads**

DL Range (years)	Category
Greater than 10	High
4 – 10	Moderate
3 and less	Low

## **Chapter 3: Comprehensive Evaluation Process of Alternative Treatments and Maintenance Policies**

### **3.1 Introduction**

To investigate the impact of current CDOT maintenance policy on LVRs, a comprehensive evaluation process was developed. This process includes pavement performance analysis to evaluate the effectiveness of applied treatments in addition to optimization techniques. To study the effectiveness of the applied treatments, the post-treatment performance of pavements should be evaluated. This chapter provides a methodology to assess the current practices applied on LVRs using the historical condition data.

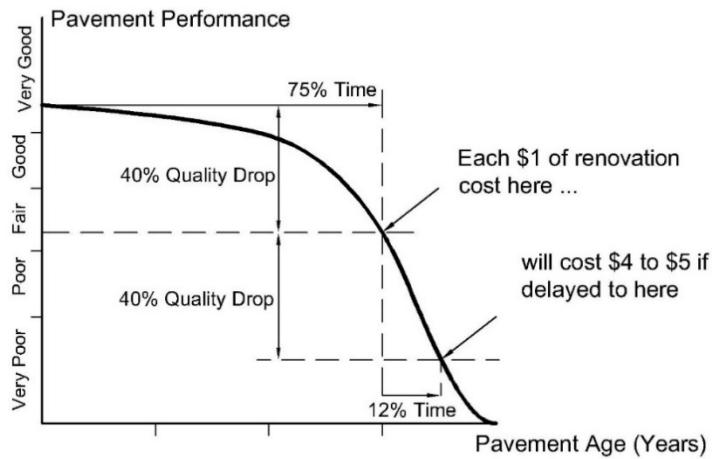

### **3.2 Evaluation Methodology of Applied Pavement Treatments**

A long-term evaluation is recommended when studying the effectiveness of treatments. This evaluation may include constructing test sections to document the performance after applying treatments. Building pavement test sections provides detailed information about the long-term performance of roads. However, it takes considerable time to complete the analysis. In addition, test sections may provide limited results since they are restricted by the condition of test section sites. There are numerous parameters affecting the performance of pavement after applying treatments. Some parameters are not considered in the analysis when studying the performance of the test sections. Another approach of evaluating treatments is by analyzing the historical data of the actual pavement performance of LVRs.

### *3.2.1 Pavement Performance Model*

Pavement performance models are predictive models developed to display the variation or the history of pavement serviceability with respect to time. Pavement performance models hold a very significant place in the development of a pavement management system. This is because many other components in the system are related to the output of the pavement performance models. Such components include the pavement structural design, maintenance treatment strategies, or priority programming (Li and XIE, 1997).

The pavement performance of an individual pavement depends on the pavement materials, soil characteristics, traffic loads, and environmental conditions. However, as displayed in Figure 3.1, the conceptual performance curves of pavements have a typical trend: older pavement sections deteriorate faster and they cost more money to fix. It is not prudent to include only the roads requiring reconstruction in the maintenance strategy of the road network. This is not only an expensive strategy, but good and fair pavements will also continue to deteriorate to very poor levels. Therefore, the process of only repairing the worst roadways when they fall into very poor condition is not a cost-effective strategy. Agencies are applying frequent early treatments in the life of pavement to keep the condition of roads at an acceptable level.

**Figure 3.1: Relationship between Pavement Performance and Repairing Costs (Shahin and Walter, 1990)**

When it comes to managing LVRs, transportation agencies have low budgets allocated for maintenance. Meanwhile, a high percentage of LVRs is currently in poor condition. Some LVRs accommodate heavier truck loads than the original design values because of increasing industrial activities (Huntington et al., 2013). In addition, most LVRs have aged beyond their design life and there is no historical maintenance and rehabilitation records on these roads. Many agencies apply low-cost treatments on LVRs even if the pavement is in poor condition. When roads receive major treatments, the pavement condition increases significantly on the pavement performance curve. However, some of these roads deteriorate rapidly after applying treatments. The various trends of pavement performance after applying treatments can be observed using the pavement performance model.

### 3.2.2 Evaluation Criteria of Applied Pavement Treatments

In order to develop evaluation criteria rating the effectiveness of treatments, the first step is to define the treatment categories. Treatments can be classified as effective or not effective treatments based on a minimum condition improvement amount and a corresponding post-

treatment performance. In addition to effective and ineffective treatment categories, another category for applied treatments effectiveness is called ‘Uniform performance’. When pavement treatments have uniform performance, they tend to show insignificant deterioration or improvement overtime. The reason for uniform performance is either the condition is at a high level and the rate of deterioration is accordingly small, or routine maintenance has been applied to lower the rate of deterioration of minor defects. These kinds of treatments are beyond the scope of this study because the study focuses only on treatments that provide major improvements. Since most of LVRs in Colorado are in the low DL category, the study focuses only on roads with significant change in the pavement performance. As will be presented in the descriptive analysis chapter, the historical condition data shows that there are some roads having overall low DL values because only one condition index has very low amount while the other indices are still in good levels. Therefore, this study is trying to define treatments that have significant effectiveness on a particular index. Accordingly, treatments were classified in this study into the following four categories:

- Effective treatment,
- Not effective treatment,
- Uniform performance, and
- Other

In order to assign each treatment to a category based on the historical performance data of the road network, three main criteria were identified as shown in Table 3.1. These criteria were simplified to meet the available PMS data parameters of all agencies including local agencies. Each criterion has a specific pavement condition range identified by transportation

agencies depending on the nature of their pavement performance parameters. When roads do not meet any of the three listed criteria, the performance curve of these roads is assigned to the “Other” category.

**Table 3.1: Pavement Performance Criteria for Treatment Categories**

Criterion	Description
1- Pavement Condition Improvement	A minimum amount of improvement in the condition index should be defined to consider the applied treatment as a major treatment.
2- First Deterioration Amount	A maximum deterioration amount should be defined for the first and second years after applying treatments. Treatments are classified as effective when the deterioration of post-treatment performance is within the First Deterioration Amount.
3- Difference in Pavement Condition for Uniform Performance	A maximum amount of difference in the condition index each year should be defined. When roads have historical values of pavement condition within this criterion, the roads have uniform performance and are assumed to receive routine maintenance.

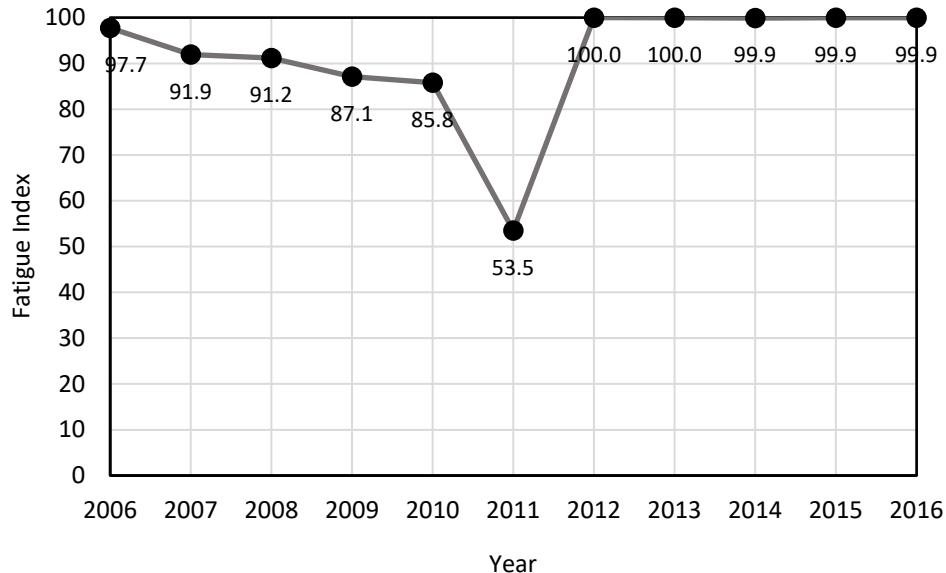

For Colorado LVRs, specific ranges of each evaluation criterion were set for the five condition indices and they are listed in Table 3.2. These effective ranges were developed based on the distribution of the condition indices of the whole network. Each treatment type can be evaluated using these effective ranges. For example, in the context of fatigue index, the applied treatment is effective when the amount of improvement is more than the first criterion of “Pavement Condition Improvement” which is 15 and the amount of deterioration in each year of the first two years is less than the second criterion of “First Deterioration Amount” which is 5. Figure 3.2 shows an example of a road segment in Colorado received an effective treatment of cold in-place recycling in 2011. For ineffective treatments, Figure 3.3 shows an example of a road segment in Colorado where a chip seal was applied in 2013. According to the historical values of transverse index, the chip seal was found to cause a major enhancement on the pavement because the transverse index was increased from 79 to 89. However, the post-

treatment performance shows high deterioration amounts in 2014 and 2015 that are more than the First Deterioration Amount of 5 for transverse index. Hence, the chip seal treatment was classified as ineffective for this case.

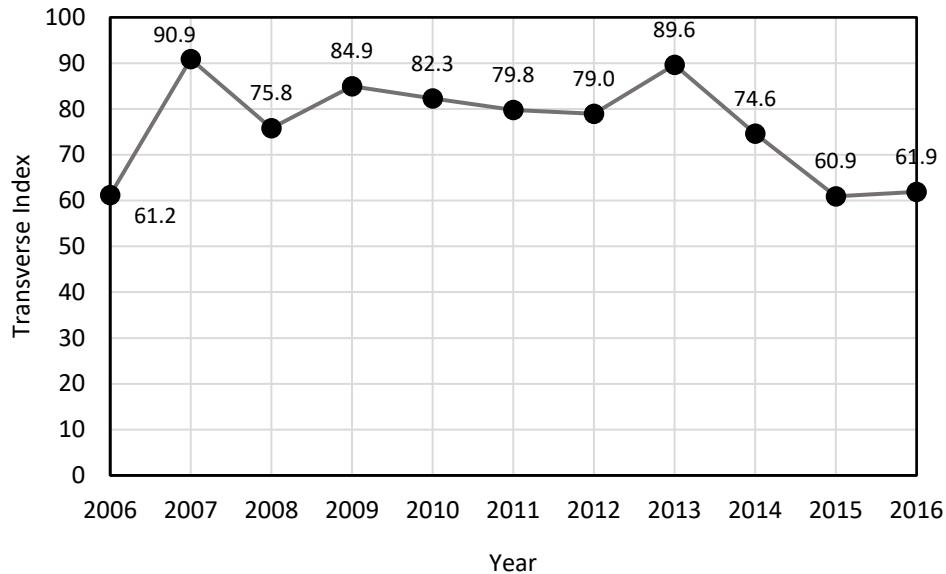

No significant improvement was considered when the historical improvement of the condition index is less than the first criterion. In addition, if the pavement performance is within the third criterion of “Difference in Pavement Condition for Uniform Performance”, then the applied treatment was considered as kinds of routine maintenance for uniform performance. Also, uniform performance was described for roads without any treatment records but the pavement condition remains relatively stable as shown in Figure 3.4.

**Table 3.2: Effective Ranges for the Evaluation Criteria of Applied Treatments**

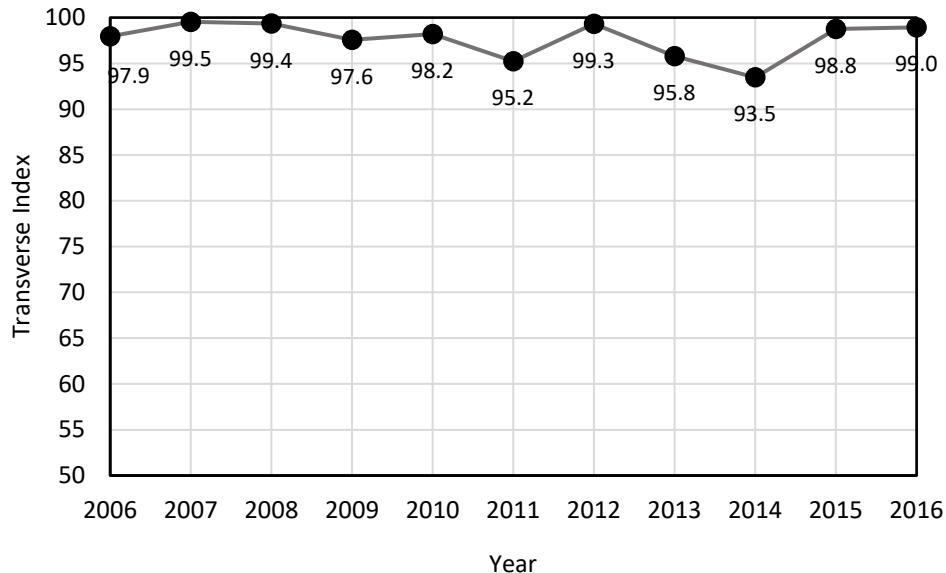

Criterion	Fatigue Index	Longitudinal Index	Transverse Index	Ride Index	Rut Index
1- Pavement Condition Improvement	15	5	10	10	10
2- First Deterioration Amount	5	2	5	5	5
3- Difference in Pavement Condition for Uniform Performance	5	2	5	5	5

**Figure 3.2: Example of Receiving an effective treatment of cold in-place recycling in 2011 shows the effectiveness on the individual performance of Fatigue Index (Route No. 36C; Reference Mile Post = 80.82; Ending Mile Post = 83.71)**

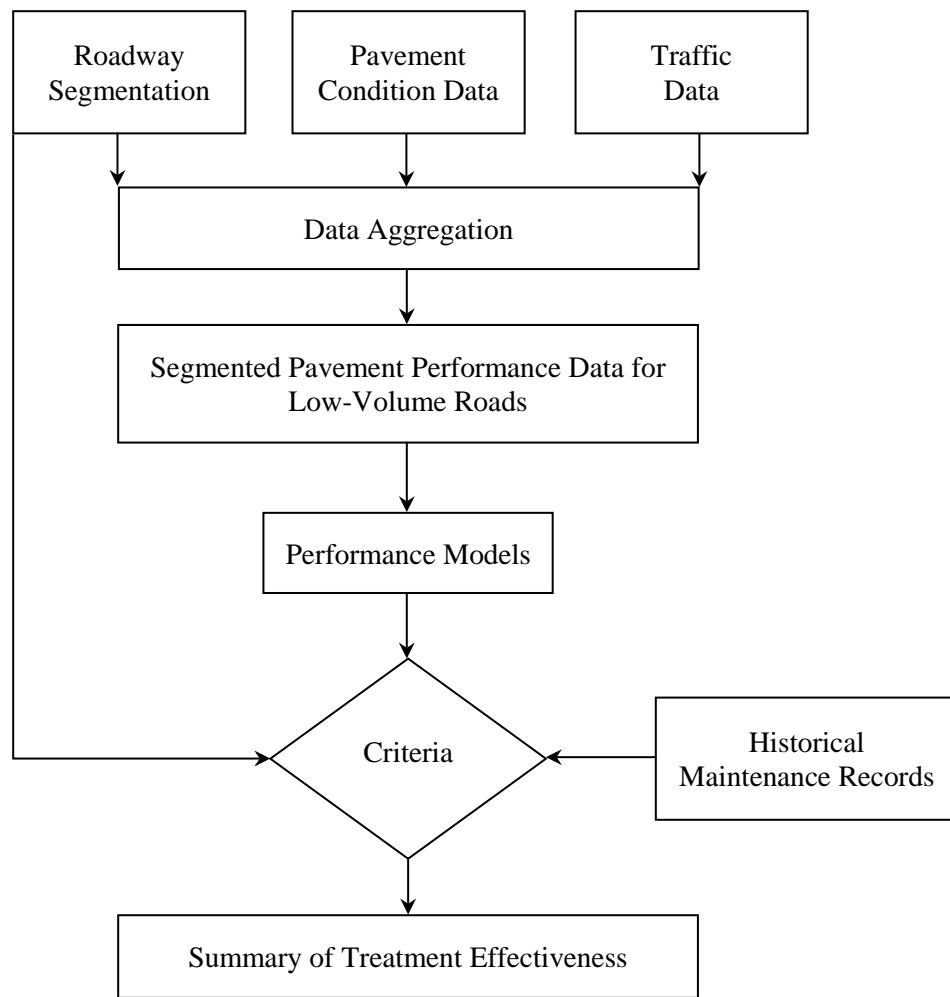

**Figure 3.3: Example of Receiving an ineffective treatment of a chip seal in 2013 shows the effectiveness on the individual performance model of Transverse Index (Route No. 72B; Reference Mile Post = 44.10; Ending Mile Post = 48.35)**

**Figure 3.4: Example of stable pavement condition shows uniform performance of Fatigue Index (Route No. 12A; Reference Mile Post = 43.03; Ending Mile Post = 56.85)**

The research methodology for evaluating applied treatments is shown graphically in Figure 3.5. Roadway segmentation is a primary task in PMS at the network level. The roadway network is divided into segments which are referenced linearly using the milepost of roads. The roadway segmentation was done by CDOT and a segmented data was received for all roads in different categories. The objective of roadway segmentation is to reduce the volume of data sets for the network. All segments should have relatively homogeneous characteristics such as usage levels, geometry, and surface types. Accordingly, the pavement condition data can be aggregated by taking average values along each segment. The pavement performance data is then filtered based on traffic volumes to include the LVRs segments only. The next step is to develop the pavement performance models for each segment. The historical maintenance records are also aggregated for each segment using the linear reference. By following the

performance criteria stated above on every treatment for every segment, the treatments effectiveness can be identified.

**Figure 3.5: Research Methodology of Evaluating Treatments**

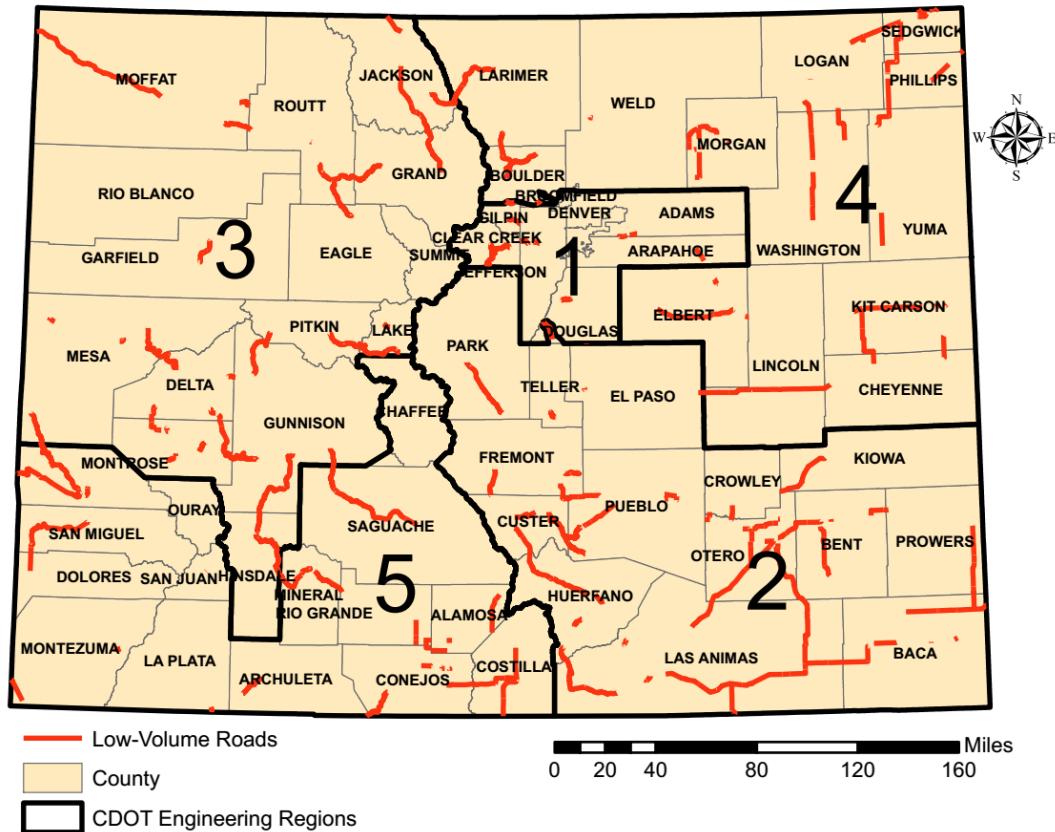

## **Chapter 4: Past Pavement Performance on Low-Volume Roads in Colorado**

### **4.1 Introduction**

A historical condition dataset was received from CDOT for the time period from 2006 to 2016 showing the recorded pavement condition data for each year on LVRs. Also, historical treatment records were analyzed to investigate how the applied maintenance activities affected the long-term pavement performance. The descriptive analysis of the past pavement performance and applied treatments is introduced in this chapter.

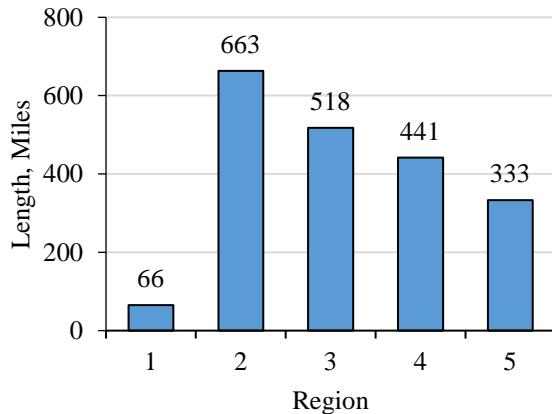

### **4.2 Descriptive Analysis of Low-Volume Paved Roads in Colorado**

In the State of Colorado, about 9,106 center-lane miles are managed and maintained by CDOT (Redd, 2013). More than 50% of these roads are not considered as national highways. There exists 2,022 miles of low-volume paved roads in Colorado's engineering regions shown in Figure 4.1.

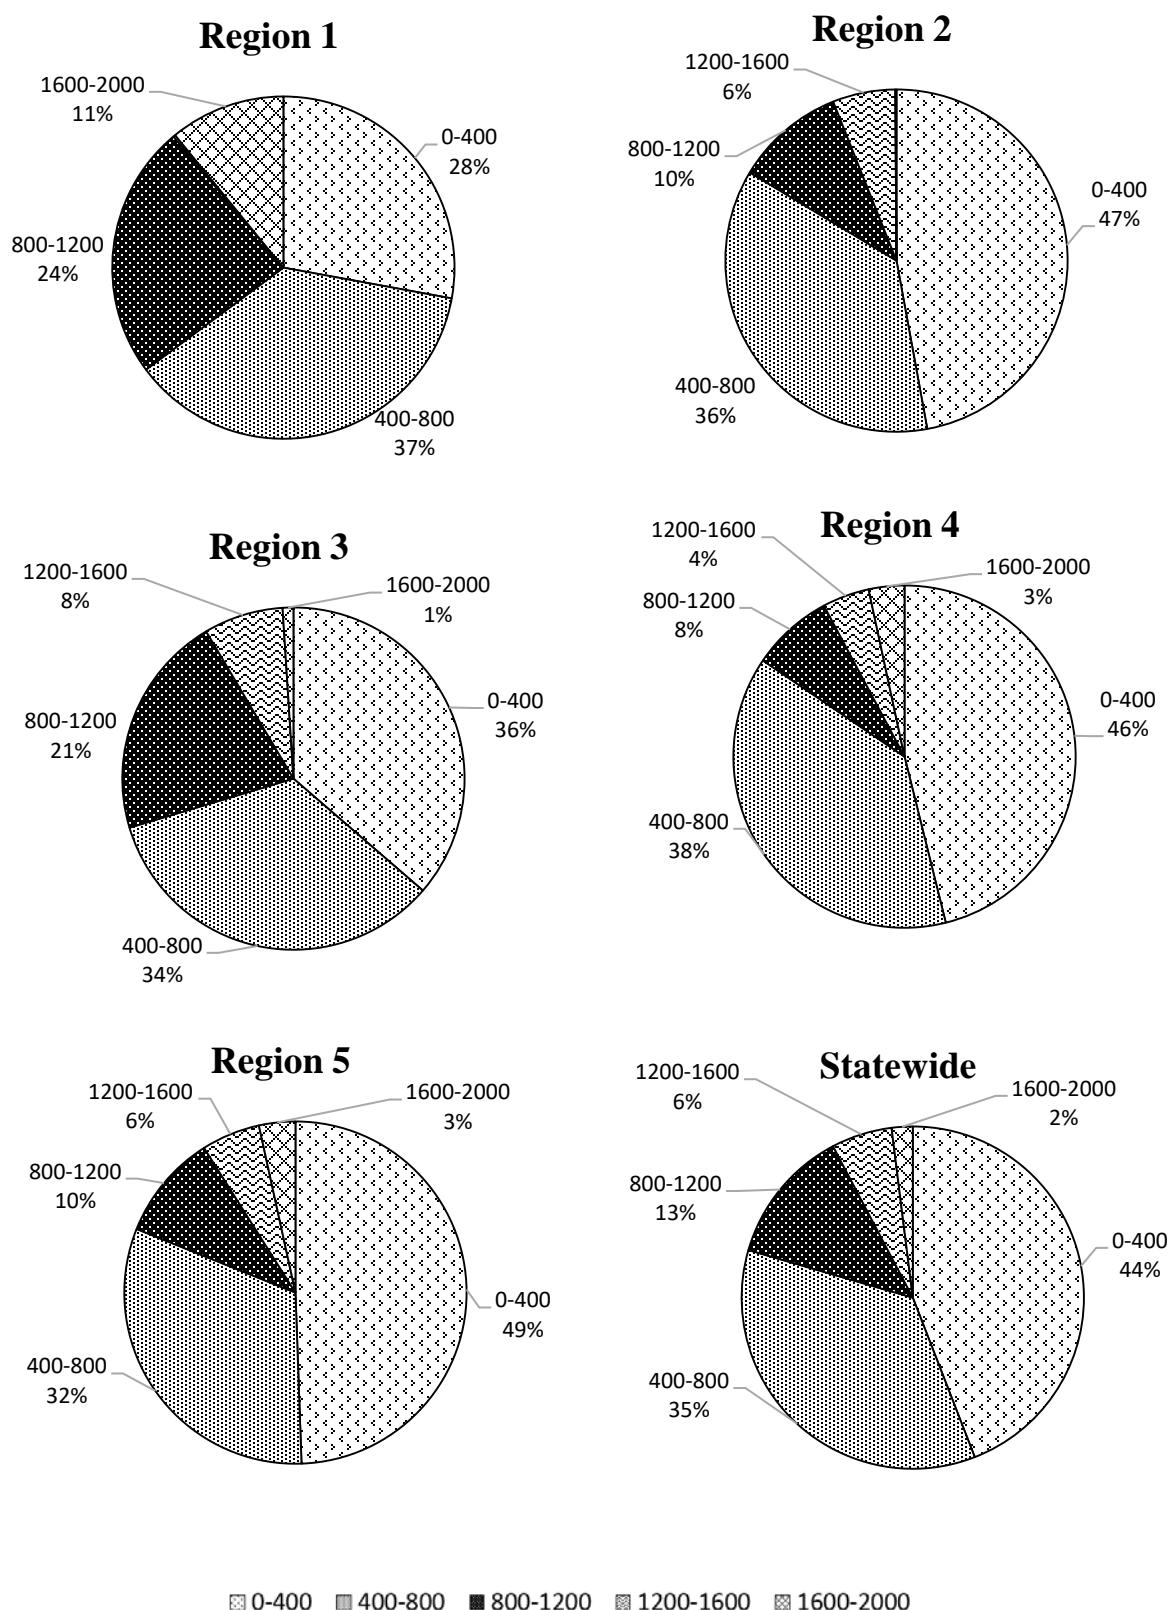

**Figure 4.1: Colorado Department of Transportation Engineering Regions (CDOT, 2017)**

As shown in Figure 4.2, low-volume paved roads are distributed differently among CDOT engineering regions. The lowest mileage of LVRs occurs in Region 1 which includes the urbanized Denver metro area. Region 2 has the highest mileage of LVRs in Colorado.

**Figure 4.2: Mileage Distribution of Low Volume Paved Roads by Region in Colorado**

Although CDOT's upper limit of traffic volume for LVRs is 2000 vehicles per day, most LVR traffic volumes are not more than 800 vehicles per day. Figure 4.3 shows the mileage split of LVRs in different traffic ranges. The range of traffic volume from 0 to 400 vehicles per day is the most distributed category on all regions except for Region 1 where higher traffic volumes are expected in the metropolitan area of Denver. The following subsections provide detailed information about the current and historical performance of pavements in the context of the five condition indices. In addition, the historical treatments records are analyzed to show the type and quantity of low-volume treatment applications in Colorado.

**Figure 4.3: Mileage Distribution of Low-Volume Paved Roads by Average Daily Traffic (vehicles per day)**

#### 4.2.1 Pavement Performance

Based on the traffic volumes, the road network of LVRs in Colorado is divided into 342 segments. CDOT has a database of pavement management parameters as shown in Table 4.1. The condition data includes the five distress indices which are originally collected every 1/10<sup>th</sup> mile on the road segment. Historical condition data was received from CDOT for the time period from 2006 to 2016 showing the behavior of pavements condition on LVRs. Based on the linear reference of roads, the pavement condition of each segment was aggregated by taking the average values of each condition index. The historical values are listed in Appendix A-1 through Appendix A-5 for the five condition indices.

**Table 4.1: A Sample of Combined Pavement Management Dataset in Colorado**

Route	Beg MP	End MP	Rehab Year	Ride Index	Rut Index	Fatigue Index	Transverse Index	Longitudinal Index	Region	DL
005A	0	14.894	1994	42	99	93	70	99	5	0
006A	11.825	13.867	1985	73	98	73	61	96	3	3
006A	11.179	11.825	1985	73	98	73	61	96	3	3
006A	11.08	11.179	1985	73	98	73	61	96	3	3

Table 4.2 lists the summary statistics of the five condition indices for all roads. Using the mean values, it can be noted that the overall performance decreases over specific lengths of time due to pavement deterioration. The increase in the means of fatigue, longitudinal, and transverse indices in 2012 can also be noticed. These improvements could be due to certain maintenance activities applied in 2012 or the accumulated effectiveness of applied treatments in the previous years. However, the research efforts of this study did not consider the overall network condition when studying the effectiveness of treatments. Discrete segments of the network were comprehensively studied according to their individual pavement performance and records of treatments applied during the analysis period. The treatment effectiveness on these segments were evaluated based on the methodology stated in Chapter 3. Figure 4.4 shows

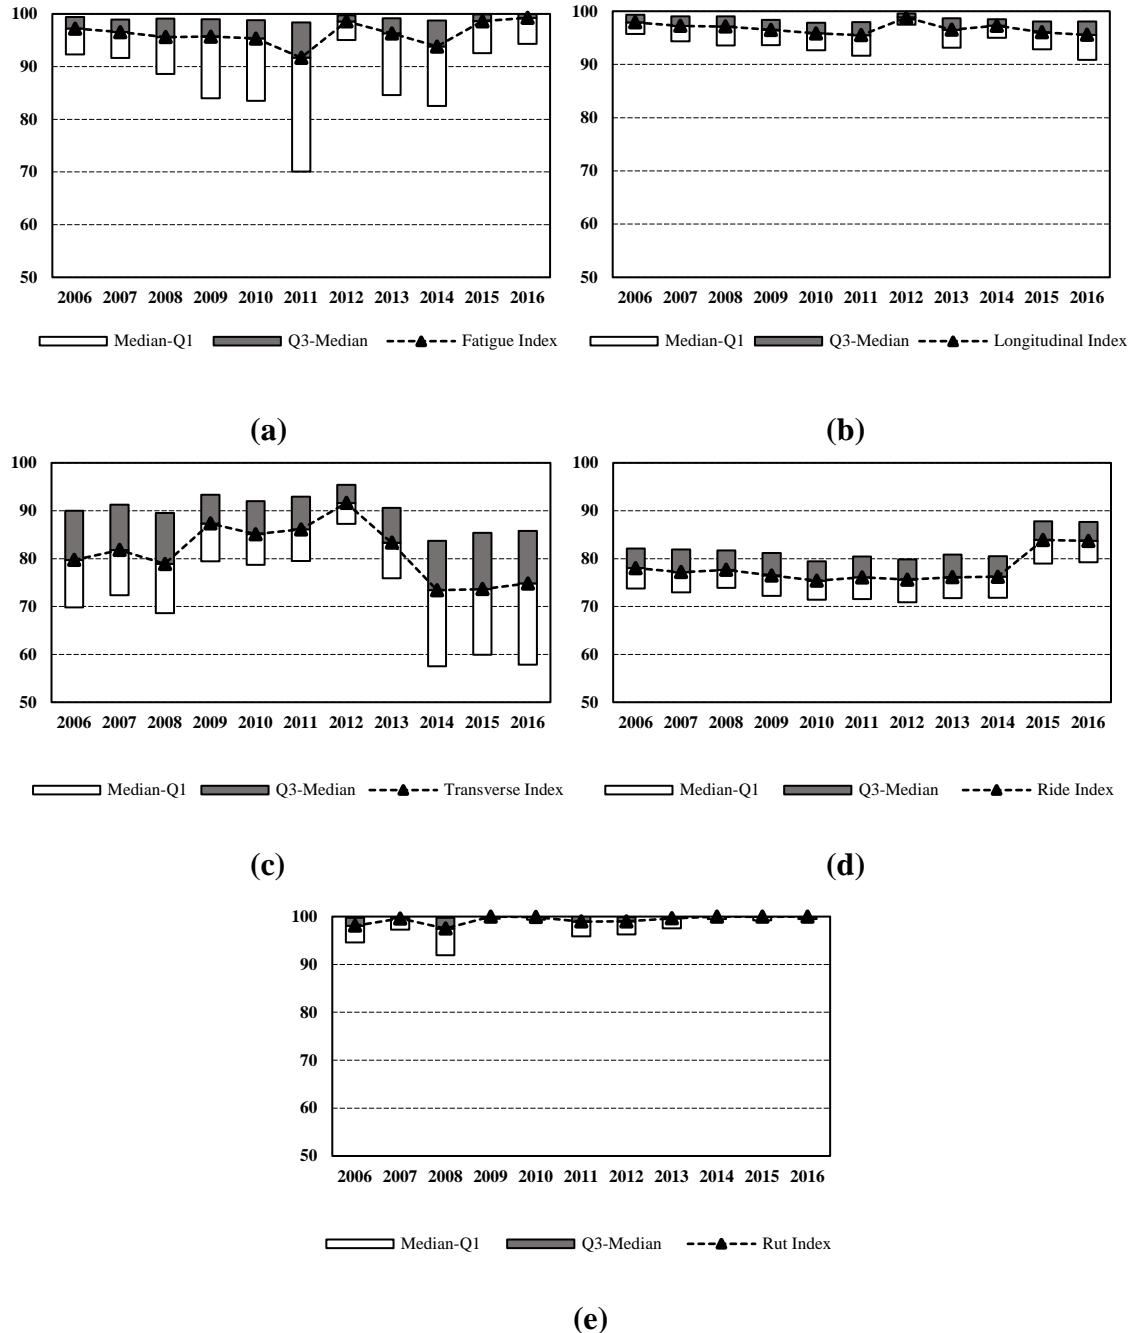

the overall performance models of the network which were developed based on the median value of the condition index in each year. For the fatigue condition index data set, it can be noted that the pavement deteriorated by typical rates from 2006 to 2011 providing high variance at 2011. Then at 2012, the overall performance was increased showing low variability of the values. After that, the segments deteriorated gradually before having a major improvement in 2015.

**Table 4.2: Summary Statistics of Condition Indices for Low-Volume Paved Roads in Colorado**

Index	Year	200 6	200 7	200 8	200 9	201 0	201 1	201 2	201 3	201 4	201 5	201 6

	St. Deviation	5.9	3.8	6.1	1.4	1.9	4.1	4.1	4.4	1.9	2.3	2.1

In the context of longitudinal cracking, an increase can be noticed in the overall performance model from 2011 to 2012. All the roads had low variability in each year since the

values of the longitudinal index are relatively high. Consequently, the rate of deterioration of longitudinal cracking is relatively low. The smallest variability was at 2012 when the roads received treatments.

**Figure 4.4: Overall Performance Models (a) Fatigue Index; (b) Longitudinal Index; (c) Transverse Index;**

**(d) Ride Index; (e) Rut Index**

For the transverse index, higher variability was found in the data set compared to the longitudinal index. The curve of the overall performance shows two different behaviors of pavement conditions. The rate of deterioration seems to be relatively less after 2009 than the rate of deterioration after 2012.

Relatively uniform performance was found in the value distribution of both ride and rut index. The inner quantiles of ride index in each year ranged approximately from 71 to 82. The uniform performance of roads in the context of roughness shows that LVRs may receive treatments that are not effective for enhancing the ride quality of roads. No major improvements for roughness were found in the performance of pavements from 2006 to 2014. However, the overall roughness of roads was enhanced at 2015 which had a uniform performance in 2016. Rut distresses of most roads are in excellent conditions, and no major improvements or deteriorations can be noticed. Table 4.3 through Table 4.7 show summaries of the five condition indices divided by CDOT regions. These summaries are also shown graphically in Figure 4.5 through Figure 4.10. It can be noticed that Region 2 and Region 5 have more miles with the fatigue cracking index rated poor than the rest of the regions. They also have more miles with the transverse cracking index rated poor than the rest of the regions. Longitudinal and rutting indices of low volume roads in all five regions are in good or excellent condition. Only 11 percent of the low volume miles have a poor or very poor ride index, and 89 percent of roads have a fair or good ride index.

**Table 4.3: Summary of Fatigue Index by Regions in 2014**

Fatigue Index	Condition	Length in Miles by Regions					Grand Total

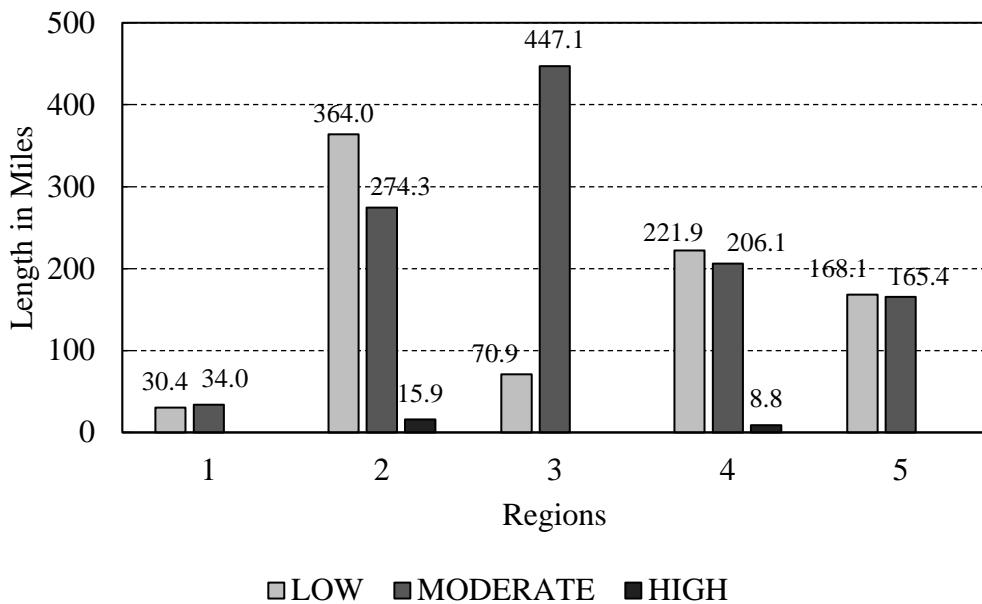

**Figure 4.10: Pavement Conditions of Low Volume Roads in 2014: Drivability Life (DL, years)**

Table 4.8 and Figure 4.11 summarize the DLs by region for all LVRs in Colorado in 2014. Most of these low-volume roads are in the low or medium categories. Only 1 percent of the whole low-volume road network is in the high DL category. The majority of roads in region 3 are in the medium DL category.

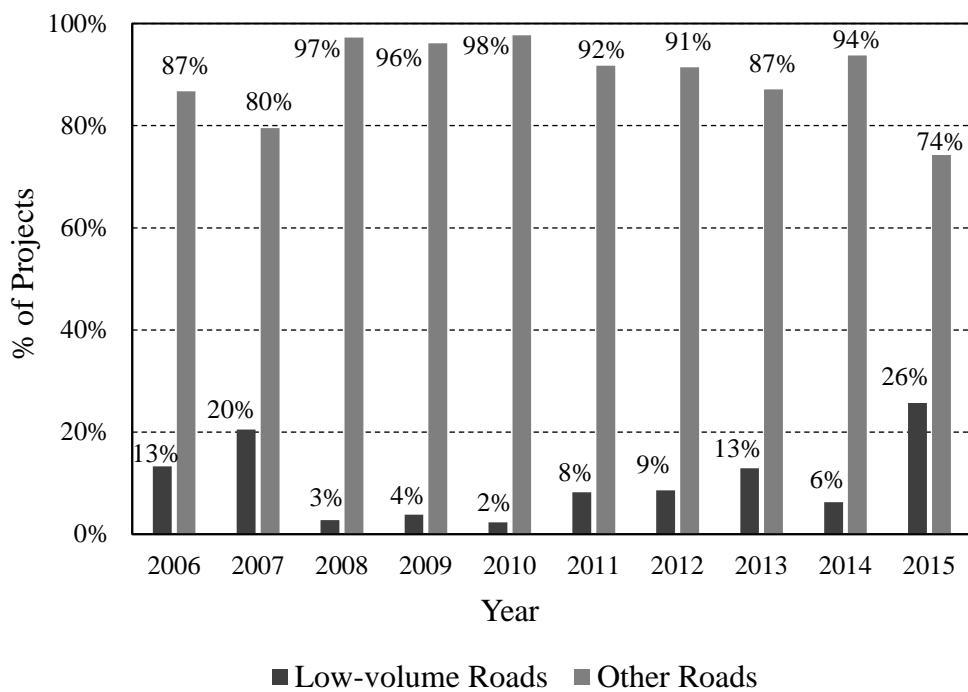

**Figure 4.11: Number of Miles in Each DL Category by Region in 2014**

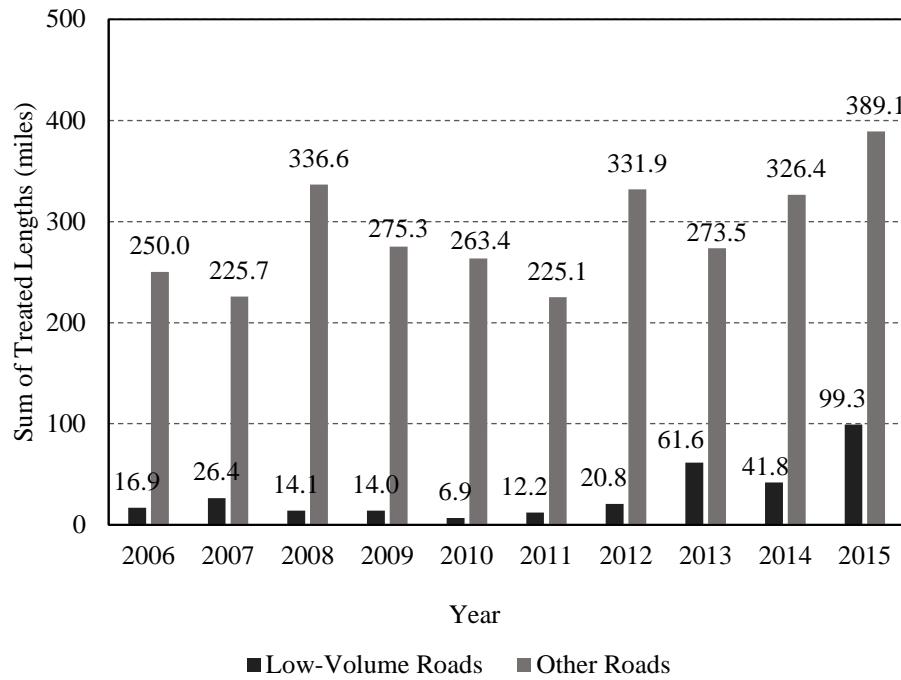

#### 4.2.2 Historical Treatments

Historical treatment records were analyzed to present a summary on the historical applications of treatments to LVRs. CDOT provided a historical treatment data set that includes information about the applied treatments on all roads (e.g., low-, medium-, and high- volume roads). The data for medium- and high- volume roads were combined as other roads. Figure 4.12 shows the percentage of projects applied to LVRs compared to the other roads from 2006 to 2015. Figure 4.13 shows the treatment summary by total lengths on roadways. The applied treatments on

LVRs were found to be less than 10% of the annual maintenance program from 2008 to 2012. The reason of having few maintenance projects on LVRs is that transportation agencies apply low-cost treatments on LVRs due to the funding constraints. Some agencies implement routine maintenance and crack sealing activities without having a proper tracking system on roads. Most of these treatment projects were potentially unrecorded by CDOT.

**Figure 4.12: Treatment Records Summary on Roadways in Colorado**

**Figure 4.13: Treatment Summary by Total Treated Lengths on Roadways in Colorado**

According to CDOT, treatments are recorded using abbreviations. The treatment data was filtered to each traffic-based network using the linear reference of both projects and segments. Eight treatments were applied to LVRs. The key defining these treatments is shown in Table 4.9. The segmented application history of these treatments is presented in Appendix B. For each treatment type, a summary of treated roads was developed from 2006 to 2016 as shown in Table 4.10. Asphalt chip seals (ACHP) and asphalt thin overlays (ATHO) were the most applied treatments on LVRs, especially in recent years.

**Table 4.9: Treatment Types Applied on Low-Volume Paved Roads in Colorado Historical Database**

Treatment	Description
ACHP	Asphalt Chip Seal
ACIP	Asphalt Cold in Place Recycle (4" + 2")
AHIP	Asphalt Hot in Place Recycling
AMDO	Asphalt Medium Overlay 2" - < 4"
AMFL	Asphalt Mill and Fill (2" R&R)
AMJO	Asphalt Major Overlay 4" - < 6"
AREC	Asphalt Reconstruction >= 6"
ATHO	Asphalt Thin Overlay < 2"

NOTE: These treatments are applied on low-volume paved roads. There are other treatments applied by CDOT on pavements which are out of the interest of this study.

**Table 4.10: Historical Summary of Treated Low-Volume Paved Roads in Colorado by Treatment Type**

Year	Sum of Treated Segment Lengths (miles)							
	ACHP	ACIP	AHIP	AMDO	AMFL	AMJO	AREC	ATHO
2006			16			0.9		
2007	10.7	15.5			0.3			
2008				7.1				7.1
2009			14					
2010				6.9				
2011		11.6					0.6	
2012	9.9			1.9	0.2	8.7	0.1	
2013	13.5		13.8		19.3			14.7
2014					25.2			16.8
2015	59.5			6.6	13.3			19.9
2016	25.2	14		13.4	1.3	3		40.7
Total	118.9	41.1	43.8	35.8	59.6	12.6	0.7	99.2

The reason for extensively employing ACHP and ATHO is that CDOT began to use a specific maintenance strategy to enhance the drivability condition of LVRs with low-cost treatments when DL-based evaluation was adopted. For the current CDOT policy, general maintenance (GM) are applied such as crack sealing and crack filling when roads have DL

values of more than 10 years (e.g., DL is high). ACHP treatments are applied for roads with DL values between 4 and 10 years (e.g., moderate DL value). When LVRs fall into poor conditions (e.g., low DL value), these roads are addressed with thin overlays which are applied with a thickness less than 2 inches. It should be understood that ACHP is a treatment cost category, not a required prescription for a chip seal treatment. The same is true for those treatments categorized as ATHO. This has been the case since late in 2013 and policy allows for any combination of treatments or single treatment by the materials engineer that remains at or below the prescribed cost limit for either ACHP or ATHO category of low cost treatment. There are occurrences of actual ACHP where chip seal treatment is specifically what was applied. This is also the case for ATHO locations that have received only a thin overlay. These will have been primarily placed between 2006 and 2012. Treatments thereafter may include broader combinations of treatments applied under these designations.

## **Chapter 5: Impact of Current Maintenance Strategy on Pavement**

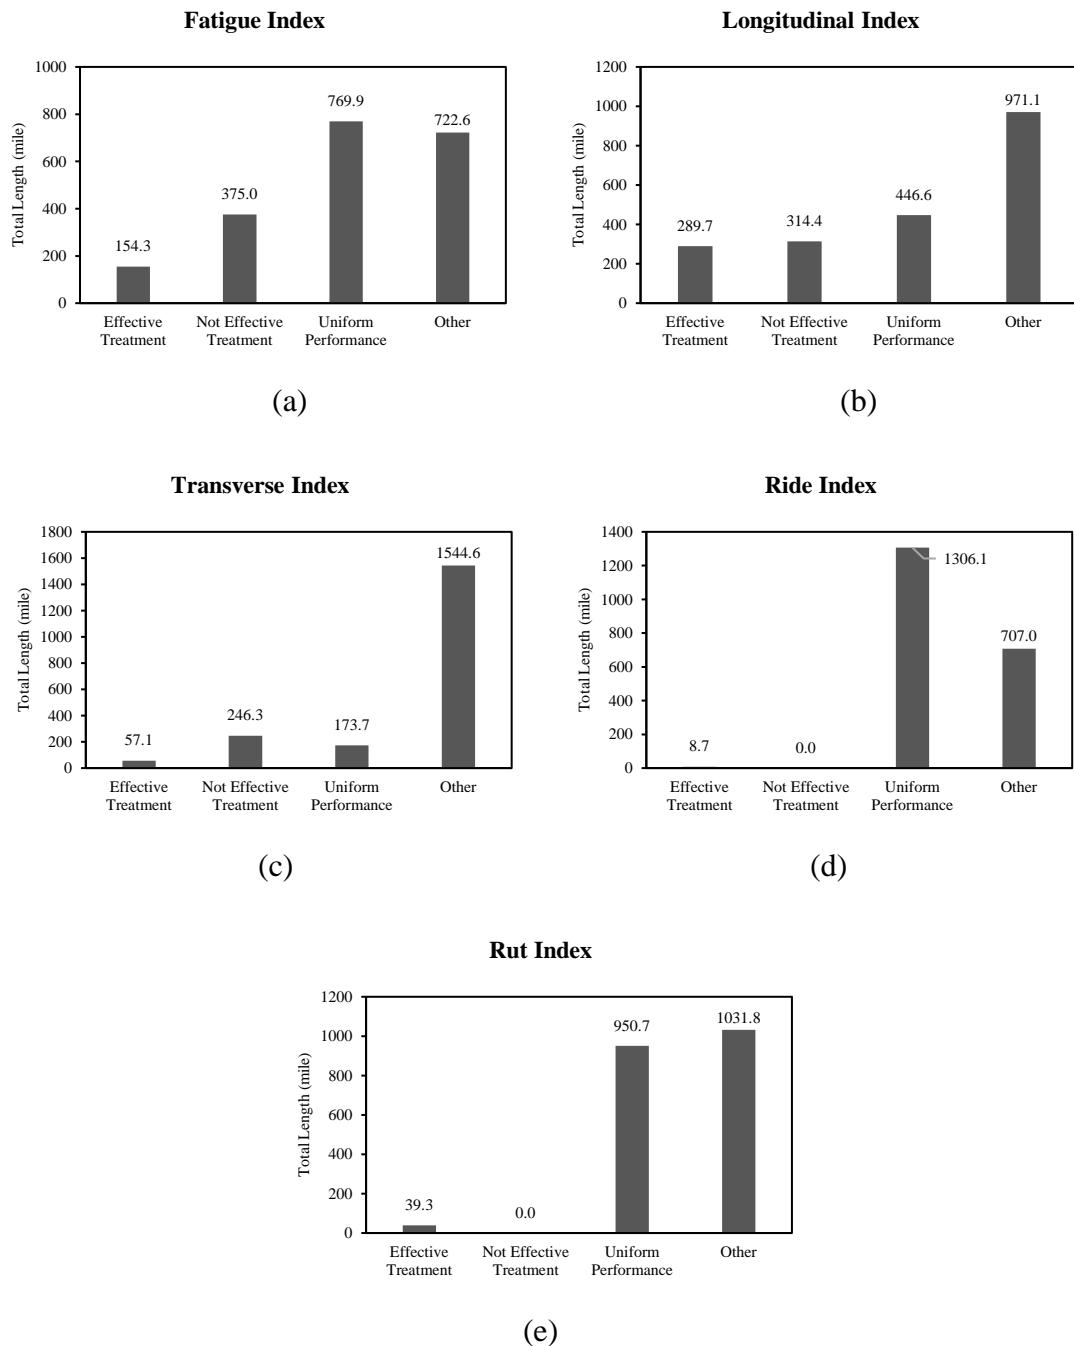

### **Conditions of Low-Volume Roads**

#### **5.1 Introduction**

The performance of pavement sections was analyzed and the results are presented in this chapter showing different trends of common treatment options applied to LVRs. The effectiveness of each treatment type in the context of fatigue, longitudinal, and transverse cracking was evaluated based on the evaluation methodology described in Chapter 3. In order to determine the impact of the current maintenance strategy, performance prediction models are developed for both deteriorated and improved roads using the historical values. Using these models and available financial resources, future maintenance activities were optimized to maximize the overall weighted drivability life. Then an alternative maintenance strategy was proposed which includes a maintenance decision tree for only effective treatments. The comparison between the impact of current maintenance policy and the proposed strategy is also introduced in this chapter.

#### **5.2 Evaluating Effectiveness of Treatments Applied on Roads**

Using the evaluation methodology stated in Chapter 3, all applied treatments were assigned to a treatment category. Then, summaries were developed of total miles of segments receiving treatments from each treatment category as shown in Figure 5.1. The results show that the applied treatment strategies had different effectiveness on the pavement performance of each road in the context of fatigue, longitudinal, and transverse distresses.

**Figure 5.1: Total Length of each Treatment Category (a) Fatigue Index; (b) Longitudinal Index;**

**(c) Transverse Index; (d) Ride Index; (e) Rut Index**

Most CDOT LVRs treatments do not produce significant improvements on ride or rut indices. Consequently, most applied treatments were classified into uniform or ‘other’

categories. The presumed reason for the high occurrence of uniform performance for roughness and rutting is the new DL-based evaluation process. When CDOT started evaluating roads in terms of DLs, treatment options focused more on surface treatments which can extend the drivability life of the road (Hafez et al. 2017). Consequently, structural enhancements are limited on LVRs which affect significantly the pavement performance in the context of roughness and rutting. Therefore, no significant improvements were achieved for ride or rutting indices.

According to the historical treatment data of CDOT, the effectiveness of five treatments were investigated. These treatments were ACHP, ACIP, ATHO, AMJO and AMFL. There was not enough historical pavement data to evaluate the effectiveness of AHIP and AMDO treatments. The last treatment option, which is AREC, was considered beyond the scope of the study due to the limited application of this method and restricted budgets allocated for reconstructing LVRs.

Table 5.1 lists the effectiveness summary of the applied treatments. The effectiveness of AMJO treatment on longitudinal index was not defined because the treated segments had uniform performance or classified into “Other”. ACIP, AMJO, and AMFL were found to be effective treatments for fatigue, longitudinal, and transverse cracking. All the segments applied with ACIP and AMJO were classified into the effective category. A minimum effective value of 2 for fatigue index was found for AMJO. There are some segments of LVRs being in very poor pavement condition. The next section in this chapter shows the performance model of pavements developed for all roads using actual data. It shows some of the deteriorated cases where condition indices reached a value of zero for some indices during the analysis period. Although AMJO could not be available for roads due to budget constraints, the evaluation

results do not recommend applying the other available treatments directly on poor roads. Chip sealing (AHP) was found to have different effectiveness on fatigue distresses depending on the initial fatigue index. The results show that it is not recommended to apply chip seal when the fatigue index is less than 84. Also, chip seals were found to be not effective to enhance the performance in the context of longitudinal and transverse cracking. The applications of thin overlays (ATHO) were not effective for transverse cracking while they have different effectiveness on fatigue and longitudinal cracking. It can be noted that the current policy of applying only low-cost treatments, followed by CDOT, may affect the overall DL of roads differently depending on the existing pavement condition.

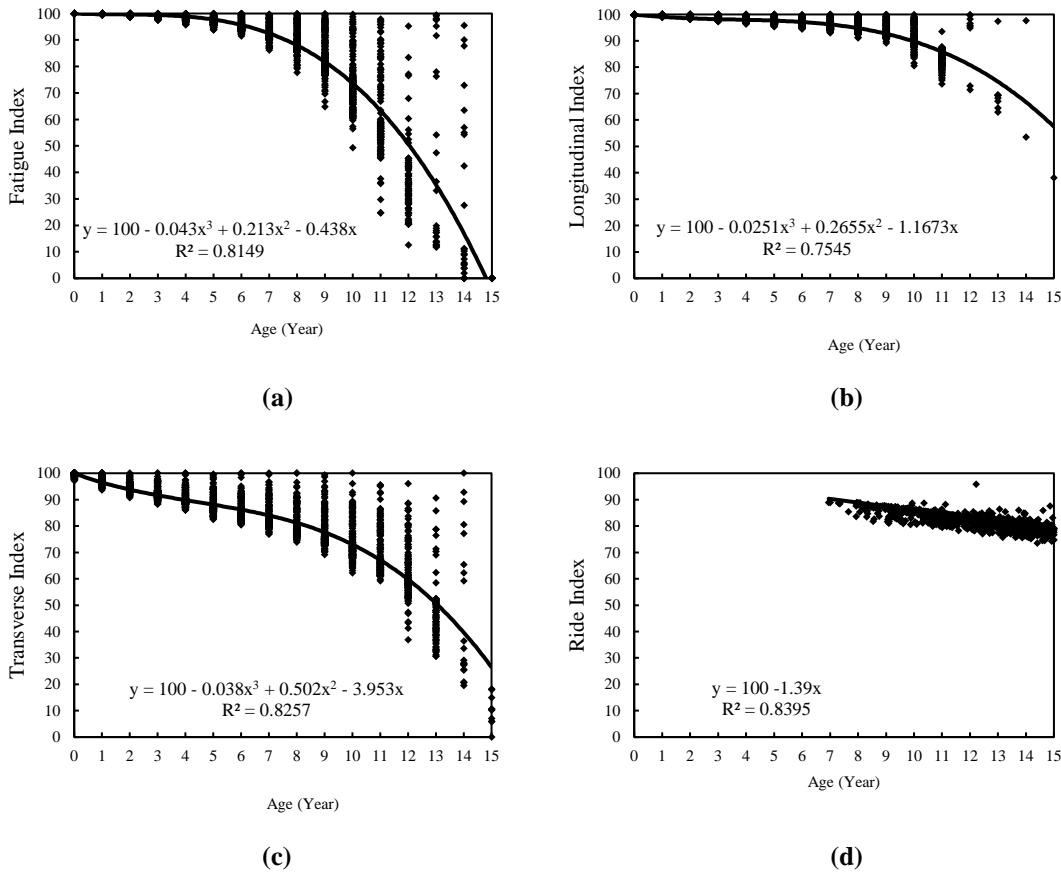

**Table 5.1: Effectiveness Summary of Applied Treatments**

Condition Index	Characteristic	AHP	ACIP	ATHO	AMJO	AMFL
Fatigue Index	Effectiveness	Effective	Effective	Effective	Effective	Effective
	Minimum value to be effective	84	53	60	2	51
Longitudinal Index	Effectiveness	Not effective	Effective	Effective	-	Effective
	Minimum value to be effective	-	85	88	-	90
Transverse Index	Effectiveness	Not effective	Effective	Not effective	Effective	Effective
	Minimum value to be effective	-	61	-	61	74

### 5.3 Pavement Performance Prediction Curves

An essential step in managing pavements is developing performance prediction curves. These curves estimate the future deteriorated values of the condition indices over the design period of the pavement, which is normally 15 years. Figure 5.2 displays four deterministic prediction models developed for fatigue, longitudinal, transverse, and ride indices. These models were developed using all the deteriorated cases on each segment of the LVRs network during the analyzed study period. Normally, there are uncertainties in behavior of pavement condition over time due to fluctuating traffic loads and measurement errors. However, the fitted regression

models provide high R-squared values with respect to the management needs of low-volume roads.

**Figure 5.2: Deterministic Performance Models of Pavement Conditions: (a) Fatigue Index; (b) Longitudinal Index; (c) Transverse Index; (d) Ride Index**

Using the performance curves, it was possible to define the trigger value of pavement age where the drivability of the road equals zero. The trigger values for both longitudinal and ride indices were found to be more than 15 years. Thus, the overall DL values are projected depending on fatigue and transverse indices for most segments.

## **5.4 Improvement Models of Applied Treatments**

An appropriate measure of improvements needs to be defined when projecting future performance. When applying the proper maintenance, the life expectancy of the road can be extended by a number of years. These extensions are introduced by an increase in the condition index of the road which is called a ‘performance jump’ (Labi and Sinha, 2004). There are multiple parameters affecting the pavement post-treatment performance, including initial conditions, environmental factors, and the maintenance quality. However, the historical condition values of pavement management projects can be used to develop a model to predict the average improvement in pavement condition following a treatment. Table 5.2 lists the improvement models for different treatments applied on LVRs. The improved condition index “terminal value” was determined based on the initial value prior to the application of road maintenance. This analysis provides satisfactory improvement models to estimate the expected jump in the condition index on LVRs, especially when the road network exhibits low traffic variability.

**Table 5.2: Improvement Models of Effective Treatments on Low-Volume Paved Roads**

Fatigue Index		
Treatment	Terminal value	R-square
ACHP	$87.91 + 0.121 * \text{FATIG\_IDX}_{(i)}^*$	0.8748
ACIP	$79.61 + 0.204 * \text{FATIG\_IDX}_{(i)}$	0.8704
ATHO	100	—
FDR	100	—
Longitudinal Index		
Treatment	Terminal value	R-square
ACIP	$93.79 + 0.062 * \text{LONG\_IDX}_{(i)}$	0.7329
ATHO	100	—
FDR	100	—
Transverse Index		
Treatment	Terminal value	R-square
ACIP	100	—
FDR	100	—

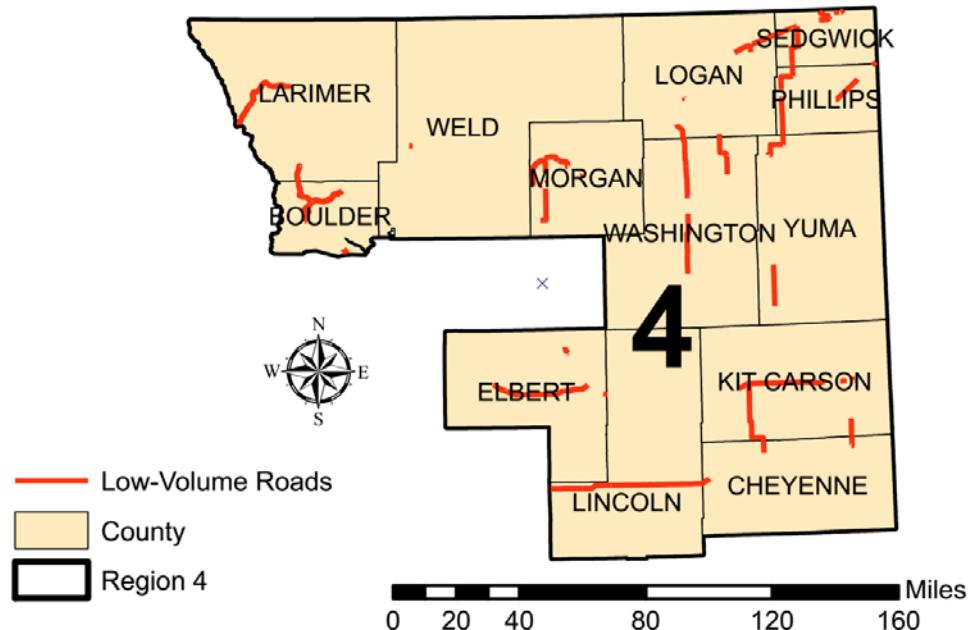

\*i: Initial Condition Index

It should be noted that the previous improvement models were developed using only cases receiving effective treatments. For those roads that were poor enough to cause the applied treatments to be classified as ineffective, average percentages of improvements were determined for each treatment type. These percentages were calculated based on the historical values of performance improvement of poor roads.

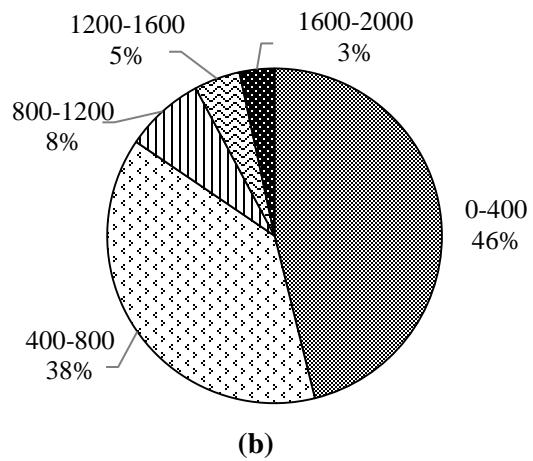

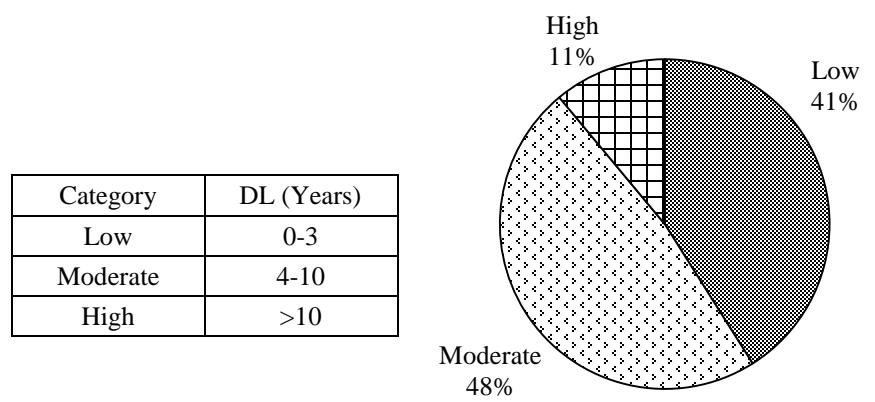

## 5.5 Future Projection of Pavement Performance Using Current Maintenance Policy

The future values of pavement performance depend mainly on the maintenance decisions assigned for each road. When roads are applied with treatments, the drivability life is expected to increase according to the expected performance jump of each condition index. However, the maintenance decision should be optimized so that the total annual maintenance costs are within the available maintenance budgets. A case study of Region 4 was analyzed to determine the

impact of current maintenance policy on future pavement performance. There are 85 road segments of LVRs in Region 4 distributed on 442 total miles as shown in Figure 5.3. Region 4 was found to be a representative case study for the LVRs of the whole state because it has various traffic volumes with different DL categories. According to the CDOT pavement management data in 2016, about half of LVRs in Region 4 (48% of road miles) have moderate DL values, as shown in Figure 5.4. There are 41% of road miles in the low DL category while only 11% of roads have high drivability lives of more than 10 years. Most traffic volumes are not more than 800 vehicles per day. The diverse pavement condition and traffic volumes would support the validity of generalizing the analysis results statewide.

**Figure 5.3: Low-Volume Roads in Colorado Region 4**

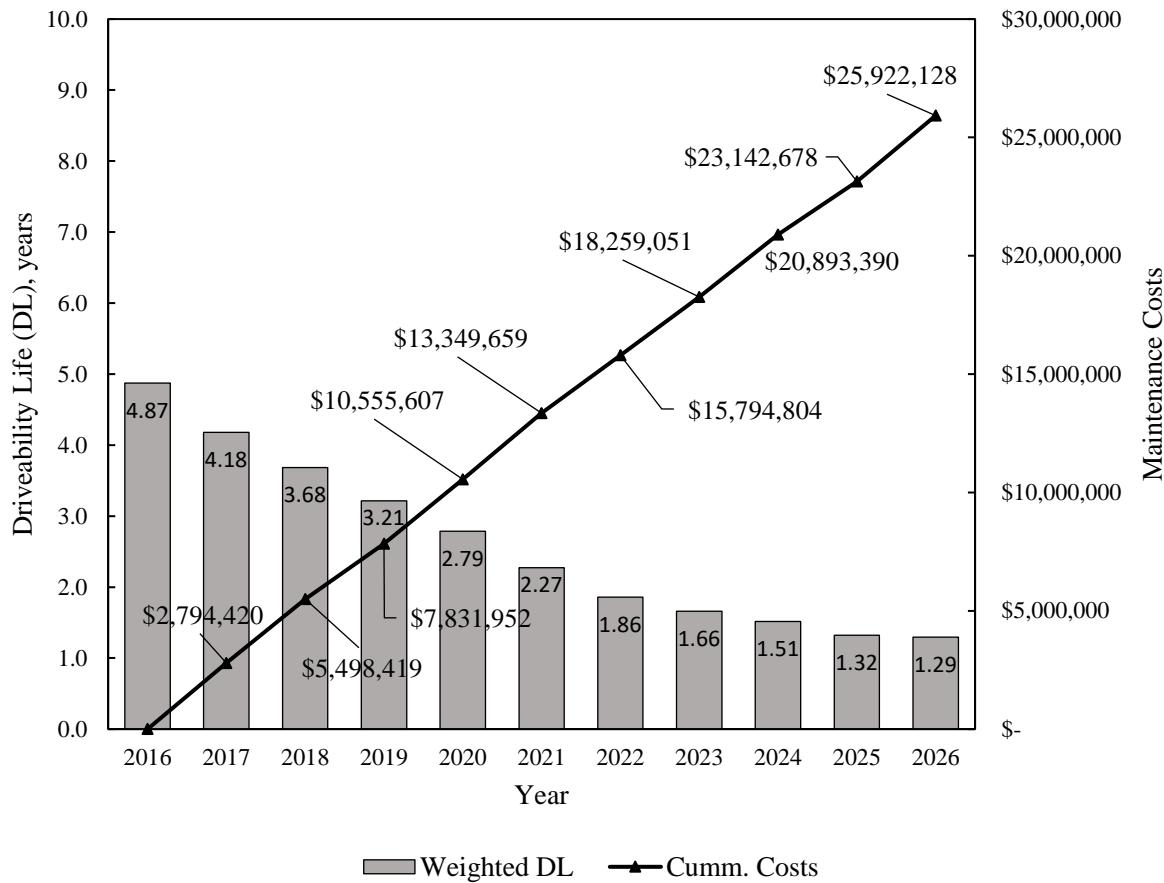

**Figure 5.4: Mileage Distribution of Region 4 Low-Volume Paved Roads: (a) Drivability Life; (b) Average Daily Traffic (vehicles per day)**

Although CDOT does not designate a budget for managing LVRs, the annual maintenance budgets can be estimated using the average value of past expenditures. These values were obtained from CDOT and it was found that LVRs in Region 4 are assigned with an average value of \$2.8M annually for maintenance. Accordingly, a multi-year optimization analysis was conducted using the current maintenance policy. The objective function was to maximize the overall weighted drivability life. The maintenance costs were set to the budget

constraint so that the total annual costs should not exceed \$2.8M. According to CDOT, the cost of applying a thin overlay is \$151,360 per lane-mile while the cost of an asphalt chip seal is \$42,240 per lane-mile.

Figure 5.5 shows the results of the optimization analysis over the study period from 2016 to 2026. Detailed maintenance decisions for each segment are listed in Appendix C-1 using the current CDOT strategy. For Region 4, the overall weighted DL is 4.87 years. This value was aimed to be maximized over the analysis period using only applications of general maintenance (GM), asphalt chip seals (ACHP), and asphalt thin overlays (ATHO).

**Figure 5.5: Impact of Current CDOT Strategy on Future Pavement Condition in Region 4**

However, it was found that the optimized weighted drivability decreases over the study time. As mentioned earlier, about half of LVRs in Region 4 are in the low DL category. According to the current maintenance policy, all of these roads require thin overlays which are an expensive treatment with respect to the available maintenance budgets. With an annual budget of \$2.8M, most poor roads are assigned with the “do nothing” option (DN). As a consequence, the poor roads extensively deteriorate resulting in lower overall weighted drivability life in Region 4. Therefore, the current maintenance strategy with the available annual budget is not adequate to enhance the pavement performance of LVRs.

## **5.6 Proposed Maintenance Strategy**

An alternative maintenance strategy is recommended to include only cost-effective treatments. The following section provides a proposed maintenance strategy for LVRs in Colorado.

### *5.6.1 Maintenance Alternatives*

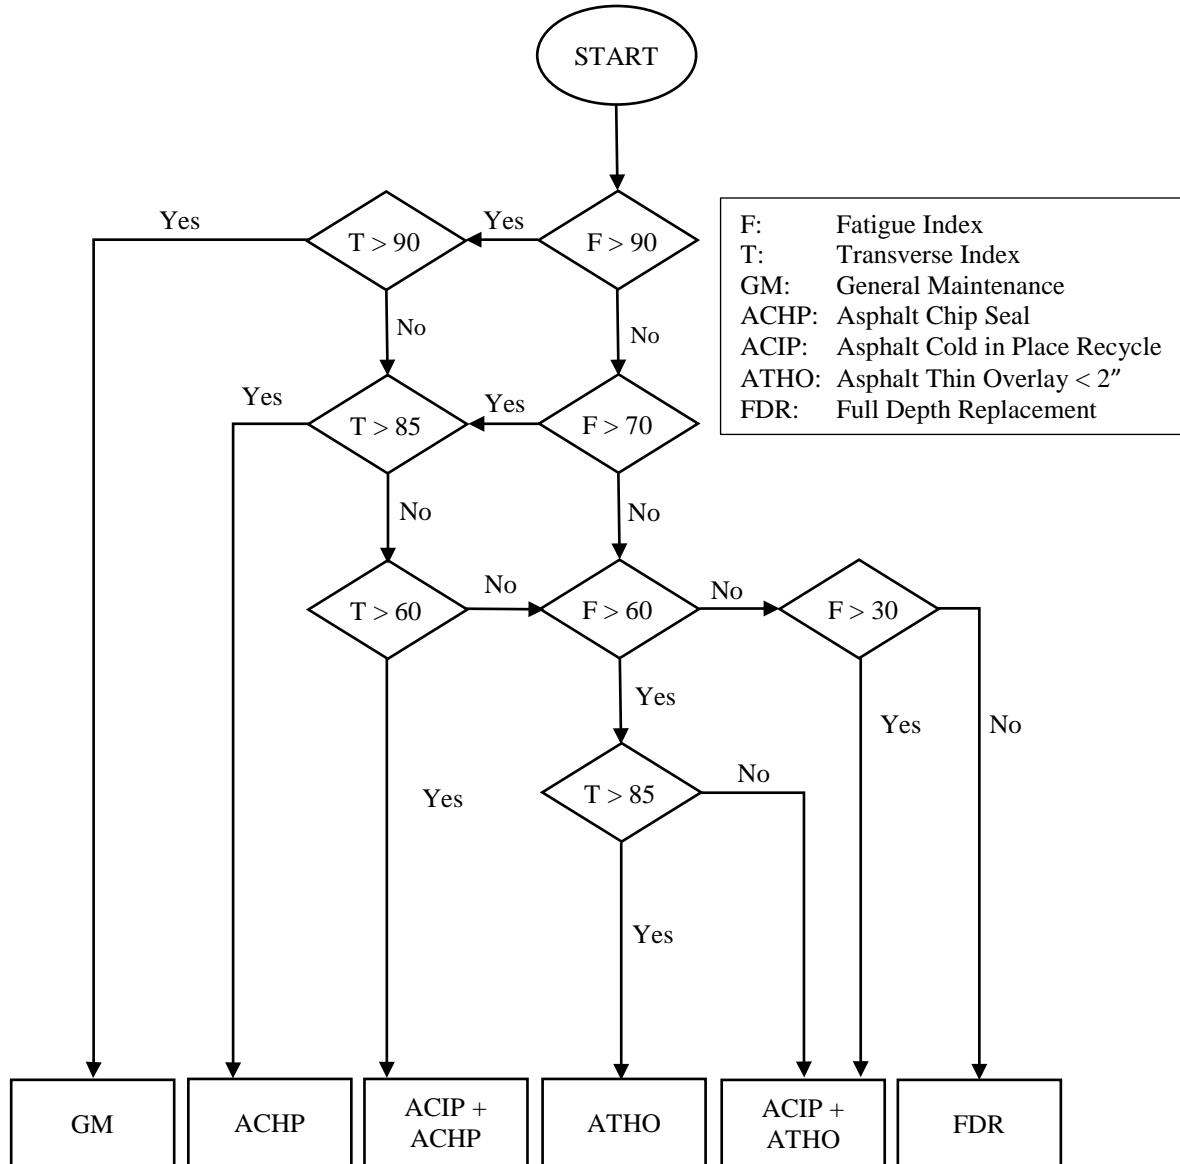

The key element of developing an effective maintenance strategy is to assign appropriate treatments to the road according to the existing condition. The right maintenance treatment should be selected based on the effectiveness of each treatment type on the different distresses and the minimum values to be effective derived from the evaluation process. Four pavement rehabilitation alternatives involving recycling technologies were proposed which are:

- ACIP layer surfaced with a chip seal (ACHP)
- ACIP layer with an asphalt thin overlay (ATHO)
- Full depth replacement (FDR) with 10% patching.

These treatments are integrated with the current strategy of ACHP and ATHO. However, the decision for all treatment options is made based on the existing value of fatigue and transverse indices and not on the overall drivability lives. A proposed decision tree was developed and it is shown in Figure 5.6. This decision tree was developed for CDOT to simplify the network-level decision making process and summarize the annual maintenance requirements and costs. It comprises a logical flow chart with a series of “Yes” and “No” answers to questions pertaining to pavement condition. Trigger values of fatigue and transverse indices were set in the decision tree since they have a direct impact to improve the overall DL of roads. For each treatment type, the trigger values were specified where both fatigue and longitudinal indices do not go below the minimum effective values listed in Table 5.1. No specific consideration was taken for the ride quality because of the uniform trend of pavement performance and the overall DL is not influenced significantly by the ride index. In a different management system, the ride quality can be considered using another parameter such as International Roughness Index (IRI). It is to be noted that all rehabilitation and reconstruction options were avoided from the maintenance strategy due to the limited financial resources. The GM option includes applications of crack sealing and filling where the roads are in good condition. The cost information was obtained from CDOT and is listed in Table 5.3. These costs are based on the dollar value in 2016 which is the base year of the analysis period.

**Table 5.3: Estimated Maintenance Unit Costs for Colorado Department of Transportation**

Maintenance	Cost (Lane – mile)
GM	\$3,000
ACHP	\$42,240
ACIP + ACHP	\$77,440
ATHO	\$151,360
ACIP + ATHO	\$186,560
FDR	\$195,350

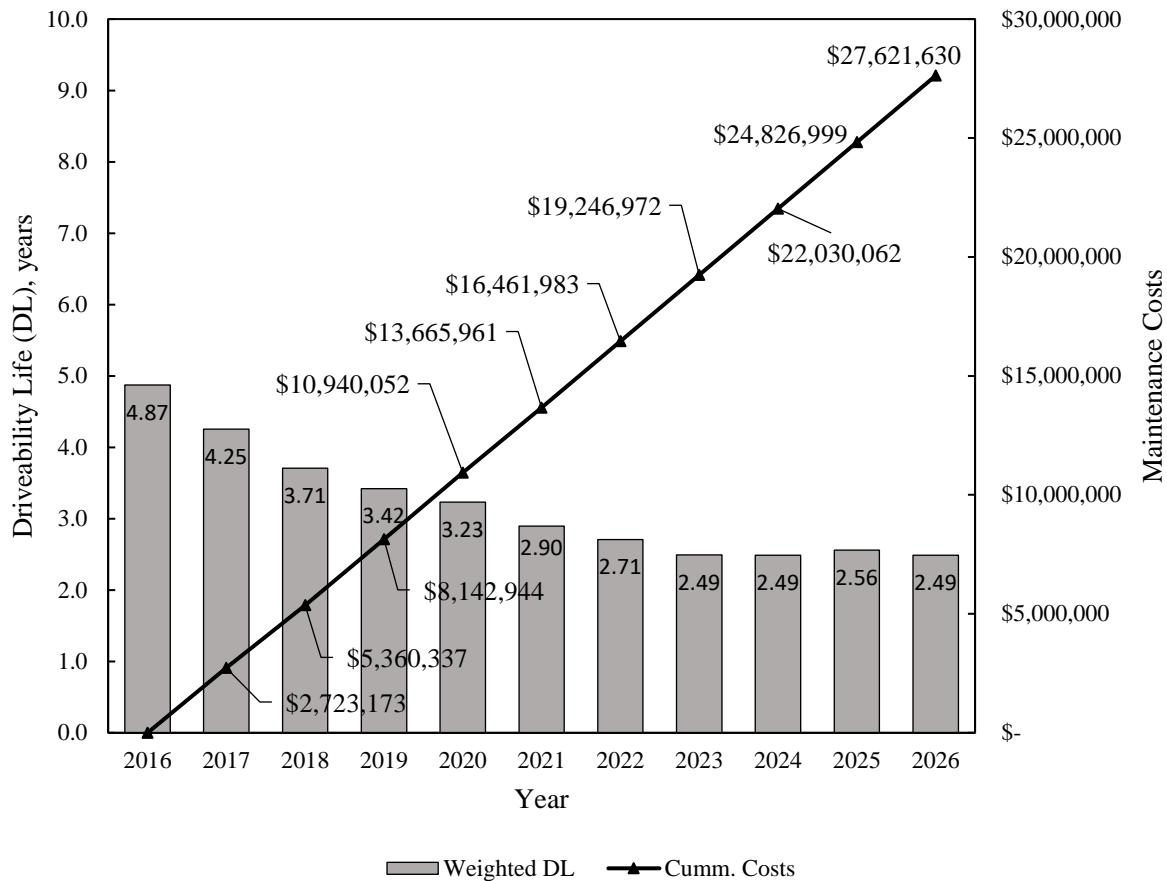

**Figure 5.6: Decision Tree of the Alternative Maintenance Strategy**

The proposed maintenance strategy has multiple treatment options with diverse maintenance costs. Hence a cost analysis is recommended to investigate the impact of both current and proposed maintenance strategy on the future performance of pavement.

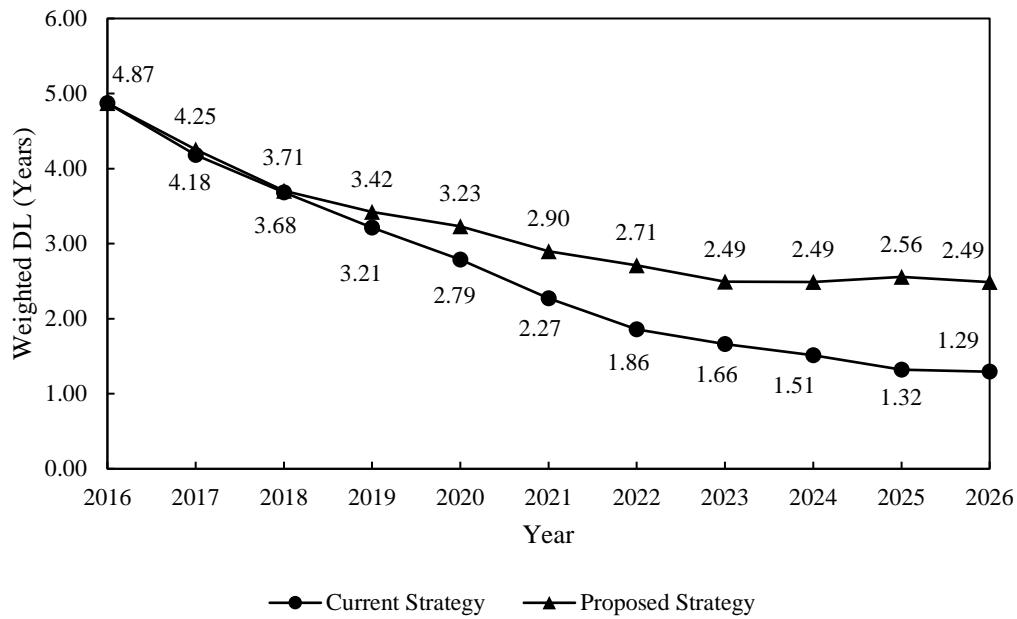

### 5.6.2 Multi-Year Optimization Analysis

The objective of the optimization models is to develop multi-year maintenance programs using both current and proposed maintenance policies over a planning horizon. The optimized maintenance decisions of the proposed maintenance strategy are listed in Appendix C-2. Figure 5.7 displays the impact of applying the proposed maintenance strategy on the future condition of pavements from 2016 to 2026. It was again found that an annual budget of \$2.8M is not sufficient to preserve the drivability performance. The overall DL value deteriorates from 4.87 years to 2.49 years at the end of 2026.

**Figure 5.7: Impact of Proposed Maintenance Strategy on Future Pavement Condition in Region 4**

In comparison with the current CDOT policy, the proposed maintenance strategy has better effectiveness at preserving pavement performance. Figure 5.8 shows the impact of the two strategies on the pavement performance over the analysis period. Applying treatments considering the existing condition and the corresponding effectiveness of each treatment type significantly delays deterioration of the weighted DL. The proposed maintenance strategy was found to be effective at reducing the amount of deterioration using the same maintenance budgets compared to current CDOT policies.

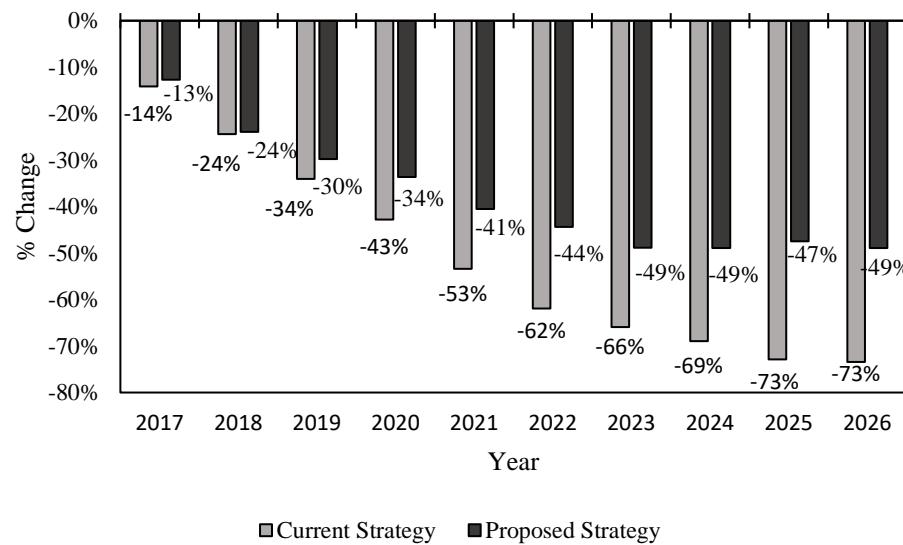

**Figure 5.8: Future Projection of Pavement Performance from Different Maintenance Strategies in Region**

4

Figure 5.9 further explains the amount of change in DL values for LVRs using the different maintenance strategies. All values are negative since the annual funding is not sufficient to preserve or enhance the overall performance. The difference between the two strategies was found to be not significant at the beginning of the analysis period. The amount

of DL change is almost the same in 2017, 2018, and 2019. The reason is that both the current CDOT and proposed strategies add performance values to the treated roads. However, the difference increases over time to the extent that DL drops 73% of its value using the current CDOT policy while this loss is only 47% for the proposed strategy at the end of 2025.

**Figure 5.9: Expected DL Percentage of Change for each Treatment Strategy**

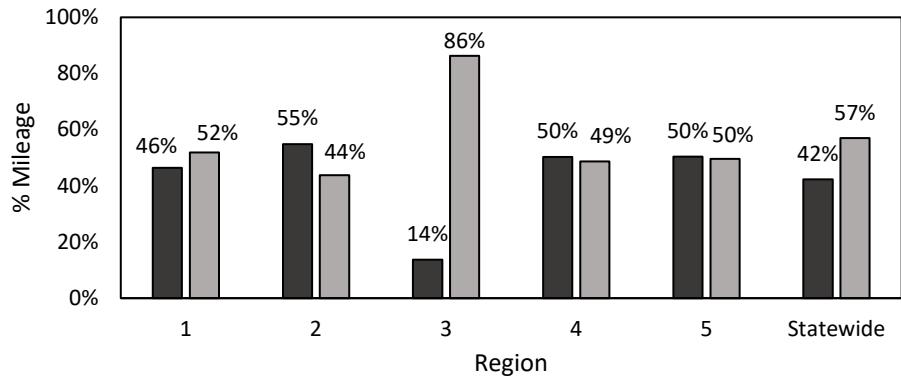

## **Chapter 6: Low-Volume Roads in Colorado with Marginal Conditions**

### **6.1 Introduction**

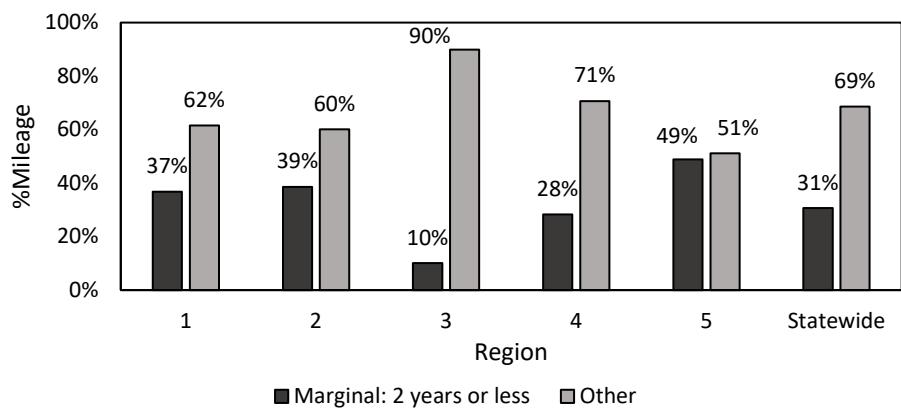

Maintaining badly deteriorated roads is the most challenging task for DOTs especially when treatments are restricted with limited funding. CDOT includes only thin overlays for roads in poor condition, which has the potential for only short-term effectiveness on the performance of pavements. As a result, roads in marginal conditions are expected to continue deteriorating to extreme levels of distress, which would make applying pavement maintenance techniques too expensive or less reliable. In this chapter, a comprehensive evaluation for roads in marginal conditions is presented to demonstrate the impact of CDOTs low-cost treatments on low-volume paved roads.

### **6.2 Definition of Low-Volume Roads in Marginal Condition**

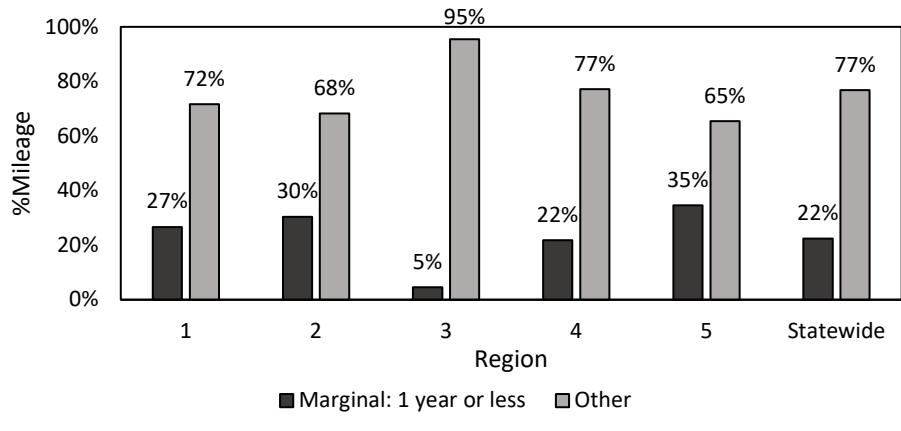

The definition of LVRs in marginal condition depends on the managing needs of each DOT. However, these agencies should have an upper limit of pavement performance that defines severe conditions. According to CDOT, poor roads in marginal condition should have extremely low drivability lives. To define these roads, a descriptive analysis was conducted first to investigate the mileage distributions of low-volume paved roads at different categories. Starting with roads having DL values equal to three years or less, Figure 6.1(a) shows the distribution of mileages in the five engineering regions as well as statewide. It can be noticed that close to half of the LVRs network statewide is in marginal condition and also they are distributed across most regions except Region 3.

(a)

(b)

(c)

**Figure 6.1: Mileage Distribution of DL values in Marginal and Other Conditions (a) 3 Years or Less; (b) 2 Years or less; (c) One Year or Less**

It is highly recommended to define these roads in a way that makes the size of the road network manageable. Figure 6.1(b) displays the distribution of roads when marginal conditions are at DL values of two years or less. The number of roads in marginal conditions reduces substantially at this category in Region 2 and Region 4. However, Region 5 still has almost 50% of its network in the marginal category. Statewide, almost one third of the LVRs network is in marginal condition according to that category. Moving to the next severity level, Figure 6.1(c) shows the distribution for marginal roads having DL values of one year or zero. This category shows a kind of uniform distribution among regions except Region 3 where 86% of LVRs are in moderate DL category. However, the portions of marginal roads in this category are more practical for focused management and can be considered for the study analysis.

In this report, roads with marginal conditions are defined as poor pavements with DL values equal to one year or zero. According to the statewide performance data in 2016, there are 361.6 miles of LVRs in the marginal category distributed on 96 segments. The current CDOT maintenance strategy as well as the proposed one were evaluated on these roads showing the long-term effectiveness within limited annual budgets.

### **6.3 Performance Curves**

It was emphasized in the evaluation process of treatments that the application of surface treatments and preservation strategies have only short term effectiveness when the pavement indices are at low values. Therefore, it is not accurate to project the future pavement condition parameters using the overall performance curves developed in Chapter 5. Special performance models should be assigned to the roads with marginal conditions. To develop these models, the

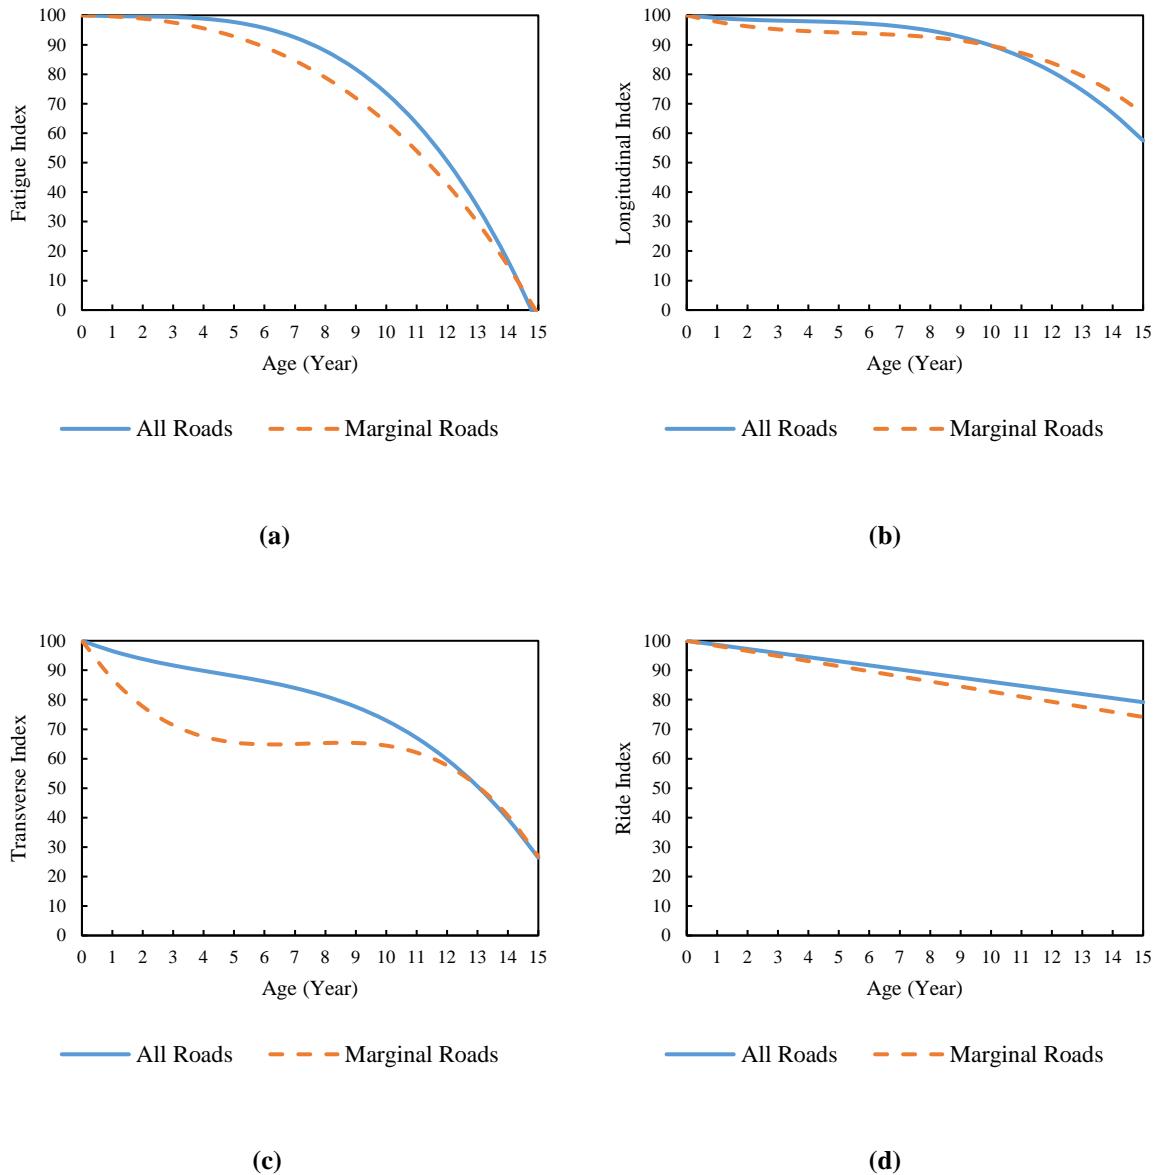

historical values were filtered to include only roads with overall DL values of one year or zero. Then, appropriate curves were fit for each condition index. The results are listed in Table 6.1.

**Table 6.1: Deterministic Performance Models for Roads with Marginal Conditions**

Index	Model	R-square
Fatigue Index	$y = 100 - 0.0188 x_3 - 0.1579 x_2 - 0.1719 x$	0.854
Longitudinal Index	$y = 100 - 0.0262 x_3 + 0.4196 x_2 - 2.6081 x$	0.672
Transverse Index	$y = 100 - 0.0933 x_3 + 2.0686 x_2 - 14.913 x$	0.621
Ride Index	$y = 100 - 1.7242 x$	0.891

NOTE: "y" represents the condition index; "x" represents the pavement age in years

In comparison with the overall performance curves for all roads, Figure 6.2 shows the pavement performance for both road categories in the context of fatigue, longitudinal, transverse, and ride indices. Although marginal roads have almost the same pavement life for fatigue cracking as other roads, they tend to show higher deterioration rates. That would affect the minimum projected drivability lives on these roads. Also, the longitudinal cracking for marginal roads has a slightly higher deterioration rate than that of all roads. However, after the age of 10 years, the annual deterioration rate for longitudinal cracking is less than that of the overall model. The observed higher performance for longitudinal cracks of marginal roads could be due to the lack of data at this stage. However, this finding wouldn't affect the evaluation analysis since the longitudinal index does not significantly affect the overall DL value and it is not included in the proposed maintenance decision tree.

**Figure 6.2: Comparison of Performance Curves of all Low-Volume Roads vs. Marginal Roads (a) Fatigue Index; (b) Longitudinal Index; (c) Transverse Index; (d) Ride Index**

In the context of transverse index, a very large difference was found between the performances of all low-volume paved roads compared to only the marginal ones. It is reasonable to obtain identical performance curves after the age of 12 years where the roads have almost a DL of zero. However, the rate of deterioration for marginal roads before that time is

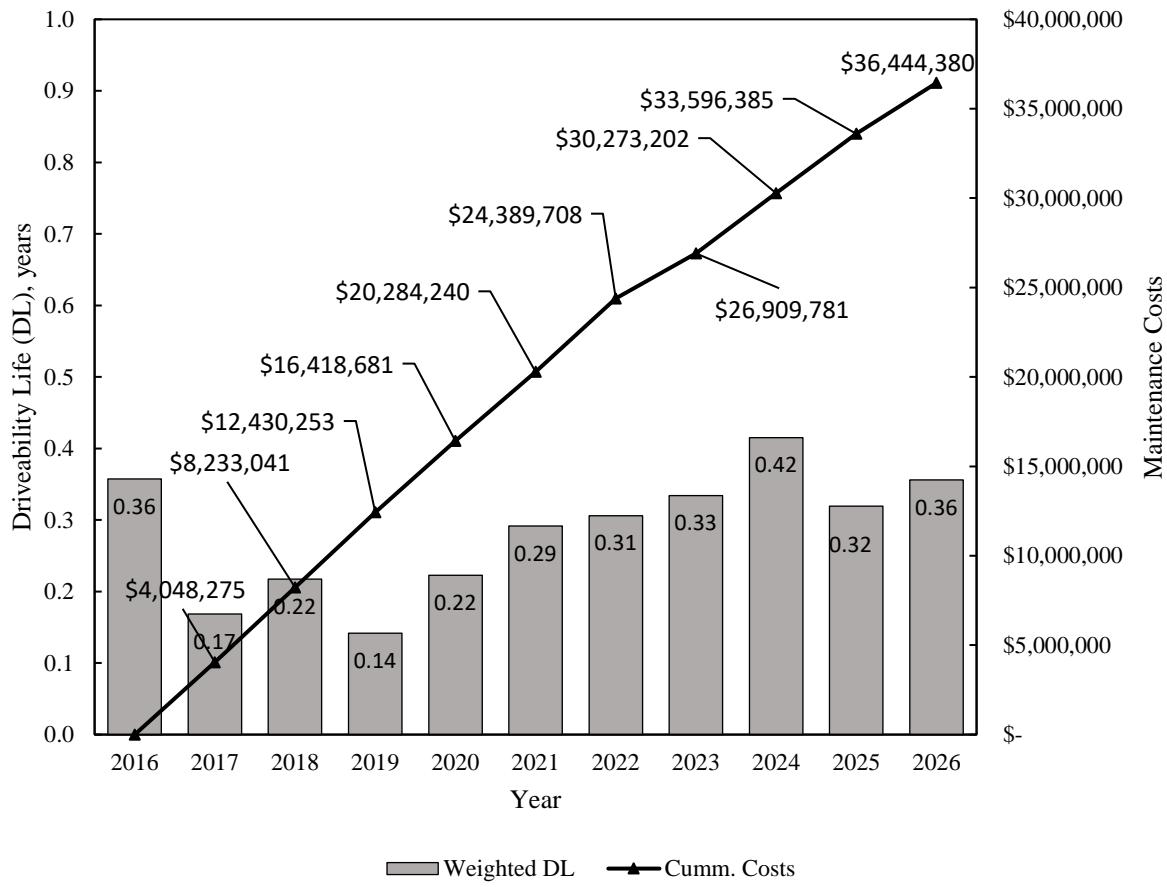

much higher than the other roads. These results imply that there were historical conditions where the roads received surface treatments. However, the post-treatment performance of these roads exhibited higher transverse cracking quantities and severities even after applying the treatment within a short time. This emphasizes the short-term effectiveness of applying low-cost surface treatments on severely damaged pavements. No major difference can be noticed for the performances of road categories in the context of ride index because of the uniform performance of roughness statewide. However, the marginal roads still show higher deterioration amounts compared to the overall performance.

#### **6.4 Impact of Maintenance Strategies on Roads with Marginal Conditions**

As implemented earlier for all roads, the annual maintenance plans for roads with marginal conditions were optimized to maximize the overall weighted drivability life within an annual maintenance budget. In order to give an appropriate estimate of the financial resources statewide, the study depends mainly on the budget available in Region 4. As mentioned earlier, Region 4 has an average of \$2.8M that is expended annually on a total 441 miles of low-volume paved roads. That is, the budget of maintaining a unit mile of pavements is about \$6,349. Therefore, there are approximately \$12.8M expended on LVRs statewide as maintenance funding. The total budget was previously split among roads depending on the condition of pavement. A survey of pavement management engineers was conducted on how the total budget should be divided on roads in the different performance categories. It was found that the total budget should be equally distributed on three condition levels which are: (1) worst segments, (2) rapidly deteriorating segments, and (3) segments requiring a routine maintenance (Hafez et al., 2017). Accordingly, one third of the total available budget was assigned on the roads with

marginal conditions which represent 22% of the whole network in Colorado. That is, the maintenance plans were optimized so that the annual maintenance budget should not exceed \$4.2M.

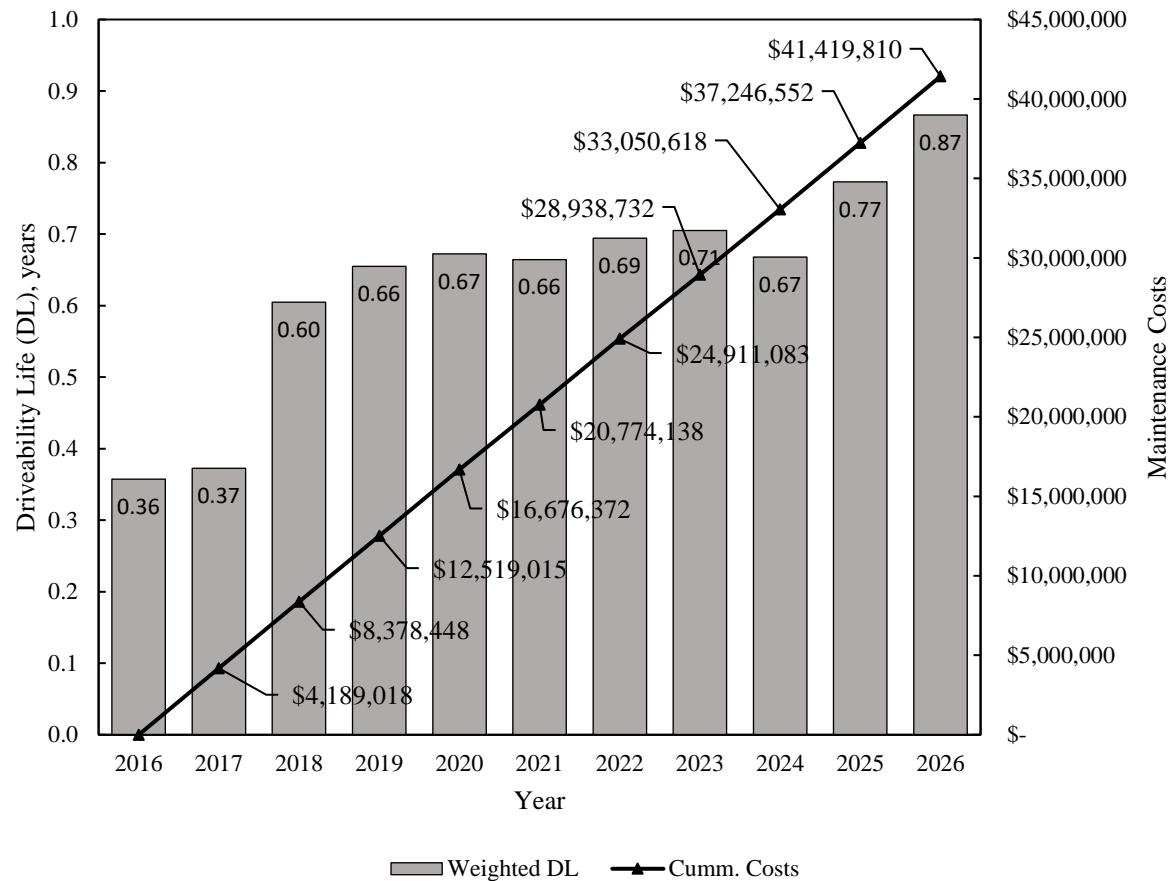

According to the performance data of 2016, the overall weighted drivability life of the roads with marginal conditions is 0.36 years. This value shows that the majority of marginal roads have no remaining drivability life. Figure 6.3 shows the cumulative repair costs required to maximize the DL value using current CDOT strategy. The detailed decisions on the 96 segments can be reviewed in Appendix D-1. It can be noticed that the optimization results do not provide any significant improvements on the network of marginal roads. Applying CDOT maintenance activities within \$4.2M annually is still not sufficient to preserve the overall performance of these roads, resulting in overall deteriorated condition of 0.14 years in 2019. Although the overall DL slightly increased after 2019, the amount of improvement is not significant. Over the five following years, the overall DL was improved from 0.14 to 0.42 years only. Then the value was decreased to 0.32 years. In general, all maintenance decisions assigned thin overlays on the marginal roads. However, the cost of thin overlays is relatively expensive which results in limited application of thin overlays. With high deterioration amounts, the overall performance cannot be enhanced significantly given the estimated budget.

**Figure 6.3: Future Projection of Overall Drivability Values for Marginal Roads in Colorado Using CDOT Maintenance Strategy**

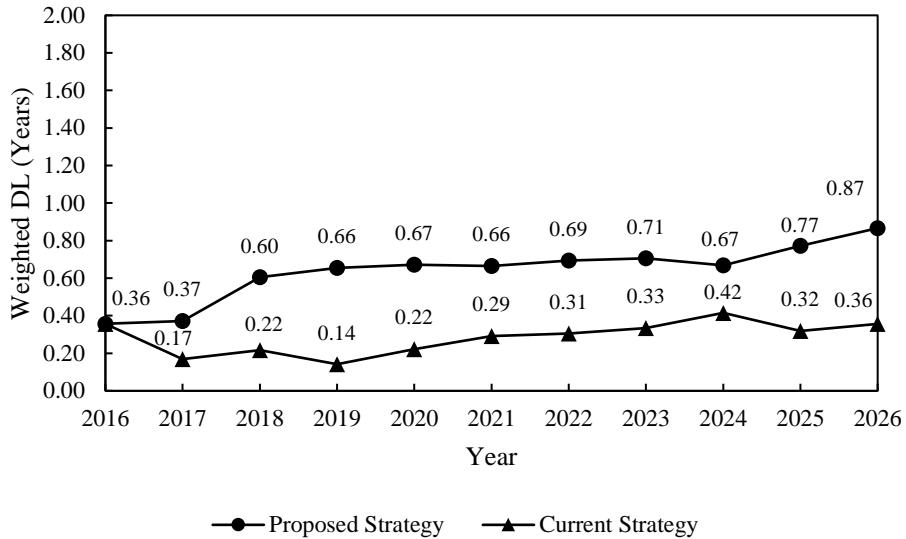

Figure 6.4 shows the optimization results when applying the proposed maintenance strategy. Appendix D-2 lists detailed maintenance decisions of the proposed strategy that were assigned to marginal roads during analysis. It was found that the available maintenance budget is also not adequate to enhance the marginal roads significantly. Although the overall drivability has an improvement behavior over the analysis period, the DL value is still less than one year at the end of the 2026. It can be noticed from the maintenance decisions that most marginal roads were assigned with thin overlays that are surfaced after cold in-place recycling of the

existing pavement. This treatment option is more expensive than the regular thin overlays. However, it has better effectiveness on the marginal roads.

**Figure 6.4: Future Projection of Overall Drivability Values for Marginal Roads in Colorado Using Proposed Maintenance Strategy**

As shown in Figure 6.5, the difference in effectiveness of both strategies is not significant on roads with marginal conditions. The current CDOT strategy cannot improve the overall drivability more than the current status. Also, the proposed strategy cannot increase the overall drivability of roads to improve the marginal conditions into a higher level.

**Figure 6.5: Effectiveness of Maintenance Strategies on Marginal Roads in Colorado**

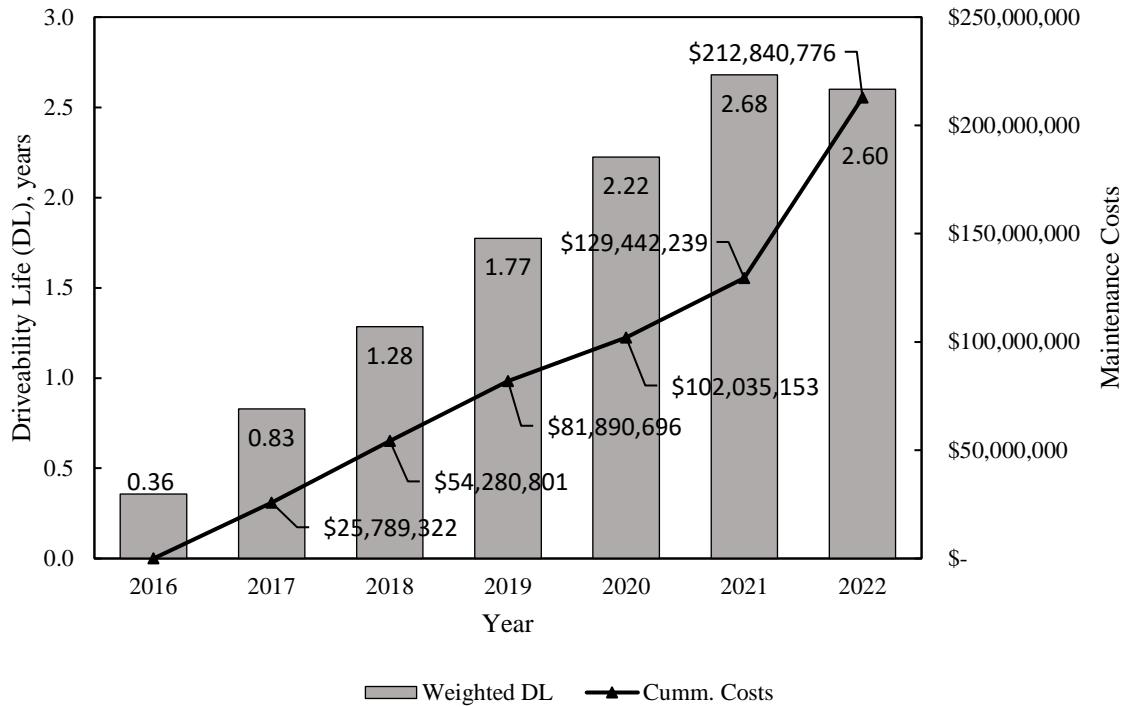

## 6.5 Optimizing Marginal Roads with Performance Targets

Since the estimated available budget is not able to enhance marginal roads, the required funding needs to be investigated. For this optimization model, the overall drivability performance was set in the objective function with a specific performance target. According to the DL distribution statewide, the performance target was set to 5 years. The multi-year optimization was adopted to minimize the annual maintenance costs so that the overall performance of marginal roads gradually increases until it reaches the performance target at the end of 2026. The marginal roads were applied with both proposed and current maintenance strategies. The following subsections provide the results obtained from the two strategies.

### 6.5.1 Current CDOT Strategy

Figure 6.6 shows the investment needs to enhance the overall drivability using CDOT's existing strategy. The optimization analysis stopped at 2022 because it was found that the overall DL decreases even after applying maintenance for all roads. Figure 6.7 shows the cash flow diagram

of the annual expenditures estimated for the marginal roads. All roads are assigned with maintenance options in 2021 which cost \$83,398,537. However, the overall DL value was decreased from 2.68 to 2.6 in the next year.

**Figure 6.6: Maintenance Costs of CDOT Strategy for Marginal Roads**

It is obvious that applying only thin overlays and chip seals over roads in marginal conditions is not practical. It cannot improve the overall drivability of these roads to the required performance target. However, the CDOT strategy can enhance the roads during the time period from 2016 to 2020. An average annual budget of \$25M is estimated to obtain a performance value of 2.68 which is achieved at 2021. The total costs were discounted to the base year of the analysis which is 2016 using Equation (4). Based on a discount rate of 4%, a total cost of \$120,047,916 is estimated for maintaining roads.

$$PV = \sum_{k=1}^N Annual\ Maintenance\ Costs \left[ \frac{1}{(1+i)^{n_k}} \right] \quad (4)$$

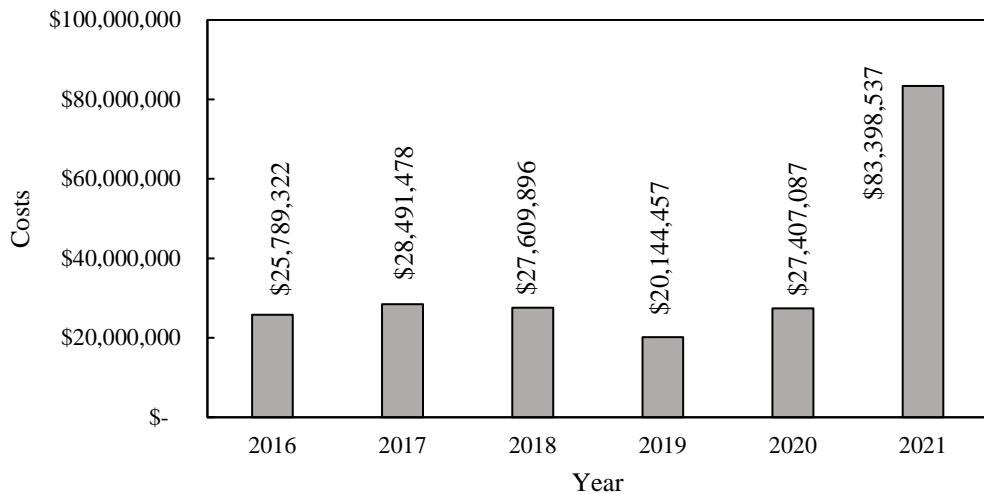

where,

$PV$  = present value

$i$  = discount rate, and

$n$  = year of expenditure

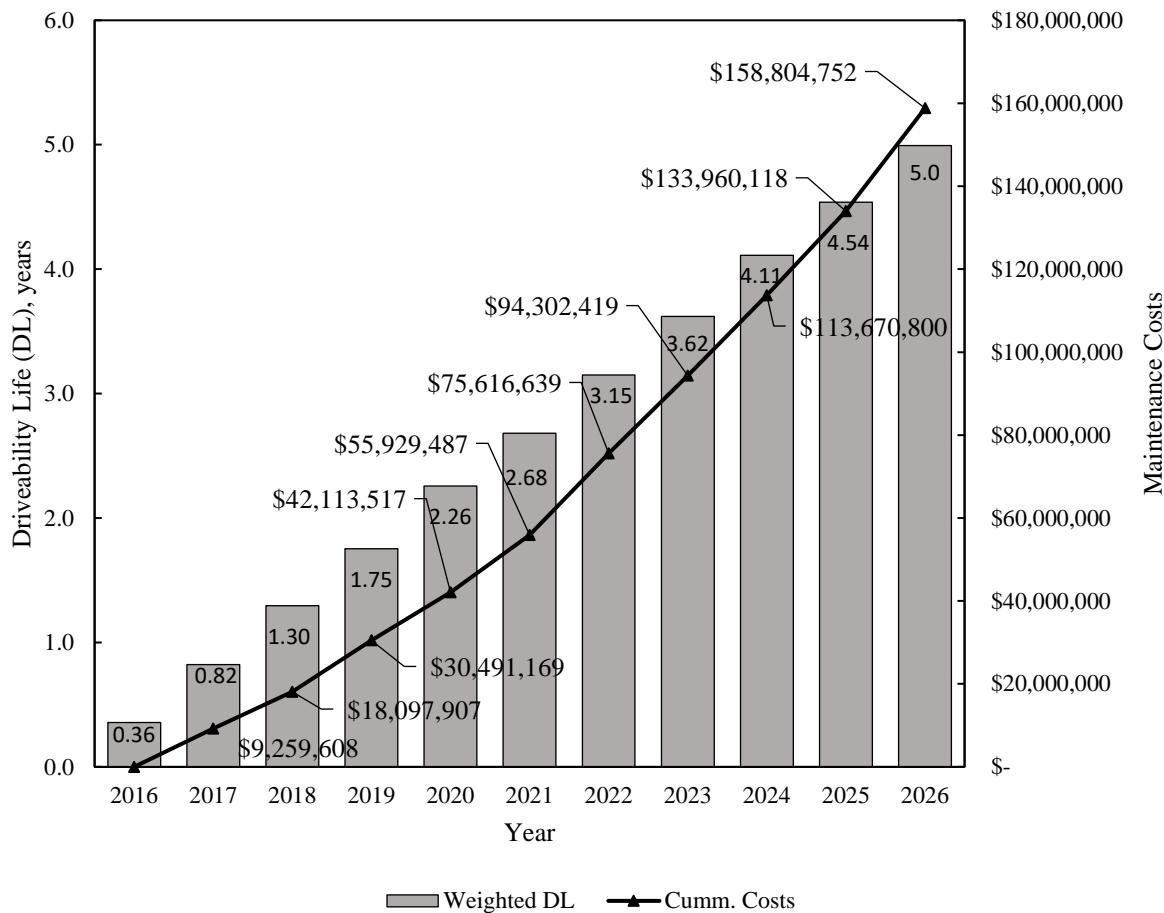

After that, applying more maintenance to these roads would not produce gains in performance. Therefore, the maintenance activities from 2016 to 2020 are called the Capital Improvement Plan (CIP). It represents the capital improvement maintenance projects required for roads with poor conditions. At the end of this plan, the road should receive the maximum cost-benefit. Detailed maintenance activities for this plan from 2016 to 2020 is listed in Appendix E-1.

**Figure 6.7: Cash Flow Diagram of Maintenance Activities on Marginal Roads Using CDOT Strategy**

### 6.5.2 Proposed Maintenance Strategy

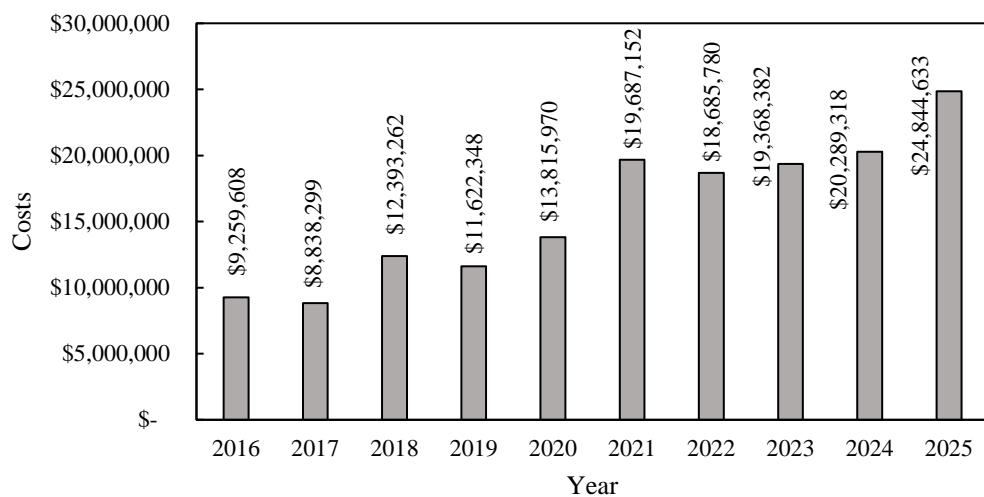

Figure 6.8 shows the results from the optimization analysis of the proposed maintenance strategy. The strategy was able to yield a solution every year and the overall DL was enhanced to the performance target. A cumulative amount of \$158,804,752 was estimated to fulfil the performance objectives.

**Figure 6.8: Maintenance Costs of Proposed Strategy for Marginal Roads**

The cash flow diagram is shown in Figure 6.9. It can be seen that the funding required is much more than the available budget, which was estimated as \$4.2M. At the beginning, the marginal roads require an average of annual budget of \$10M. However, maintaining these roads

is more challenging after 2020. The funding needs are raised to about \$20M annually to reach the performance target. Therefore, the capital improvement plan can be defined to be from 2016 to 2020 where the roads would have maximum benefits with a cumulative discounted cost of \$51,358,414. The maximum benefit of the CIP would enhance the overall drivability value on marginal roads from 0.36 to 2.68 at 2021.

**Figure 6.9: Cash Flow Diagram of Maintenance Activities on Marginal Roads Using Proposed Strategy**

## **Chapter 7: Conclusions**

This report provides a comprehensive analysis conducted to investigate the impact of CDOT maintenance policy on the pavement life of low-volume paved roads in Colorado. A collection of models and tools was adopted to evaluate the effectiveness of different treatment options and to develop alternative maintenance plans recommended for LVRs. The findings of this report emphasize the need to consider a number of treatments and light rehabilitations on roads depending on the existing condition of pavement and not on the overall drivability performance.

### **7.1 Conclusions from Evaluating Effectiveness of Treatments**

The effectiveness of pavement maintenance programs on LVRs is not well investigated by DOTs. This study developed an evaluation methodology to investigate the effectiveness of pavement treatments applied to LVRs. The proposed methodology has the advantage of analyzing historical treatment data and classifying treatment effectiveness based on the historical performance of pavements. This alternative process avoids constructing pavement test sections which require considerable time to analyze and document the findings. A comprehensive analysis of historical PMS data in Colorado was analyzed for roads in the low-volume category. Based on the improvements of pavement condition and the post-treatment performance, five low-cost treatments were evaluated which lead to the following conclusions:

- The application of chip seals provides effective enhancements for fatigue cracking as long as the fatigue index is more than 84. However, chip seal is not an effective treatment for transverse and longitudinal cracking.

- Cold-in-place recycling provides effective maintenance on LVRs that have condition indices ranging from 53 to 100.
- Fatigue cracking can be maintained effectively by thin overlays when the value of fatigue index is more than 60. However, it is not recommended to apply thin overlays directly on severe transverse cracking.
- In the context of fatigue and transverse cracking, the application of mill and fill is considered an effective treatment for condition indices not less than 70.
- Major overlays with thicknesses ranging from 4" to 6" are effective to enhance the performance of pavements. This treatment has the ability to address fatigue cracking effectively even if the pavement is in very poor condition. However, AMJO could not be available for roads due to budget constraints.
- The historical performance values reveal that all applied treatments do not produce significant improvements to the road roughness. All maintenance activities are considered surface low-cost treatments which enhance the quantity and severity of cracks on the surface. However, they do not add structural value to the treated roads. Most roads exhibit uniform performance of ride index during the analysis period.
- The results from the evaluation process enabled development of an effective maintenance strategy. This strategy includes a combination of low-cost treatments that are applied to roads depending on fatigue and transverse indices thresholds. No specific consideration was taken in the proposed strategy for ride quality because of the uniform historical performance of the ride index.

- Future deterioration can be estimated using well fit deterministic models of each condition index. Although road roughness has an overall uniform performance over time, the average annual decline of ride index can be estimated as 1.4.
- Pavement improvements can be predicted by analyzing the post-treatment performance data of the road network. This analysis is important in determining the long-term effectiveness of the applied treatments at extending the life expectancy of pavements.
- CDOT engineering regions may not have sufficient budgets to preserve the overall condition of pavement on LVRs. The performance and cost analysis of maintaining roads show that expending \$2.8M annually on LVRs in Region 4 will result in having more deteriorated roads and poor pavement conditions.
- The proposed maintenance strategy for LVRs in Colorado is more cost-effective than the current policy of applying only chip seals and thin overlays followed by CDOT. This proposed strategy is able to reduce the annual deterioration amounts using the same available budgets compared to the current CDOT policy.
- The current CDOT policy has almost the same effectiveness as the proposed strategy at the beginning of maintenance period. However, thin overlays have short-term effectiveness on poor roads that make pavements deteriorate into very low performance at the end of the analysis period.

## 7.2 Conclusions from Roads with Marginal Conditions

Badly deteriorated LVRs were investigated in Colorado considering a specific characteristic of marginal pavement conditions. The different treatment strategies were evaluated to explore how

reliable applying more pavement maintenance techniques is on these roads. Based on the findings of this research study, the following conclusions are drawn:

- According to the distribution of pavement condition on LVRs statewide, marginal roads should be defined considering a maximum limit of DL value. This limit represents the extreme deterioration of pavements on these roads.
- In order to project future conditions of the badly deteriorated roads, specific performance curves should be developed using actual performances of these roads. The roads in marginal condition tend to show higher deterioration rates even after maintenance.
- Based on the historical values, the application of low-cost surface treatments provides short-term effectiveness in enhancing the transverse cracking on roads in marginal condition. The post-treatment performance of transverse index exhibits a significantly higher deterioration rate on marginal roads compared to the roads in better condition.
- The current performance of marginal roads indicates that the pavement is unserviceable. However, the available maintenance budgets may not be sufficient to improve the overall drivability of these roads.
- The proposed maintenance strategy has better effectiveness on marginal roads compared to the current CDOT policy. However, it cannot improve the overall performance significantly. Marginal roads require a budget of more than an estimated annual amount of \$4.2M to enhance the roads significantly.
- The analysis of funding needs shows that marginal roads can be improved effectively within a maintenance capital improvement plan of five years from 2016 to 2020. Over

this plan, the overall DL value of marginal roads is expected to rise from 0.36 to 2.68 years at 2021.

- The proposed maintenance strategy is more cost-effective than the current maintenance program followed by CDOT during the capital improvement plan. The proposed strategy can enhance the overall DL to the level of 2.68 years using a cumulative discounted budget of \$51,358,414 at 2016. On the other hand, CDOT policy requires a discounted budget of \$120,047,916 to achieve the same performance target.

## **Chapter 8: Recommendations to Colorado DOT**

Based on the findings of this report, it is highly recommended that CDOT identifies the specific needs and desired benefits from managing LVRs. This report provides the following recommendations for consideration:

- CDOT is recommended to define the criteria (e.g. cut-off values) for effective treatments that meet its policy and public expectation. Based on this criteria, engineers are recommended to evaluate the applied treatments on LVRs. Other variables such as traffic volumes, type of pavement, road classification, and environmental parameters can be included in the evaluation process to increase the accuracy or to meet specific objectives.
- It is not recommended to make a maintenance decision considering only the DL value of LVRs. The results from this study emphasize that each treatment type has different effectiveness on each type of pavement distress. So considering DL in the decision tree for simplification would not address the exact deficiency of the pavement and the selected treatment may not be the right maintenance.
- Applying thin overlays directly on deteriorated roads is not recommended especially when transverse cracking is severe. CDOT is recommended to consider the appropriate pre-overlay treatments before applying asphalt overlays to avoid reflecting the cracks through the overlaid layers.
- CDOT is encouraged to consider light rehabilitations with recycling techniques in the maintenance strategy on LVRs. Cold in-place recycle and full depth replacement are recommended to be integrated with the current applications of chip seals and thin

overlays. Treatment options should be selected based on threshold values of fatigue and transverse indices.

- Innovative low-cost treatment alternatives should be investigated on LVRs. These treatments should add structural value to the roads in order to improve the road roughness significantly.
- Applying maintenance activities within the currently available budgets will result in having more deteriorated LVRs. A large scale optimization analysis should be implemented to define the performance targets and the corresponding maintenance policy and budgets.
- More advanced optimization tools are recommended to apply such as Genetic Algorithms. These optimization techniques are capable of resolving the computational complexity of optimization problems in a timely fashion. Therefore, state wide implementation plans can be developed for LVRs in Colorado.
- Different maintenance scenarios should be optimized using both current and proposed maintenance strategies. These scenarios have different performance targets so that a more comprehensive comparison can be investigated between the two strategies while minimizing the maintenance costs.
- Specific considerations should be included while managing roads with marginal conditions. An appropriate limit of DL equal to one year or less is recommended on these roads in Colorado. Depending on this definition, the size of this road network is more practical to manage.
- CDOT is advised to consider the capital improvement plan attached in the report when enhancing the marginal roads. Also, the strategy of maintaining roads by recycling

treatments is more encouraging for marginal roads because it is more cost-effective compared to the regular thin overlays.

- Another maintenance strategy or technique is needed when CDOT seeks higher performance than performance targets mentioned in the capital improvement plan. Investing more effort on the marginal roads using low-cost strategies is not recommended. The effectiveness of these treatments at this stage may not be reliable.
- CDOT is also advised to investigate the possibility of depaving marginal roads when the optimized budgets are not affordable or the expected performance is not adequate. This could be a more sustainable solution. However, the issues of depaving roads should be taken into consideration such as traffic volumes, reducing speed, material availability, and dust control.
- A better tracking system should be developed to document the applied treatments and associated costs on LVRs. This enables having a more reliable database for managing LVRs where treatment strategies can be optimized effectively.
