McLean, VA 22101-2296

## FOREWORD

Broad-based advancements in concrete materials have led to significant enhancements in the performance of lightweight concrete (LWC). Although the value of using LWC within the constructed infrastructure is clear, decades-old performance perceptions continue to hinder wider use of the concrete. Additionally, the lack of modern updates to structural design provisions for LWC has perpetuated additional barriers to the use of LWC. In 2007, the Federal Highway Administration (FHWA) began an investigation of the structural performance of modern LWCs.<sup>(1,2)</sup> The study described in this report engaged the academic as well as the public- and private-sector communities to compile the body of knowledge on LWC while also conducting nearly 100 full-scale structural tests on LWCs.

This report presents the results of shear tests on high-strength LWC prestressed girders as well as a compilation of data available from the literature. It also provides potential revisions to the *American Association of State Highway and Transportation Officials Load and Resistance Factor Design Bridge Design Specifications* with a focus on nominal shear resistance and the resistance factor for LWC in shear.<sup>(3)</sup> This report corresponds to the TechBrief, *Lightweight Concrete: Shear Performance*.<sup>(4)</sup> This report will provide valuable information for researchers interested in the shear performance and reliability of LWC.

Cheryl Allen Richter, P.E., Ph.D.  
Director, Office of Infrastructure  
Research and Development

### Notice

This document is disseminated under the sponsorship of the U.S. Department of Transportation (USDOT) in the interest of information exchange. The U.S. Government assumes no liability for the use of the information contained in this document.

The U.S. Government does not endorse products or manufacturers. Trademarks or manufacturers' names appear in this report only because they are considered essential to the objective of the document.

### Quality Assurance Statement

The Federal Highway Administration (FHWA) provides high-quality information to serve Government, industry, and the public in a manner that promotes public understanding. Standards and policies are used to ensure and maximize the quality, objectivity, utility, and integrity of its information. FHWA periodically reviews quality issues and adjusts its programs and processes to ensure continuous quality improvement.

15. Supplementary Notes This document was developed by research staff at the Turner-Fairbank Highway Research Center. Portions of the work were completed by PSI, Inc. under contract DTFH61-10-D-00017. Gary Greene formerly of PSI, Inc., who was the lead contract researcher on FHWA's lightweight concrete research efforts, and Ben Graybeal of FHWA, who manages the FHWA Structural Concrete Research Program, developed this document.			
16. Abstract Much of the fundamental basis for the current lightweight concrete (LWC) provisions in the <i>American Association of State Highway and Transportation Officials (AASHTO) Load and Resistance Factor Design (LRFD) Bridge Design Specifications</i> is based on research of LWC from the 1960s. <sup>(3)</sup> The LWC that was part of this research used traditional mixes of coarse aggregate, fine aggregate, portland cement, and water. Broad-based advancement in concrete technology over the past 50 yr has given rise to significant advancements in concrete mechanical and durability performance.  This document describes the results of shear tests on high-strength LWC prestressed girders that were conducted as part of an overall Federal Highway Administration (FHWA) research project on LWC. The FHWA test results are included in an internal database of shear tests with over 400 tests on LWC specimens available in the literature. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.) An analysis of the database was used to develop potential revisions to provisions related to LWC within section 5 of the <i>AASHTO LRFD Bridge Design Specifications</i> . <sup>(3)</sup> The framework for addressing LWC in the specifications that was proposed previously as a part of this research effort is applied to the design expression for nominal shear resistance. <sup>(1)</sup> The framework includes a proposed revision to the definition of LWC, a proposed modification factor relevant to LWC structural performance, and a proposed revision to the resistance factor for LWC in shear.			
17. Key Words LWC, Lightweight concrete, Bridge design, LRFD design specifications, Shear strength, Shear resistance, Resistance factor, Reliability analysis		18. Distribution Statement No restrictions. This document is available to the public through the National Technical Information Service, Springfield, VA 22161. <a href="http://www.ntis.gov">http://www.ntis.gov</a>

## LIST OF ABBREVIATIONS AND SYMBOLS

### Abbreviations

AASHTO	American Association of State Highway and Transportation Officials
ACI	American Concrete Institute
BT	bulb tee
CDF	cumulative distribution function
CIP	cast-in-place
C.L.	centerline
COV	coefficient of variation
DafStb	Deutscher Ausschuss für Stahlbeton (German Committee for Structural Concrete)
ERS	electric resistance strain gauge
FHWA	Federal Highway Administration
GFRP	glass fiber reinforced polymer
HG	haydite girder
kcf	kip per cubic foot
LRFD	Load and Resistance Factor Design
LVDT	linear variable differential transformer
LWC	lightweight concrete
MCFT	modified compression field theory
NCHRP	National Cooperative Highway Research Program
NWC	normal-weight concrete
PC	prestressed concrete
RC	reinforced concrete
SCOBS	Subcommittee on Bridges and Structures
SDC	specified density concrete
SG	stalite girder
SMR	triple-mirror prism in a spherical steel ball followed by FARO®
SP	string potentiometer
TDL	taut-line deflection
TFHRC	Turner-Fairbank Highway Research Center
UG	utelite girder

## Symbols

$a$	shear span or depth of equivalent rectangular stress block
$A_{beam}$	beam cross-sectional area
$A_{ct}$	area of concrete on the flexural tension side of the member
$a_g$	maximum aggregate size
$A_{ps}$	area of the longitudinal prestressing steel
$A_s$	area of the longitudinal tension reinforcement
$A'_s$	area of the longitudinal compression reinforcement
$A_v$	area of the shear reinforcement within the spacing
$b$	width of the compression face of a rectangular member
$b_{deck}$	deck width of the simulated cross section
$b_{flange,btm}$	beam bottom flange width of the simulated cross section
$b_{flange,top}$	beam top flange width of the simulated cross section
$b_v$	effective web width
$b_w$	width of member's web
$c$	depth from the compression face to the neutral axis
$d$	distance from the compression face to the centroid of the tension reinforcement
$d_p$	distance from the compression face to the centroid of the prestressing steel
$d_s$	distance from the compression face to the centroid of the nonprestressed tension reinforcement
$d'_s$	distance from the compression face to the centroid of the nonprestressed compression reinforcement
$d_v$	effective shear depth
$E_c$	modulus of elasticity of concrete
$E_p$	modulus of elasticity of prestressing steel
$E_s$	modulus of elasticity of reinforcing bars
$f'_c$	concrete compressive strength in reference to material test values and specified compressive strength
$f'_{ci}$	concrete compressive strength at the time of prestressing in reference to material test values and specified compressive strength at the time of prestressing
$f_{cpe}$	compressive stress in the concrete at the extreme tensile fiber after all prestress losses have occurred

$f_{ct}$	concrete-splitting tensile strength
$f_{pc}$	compressive stress at the centroid of the concrete after all prestress losses have occurred
$f_{pe}$	effective stress in the prestressing steel after losses
$f_{po}$	parameter taken as the modulus of elasticity of prestressing steel multiplied by the locked-in difference in strain between the prestressing steel and the surrounding concrete
$f_{ps}$	average stress in prestressing steel at the time for which the nominal resistance of member is required
$f_{pu}$	tensile strength of prestressing steel in reference to material test values and specified tensile strength of prestressing steel
$f_r$	modulus of rupture of concrete
$f_s$	stress in mild tension reinforcement at nominal flexural resistance
$f'_s$	stress in the mild steel compression reinforcement at nominal flexural resistance
$f_t$	concrete tensile strength
$f_y$	yield strength of reinforcing bars in reference to material test values and specified minimum yield strength
$f_{yt}$	specified yield strength of the shear reinforcement
$h$	member height
$h_f$	compression flange depth
$h_{web}$	height of the beam below the top flange of the simulated reinforced concrete section and height of the beam below the deck of the simulated prestressed concrete section
$IM$	nominal dynamic load allowance
$k$	prestressing factor
$L$	span length
$L1$	distance from the end of the girder to the rolling support
$L2$	distance to the first deck concrete anchor
$L3$	anchor spacing
$L4$	distance from the rolling support to the first anchor of the linear variable differential transformer average strain rosette
$M$	applied moment
$M_{cr}$	flexural cracking moment
$M_{cre}$	moment causing flexural cracking at the section due to externally applied loads

$M_{dnc}$	total unfactored dead load moment acting on the noncomposite section
$m_i$	mean load effect of an individual load
$M_{max}$	maximum factored moment at the section due to externally applied loads
$M_n$	nominal flexural resistance
$m_Q$	total mean load effect
$m_{Qi}$	mean of the individual load effects
$m_R$	mean resistance
$M_u$	factored moment at the section
$n$	smallest ratio of test-to-predicted shear resistance
$N$	total number of ratios of test-to-predicted shear resistance
$N_2$	total number of anchors
$N_u$	factored axial force of the section (positive if tensile)
$p_n$	cumulative probability
$Q$	total factored load effects
$Q_{DC}$	load effects due to dead load of structural components
$Q_{DW}$	load effects due to dead load of the wearing surface
$Q_i$	unfactored load effects
$Q_{IM}$	load effects due to vehicular dynamic load allowance
$Q_{LL}$	load effects due to vehicular live load
$Q_{LL+IM}$	load effects due to combined vehicular live load and dynamic load allowance
$R$	radius of Mohr's circle
$r_{DW}$	ratio of the load effects due to the dead load of the wearing surface to the load effects due to the dead load of structural components
$R_n$	nominal resistance
$r_Q$	ratio of unfactored permanent loads to the total unfactored force effect
$s$	spacing of the shear reinforcement
$s_{beam}$	beam spacing
$S_c$	section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads
$s_{max}$	maximum permitted spacing of the shear reinforcement
$S_{nc}$	section modulus for the extreme fiber of the noncomposite section where tensile stress is caused by externally applied loads

$s_x$	lesser of effective shear depth or the maximum distance between layers of longitudinal crack-control reinforcement
$s_{xe}$	crack-spacing parameter
$t_{deck}$	deck thickness of the simulated cross section
$t_{flange,btm}$	beam bottom flange thickness of the simulated cross section
$t_{flange,top}$	beam top flange thickness of the simulated cross section
$t_{slab}$	concrete slab thickness
$t_{ws}$	wearing surface thickness
$V$	applied shear force
$V_c$	nominal shear resistance provided by tensile stresses in the concrete
$V_{ci}$	nominal shear resistance provided by concrete when inclined cracking results from combined shear and moment
$V_{cr}$	applied shear force at web cracking
$v_{cw}$	average shear stress at inclined cracking
$V_{cw}$	nominal shear resistance provided by concrete when inclined cracking results from excessive principal tensions in the web
$V_d$	shear force at the section due to unfactored dead load
$V_{DC}$	coefficient of variation for the dead load of structural components
$V_{DW}$	coefficient of variation for the dead load of the wearing surface
$V_F$	coefficient of variation for the uncertainty in the fabrication
$V_{FM}$	coefficient of variation for the combined uncertainty in the fabrication and materials
$V_i$	factored shear force at the section due to externally applied loads occurring simultaneously with the maximum factored moment at the section due to externally applied loads
$V_{IM}$	coefficient of variation for the vehicular dynamic load allowance
$V_{LL}$	coefficient of variation for the vehicular live load
$V_M$	coefficient of variation for the uncertainty in the materials
$V_n$	nominal shear resistance of the section
$V_{n1}$	calculated nominal shear resistance of the section ( $V_n$ ) corresponding to first assumed value of the factored shear force at the section ( $V_u$ )
$V_{n2}$	calculated nominal shear resistance of the section ( $V_n$ ) corresponding to second assumed value of the factored shear force at the section ( $V_u$ )
$V_p$	component of the effective prestressing force in the direction of the applied shear

$V_P$	coefficient of variation for the uncertainty in the analysis
$V_{Qi}$	coefficient of variation of the unfactored load effect
$V_R$	coefficient of variation for resistance
$V_s$	nominal shear resistance provided by the shear reinforcement
$V_{test}$	maximum applied shear force
$v_u$	average shear stress
$V_u$	factored shear force at the section
$V_{u, assumed}$	assumed value of factored shear force at the section ( $V_u$ ) equals the nominal shear resistance of the section ( $V_n$ )
$V_{u1, assumed}$	first assumed value of factored shear force at the section ( $V_u$ )
$V_{u2, assumed}$	second assumed value of factored shear force at the section ( $V_u$ )
$w_{beam}$	beam unit weight
$w_c$	concrete unit weight
$w_{slab}$	slab unit weight
$w_{ws}$	wearing surface unit weight
$\beta$	factor indicating ability of diagonally cracked concrete to transmit tension and shear
$\beta_1$	ratio of the depth of the equivalent uniformly stressed compression zone assumed in the strength limit state to the depth of the actual compression zone
$\beta_{LWC}$	reliability index for lightweight concrete
$\beta_{LWC, \phi = 0.90}$	reliability index for lightweight concrete using a resistance factor of 0.90
$\beta_{NWC}$	reliability index for normal-weight concrete
$\beta_{RQ}$	reliability index
$\beta_{target}$	target reliability index
$\gamma_{DC}$	load factor for load effects due to dead load of structural components
$\gamma_{DW}$	load factor for load effects due to dead load of the wearing surface
$\gamma_i$	load factors
$\gamma_{LL+IM}$	load factor for load effects due to combined vehicular live load and dynamic load allowance
$\delta$	factor multiplied by the internal shear force and internal moment as part of the iterative procedure to determine nominal shear resistance
$\varepsilon_s$	net longitudinal tensile strain in the section at the centroid of the tension reinforcement
$\varepsilon_t$	strain measured in the stirrups by electronic resistance strain gauges

$\epsilon_{ty}$	stirrup yield strain
$\epsilon_x$	longitudinal strain at the middepth of the beam
$\theta$	angle of inclination of diagonal compressive stresses
$\lambda$	lightweight concrete modification factor
$\lambda_{DC}$	bias factor for the load effects due to dead load of structural components
$\lambda_{DW}$	bias factor for the load effects due to dead load of the wearing surface
$\lambda_F$	bias factor for the uncertainty in the fabrication
$\lambda_{FM}$	bias factor for the combined uncertainty in the fabrication and materials
$\lambda_{IM}$	bias factor for the load effects due to vehicular dynamic load allowance
$\lambda_{LL}$	bias factor for the load effects due to vehicular live load
$\lambda_M$	bias factor for the uncertainty in the materials
$\lambda_P$	bias factor for the uncertainty in the analysis
$\lambda_{Qi}$	bias factor for the load effects
$\lambda_R$	bias factor for resistance
$\rho$	reinforcement ratio
$\rho_\ell$	nonprestressed longitudinal reinforcement ratio ( $A_s/bd_s$ )
$\rho_p$	prestressed longitudinal reinforcement ratio ( $A_{ps}/bd_p$ )
$\rho_v$	shear reinforcement ratio ( $A_v/b_v s$ )
$\sigma_Q$	standard deviation of the total load effects
$\sigma_Q^2$	variance of the mean unfactored load effects
$\sigma_{Qi}$	standard deviation of the individual load effects
$\sigma_R$	standard deviation of resistance
$\sigma_R^2$	variance of the resistance
$\Sigma Q_i$	total nominal unfactored load effects
$\phi$	resistance factor
$\phi R_n$	factored nominal resistance

## CHAPTER 1. REPORT INTRODUCTION

### INTRODUCTION

Much of the fundamental basis for the current lightweight concrete (LWC) provisions in the *American Association of State Highway and Transportation Officials (AASHTO) Load and Resistance Factor Design (LRFD) Bridge Design Specifications* is based on research of LWC from the 1960s.<sup>(3,5-8)</sup> The LWC that was part of this research used traditional mixes of coarse aggregate, fine aggregate, portland cement, and water. Broad-based advancements in concrete technology over the past 50 yr have given rise to significant advancements in concrete mechanical and durability performance. Research during the past 30 yr, including the recent National Cooperative Highway Research Program (NCHRP) studies on different aspects of high-strength concrete, has resulted in revisions to the *AASHTO LRFD Bridge Design Specifications* to capitalize on the benefits of high-strength normal-weight concrete (NWC).<sup>(9-11,3)</sup> However, as described by Russell, many of the design equations in the *AASHTO LRFD Bridge Design Specifications* are based on data that do not include tests of LWC specimens, particularly with regard to structural members with compressive strengths in excess of 6 ksi (41 MPa).<sup>(12)</sup>

The Federal Highway Administration's (FHWA) Turner-Fairbank Highway Research Center (TFHRC) has executed a research program to investigate the performance of LWC with concrete compressive strengths in the range of 6 to 10 ksi (41 to 69 MPa) and equilibrium densities between 0.125 and 0.135 kip per cubic foot (kcf) (2,000 and 2,160 kg/m<sup>3</sup>). The research program used LWC with three different lightweight aggregates that are intended to be representative of those available in North America. The program included tests from 27 precast/prestressed LWC girders to investigate topics including transfer length and development length of prestressing strand, the time-dependent prestress losses, and shear strength of LWC. The development and splice length of mild steel reinforcement used in girders and decks made with LWC was also investigated using 40 reinforced concrete (RC) beams. While much of the research program focused on structural behavior, it also included a material characterization component wherein the compressive strength, elastic modulus, and splitting tensile strength of the concrete mixtures used in the structural testing program were assessed. One key outcome of the research program is to recommend changes to the *AASHTO LRFD Bridge Design Specifications* relevant to LWC.<sup>(3)</sup>

This report describes the results of 30 shear tests on 15 prestressed girders used to evaluate the shear resistance of high-strength LWC. The LWC prestressed girders tested in this study are included in an internal database of shear tests on LWC and NWC specimens that were collected from test results available in the literature.<sup>1</sup> This document describes the database and the analysis of the database. Design expressions in the current edition of the *AASHTO LRFD Bridge Design Specifications* are compared to the database.<sup>(3)</sup> This report also presents potential revisions to the *AASHTO LRFD Bridge Design Specifications* relating to LWC.

---

<sup>1</sup>The ACI-DAfStb database is not publicly available. For a list of available sources, see Bibliography section NWC Sources for ACI-DafStb Database.

## REPORT OBJECTIVES

This report has four main objectives. First, it provides the results of 30 shear tests on LWC prestressed girders conducted at TFHRC. Second, it describes the internal database, including the TFHRC test results and the analysis of the database. Third, the report presents the reliability analysis performed to evaluate the reduction factor for LWC in shear. Finally, it develops and presents potential revisions to the *AASHTO LRFD Bridge Design Specifications* relating to the nominal shear resistance with a focus on the performance of LWC.<sup>(3)</sup>

## REPORT ORGANIZATION

This report is organized as follows:

- Chapter 2 presents introductory material that summarizes the properties of LWC, the treatment of LWC in the *AASHTO LRFD Bridge Design Specifications*, the mechanism of shear transfer, the factors affecting shear resistance, and the design expressions for nominal shear resistance in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>
- Chapter 3 describes the shear tests of LWC prestressed girders, summarizes the test results, and provides a discussion of the results.
- Chapter 4 includes a description of the shear resistance database as well as statistical information about the database.
- Chapter 5 provides an analysis of the database and comparisons of the shear resistance predicted by design expressions to the shear resistance determined from the tests in the database.
- Chapter 6 describes a reliability analysis to evaluate the resistance factor for LWC in shear.
- Chapter 7 includes potential revisions to the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>
- Chapter 8 provides concluding remarks.
- Appendix A provides the material properties for the reinforcing bars.
- Appendix B provides a list of all of the LWC specimen names in the TFHRC shear database.
- Appendix C provides a list of all of the NWC specimen names in the ACI-DafStb database.
- Appendix D provides derivations for selected equations used in the reliability analysis.
- Appendix E provides statistical parameters for LWC tests excluded from the reliability analysis.

- Appendix F provides the drawings for the prestressed concrete (PC) girders tested at TFHRC.
- Appendix G provides details for obtaining the draft version of the research data contained therein.
- The References provides a list of sources found throughout the report, while the Bibliography includes all available source information for the two databases (i.e., TFHRC shear database and ACI-DafStb database).

Note that throughout the report, stress and elastic modulus are shown in kilopounds per square inch (ksi), and unit weight is shown in kcf for all expressions unless stated otherwise. SI units are provided in parentheses for values in the text, and conversion factors are provided for values in the tables. In some equations, U.S. customary units are intentional. If working in metric units, readers should convert variables to U.S. customary units first, apply the equation, and then convert it back to SI units.

## **SUMMARY OF PRELIMINARY RECOMMENDATIONS**

Several revisions to the *AASHTO LRFD Bridge Design Specifications* related to shear resistance of LWC in shear are proposed in this report.<sup>(3)</sup> The revisions involve the expressions for nominal resistance of LWC in shear, the expression for minimum shear reinforcement, and the resistance factor for LWC in shear. The proposed revisions are based on the recommendations made in previous documents that are a part of this research effort.<sup>(1,2)</sup> The previous recommendations relate to the definition of LWC and a modification factor for LWC. The definition of LWC was proposed to include concrete with lightweight aggregates up to a unit weight of 0.135 kcf (2,160 kg/m<sup>3</sup>), which is considered the lower limit for NWC. Also, the terms “sand-lightweight concrete” and “all-lightweight concrete” were removed in the proposed definition to allow other types of LWC mixtures. An LWC modification factor was proposed to potentially allow a more unified approach of accounting for the mechanical properties of LWC in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

The proposed LWC modification factor is included in the proposed expressions for nominal resistance of LWC in shear and the proposed expression for minimum shear reinforcement. The validation of the proposed revisions is described in chapters 5 and 6. The proposed code language is presented in chapter 7.

## CHAPTER 2. BACKGROUND

### INTRODUCTION

This chapter provides background information relevant to the focus of the research effort. It begins with a description of the mechanical properties of LWC, the gap of equilibrium densities on the *AASHTO LRFD Bridge Design Specifications*, and the LWC modification factor.<sup>(3)</sup> The rest of the chapter covers the shear strength of LWC, including the mechanism of shear transfer, factors that affect shear resistance, and design expressions for nominal shear resistance in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

### MECHANICAL PROPERTIES OF LWC

The aggregate in LWC can either be manufactured or natural with a cellular pore system providing for a lower density particle. The density of lightweight aggregate is approximately half that of normal-weight rock. The reduced dead weight of the LWC has many benefits in building and bridge construction such as smaller, lighter members; longer spans; and reduced substructure and foundation requirements.<sup>(13)</sup>

As compared to NWC, LWC tends to exhibit a reduction in tensile strength. This difference is generally attributed to the characteristics of the lightweight aggregate. The performance of concrete structures is affected by the tensile strength of concrete in several significant ways. The reduced tensile strength of LWC can affect the shear strength, cracking strength at the release of prestress, and bond strength of prestressed and nonprestressed reinforcement.<sup>(13)</sup>

### EQUILIBRIUM DENSITY GAP IN *AASHTO LRFD BRIDGE DESIGN SPECIFICATIONS*<sup>(3)</sup>

According to the *AASHTO LRFD Bridge Design Specifications*, LWC is defined as concrete having lightweight aggregate and an air-dry unit weight less than or equal to 0.120 kcf (1,920 kg/m<sup>3</sup>), while NWC is defined as having a unit weight of 0.135 to 0.155 kcf (2,160 to 2,480 kg/m<sup>3</sup>).<sup>(3)</sup> Concretes in the gap of densities between 0.120 and 0.135 kcf (1,920 to 2,160 kg/m<sup>3</sup>) are commonly referred to as “specified density concrete” (SDC) and are not directly addressed by the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> SDC typically contains a mixture of normal-weight and lightweight coarse aggregate.

Modifications to the *AASHTO LRFD Bridge Design Specifications* are needed to remove the SDC-related ambiguity, give the designer the freedom of specifying a slightly lower density than NWC, and allow for appropriate design with SDC.<sup>(3)</sup> The inclusion of SDC into the *AASHTO LRFD Bridge Design Specifications* could take many forms but would likely require modifications to both terminology and design expressions.

### MECHANISM OF SHEAR TRANSFER IN RC BEAMS

The mechanism of shear transfer depends on whether the beam is cracked or uncracked and whether it is reinforced or unreinforced in the transverse direction. In concrete beams without shear reinforcement, the shear is transferred by developing shear stresses in the uncracked

concrete, through interface shear transfer across a crack, and by dowel action of the longitudinal reinforcement. If the load is applied near the support, arching action may also develop. In concrete beams with reinforcement in the transverse direction, a portion of the shear is transferred by the shear reinforcement. The shear reinforcement also increases the shear transferred through interface shear and dowel action.

### **Shear Stress in Uncracked Concrete**

Uncracked beams or the uncracked portions of beams transfer the shear by developing shear stresses in combination with compressive stresses due to bending. Before cracking, the entire vertical shear force is transferred through a parabolic shear stress distribution. Experimental work has shown that after cracking, between 20 and 40 percent of the total shear was transferred in the uncracked compression zone.<sup>(14)</sup>

### **Interface Shear Transfer**

Sometimes referred to as “aggregate interlock,” interface shear transfer is the transfer of a portion of the total shear across a crack due to surface roughness. Interface shear transfer resists slippage or relative movement along the crack. Experimental work has shown that after cracking, between 33 and 50 percent of the total shear was transferred through interface shear.<sup>(14)</sup>

Walraven performed a study on the fundamental behavior of interface shear transfer.<sup>(15)</sup> The study showed that the mechanism of interface shear transfer is dependent on the crack width and shear displacement. Other important variables are the aggregate size, concrete strength, friction coefficient between aggregate and cement paste, and fraction and grading of the aggregate. The shear that can be transferred across a crack is reduced as the crack width increases, the aggregate size decreases, and the shear displacement increases. The shear resistance of specimens with a higher compressive strength or a larger fraction of coarse aggregate was greater for a given crack width or shear deformation. Walraven concluded that the concrete stress is the most important factor in determining the resistance of the crack faces to shear deformation, even more so than the aggregate size.<sup>(15)</sup> He also concluded that a considerable part of the shear transfer occurs due to friction between the crack faces.

### **Dowel Action**

Some of the shear is resisted by doweling force in the longitudinal reinforcement. The doweling force can result in longitudinal splitting cracks running along the length of the bar. These splitting cracks reduce the stiffness of the concrete around the bar and, as a result, the portion of the shear force transferred by dowel action. Splitting cracks resulting from dowel action can reduce the interface shear transfer. In beams, the dowel shear force is not typically dominant, and experimental work has shown that, after cracking, only 15 to 25 percent of the total shear was transferred through dowel action.<sup>(14)</sup>

### **Arching Action**

In beams with a concentrated load near the support, a portion of the vertical shear is transferred directly to the support by what is known as “arching action.” Arching action produces a strut of

compressive stress from the applied load to the support and is kept in equilibrium by a tensile force developed in the longitudinal reinforcement.<sup>(14)</sup>

## Shear Reinforcement

Transverse shear reinforcement in a beam, or stirrups, carries a portion of the total shear by acting as part of a truss. The concrete between the diagonal cracks carries compression, and the stirrups and longitudinal reinforcement carry the tension. The stirrups also resist the widening of the diagonal cracks, which has the effect of increasing the shear transferred by interface shear transfer and holds the longitudinal bars, which increases the shear transferred by dowel action.<sup>(14)</sup>

## MODES OF SHEAR FAILURE

An inclined diagonal crack forms as the principle stress exceeds the concrete tensile strength.<sup>(16)</sup> Shear failure modes are characterized by the occurrence of inclined cracking. Inclined cracking that occurs independently of a flexural crack is known as a “web-shear crack,” while inclined cracking that occurs as an extension of a flexural crack is known as a “flexure-shear crack.” After the occurrence of the primary shear or flexural crack, secondary cracks can occur due to dowel action or slip between the concrete and longitudinal reinforcement.<sup>(17)</sup>

For beams under concentrated loads, failure modes are strongly influenced by the ratio of the shear span ( $a$ ) to the effective shear depth ( $d_v$ ). The ratio of the web thickness to the width of the tension flange and the presence of prestressing will also influence the failure mode.

## Deep Beams

Beams with a rectangular cross section and  $a/d_v < 1$  can be considered deep beams. After inclined cracking, arching action becomes the dominant shear transfer mechanism. Failure can occur by loss of anchorage of the longitudinal reinforcement, concrete crushing above the support reaction, or compression or tension failure of the concrete arch above the inclined crack.<sup>(14,17)</sup>

## Short Beams

Beams with a rectangular cross section and  $1 < a/d_v < 2.5$  generally develop an inclined crack as an extension of a flexural crack. As the load increases, the inclined crack progresses toward the point of concentrated applied load application. A secondary crack can form from the inclined crack downward to the longitudinal reinforcement and then extend horizontally toward the support. The horizontal crack can be due to dowel action and can contribute to loss of anchorage.<sup>(14,17)</sup>

Failure of short beams may occur as a loss of anchorage and is termed a “shear-tension failure.” Failure may also occur by concrete crushing over the upper end of the inclined crack and is termed a “shear-compression failure.”<sup>(14,17)</sup>

## Long Beams

Beams with a rectangular cross section and  $a/d_v > 2.5$  form several flexural cracks first. An inclined crack will form as an extension of the flexural cracks. Beams without stirrups tend to fail immediately after the first inclined crack in a diagonal tension failure. Beams with stirrups tend to fail in shear-compression or flexure.<sup>(14,17)</sup>

## I-Beams

Beams with an I-shaped cross section have increased shear stress due to thinner webs. The inclined cracks tend to be straighter than in beams with rectangular cross sections. In I-beams with very thin webs or in prestressed I-beams, inclined cracks may occur before flexural cracking. In I-shaped beams with stirrups, the shear force may crush the concrete struts after inclined cracking. This is termed “web-crushing failure.”<sup>(14)</sup>

## SHEAR CRACKING STRENGTH OF REINFORCED AND PRESTRESSED BEAMS

This section describes the mechanism causing the formation of web-shear and flexure-shear cracks. The empirical expressions developed to predict web-shear and flexure-shear cracking are presented.

### Web Shear Cracks

Web shear cracks typically only occur in prestressed I-beams. They form near the neutral axis of the beam after the principle tensile stress has been exceeded. The approximate expression used in American Concrete Institute (ACI) 318-63 for the web-shear cracking strength is given by equation 1.<sup>(18)</sup> This expression assumes the concrete tensile strength is  $3.5\sqrt{f'_c}$ , where  $f'_c$  is the concrete compressive strength in reference to material test values and specified compressive strength (ksi), and is given in the form presented by ACI-ASCE Committee 426.<sup>(14)</sup>

$$v_{cw} = 3.5\sqrt{f'_c} + 0.3f_{pc} + \frac{V_p}{b_w d_p} \quad (1)$$

Where:

$v_{cw}$  = average shear stress at inclined cracking (psi).

$f_{pc}$  = compressive stress at the centroid of the concrete after all prestress losses have occurred (psi).

$V_p$  = component of the effective prestressing force in the direction of the applied shear (lb).

$b_w$  = width of member's web (inches).

$d_p$  = distance from compression face to the centroid of the prestressing steel (inches).

### Flexure-Shear Cracks

Before the formation of the inclined crack, the concrete between the flexural cracks or “teeth” experience bending and shearing. These forces are due to the variations in steel stress on either side of the tooth. Shear is transferred by dowel action and interfacial shear stress between the teeth. The inclined cracks that develop at the end of the flexural crack are dependent on the  $a/d_v$

ratio, the height of the flexural crack, and the amount of shear transferred by dowel action and interfacial shear stress.

Several expressions have been traditionally used to predict flexure-shear cracking in RC beams. The first expression, proposed by Viest and ACI-ASCE Committee 326, is given by equation 2.<sup>(19,20)</sup> A second expression, given by equation 3, was proposed by Bresler and Scordelis as a simplification of equation 2.<sup>(21)</sup>

$$V_c = bd \left( 1.9 \sqrt{f'_c} + 2,500 \frac{\rho V_d}{M} \right) \leq 3.5 \sqrt{f'_c} bd \quad (2)$$

Where:

$V_c$  = nominal shear resistance provided by tensile stresses in the concrete (lb).

$b$  = width of the compression face of a rectangular member (inches).

$d$  = distance from the compression face to the centroid of the tension reinforcement.

$\rho$  = reinforcement ratio.

$V_d$  = shear force at the section due to unfactored dead load (lb).

$M$  = applied moment (lb-inch).

$$V_c = bd \left( 2.0 \sqrt{f'_c} \right) \quad (3)$$

For prestressed beams, an expression for the inclined cracking load was proposed by MacGregor and is given by equation 4.<sup>(17,22)</sup> The first term in equation 4 represents the load to cause flexural cracking at a point along the shear span. The second term represents an additional increment of shear required to cause the inclined crack.

$$V_{ci} = \frac{M_{cr}}{\frac{M}{V} - \frac{d}{2}} + 0.6b_w d \sqrt{f'_c} \leq 1.7 \sqrt{f'_c} b_w d \quad (4)$$

Where:

$V_{ci}$  = nominal shear resistance provided by concrete when inclined cracking results from combined shear and moment (lb).

$M_{cr}$  = flexural cracking moment (lb-inch).

$V$  = applied shear force (lb).

## FACTORS AFFECTING SHEAR STRENGTH

This section describes three factors that affect shear strength: the ratio of shear span to beam depth, the depth of the beam, and lightweight aggregate. The effect that other factors, such as concrete strength and aggregate size, have on the shear transfer mechanism were described previously in the Interface Shear Transfer section of this chapter.

## Shear Span to Beam Depth Ratio

As described previously in the Modes of Shear Failure section of this chapter, the  $a/d_v$  ratio has considerable effect on the shear resistance of a beam. For beams with an  $a/d_v$  ratio greater than 2.5 or 3, inclined cracking occurs as an extension of flexural cracks. As the  $a/d_v$  ratio decreases below 2.5, some of the vertical applied load is transferred directly to the support through arching action. As the  $a/d_v$  ratio becomes smaller, a larger fraction of the vertical load is transferred to the support, which has the effect of increasing the average shear stress at failure. The failure mode also changes from diagonal tension failures at large  $a/d_v$  ratios, shear-compression and shear-tension failures (i.e., anchorage failures) at intermediate  $a/d_v$  ratios, and failures related to the compression arch for short  $a/d_v$  ratios.<sup>(14)</sup>

## Beam Depth

Since the 1960s, there has been much research on the effect that beam size has on shear strength. Many studies have shown that for beams without stirrups, the shear stress at failure reduces as the beam depth increases.<sup>(14)</sup> This is commonly referred to as “size effect.” Size effect in beams without shear reinforcement is not considered in the provisions of the ACI 318-11 building code.<sup>(23)</sup> In the *AASHTO LRFD Bridge Design Specifications*, some of the methods to predict shear resistance include the effect of depth for members without shear reinforcement.<sup>(3)</sup> Size effect in beams with shear reinforcement is usually considered to be minimal. Neither the *AASHTO LRFD Bridge Design Specifications* nor the ACI-318-11 building code includes the effect of beam depth in members with shear reinforcement.<sup>(3,23)</sup>

## Lightweight Aggregate

This subsection provides a summary of some of the research on shear strength of LWC beams. Most of the studies saw a reduction in the average shear stress at failure for LWC beams when compared to similar NWC beams.<sup>(5)</sup>

A study by Hanson showed that the average shear stress at failure of LWC RC beams without stirrups was between 60 and 100 percent of the stress of comparable NWC beams.<sup>(6)</sup> The results of the study also showed a good correlation between the splitting tensile strength of cylinders and the shear strength of the LWC beams.

Research by Ivey and Buth proposed factors of 0.75 for all-lightweight concrete and 0.85 for sand-lightweight concrete as a conservative method to account for the shear strength of the RC beams without stirrups considered in their study.<sup>(24)</sup>

LWC T-beams tested by Hamadi and Regan failed at a lower average shear stress than similar NWC beams in their study.<sup>(25)</sup> Also, increases in the amount of stirrups in their LWC beams did not result in similar increase in shear stress at failure as similar NWC beams.

Large RC I-beams without stirrups were tested by Walraven and Al-Zubi. The study compared LWC and NWC beams with different amounts of longitudinal reinforcement.<sup>(26)</sup> The LWC beams had similar shear strengths as the NWC beams in their study. Walraven and Al-Zubi concluded that, although the shear cracks went through the aggregate, the irregular shape of the

crack faces was still able to transfer shear stress. The resulting measured shear displacements along the inclined cracks in the LWC beams was approximately twice that of the NWC beams.

## **HISTORICAL DESIGN METHODOLOGIES FOR SHEAR**

It is common for design codes to ignore the interaction of shear and flexure and design for the worst case of flexure and shear separately.<sup>(27)</sup> This is the case for the ACI 318-95 building code, where the interaction is accounted for by extending the cut-off locations of the longitudinal reinforcement.<sup>(28)</sup>

A truss model has been used for the design of RC beams with stirrups. The model (commonly referred to as the “45-degree truss model”) consists of two parallel chords with inclined compression diagonal inclined at 45 degrees with respect to the beam’s longitudinal axis. The upper chord is under compression, and the lower chord is under tension. Vertical or slightly inclined stirrups carry tension to maintain equilibrium. The truss model has historically neglected concrete acting in tension, interface shear transfer, and dowel action.

The shear strength of beams without stirrups is typically limited to the load to cause the first inclined crack. For beams with stirrups, the truss model was used to estimate the additional shear that could be carried by the stirrups. The shear at first inclined cracking has been considered the concrete contribution to the nominal shear resistance provided by tensile stresses in the concrete ( $V_c$ ), and the additional shear carried by the stirrups has been considered the nominal shear resistance provided by the shear reinforcement ( $V_s$ ).

Design for shear then involves predicting the shear to cause inclined cracking. Beams with an applied shear less than the predicted shear to cause inclined cracking were considered adequate for shear. Shear reinforcement was provided for any excess shear (i.e., the difference between the applied shear and shear load at cracking). The basic form of this methodology is still used in the ACI-318-11 building code and in the *AASHTO LRFD Bridge Design Specifications*.<sup>(23,3)</sup>

## **DESIGN METHODOLOGIES FOR SHEAR USED IN THE *AASHTO LRFD BRIDGE DESIGN SPECIFICATIONS*<sup>(3)</sup>**

This section describes the critical section for shear and the requirements for minimum area of shear reinforcement and maximum spacing in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The three design methodologies for determining nominal shear resistance in the *AASHTO LRFD Bridge Design Specifications* are then presented. Last, the modification of the design expressions for LWC is described.

### **Critical Section for Shear**

In beams where the vertical load causes compression in the end region of a member, the critical section for shear is taken as the effective shear depth ( $d_v$ ) from the internal face of the support as given by Article 5.8.3.2 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> This occurs in the common case of the bottom surface of a beam resting on its supports with a downward vertical applied load on the top surface of the beam. The effective depth (see equation 5) is determined using the calculated nominal flexural resistance ( $M_n$ ), which is determined by first

calculating the depth from the compression face to the neutral axis ( $c$ ) for T-section behavior or rectangular section behavior given by equation 6 and equation 7, respectively.

$$d_v = \frac{M_n}{A_s f_y + A_{ps} f_{ps}} \quad (5)$$

Where:

$A_s$  = area of the longitudinal tension reinforcement (inches<sup>2</sup>).

$f_y$  = yield strength of reinforcing bars in reference to material test values and specified minimum yield strength (ksi).

$A_{ps}$  = area of the longitudinal prestressing steel (inches<sup>2</sup>).

$f_{ps}$  = Average stress in prestressing steel at the time for which the nominal resistance of member is required (ksi).

$$c = \frac{A_{ps} f_{pu} + A_s f_s - A'_s f'_s - 0.85 f'_c (b - b_w) h_f}{0.85 f'_c \beta_1 b_w + k A_{ps} \frac{f_{pu}}{d_p}} \quad (6)$$

Where:

$f_{pu}$  = tensile strength of prestressing steel in reference to material test values and specified tensile strength (ksi).

$f_s$  = stress in mild tension reinforcement at nominal flexural resistance (ksi).

$A'_s$  = area of the longitudinal compression reinforcement (inches<sup>2</sup>).

$f'_s$  = stress in the mild steel compression reinforcement at nominal flexural resistance (ksi).

$h_f$  = compression flange depth (inches).

$\beta_1$  = ratio of the depth of the equivalent uniformly stressed compression zone assumed in the strength limit state to the depth of the actual compression zone.

$k$  = prestressing factor.

$$c = \frac{A_{ps} f_{pu} + A_s f_s - A'_s f'_s}{0.85 f'_c \beta_1 b + k A_{ps} \frac{f_{pu}}{d_p}} \quad (7)$$

The average stress in the prestressing steel at nominal moment capacity is given by equation 8, where the parameter  $k$  has a value of 0.28 for low relaxation strand. The expression for the nominal moment capacity in the *AASHTO LRFD Bridge Design Specifications* is then determined using equation 9.<sup>(3)</sup> Rectangular section behavior can be assumed to occur when the depth of the assumed uniform concrete stress distribution ( $a = \beta_1 c$ ) is less than the compression flange depth ( $h_f$ ). In the case of rectangular section behavior,  $b_w$  is taken as  $b$  in equation 9.

$$f_{ps} = f_{pu} \left( 1 - k \frac{c}{d_p} \right) \quad (8)$$

$$M_n = A_{ps} f_{ps} \left( d_p - \frac{a}{2} \right) + A_s f_s \left( d_s - \frac{a}{2} \right) - A'_s f'_s \left( d'_s - \frac{a}{2} \right) + 0.85 f'_c (b - b_w) h_f \left( \frac{a}{2} - \frac{h_f}{2} \right) \quad (9)$$

Where:

$d_s$  = distance from the compression face to the centroid of the nonprestressed tension reinforcement (inches).

$d'_s$  = distance from compression face to the centroid of the nonprestressed compression reinforcement (inches).

The stress in the mild steel acting in tension ( $f_s$ ) is assumed to be yielding if the ratio  $c/d_s$  does not exceed 0.6. If this limit is not met, a strain compatibility analysis is necessary to determine  $f_s$ . The stress in the mild steel acting in compression ( $f'_s$ ) is assumed to be yielding if the ratio  $c/d'_s$  is greater than or equal to 3.0. If this limit is not met, the compression steel can be conservatively ignored according to Article 5.7.2.1 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

### Minimum Amount of Shear Reinforcement

The minimum amount of shear reinforcement required by Article 5.8.2.5 of the *AASHTO LRFD Bridge Design Specifications* is given by equation 10.<sup>(3)</sup> This minimum amount of shear reinforcement is intended to prevent failure after inclined cracking, restrain the growth of the inclined cracking, and increase the ductility in the section.

$$A_v \geq 0.0316 \sqrt{f'_c} \frac{b_v s}{f_y} \quad (10)$$

Where:

$A_v$  = area of the shear reinforcement within the spacing (inches<sup>2</sup>).

$b_v$  = effective web width (inches).

$s$  = spacing of the shear reinforcement (inches).

### Maximum Spacing of Shear Reinforcement

In order to provide adequate crack control, the maximum spacing of the shear reinforcement is limited. The maximum spacing is dependent on the average shear stress with higher levels of shear stress requiring a closer spacing of shear reinforcement. The maximum spacing is given by Article 5.8.2.7 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> For an average shear stress ( $v_u$ ) less than  $0.125f'_c$ , the maximum permitted spacing of the shear reinforcement ( $s_{max}$ ) is given by equation 11. For  $v_u$  greater than or equal to  $0.125f'_c$ ,  $s_{max}$  is given by equation 12.

$$\text{For } v_u < 0.125f'_c, s_{max} = 0.8d_v \leq 24.0 \text{ inches (609.6 mm)} \quad (11)$$

$$\text{For } v_u \geq 0.125f'_c, s_{max} = 0.4d_v \leq 12.0 \text{ inches (304.8 mm)} \quad (12)$$

### Nominal Shear Resistance

The sectional design approach is used in the *AASHTO LRFD Bridge Design Specifications* to evaluate the shear resistance of beams away from the supports, points of concentrated loads, or geometric discontinuities.<sup>(3)</sup> In the sectional design approach, the factored shear force is compared to the factored shear resistance at multiple locations along the length of the beam.

The *AASHTO LRFD Bridge Design Specifications* includes a design method of considering the nominal shear resistance to be the sum of the individual nominal shear resistance provided by tensile stresses in the concrete ( $V_c$ ), nominal shear resistance provided by the shear reinforcement ( $V_s$ ), and component of the effective prestressing force in the direction of the applied shear ( $V_p$ ). The expression for nominal shear resistance of the section ( $V_n$ ) is given by equation 13.  $V_c$  and  $V_s$  are limited to 25 percent of the concrete compressive strength multiplied by the section shear area. The expression for  $V_n$  including this limit is given by equation 14. The sectional design approach has an additional limit of  $0.18f'_c$  placed on the shear stress using equation 15.

$$V_n = V_c + V_s + V_p \quad (13)$$

$$V_n = 0.25f'_c b_v d_v + V_p \quad (14)$$

$$v_u = \frac{|V_u - \phi V_p|}{\phi b_v d_v} \quad (15)$$

Where  $\phi$  is the resistance factor. There are four different methods in the *AASHTO LRFD Bridge Design Specifications* to determine  $V_c$  in equation 13. The first three methods given in Articles 5.8.3.4.1 and 5.8.3.4.2 and appendix B5 use equation 16 to determine  $V_c$ . These methods each provide a methodology to determine the factor indicating ability of diagonally cracked concrete to transmit tension and shear ( $\beta$ ) in equation 16. The fourth method given in Article 5.8.3.4.3 calculates two terms: nominal shear resistance provided by concrete when inclined cracking results from combined shear and moment ( $V_{ci}$ ) and nominal shear resistance provided by concrete when inclined cracking results from excessive principal tensions in the web ( $V_{cw}$ ). The lesser of the two terms is used for  $V_c$ . All four methods include the determination of the angle of inclination of diagonal compressive stresses ( $\theta$ ), which is used to determine  $V_s$  in equation 17.

$$V_c = 0.0316\beta \sqrt{f'_c} b_v d_v \quad (16)$$

$$V_s = \frac{A_v f_y d_v \cot \theta}{s} \quad (17)$$

### ***Simplified Procedure for Nonprestressed Sections***

The method in Article 5.8.3.4.1 of the *AASHTO LRFD Bridge Design Specifications* is titled “Simplified Procedure for Nonprestressed Sections” and is applicable only to RC slabs with or without stirrups and to RC beams with stirrups.<sup>(3)</sup> Throughout this report, it is referred to as “Simplified-RC.” The overall member depth is limited to 16 inches (406 mm). This method is based on the simple expression for the average shear stress at inclined cracking (see equation 3) proposed by Bresler and Scordelis and the 45-degree truss model.<sup>(21)</sup> For this method,  $\beta$  is taken as 2.0, and  $\theta$  is taken as 45 degrees.

## General Procedure Methods

Two methods of the *AASHTO LRFD Bridge Design Specifications* are based on the modified compression field theory (MCFT).<sup>(3,29,30)</sup> MCFT was developed by Vecchio and Collins to describe the strength and load–deformation behavior of RC membrane elements.<sup>(29)</sup> Such elements are subjected only to in-plane normal and shear stresses. When the model is applied to the web of RC or PC beams, the only mechanism for shear transfer assumed by the model is that due to interface shear transfer. The contributions of the uncracked concrete in the compression zone and dowel action are not considered.

The method given in appendix B5 of the *AASHTO LRFD Bridge Design Specifications* is an iterative design procedure that is similar to the method originally proposed by Vecchio and Collins and described for prestressed structures by Mitchell and Collins.<sup>(3,29,30,31)</sup> The method is based on MCFT and involves the use of tables B5.2-1 and B5.2-2 in appendix B to iteratively determine  $\beta$  and  $\theta$ . In this report, it is referred to as the “general procedure with tables” (i.e., GP-table). The method in appendix B5 was simplified by Bentz et al. and validated for the design of reinforced and prestressed beams as part of NCHRP Project 12-61.<sup>(30,32)</sup> The simplified method uses equations to directly solve for  $\beta$  and  $\theta$  without iteration and is presented in Article 5.8.3.4.2 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> In this report, this simplified method is referred to as “general procedure with equations” (i.e., GP-equation).

The two general procedure methods (i.e., GP-table and GP-equation) determine the average strain at a section due to the combined effects of applied bending moment, shear force, axial force, and internal prestressing force. This is a different approach than the historical method for determining shear resistance where the interaction of shear, bending, and axial force is ignored.

In the GP-equation method, the net longitudinal tensile strain in the section at the centroid of the tension reinforcement ( $\varepsilon_s$ ) is determined using equation 18. The axial stiffness terms in the denominator of the equation are applicable when  $\varepsilon_s$  is positive, indicating a net tensile strain. When  $\varepsilon_s$  is negative, such as in the case of some prestressed beams, the expression in equation 19 is used and includes an additional stiffness term for the concrete in the lower half of the section acting in compression. The absolute value for the factored moment at the section ( $|M_u|$ ) shall not be taken less than  $|V_u - V_p|d_v$ , where  $V_u$  is the factored shear force at the section,  $V_p$  is the coefficient of variation (COV) for the uncertainty in the analysis, and  $A_s$  and  $A_{ps}$  are adjusted for development length.

$$\varepsilon_s = \frac{\left( \frac{|M_u|}{d_v} + 0.5N_u + |V_u - V_p| - A_{ps}f_{po} \right)}{E_s A_s + E_p A_{ps}} \leq 0.0060 \quad (18)$$

Where:

$N_u$  = factored axial force the section (kip).

$f_{po}$  = parameter taken as the modulus of elasticity of prestressing steel multiplied by the locked-in difference in strain between the prestressing steel and the surrounding concrete (ksi).

$E_s$  = modulus of elasticity of reinforcing bars (ksi).

$E_p$  = modulus of elasticity of prestressing steel (ksi).

$$\varepsilon_s = \frac{\left( \frac{|M_u|}{d_v} + 0.5N_u + |V_u - V_p| - A_{ps}f_{po} \right)}{E_s A_s + E_p A_{ps} + E_c A_{ct}} \geq -0.00040 \quad (19)$$

Where:

$E_c$  = modulus of elasticity of concrete (ksi).

$A_{ct}$  = area of concrete on the flexural tension side of the member (inches<sup>2</sup>).

In equation 18 and equation 19,  $V_u - V_p$  is a simplification of tensile force in each flange due to the applied shear. The longitudinal demand due to shear determined by equilibrium is given by the left-hand term in equation 20. By assuming a value of 26.6 degrees for  $\theta$ , the simplification shown by the right-hand term in equation 20 can be made. The result of this simplification is that equation 18 and equation 19 are not a function of  $\theta$ , and the design procedure is not iterative.

$$0.5(V_u - V_p) \cot \theta \approx V_u - V_p \quad (20)$$

For beams with the minimum amount of stirrups given in Article 5.8.2.5 of the *AASHTO LRFD Bridge Design Specifications* (see equation 10),  $\beta$  is determined using equation 21.<sup>(3)</sup> The factor  $\beta$  for beams without the specified minimum amount of stirrups (see equation 22) also includes a term with a crack-spacing parameter ( $s_{xe}$ ). The expression for  $s_{xe}$  is given by equation 23 and accounts for the effect of maximum aggregate size ( $a_g$ ) on interface shear transfer and for size effect in beams without stirrups. For beams with the concentrated longitudinal reinforcement (i.e., not distributed along the depth of the beam), the lesser of effective shear depth ( $d_v$ ) or the maximum distance between layers of longitudinal crack-control reinforcement ( $s_x$ ) is taken as equal to  $d_v$ . Combinations of  $d_v$  and  $a_g$  that result in  $s_{xe}$  being greater than 12 inches (305 mm) have the effect of reducing the factor  $\beta$  and, as a result,  $V_c$  of the nominal shear resistance (see equation 13). The value of  $\theta$  (degrees) is determined using the expression in equation 24 or the value of the beams with or without the minimum amount of stirrups specified in Article 5.8.2.5 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

$$\beta = \frac{4.8}{(1 + 750\varepsilon_s)} \quad (21)$$

$$\beta = \frac{4.8}{(1 + 750\varepsilon_s)} \frac{51}{(39 + s_{xe})} \quad (22)$$

$$12 \text{ inches (305 mm)} \leq s_{xe} = s_x \frac{1.38}{(a_g + 0.63)} \leq 80 \text{ inches (2,030 mm)} \quad (23)$$

$$\theta = 29 \text{ degrees} + 3,500\varepsilon_s \quad (24)$$

The GP-table method (see appendix B5 of the *AASHTO LRFD Bridge Design Specifications*) differs from the GP-equation method in Article 5.8.3.4.2 of the *AASHTO LRFD Bridge Design Specifications* in several ways.<sup>(3)</sup> Instead of calculating the strain at the level of the tensile reinforcement, the strain is calculated at the middepth of the beam. When the calculated strain is tensile, different expressions are used depending on whether the specified minimum amount of

stirrups is provided. The simplification given by equation 20 is not made. As a result, the method is iterative in that a value of  $\theta$  must be assumed for the first set of calculations. The values of  $\beta$  and  $\theta$  are determined from tables instead of directly from an expression. For members with stirrups,  $\beta$  and  $\theta$  are functions of both the average shear stress and the concrete compressive strength instead of only the calculated strain.

In the GP-table method, the longitudinal strain at the middepth of the beam ( $\epsilon_x$ ) is determined using equation 25 for a member with at least the minimum amount of stirrups as specified in Article 5.8.2.5 of the *AASHTO LRFD Bridge Design Specifications* (see equation 10) and determined using equation 26 for beams with less than the minimum amount of stirrups.<sup>(3)</sup> The difference between equation 25 and equation 26 is a factor of 2 in the denominator that doubles the calculated strain for beams with less than the minimum specified amount of stirrups. When  $\epsilon_x$  is negative, the expression in equation 27 is used. These expressions for  $\epsilon_x$  assume that the strain at the centroid of the compressive flange is 0, which is conservative unless the combination of  $M_u$ ,  $V_u$ , and  $N_u$  produces net tension in both flanges.

$$\epsilon_x = \frac{\left(\frac{|M_u|}{d_v} + 0.5N_u + 0.5|V_u - V_p| \cot \theta - A_{ps}f_{po}\right)}{2(E_sA_s + E_pA_{ps})} \leq 0.0030 \quad (25)$$

$$\epsilon_x = \frac{\left(\frac{|M_u|}{d_v} + 0.5N_u + 0.5|V_u - V_p| \cot \theta - A_{ps}f_{po}\right)}{E_sA_s + E_pA_{ps}} \leq 0.0030 \quad (26)$$

$$\epsilon_x = \frac{\left(\frac{|M_u|}{d_v} + 0.5N_u + 0.5|V_u - V_p| \cot \theta - A_{ps}f_{po}\right)}{2(E_sA_s + E_pA_{ps} + E_cA_{ct})} \geq -0.00020 \quad (27)$$

In beams with at least the minimum specified amount of stirrups, the values of  $\beta$  and  $\theta$  are determined from table B5.2-1 in the *AASHTO LRFD Bridge Design Specifications*, which is reproduced in this report as table 1.<sup>(3)</sup> The normalized shear stress ( $v_u/f'_c$ ) and  $\epsilon_x$  are needed for the table. The commentary of appendix B5 allows the values of  $\beta$  and  $\theta$  determined from the tables to be applied over a range of values. The values of  $\beta$  and  $\theta$  in a particular cell are applicable for a pair of  $v_u/f'_c$  and  $\epsilon_x$  values that are less than or equal to the limiting  $v_u/f'_c$  and  $\epsilon_x$  values given for each row and column. By using this method, a lower value of  $\beta$  and a higher value of  $\theta$  can be conservatively selected for design. Alternatively, three-way interpolation between the table cells that bound the pair of  $v_u/f'_c$  and  $\epsilon_x$  values can be used to determine a more exact value of  $\beta$  and  $\theta$ .

In beams without the minimum specified amount of stirrups, the values of  $\beta$  and  $\theta$  are determined from table B5.2-2, which is reproduced in this report as table 2.<sup>(3)</sup> In this table,  $s_{xe}$  and  $\epsilon_x$  are used to determine the values of  $\beta$  and  $\theta$ . The expression for  $s_{xe}$  in the GP-table method is the same as the expression in the GP-equation method (see equation 24) except that the lower limit of 12 inches (305 mm) is effectively reduced to 5 inches (127 mm). Similar to table 1, values of  $\beta$  and  $\theta$  in a particular cell of table 2 can be applied to a pair of  $s_{xe}$  and  $\epsilon_x$  values that are less than or equal to the limiting  $s_{xe}$  and  $\epsilon_x$  values given for each row and column. Alternatively, three-way interpolation between the table cells can be used.

### ***Simplified Procedure for Prestressed and Nonprestressed Sections***

The simplified procedure for prestressed and nonprestressed sections (referred to as “Simplified-PC/RC” throughout this report) is based on a model that uses  $V_{cw}$  and  $V_{ci}$  for web-shear cracks and flexural shear cracks in prestressed beams. This is the model that was introduced into the ACI 318-63 building code, and the expressions are given by equation 1 and equation 4.<sup>(18)</sup> The method in the *AASHTO LRFD Bridge Design Specifications* was proposed by NCRHP Project 12-61 and is based on the  $V_{cw}$ - $V_{ci}$  approach.<sup>(3,32)</sup> The  $V_{cw}$ - $V_{ci}$  approach had already been included in the *AASHTO Standard Specifications for Highway Bridges* and the ACI 318-02 building code.<sup>(33,34)</sup> The average shear stress at failure included in the *AASHTO LRFD Bridge Design Specifications* version of the  $V_{cw}$ - $V_{ci}$  approach has been reduced from the other design documents in order to make the approach applicable to RC beams and PC beams with smaller amounts of longitudinal reinforcement.<sup>(32)</sup>

The expression for web-shear cracking in the *AASHTO LRFD Bridge Design Specifications* is given by equation 28. The term  $0.06\sqrt{f'_c}$  (ksi) corresponds to  $1.9\sqrt{f'_c}$  (psi). As described previously in this report, a concrete tensile strength of  $3.5\sqrt{f'_c}$  was assumed in the traditional expression for  $V_{cw}$  given by equation 1. The term  $0.06\sqrt{f'_c}$  represents a lower-bound estimate of the concrete tensile strength applicable to RC beams.

$$V_{cw} = \left( 0.06\sqrt{f'_c} + 0.3f_{pc} \right) b_v d_v + V_p \quad (28)$$

The expression for flexural shear cracking in the *AASHTO LRFD Bridge Design Specifications* is given by equation 29.<sup>(3)</sup> In comparison to the more traditional version of  $V_{ci}$  given by equation 4, the term  $0.02\sqrt{f'_c}$  (ksi) in equation 29 corresponds to  $0.63\sqrt{f'_c}$  (psi). The term  $d/2$  was dropped for simplification. The term  $0.06\sqrt{f'_c}d_v$  (ksi and inches) corresponds to  $1.9\sqrt{f'_c}d_v$  (psi and inches). This is similar to the term  $1.7\sqrt{f'_c}d$  (psi and inches) if the depth is assumed equal to  $0.9d_v$ . The use of  $0.06\sqrt{f'_c}$  as the minimum average shear stress in equation 29 makes this value the uniform minimum shear stress regardless of location along the beam as  $0.06\sqrt{f'_c}$  is also in equation 28.<sup>(32)</sup> The moment causing flexural cracking at the section due to externally applied loads ( $M_{cre}$ ) in equation 29 is given by equation 30.

$$V_{ci} = 0.02\sqrt{f'_c}b_v d_v + V_d + \frac{V_i M_{cre}}{M_{max}} \geq 0.06\sqrt{f'_c}b_v d_v \quad (29)$$

Where:

$V_i$  = factored shear force at the section due to externally applied loads occurring simultaneously with the maximum factored moment at the section due to externally applied loads.

$M_{max}$  = maximum factored moment at the section due to externally applied loads.

$$M_{cre} = S_c \left( f_r + f_{cpe} - \frac{M_{dnc}}{S_{nc}} \right) \quad (30)$$

Where:

$S_c$  = section modulus for the extreme fiber of the composite section where tensile stress is caused by externally applied loads (inches<sup>3</sup>).

$f_r$  = modulus of rupture of concrete (psi).

$f_{cpe}$  = compressive stress in the concrete at the extreme tensile fiber after all prestress losses have occurred (psi).

$M_{dnc}$  = total unfactored dead load moment acting on the noncomposite section (lb-inch).

$S_{nc}$  = section modulus for the extreme fiber of the noncomposite section where tensile stress is caused by externally applied loads (inches<sup>3</sup>).

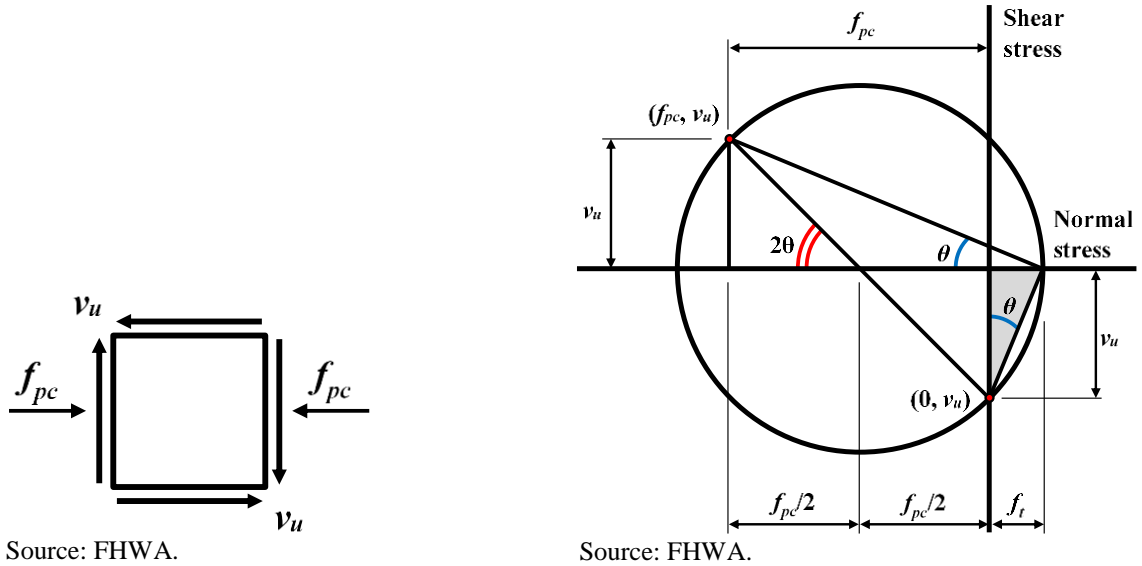

The inclination angle of a crack ( $\theta$ ) of diagonal compressive stresses can be predicted using Mohr's circle for an element subjected to combined shear and compression, as shown in figure 1. The radius of Mohr's circle ( $R$ ) can be used to write an expression that relates the compressive stress at the centroid of the concrete after all prestress losses have occurred ( $f_{pc}$ ), the shear stress ( $v_u$ ), and the tensile strength of concrete ( $f_t$ ), as given by equation 31. Both sides of the expression are squared as given by equation 32. The expression is simplified and solved for  $v_u$  as given by equation 33. The expression for  $v_u$  from equation 33 is substituted into the expression for  $\cot \theta$  to give equation 34. An expression for  $\cot \theta$  can be determined from the shaded triangle shown on the Mohr's circle (see figure 1).

$$\sqrt{\left(\frac{f_{pc}}{2}\right)^2 + (v_u)^2} = R = \frac{f_{pc}}{2} + f_t \quad (31)$$

$$\left(\frac{f_{pc}}{2}\right)^2 + (v_u)^2 = \left(\frac{f_{pc}}{2}\right)^2 + 2f_t \frac{f_{pc}}{2} + (f_t)^2 \quad (32)$$

$$v_u = \sqrt{f_t f_{pc} + (f_t)^2} = f_t \sqrt{1.0 + \frac{f_{pc}}{f_t}} \quad (33)$$

$$\cot \theta = \frac{v_u}{f_t} = \sqrt{1.0 + \frac{f_{pc}}{f_t}} \quad (34)$$

Source: FHWA.  
 A. Element subjected to shear and compression. Source: FHWA.  
 B. Mohr's circle for stress state of element.

**Figure 1. Illustrations. Stress condition on an element subjected to shear and compression and Mohr's circle for stress state of an element.**

The expression for  $\cot \theta$  in the *AASHTO LRFD Bridge Design Specifications* is given by equation 35 and is the first two terms of a Taylor Series expansion of equation 34.<sup>(32)</sup> A lower limit of 29 degrees on  $\theta$  is used for design purposes, which corresponds to the upper limit of 1.8 on  $\cot \theta$  in equation 35. The  $\cot \theta$  is used directly in the expression for  $V_s$  in equation 17.

$$\cot \theta = 1.0 + 3 \left( \frac{f_{pc}}{\sqrt{f'_c}} \right) \leq 1.8 \quad (35)$$

### Modification of Shear Resistance for LWC in *AASHTO LRFD Bridge Design Specifications*<sup>(3)</sup>

Modification for LWC is explicitly stated in the *AASHTO LRFD Bridge Design Specifications* regarding shear.<sup>(3)</sup> Specifically, Article 5.8.2.2 states that all expressions in Articles 5.8.2 and 5.8.3, which are the provisions covering design for shear and torsion, shall be modified for the effects of LWC. The modification consists of replacing  $\sqrt{f'_c}$  with  $4.7f_{ct}$ , where  $f_{ct}$  is the concrete-splitting tensile strength, when the splitting tensile strength is specified. When  $f_{ct}$  is not specified,  $\sqrt{f'_c}$  is replaced with  $0.75\sqrt{f'_c}$  when all-lightweight concrete is used or  $0.85\sqrt{f'_c}$  when sand-lightweight concrete is used.

The modification for LWC described by Article 5.8.2.2 applies to many of the design expression described previously in this chapter.<sup>(3)</sup> For example, it applies to equation 10 for the minimum amount of shear reinforcement. It also applies to the expression for  $V_c$  given by equation 16 that is part of the Simplified-RC method and both methods of the general procedure. The modification affects  $V_{cw}$  and  $V_{ci}$  (equation 28 and equation 29) of the Simplified-PC/RC method. The modification also applies to the expression for  $\cot \theta$  given by equation 35. The modification

of  $\sqrt{f'_c}$  in equation 35 affects the shear resistance of prestressed beams with stirrups. The modification for LWC reduces the value of the denominator in the second term and results in a larger overall value of  $\cot \theta$ . The increase in  $\cot \theta$  directly increases  $V_s$  and could result in a calculated  $V_n$  for prestressed LWC beams with stirrups that is larger than the calculated  $V_n$  for a similar NWC beam. The effect of including a modification for LWC in the expression for  $\cot \theta$ , and the resulting effect on the calculated shear resistance of prestressed LWC beams is described quantitatively in chapter 5 of this report.

## FACTOR FOR LWC TENSILE STRENGTH

The tendency for LWC to have a reduced tensile strength is not treated consistently in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> There are many articles where  $\sqrt{f'_c}$  is used to represent concrete tensile strength. The provisions for shear- and tension-development length of mild reinforcement currently include a modification for LWC. However, the tensile stress limits in PC do not include a modification for LWC. A potential option to provide a more uniform treatment of LWC tensile strength would be to add the definition of a modification factor for LWC, such as the LWC modification factor ( $\lambda$ ), to section 5.4 of the *AASHTO LRFD Bridge Design Specifications*, which could then be referenced in other articles.<sup>(3)</sup> Then the factor could be added to design expressions where the  $\sqrt{f'_c}$  is used to represent concrete tensile strength.

A modification factor for LWC was previously developed from tests on LWC and applied to the prediction of bar stress developed in lap splices of mild steel reinforcement.<sup>(1,2)</sup> The modification factor is based on the splitting tensile strength when available and the concrete unit weight ( $w_c$ ) otherwise. An expression for the modification factor for LWC that is based on  $w_c$  is convenient to designers because this is a quantity, like compressive strength, that is determined during the design phase. The expression for the modification factor for LWC ( $\lambda$ ) based on  $w_c$  is given by equation 36 through equation 38. The expression for  $\lambda$  based on splitting tensile strength ( $f_{ct}$ ) is given by equation 39.

$$\text{For } w_c \leq 0.100 \text{ kcf: } \lambda = 0.75 \quad (36)$$

$$\text{For } 0.100 < w_c < 0.135 \text{ kcf: } \lambda = 7.5w_c \leq 1.00 \quad (37)$$

$$\text{For } w_c \geq 0.135 \text{ kcf: } \lambda = 1.00 \quad (38)$$

$$\lambda = 4.7 \frac{f_{ct}}{\sqrt{f'_c}} \leq 1.00 \quad (39)$$

## CHAPTER 3. RESEARCH ON SHEAR RESISTANCE OF LWC

### INTRODUCTION

This research program focused on LWC with compressive strengths from 6 to 10 ksi (41 to 69 MPa) and equilibrium densities between 0.125 and 0.135 kcf (2,000 and 2,160 kg/m<sup>3</sup>). LWC used in this research program can be considered high-strength SDC. The program used LWC with three different lightweight aggregates to produce 27 precast/prestressed LWC girders and 40 RC splice beam specimens. Russell recognized the lack of mild steel bond test data and shear test data for LWC.<sup>(12)</sup> While this research program focused on structural behavior, it also had a material characterization component, as described in *Lightweight Concrete: Mechanical Properties*, and included mechanical property tests on the concrete mixtures used in the structural testing program.<sup>(1)</sup> Mechanical tests included the compressive strength, elastic modulus, and splitting tensile strength.  $w_c$  was determined using several methods (see *Lightweight Concrete: Mechanical Properties* for more information).<sup>(1)</sup> The 40 splice beam specimens tested by FHWA and used to evaluate the development length of mild steel reinforcement are also described in *Lightweight Concrete: Development of Mild Steel in Tension*.<sup>(2)</sup>

The details of the FHWA research program involving the shear resistance of precast/prestressed LWC girders are provided in this chapter. It also summarizes the selection process of LWC mix design, the specimen fabrication at the precastor's facility, and the material property testing. The girder design, test setup, and test results for the 30 shear tests on 15 LWC girders are discussed in detail. The results include observations of girder behavior such as failure mode, peak shear force, web cracking shear force, and web cracking angle. The peak shear force, web cracking shear force, and web cracking angle are compared to several design procedures in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

### RESEARCH SIGNIFICANCE

There is a limited amount of test data on the shear resistance of high-strength LWC. This research project included 30 girder tests on this type of concrete. These tests on shear resistance were combined with the results of other tests on LWC to determine the effect of lightweight aggregates. Design expressions for shear resistance that include a proposed modification factor for LWC ( $\lambda$ ) were validated using the tests on LWC.

### LWC MIX DESIGNS

The Expanded Shale, Clay, and Slate Institute assisted FHWA in obtaining SDC mixes that had been used in production. One of the criteria for this research project was to use lightweight aggregate sources that were geographically distributed across the United States. Additional selection criteria included mixes using a large percentage of the coarse aggregate as lightweight coarse aggregate, mixes using natural sand as the fine aggregate, and mixes with a target equilibrium density between 0.125 and 0.135 kcf (2,000 and 2,160 kg/m<sup>3</sup>). In order to make sure that the behavior of the concrete would be controlled by the lightweight aggregate, only mixes with greater than 50 percent of the coarse aggregate as lightweight aggregate were considered. The concrete density needed to be in the range of densities not currently covered by the *AASHTO*

*LRFD Bridge Design Specifications* because of the limited amount of test data in this density range.<sup>(3)</sup> Literature has shown that silica fume can increase LWC compressive strength and has also been revealed to improve bond of mild steel reinforcement and prestressing strand.<sup>(35–38)</sup> As a result, mixes that included silica fume were not selected for this experimental study so that the results would be representative of mechanical properties for SDC without silica fume and most likely conservative for SDC with silica fume.

Three mix designs were selected with a design compressive strength greater than 6.0 ksi (41.3 MPa) to represent concrete that could be used for bridge girders. A fourth mix design was selected that had a design compressive strength less than 6.0 ksi (41.3 MPa) to represent concrete that could be used for a bridge deck.

The selected mix designs are shown in table 3. Each uses partial replacement of the coarse aggregate with lightweight aggregate to achieve its reduced unit weight. The lightweight aggregates in the mixes were haydite, an expanded shale from Ohio; stalite, an expanded slate from North Carolina; and utelite, an expanded shale from Utah. The normal-weight coarse aggregate was No. 67 Nova Scotia granite. Natural river sand was used as the fine aggregate. Type III portland cement was used to obtain the high early strengths typically required in high-strength precast girders. Admixtures included a water reducer, an air entrainer, and a high-range water reducer.

**Table 3. Selected concrete-mixture designs.**

<b>Design Values and Component Materials</b>	<b>Haydite Girder (HG)</b>	<b>Stalite Girder (SG)</b>	<b>Utelite Girder (UG)</b>
Design 28-day strength (ksi)	6.0	10.0	7.0
Design release strength (ksi)	3.50	7.50	4.20
Target unit weight (kcf)	0.130	0.126	0.126
Lightweight coarse aggregate (kip)	0.80	0.88	0.74
Normal-weight coarse aggregate (kip)	0.52	0.25	0.39
Normal-weight sand (kip)	1.19	1.22	1.27
Class F fly ash (kip)	0.00	0.00	0.15
Type III portland cement (kip)	0.75	0.80	0.60
Water (kip)	0.27	0.25	0.26
Water reducer (oz)	19	19	19
Air entrainer (oz)	2	2	2
High-range water reducer (oz)	34	34	34
Water/cementitious materials ratio	0.36	0.31	0.34

1 ksi = 6.89 MPa.

1 kcf = 16,020 kg/m<sup>3</sup>.

1 kip = 4.45 kN.

1 oz = 29.6 mL.

## EXPERIMENTAL PROGRAM

The experimental program consisted of 30 tests on 15 PC girders made using three different LWC mixes. Key test parameters included the lightweight aggregate, the amount of shear reinforcement, girder depth, and the use of straight or draped strands. Five girder designs were developed to evaluate the effect of the key parameters. The end of each girder had different amounts of shear reinforcement. A set of five girders was cast for each of three different concrete mixtures intended to represent typical LWC for girders. Table 4 gives the nominal details for the six girder end designs that were AASHTO type II girders (i.e., type II). Table 5 provides similar details for the four girder end designs that were AASHTO/Precast/Prestressed Concrete Institute bulb tee girders with a 54-inch (1.37-m) height (i.e., BT-54).

A naming scheme was developed for the 30 girder tests that included the concrete mixture, girder design, and girder end. The concrete mixtures were designated A through C and were UG, HG, or SG, respectively. The girder design number was used in the naming scheme, as seen in the girder test columns. An “L” or a “D” was used to denote a test near the live or dead end of the girder, respectively. The end of the girder closer to the prestressing bed bulkhead where the strands were jacked is known as the live end, and the end towards the bulkhead with the stationary anchorage is known as the dead end.

**Table 4. Design details of type II girders.**

Girder Test	$d_v$ (Inches)	$v_{ul}f'_c$ *	Number of Strands		Stirrups		Design Amount of Stirrups, $\rho_v f_y$ (ksi)
			Bottom	Top	Bar Size	Spacing (Inches)	
5D	35.0	0.068	10 straight	2	No. 3	22	0.12
5L	35.0	0.075	10 straight	2	No. 3	15	0.18
6D	31.7	0.088	10 straight and 4 drape	2	No. 4	15	0.32
6L	31.7	0.096	10 straight and 4 drape	2	No. 4	12	0.40

7L	32.8	0.120	18 straight	4	No. 4	12	0.40

1 inch = 25.4 mm.

1 ksi = 6.89 MPa.

\*Assumed  $f'_c$  for design was 10 ksi (68.9 MPa).

**Table 5. Design details of BT-54 girders.**

Girder Test	$d_v$ (Inches)	$v_u/f'_c$ *	Number of Strands		Stirrups		$\rho_v f_y$ (ksi)
			Bottom	Top	Bar Size	Spacing (Inches)	
8D	51.6	0.068	16 straight	2	No. 3	22	0.12
8L	51.6	0.076	16 straight	2	No. 3	14	0.19
9D	47.5	0.150	28 straight	4	No. 4	8	0.60
9L	47.5	0.140	28 straight	4	No. 4	10	0.48

1 inch = 25.4 mm.

1 ksi = 6.89 MPa.

\*Assumed  $f'_c$  for design was 10 ksi (68.9 MPa).

The shear test girders were designed as part of a larger study that included the transfer and development length of prestressing strands in high-strength LWC. A total of nine different girder designs were used in the overall research program. The first four designs were type II girders that were tested to failure to evaluate development length of prestressing strand. Girder designs 5–9 were for the evaluation of shear performance.

### Test Specimens

Girder designs 5–7 were type II girders. The amount of shear reinforcement (stirrups) in the test regions near the live and dead ends of the girder varied. The design details for each girder end were shown previously in table 4. A sketch of each girder design showing the cross section, strand pattern, and mild steel reinforcement is shown in figure 2 through figure 4 for girder designs 5–7, respectively. The dead end of girder design 5 (5D) was designed to have the minimum amount of shear reinforcement allowed by the *AASHTO LRFD Bridge Design Specifications* (see Article 5.8.2.5) at nearly the maximum spacing (see Article 5.8.2.7).<sup>(3)</sup> The dead end of girder design 7 (7D) was designed to have a ratio of shear stress to concrete compressive stress ( $v_u/f'_c$ ) near the limit of 0.18 given in the *AASHTO LRFD Bridge Design Specifications* for the applicability of the sectional design method (see Article 5.8.3.2).<sup>(3)</sup> Girder design 6 had draped strands and an amount of shear reinforcement between the amounts used in girder designs 5 and 7.

Note: The following reinforcement is symmetric about the girder centerline: confinement (bars V), splitting (stirrups at 7-inch (177.8-mm) spa), and additional longitudinal for shear (bars W).

**Figure 6. Illustrations. Beam girder design 9 showing cross-section dimensions, prestressing strand location, mild steel reinforcement, and elevation view.**

The end of each girder had additional reinforcement as required by the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> No. 6 rebar was added between the strands in the bottom flange to satisfy the requirements of Article 5.8.3.5 for additional longitudinal reinforcement.<sup>(3)</sup> Additional shear reinforcement (as stirrups) was provided as splitting resistance in the pretensioned anchorage zone per Article 5.10.10.1, and confinement reinforcement was provided around the strands to satisfy Article 5.10.10.2.<sup>(3)</sup>

The girders were designed with an amount of flexural reinforcement that was intended to ensure that a shear failure would occur prior to a flexural failure. For the design of the girders, a concrete compressive strength ( $f'_c$ ) of 10 ksi (68.9 MPa) was assumed for all girders, and no modification of the shear resistance for LWC was used.

## Specimen Fabrication

The girders were fabricated at a plant in Mobile, AL. The fabricator was asked to prescriptively produce the concrete mixtures without trying to adjust them for target strengths or unit weight. This was intended to remove batch-to-batch variations as a variable in the study. The lightweight aggregates were stored in three piles at the plant and watered continuously using a sprinkler on each pile, as shown in figure 7.

Source: FHWA.

**Figure 7. Photo. Lightweight aggregate stockpiles at precaster's facility with continuous sprinklers.**

## Concrete Properties

Concrete for the three girder mixes was supplied by the precaster. After mixing, the precaster's personnel performed testing of the fresh concrete properties and produced 4- by 8-inch (102- by 203-mm) cylinders for quality-control purposes. The fresh concrete properties, concrete batch weights, and compressive strength tests performed by the precaster's personnel can be found in *Lightweight Concrete: Mechanical Properties*, which covers material properties of the LWC tested within this research program.<sup>(1)</sup>

Independently, research personnel made 4- by 8-inch (102- by 203-mm) cylinders following ASTM C31 for mechanical property testing and density measurements.<sup>(39)</sup> Compression tests were performed according to ASTM C39 to determine the compressive strength at the release of prestressing, at 28 days, and at girder testing.<sup>(40)</sup> Neoprene pads were used inside steel caps at each end of the cylinders. The indirect tensile strength was measured using the splitting tensile test described in ASTM C 496.<sup>(41)</sup> The elastic modulus was determined following ASTM C469 using one of the cylinders intended for compressive strength testing.<sup>(42)</sup> Typically, one cylinder was tested first for compressive strength to determine the proper load level for determining the elastic modulus. The air-dry density was calculated using the measured cylinder weight and measured cylinder lengths and diameters to calculate an average volume. The mechanical properties of the LWC used in the prestressed girders are given in table 6, and the measured unit weights are given in table 7. The compressive strengths, splitting tensile strengths, modulus of elasticity, and air-dry densities shown are based on the average of three cylinders.

**Table 6. Mean girder concrete properties by mix design.**

### Reinforcing Bar Properties

The reinforcing bars were ASTM A615 grade 60.<sup>(43)</sup> The mechanical properties were tested under displacement control in a 100-kip (445-kN) testing machine. Two bars were tested for each nominal size used in the prestressed girders. Strain was measured with an 8-inch (203-mm) extensometer. When the extensometer reached a measured strain of 2 percent at the beginning of the assumed strain-hardening regime, the test was paused to remove the extensometer. The test was then continued until the bar fractured. The yield strength was determined using the 0.2 percent offset method. The average yield strength and the ultimate strength of two bars used as stirrups, confinement reinforcement, and girder end longitudinal reinforcement are given in table 8. Test data and stress–strain relationships from individual bars are provided in appendix A.

**Table 8. Reinforcing bar properties.**

Property	Stirrup Girder Design				Girder End Longitudinal Reinforcement	Confinement Reinforcement
	5	6 and 7	8	9		
Bar size (unitless)	No. 3	No. 4	No. 3	No. 4	No. 6	No. 4

1 inch = 25.4 mm.

1 inch<sup>2</sup> = 645 mm<sup>2</sup>.

1 ksi = 6.89 MPa.

## NWC Concrete Deck

An 8-inch (200-mm)-thick composite NWC deck was cast onto each LWC girder at TFHRC in order to move the neutral axis above the web and top flange. The concrete used in the decks had a specified compressive strength of 4 ksi (28 MPa). The mean mechanical properties at 28 days and test day for the NWC decks are provided in table 9. As a reminder, type II girders include girder designs 5–7, while BT-54 girders include girder designs 8–9. The decks had two orthogonal mats of reinforcing, as specified in Article 9.7.3 of the *AASHTO LRFD Bridge Design Specifications* for bridge decks.<sup>(3)</sup> The deck reinforcement is shown in typical cross sections in figure 8.

**Table 9. Mean NWC deck properties by girder size.**

Girder Type	Compressive Strength (ksi)		Test Day Modulus of Elasticity (ksi)
	28 Day	Test Day	
Type II	3.15	4.72	4,970
BT-54	3.88	6.06	4,700

**Figure 8. Illustrations. NWC deck cast onto LWC girders for type II and BT-54 girders.**

After the first test failed in horizontal shear, the decks of all subsequent tests on type II girders were strengthened to resist horizontal shear throughout the test region by installing concrete wedge anchors through the deck. The holes for the anchors were drilled through the deck so the anchor could be mounted into the top flange of the girders. The concrete anchors were 12 inches (305 mm) long with a 0.75-inch (19.1-mm) nominal diameter. A 1.5-inch (38.1-mm)-thick square bearing plate was placed on the concrete deck. The nuts on the concrete anchors were torqued to 1.5 kip-inch (170 N-m) to provide a small compressive force to the deck.

## Flexural Strengthening Using Glass Fiber Reinforced Polymer (GFRP)

The first three shear tests (i.e., A7L, B7L, and C7L) reached a much higher applied shear force than expected, and there was concern that subsequent tests would not experience shear failures unless the flexural resistance of the girders was increased. GFRP was bonded to the lower surface and sides of the bottom flange on many of the remaining shear tests in order to increase the girder flexural capacity. For the tests that included GFRP, the distance from the support centerline to the start of each bottom and side layer is given in table 10. The GFRP layers were kept as far from the critical section for shear as possible in order to avoid increasing the girder's shear resistance due to the increased longitudinal restraint provided by the GFRP. The effect that longitudinal strain has on shear resistance was described previously in this report.

**Table 10. GFRP used on the shear girders for flexural strengthening.**

Test Number	Girder Design	Distance from Support Centerline to Start of Layer (Inches)					
		Bottom Layer 1	Bottom Layer 2	Bottom Layer 3	Bottom Layer 4	Side Layer 1	Side Layer 2
4	7	48	54	60	66	60	66
5-6	7	30	42	54	66	54	66
8-9	5	42	60	78	—	72	—
10-12	5	42	60	78	96	72	90
16-18	6	42	66	78	—	72	—
19-30	8, 9	84	108	—	—	120	—

1 inch = 25.4 mm.

—Layer not used.

GFRP used for flexural strengthening of the shear girders consisted of a unidirectional fiber fabric (SikaWrap Hex 107G) with impregnating resin (Sikadur 300) over a substrate primer (Sikadur 330). The datasheet for the fiber fabric stated that average tensile strength for the cured laminate was 87.6 ksi (604.0 MPa) and the elastic modulus was 3,700 ksi (25.5 GPa).

The surface was prepared using a concrete grinder to remove the surface paste and was then roughened using an abrasive coal-slag blasting media (grit 20-40). The substrate primer was applied using a roller immediately prior to applying the GFRP layers. The resin and hardener were blended with an electric paddle mixer. A roller was used to saturate both faces of fiber fabric. The saturated fabric was unrolled onto the bottom surface of the girder. A hard rubber roller was used to press the fabric layer in to the substrate primer and remove air bubbles. Additional layers of GFRP were installed in the same manner.

### Test Setup

A sketch of the test setup is shown in figure 9. Figure 10 shows a photograph of the setup for test C8D after the completion of the test. Before a test, the girder was supported by a roller at the end being subjected to high shear and by a hydraulic jack at the other end of the span. These supports are referred to as the “roller support” and the “loading jack,” respectively. The roller support consisted of a 6-inch (152-mm)-diameter steel roller and a 2-inch (51-mm)-thick steel bearing plate. The bearing plate had a width of 12 inches (305 mm) and was long enough to fully support

the width of the girder's bottom flange. Grout was placed between the girder and bearing plate to uniformly support the girder.

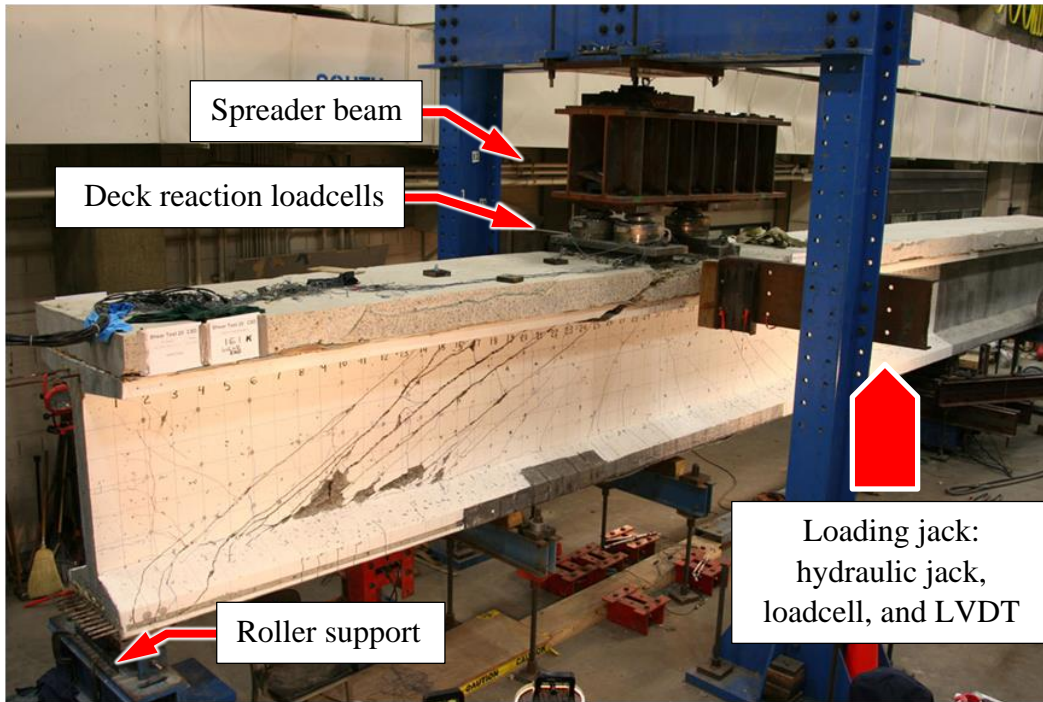

Source: FHWA.

1 inch = 25.4 mm.

C.L. = centerline.

**Figure 9. Illustration. Elevation view of the setup for girder shear tests.**

Source: FHWA.

**Figure 10. Photo. Test setup on girder test C8D with concrete crushing along the web.**

The loading jack is shown in figure 11. The girder rested directly on another 2-inch (51-mm)-thick and 12-inch (305-mm)-wide steel bearing plate. A greased Teflon™ sheet was placed between the bearing plate and a roller assembly. The roller assembly consisted of a 6-inch (152-mm)-diameter roller between two grooved plates. Below the roller assembly was a loadcell with a 300-kip (1,340-kN) capacity and then a hydraulic jack with a 1,000-kip (4,450-kN) capacity. If the full 10-inch (254-mm) stroke of the 1,000-kip (4,450-kN) primary actuator was inadequate to complete a test, two smaller auxiliary hydraulic actuators were used to temporarily support the girder while spacer plates were installed.

Source: FHWA.  
1 kip = 6.89 MPa.

A. End view.

Source: FHWA.

B. Side view.

**Figure 11. Photos. Loading jack end and side views.**

The load in the jack was controlled by a closed-loop servo-valve system. The feedback for the closed-loop system was provided by the loadcell and by a linear variable differential transformer (LVDT) with a 10-inch (254-mm) stroke. The loading was applied by specifying the jack force in load control or by specifying the jack travel in displacement control.

When the jack applied load to the girder, it was reacted by a heavy load frame through a spreader beam, spherical bearing plates, and two pairs of 300-kip (1,340-kN) loadcells on the deck that applied the reaction force into the girder. The loadcells were mounted to 4-inch (102-mm)-thick bearing plates that were grouted to the top of the deck. Figure 9, figure 10, and figure 12 show the bearing plates, loadcells, and spreader beams. The locations of the loadcell pairs on the deck are referred to as “deck reaction points” in this report.

Source: FHWA.

**Figure 12. Photo. Concrete deck anchors, loadcells at deck reaction points, and deck strain gauges.**

The distance from the roller support to the deck reaction points and the loading jack is shown in table 11 for the tests on the type II girders and in table 12 for the tests on the BT-54 girders. The distance between the centerline of the roller support and the closest deck reaction point is the shear span ( $a$ ). The test region for each girder end is defined as the portion of the girder along the shear span. The distance from the roller support to the loading jack is the span length ( $L$ ). The distance from the end of the girder to the rolling support ( $L1$ ) and the distance from the rolling support to the first anchor of the LVDT average strain rosette ( $L4$ ) are shown in table 11 and table 12. The variable dimensions  $a$ ,  $L$ ,  $L1$ , and  $L4$  are shown in figure 13 for the type II girders. These four dimensions were held constant for the tests on the BT-54 girders, as shown in figure 14, but for comparison purposes, the dimensions are shown in table 12. The distance to the first deck concrete anchor ( $L2$ ), the total number of anchors ( $N2$ ), and the ( $L3$ ) are found in table 11 and figure 13 for the type II girders.

### Instrumentation

The shear tests were extensively instrumented to measure applied jack force, deck reaction forces, girder deformations, girder curvature, reinforcement strain, average concrete strain in the web, strand end slip, and concrete deck strain. The electronic instruments were connected to a data acquisition system that recorded data at a rate of 0.1 Hz.

Horizontal and vertical deflections were measured using SPs. The locations of the anchor points for the SPs on the exterior of the type II and BT-54 girders are shown in figure 13 and figure 14,

respectively. Vertical deflections were measured using SPs attached to the bottom flange directly below the deck reaction points. Vertical and horizontal deflections were measured using SPs attached to the bottom flange directly over the loading jack. Horizontal deflections were measured using SPs attached to the bottom flange directly over the roller support. These SPs indirectly measured the deflection of the girder at the deck reaction points. The deflection at the deck reaction points was calculated as the measured change in vertical distance between the deck reaction anchor points and a straight line between the SP anchor points at the roller support and loading support. Girder deflection was directly measured at the deck reaction points using a taut-line system consisting of a weighted wire passing by pairs of rulers and mirrors attached to the top flange directly below the deck reaction points. The mirrors were used to correct for parallax before reading the deflection to the nearest  $\frac{1}{128}$  inch (0.20 mm) on the rulers. Photographs showing the components of the taut-line system are in figure 15.

**Figure 15. Photos. The anchor, measuring point, and loading point of the TLD measurement system.**

Four LVDTs mounted to the top and bottom flanges were used to measure girder curvature between the deck reaction points. At the girder ends, LVDTs were attached to four strands on the bottom row to measure any slip between the strands and the end of the girder. Figure 16 shows an LVDT mounted to an exterior strand to measure strand slip.

Source: FHWA.

**Figure 16. Photo. LVDTs used to measure strand slip.**

Strain in the shear reinforcement and strain in the end region reinforcement was measured using electric resistance strain gauges (ERSs). Figure 2 through figure 6 show the locations of ERSs for the five girder designs. ERSs were also used to measure the strain on the top surface of the deck between the deck loading points and the strain near the ends of the GFRP layers bonded to the bottom flange. Figure 12 shows the ERSs on the concrete deck.

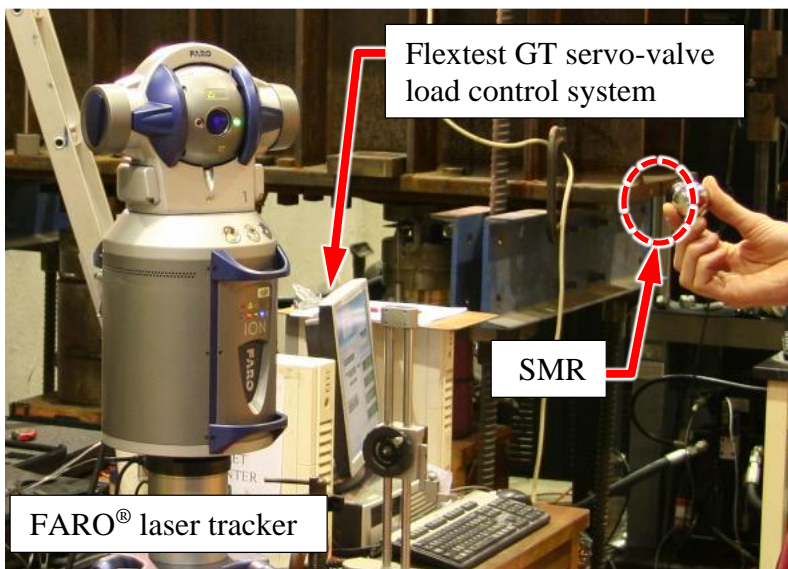

Average concrete strain over several cracks was measured using two LVDT rosettes mounted to the web near the critical section for shear. A rosette consisted of three LVDTs oriented to measure the displacement in the horizontal, vertical, and diagonal (45 degrees) directions. ERSs only measure the local strain on a stirrup and will measure much larger strains when a crack opens near the gauge. An LVDT measuring the displacement across several cracks measures an average strain and can be used to calculate the angle of inclination of the diagonal compressive stresses. Figure 17 shows a photograph of the two LVDT rosettes.

Source: FHWA.

**Figure 17. Photo. LVDTs used to measure the average concrete strain in a rosette.**

A noncontact laser tracking system, FARO<sup>®</sup>, was also used to measure average concrete strain. A laser from the FARO<sup>®</sup> tracker followed the triple-mirror prism in a spherical steel ball (SMR). The FARO<sup>®</sup> tracker and SMR are shown in figure 18. The ball was then placed in multiple targets mounted to the surface of the girder web and bottom flange. FARO<sup>®</sup> target locations are shown in figure 13 and figure 14. The FARO<sup>®</sup> tracker was used to record the three-dimensional position of all the targets at various loading increments. The change in position of adjacent targets was used to calculate the average strain. The FARO<sup>®</sup> measurements were repeatable to around 0.0010 inch (0.025 mm), which corresponds to less than 100 microstrain when the targets are spaced 12 inches (305 mm) apart.

Source: FHWA.

**Figure 18. Photo. FARO<sup>®</sup> laser tracker and load control system.**

The angle of the web-shear cracks was measured at the midheight of the web using the crack protractor shown in figure 19. A pencil line was drawn to estimate the path of the crack near the midheight of the web. A horizontal line on the protractor was aligned over the black horizontal line drawn at the midheight of the web. The axis of the protractor was centered over the intersection of the pencil line and the horizontal line. The protractor arm was rotated so that its tip aligned with the pencil line. The angle indicated by the tip of the protractor arm was read to the nearest 1.0-degree angle. The widths of the cracks crossing the midheight of the web were measured using a hand-held optical microscope. The microscope had 0.001-inch (0.025-mm) divisions. The location of the crack width reading was marked so that subsequent readings would be made at the same location.

Source: FHWA.

**Figure 19. Photo. Crack angle measurement using a crack protractor.**

### **Test Procedure**

Each test began in load control with the jack force increased in 5-kip (22-kN) increments up to about 80 percent of the load expected to cause web-shear cracking. Then the load increment was reduced to 2 kip (9 kN) until web-shear cracking occurred. The loading was paused at web-shear cracking in order to mark cracks, take photographs, measure deflections using the TLD system, measure crack widths and angles at the midheight of the web, and take FARO<sup>®</sup> measurements. After web-shear cracking, the loading was continued in 5-kip (22-kN) increments. The loading was paused four or five times to take measurements and photographs. The load increment after flexural cracking occurred was also recorded. At 80 percent of the expected failure load, the loading was switched to displacement control, and the girder was ramped to failure in increments of 0.25 to 0.45 inch (6.4 to 11.4 mm) corresponding to a load rate of 2 to 3 kip (9 to 13 kN) per 20 s. Flexural shear cracking typically occurred at higher load levels, commonly during the ramp to failure, so the test was not stopped to record these values.

## ANALYSIS OF TEST RESULTS

A summary of the girder tests is given in table 13 and table 14 for the type II and BT-54 girders, respectively. The summary includes the effective shear depth ( $d_v$ ), ratio of the shear span to effective shear depth ( $a/d_v$ ), concrete compressive strength ( $f'_c$ ) and splitting tensile strength ( $f_{ct}$ ) at age of testing, the total area of prestressing strands ( $A_{ps}$ ), the calculated effective stress in the prestressing steel after losses ( $f_{pe}$ ), the stirrup strength ( $\rho_v f_{yt}$ ) (which is the product of the shear reinforcement ratio given by equation 40 and the measured yield strength of the stirrups given in table 8), and whether the girder test was flexurally strengthened using GFRP. The effective shear depth was calculated using Article 5.8.2.9 in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The effective prestress was calculated using the approximate estimate of time-dependent losses in Article 5.9.5.3.

1 inch = 25.4 mm.

1 ksi = 6.89 MPa.

$$\rho_v = \frac{A_v}{b_v s} \quad (40)$$

The  $a/d_v$  ratios for the girder tests are given in table 13 and table 14. An  $a/d_v$  ratio of less than between 2.5 to 3.0 has been shown to increase the shear strength of a girder.<sup>(17,24)</sup> The target  $a/d_v$  ratio was 3.0; however, the girders were tested over a range of  $a/d_v$  ratios between 2.65 to 3.3. The shear span was adjusted from test to test during the first seven tests on type II girders in order to force a shear failure. However, starting with the seventh test, the shear span was left constant so variations in the  $a/d_v$  ratio in subsequent tests can be attributed to the differences in the calculated  $d_v$  for different girder designs.

A summary of the applied shear force and failure mode for the tested girders is given in table 15 and table 16 for the type II and BT-54 girders, respectively. The summary of shear forces includes the applied shear force at web cracking ( $V_{cr}$ ), the maximum applied shear force ( $V_{test}$ ), the average shear stress on the concrete ( $v_u$ ), and the ratio of the average shear stress on the concrete to the concrete compressive strength ( $v_u/f'_c$ ). The average shear stress was calculated from  $V_{test}$  using Article 5.8.2.9 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The effect of girder self-weight was included in the determination of  $V_{test}$ . A flexural failure was observed by concrete deck crushing. A flexural failure mode was indicated by the measured deck strain reaching its peak at  $V_{test}$  or slightly before  $V_{test}$ . The failure mode of GFRP debonding was indicated by the measured GFRP strain reaching its peak before  $V_{test}$ . The failure mode of strand slip was indicated by the maximum measured strand slip from four LVDTs reaching a value of 0.010 inch (0.25 mm) before  $V_{test}$ .

1 ksi = 6.89 MPa.

A summary of the level of yielding in the stirrups at  $V_{test}$ , the strand slip at  $V_{test}$ , and the peak strain in the concrete deck and GFRP at  $V_{test}$  is given in table 17 and table 18 for the type II and BT-54 girders, respectively. The level of yielding at  $V_{test}$  is given by the number of stirrups with a strain measured by ERSs ( $\epsilon_t$ ) greater than the yield strain ( $\epsilon_{ty}$ ), the number of stirrups with  $\epsilon_t$  greater than  $3\epsilon_{ty}$ , and the ratio of  $\epsilon_t$  to  $\epsilon_{ty}$ . In some tests, the failure modes of flexure (i.e., concrete deck crushing), GFRP debonding, and strand slip occurred prior to reaching  $V_{test}$ . Three columns in table 17 and table 18 indicate whether any of these three events (deck crushing, GFRP disbond, or strand slip) occurred prior to the applied shear force reaching  $V_{test}$ . In tests where these events occurred prior to  $V_{test}$ , the ratio of the applied shear at the event to  $V_{test}$  is given. A ratio of 1.000 indicates that the events (deck crushing, GFRP disbond, or strand slip) occurred at  $V_{test}$ . The columns state “No” if deck crushing, GFRP disbond, or strand slip occurred after the applied shear force reached  $V_{test}$ .

**Table 17. Stirrup strain, strand slip, and occurrence of deck crushing, GFRP debonding, or strand slip prior to ultimate for type II girders.**

## Failure Modes

The first girder tested, A7D, failed in horizontal shear through the concrete deck. Of the remaining tests on the type II girders, 4 girders failed in shear, and 13 girders failed in flexure. Six of the tests on the BT-54 girders failed in shear, and the remaining six girders failed in flexure.

As shown in table 15 and table 16, three different types of shear failures were experienced in the tests: concrete crushing over a large region of the web (i.e., shear web compression), concrete crushing near the support (i.e., shear compression at support), and rupture of the stirrups (i.e., shear bar rupture). In each test resulting in a shear failure, there was significant yielding in several of the stirrups as indicated by measured strains greater than three times the yield strain. Two of the type II girder tests that failed in shear experienced concrete crushing in the web over much of the test region. The other two type II girder tests failing in shear had concrete crushing as the diagonal compression was funneled to the support. An example of this kind of failure is shown in figure 27 for the test on C7L. Three of the BT-54 girders tests failed in shear after multiple stirrups ruptured. Two of the tests on BT-54 girders failed in shear after experiencing general yielding in the stirrups followed by local crushing in the web. This kind of failure is shown in figure 10 and figure 28 for the tests on C8D and C8L. The failure of test A9L is shown in figure 29 and was due to concrete crushing as the diagonal compression was funneled to the support.

Source: FHWA.

Source: FHWA.

**Figure 28. Photo. Shear failure of girder test C8L showing concrete crushing along web.**

Source: FHWA.

**Figure 29. Photo. Shear failure of girder test A9L showing concrete crushing near support.**

The tests resulting in flexural failures (see table 15 and table 16) were caused by crushing of the deck (i.e., flexural deck crushing) or by loss of resistance in the GFRP (i.e., flexural GFRP debonding). The loss of resistance in the GFRP was due to the GFRP at the end of a layer debonding from the concrete substrate or the GFRP, causing the concrete substrate to peel away from the bottom layer of strands. Five of the tests on type II girders and three of the tests on BT-54 girders failed after the deck concrete crushed. The flexural failure was initiated by loss of resistance in the GFRP in eight of the tests on type II girders and three of the tests on BT-54 girders.

## Test Observations

The first girder tested, A7D, was unintentionally loaded rapidly to an applied shear of 193 kip (858.9 kN) and then immediately unloaded. This shear was 64 percent of the maximum applied shear and below the shear that caused yielding of the stirrups. As a result of the rapid loading, the applied shear at web cracking was not determined. Girder test A7D ended after an arc-shaped crack formed through the thickness the deck, as shown in figure 30, resulting in a horizontal shear failure. Concrete anchors were installed through the decks along the test region in all subsequent tests of type II girders to prevent additional horizontal shear failures.

Source: FHWA.

**Figure 30. Photo. Horizontal shear failure of girder test A7L.**

Before test A7L failed in horizontal shear, there were eight stirrups that had reached a measured strain greater than three times the yield strain. The other two tests on girder design 7L (i.e., test 2 on girder B7L and test 3 on girder C7L) had fewer stirrups that had reached yielding and resulted shear-compression failures at the support. Almost no measurable strand slip was observed in these three tests.

Test 4 on A7D was the first girder test that was flexurally strengthened with GFRP. During the test, the end layer of GFRP removed some of the cover from the bottom face of the bottom flange. The test was continued and resulted in a web compression failure throughout the web. Evaluation of a video taken of the test region using a digital video camera showed that the failure initiated in the web between the support and the end of the GFRP. This observation supports the conclusion that the failure was due to shear and was not limited by the GFRP debonding.

The remaining six tests on type II girders resulted in flexural failures. All of the failures on specimens that were flexurally strengthened with GFRP were due to the debonding of the GFRP except for the test on girder C6L.

All three tests on girder design 8D failed in shear. This girder end had the lower amount of prestressing strands (when compared to girder design 9) and an amount of stirrups nearly equal to the minimum amount specified in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The test on B8L resulted in a flexural failure, but the other two tests on girder design 8L resulted in shear failures. The tests on girder design 8, except test C8L, had a maximum strand slip that exceeded 0.010 inch (0.25 mm) at  $V_{test}$ . The strand slip of test A8L had a maximum strand slip that exceeded 0.010 inch (0.25 mm) at an applied shear force of 50 percent of  $V_{test}$ .

Of the six tests on girder design 9, only test A9L resulted in a shear failure. Girder design 9 had a larger amount of prestressing strands and had a larger amount of shear reinforcement when compared to girder design 8.

### **Web Shear Cracking Angles**

The measured angles of the web-shear cracks are given in table 19 and table 20 for the type II and BT-54 girders, respectively. The crack angle was measured directly using a crack protractor. The FARO® and LVDT measurements were determined from smeared strain in the horizontal, vertical, and diagonal directions to calculate the direction of the principle compression strain. The minimum angle, maximum angle, and average angle of the cracks that crossed the midheight of the web between the centerline of the support and a distance of two times the effective depth ( $d_v$ ) from the centerline of the support are given in table 19 and table 20.

**Table 19. Web-shear-cracking angles for type II girders.**

—Direct measurements were not made.

Web shear crack angles were determined using the FARO® noncontact laser tracking system. The change in the distance between measurement targets was used to determine the average concrete strain in the horizontal, vertical, and diagonal directions. The locations of the targets are shown in figure 13 and figure 14 for the type II and BT-54 girders, respectively. The measurements between four targets were used to determine the crack angle. The horizontal strain was taken as the average of the strain determined from the two upper targets and the two lower targets. The vertical strain was taken as the average strain of two sets of targets spaced 12 inches (305 mm) apart. The diagonal strain was measured between the upper-left and lower-right targets. A diagonal average strain measured in this orientation crossed the cracks to give a tensile strain (i.e., not in the direction of the cracks to give a compressive strain). The horizontal, vertical, and diagonal average strains were used to determine the angle of the principle compressive strain (i.e., in the direction of the cracks). The minimum, maximum, and average angles determined from four targets centered between a distance of  $0.5d_v$  and  $1.5d_v$  from the centerline of the support are shown in table 19 and table 20.

The crack angles were also determined using the LVDT rosettes. The change in displacement measured by the LVDT was used to determine the average concrete strain in the horizontal, vertical, and diagonal directions. The locations of the LVDT anchors are shown in figure 13 and figure 14 for the type II and BT-54 girders, respectively, while figure 17 shows a photograph of the two LVDT rosettes. The horizontal, vertical, and diagonal average strains were used to determine the angle of the principle compressive strain (i.e., in the direction of the cracks). The angles given in table 19 and table 20 were the mean of the angles determined from the three LVDTs shown in figure 17 forming the rosette on the left-hand side with the angle determined from the three LVDTs forming the rosette on the right-hand side.

There was considerable variation in the web cracking angles determined from the crack protractor, FARO® measurements, and LVDT measurements. A comparison of individual crack measurements for each girder test is shown in the draft version of the research data; see appendix G for further details. Most of the individual crack measurements from the crack protractor ranged from 20 to 40 degrees with the mean crack measurements ranging from 23 to 37 degrees. Many of the crack angles determined using the FARO® and LVDT measurements were much smaller than the angles measured using the crack protractor. This is because the FARO® and LVDT measurements are sensitive to the location and number of cracks between the FARO® targets and LVDT anchors. For example, when a web-shear crack did not pass between two vertical measurement points (i.e., FARO® targets and LVDT anchors), the resulting principle angle was much smaller than if web-shear cracks had passed between vertical, horizontal, and diagonal measurement points.

## **EFFECT OF TEST PARAMETERS ON MAXIMUM SHEAR STRESS**

Three major variables in this study were the girder mix design, the amount of stirrups, and the girder depth. This section compares the test results for each of these variables.

### **Girder Mix Design**

The girder tests that resulted in a shear failure are provided in table 21. The tests are grouped by girder end design to compare the average shear stress ( $v_u$ ) of different mix designs, which was

based on  $V_{test}$  and determined using Article 5.8.2.9 in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>  $v_u$  normalized by concrete compressive strength and the splitting tensile strength is also shown in table 21. A comparison of the normalized  $v_u$  shows that there was very little difference between the different concrete mixtures.

**Table 21. Comparison of girder concrete mixture on the normalized shear stress at failure for girder tests resulting in shear failure.**

Girder Test	$v_u$ (ksi)	$v_u/f'_c$	$v_u/f_{ct}$	Failure Mode
B7L	1.90	0.184	2.41	Shear compression at support
C7L	1.83	0.177	2.52	Shear compression at support
A7D	1.93	0.209	2.37	Shear web compression
B7D	2.17	0.210	2.75	Shear web compression
A8D	0.92	0.082	1.21	Shear bar rupture
B8D	0.93	0.078	1.20	Shear bar rupture
C8D	0.84	0.072	1.14	Shear web compression
A8L	1.00	0.089	1.31	Shear bar rupture
C8L	0.97	0.084	1.33	Shear web compression

1 inch = 25.4 mm.

1 ksi = 6.89 MPa.

### Amount of Stirrups

$v_u$  is compared to the shear reinforcement ratio in figure 25.  $v_u$  is normalized by the concrete compressive strength and is compared to stirrup strength ( $\rho_v f_{yt}$ ), where the shear reinforcement ratio ( $\rho_v$  or also referred to as  $A_v/b_v s$ ) is given by equation 40. The test results are grouped by girder type (i.e., type II or BT-54 girders) and by failure type (i.e., shear failure or flexural failure). Regression lines are shown for the test results in each group. As expected, the regression lines in the figure showed a trend of  $v_u$  increasing as the amount of shear reinforcement increased. The regression lines shown in the figure are all nearly parallel, even the lines for tests ending in a shear failure and flexural failure.

### Girder Depth

The effect that girder depth had on the  $v_u$  is also shown in figure 25. The regression lines for the type II girders resulting in shear and flexural failures are parallel and nearly overlapping. Similarly, the regression lines for the BT-54 girders are parallel and overlapping. The regression lines for the type II girders are clearly above the regression lines for the BT-54 girders, indicating that, on average, the type II girders had larger  $v_u$  for a given amount of shear reinforcement.

$v_u$  is shown in table 22 for the two different girder depths. The table provides the results for three pairs of girder tests with similar amounts of longitudinal and shear reinforcement. Girder design 5D is compared to 8D, 5L is compared to 8L, and 7D is compared to 9D. Effective shear depth ( $d_v$ ), stirrup strength ( $\rho_v f_{yt}$ ), and prestressed longitudinal reinforcement ratio ( $A_{ps}/bd_v$  or also referred to as  $\rho_p$ ) are shown for each pair. For each pair,  $d_v$  of the BT-54 girders were approximately 50 percent greater than  $d_v$  of the type II girders, but  $\rho_v f_{yt}$  and  $A_{ps}/bd_v$  were nearly

equal. The mean normalized  $v_u$  for girder design 5D was 25 percent larger than the mean normalized  $v_u$  for girder design 8D. For girder design 5L, the mean normalized  $v_u$  was 16 percent larger than the mean normalized  $v_u$  for girder design 8L. Similarly, the mean normalized  $v_u$  for girder design 7D was 42 percent larger than the mean normalized  $v_u$  for girder design 9D. Except for girder design 8D, some or all of the tests in each of the groups failed in flexure, so the exact magnitude was not as important as the observation that for each girder test compared, the normalized  $v_u$  for the type II girders was noticeably higher.

**Table 22. Comparison of girder end design on the normalized shear stress at failure for girder tests resulting in shear failure.**

Girder Test	$d_v$ (Inches)	$\rho_v f_{yt}$ (ksi)	$A_{ps}/bd_v$ (Percent)	$v_u$ (ksi)	$v_u/f'_c$	Failure Mode

## COMPARISON OF TEST RESULTS TO PREDICTED SHEAR RESISTANCE

The shear resistances predicted by the design expressions in the *AASHTO LRFD Bridge Design Specifications* were compared to  $V_{test}$ .<sup>(3)</sup> The design expressions include the two general procedure methods (GP-table and GP-equation) and the Simplified-PC/RC method.<sup>(3)</sup> The comparisons are given as test-to-prediction ratios for each design expression. Two parameters,  $\beta$  and  $\theta$ , were calculated to determine the shear resistance using the GP-table and GP-equation methods. The *AASHTO LRFD Bridge Design Specifications* allows parameters  $\beta$  and  $\theta$  to be determined using equations in Article 5.8.3.4.2 (i.e., GP-table), or the parameters can be determined using table B5.2-1 and table B5.2-2 in appendix B5 (i.e., GP-equation).<sup>(3)</sup> Test-to-prediction ratios were determined for  $\beta$  and  $\theta$  using the GP-table, GT-equation, and Simplified-PC/RC methods.

## Procedure for Determining Shear Resistance

For the GP-equation method,  $\beta$  and  $\theta$  are a function of the net longitudinal tensile strain in the section at the centroid of the tension reinforcement ( $\varepsilon_s$ ) and are solved for in equation 21 and equation 24, respectively.  $\varepsilon_s$  is also given by equation 18 and equation 19. Specifically, when the calculated  $\varepsilon_s$  is positive, indicating a net tensile strain at the centroid of the reinforcement, equation 18 is used. When the calculated  $\varepsilon_s$  is negative, indicating a net compressive strain, equation 19 is used.

For the GP-table method,  $\beta$  and  $\theta$  depend on the longitudinal strain at the middepth of the beam ( $\varepsilon_x$ ) and the normalized shear stress in the section ( $v_u/f'_c$ ).  $\varepsilon_x$  is determined using equation 26 when its value is positive, and it is determined using equation 27 when  $\varepsilon_x$  is negative. Both equation 26 and equation 27 are a function of  $\theta$ , which makes the GP-table method iterative.  $v_u$  is determined using equation 15. The commentary of appendix B5 allows the values of  $\beta$  and  $\theta$  determined from table B5.2-1 and table B5.2-2 in the *AASHTO LRFD Bridge Design Specifications* to be applied over a range of values.<sup>(3)</sup> For this analysis, three-way interpolation between the table cells that bound the pair of  $v_u/f'_c$  and  $\varepsilon_x$  values were used to determine a more exact value of  $\beta$  and  $\theta$ .

The parameters  $\beta$  and  $\theta$  are determined using either the GP-equation or GP-table methods. They are used to determine the nominal shear resistance provided by tensile stresses in the concrete ( $V_c$ ) and the nominal shear resistance provided by the shear reinforcement ( $V_s$ ) to the nominal shear resistance ( $V_n$ ). The expressions for  $V_c$  and  $V_s$  are provided in equation 16 and equation 17, respectively.  $V_n$  is the smaller of the values determined using equation 13 and equation 14.

The Simplified-PC/RC uses the smaller of  $V_{cw}$  determined using equation 28 and  $V_{ci}$  determined using equation 29 as the contribution of  $V_c$ .  $V_s$  is a function of  $\cot \theta$ , which is taken as 1.0 when  $V_{ci}$  is less than  $V_{cw}$  and is shown in equation 35 when  $V_{ci}$  is greater than  $V_{cw}$ . Similar to the two general procedure methods, the nominal shear resistance is the smaller of the values determined using equation 13 and equation 14.

The nominal shear resistance was calculated for each girder test at the critical section for shear. The critical section for shear is given by Article 5.8.3.2 of the *AASHTO LRFD Bridge Design Specifications* as  $d_v$  from the internal face of the support.<sup>(3)</sup> For the girder tests, the critical section was taken as the distance from the centerline of the rolling support equal to half the width of the 12-inch (305-mm)-wide bearing plate plus  $d_v$  calculated using equation 5.

## Iterative Process for the General Procedure

The expressions for  $\varepsilon_s$  used in the GP-equation method and  $\varepsilon_x$  used in the GP-table method are functions of the applied shear. As the applied shear increases, the calculated longitudinal strain as  $\varepsilon_s$  or  $\varepsilon_x$  also increases. The values of  $\beta$ , and, as a result,  $V_c$  and  $V_n$ , decrease as the applied shear and the longitudinal strain increase.  $V_n$  calculated directly from  $V_{test}$  would result in  $V_n$  that is too small when  $V_{test}$  is greater than  $V_n$  and too large when  $V_{test}$  is less than  $V_n$ . This concept is illustrated by figure 31 for the case of  $V_{test}$  greater than  $V_n$  (i.e.,  $V_{test}/V_n > 1$ ). The figure shows that for the first calculation of  $V_n$ ,  $V_u$  was taken equal to  $V_{test}$ . Because the calculated  $V_n$  was less than the assumed  $V_u$ , the calculation of  $V_n$  was repeated (i.e., iteration 2) with a smaller assumed

value of  $V_u$ . The iterations were continued until the calculated  $V_n$  equaled the assumed  $V_u$ . The resulting test-to-prediction ratios for each successive iteration decreased because the calculated  $V_n$  increased. This procedure of iteratively determining for  $V_n$  was performed independently for both the GP-equation and GP-table methods. The actual process of varying  $V_u$  was handled numerically by multiplying the calculated support reaction due to the applied load by a factor (i.e.,  $\delta$ ).  $\delta$  is a factor multiplied by the internal shear force and internal moment as part of the iterative procedure to determine nominal shear resistance. As a result, both  $V_u$  and  $M_u$  in equation 18 and equation 19 for  $\varepsilon_s$  and equation 25 through equation 27 for  $\varepsilon_x$  were affected by the  $\delta$ -factor. Iterations to determine  $V_n$  using Simplified-PC/RC are not required. This is because the  $\delta$ -factor in the  $V_i$  and  $M_{max}$  terms of the expression for  $V_{ci}$  cancel out.

**Figure 31. Graph. Iteration procedure to determine shear resistance for a test-to-prediction ratio greater than 1.**

Where:

$V_{n1}$  = calculated nominal shear resistance of the section ( $V_n$ ) corresponding to first assumed value of the factored shear force at the section ( $V_u$ ).

$V_{n2}$  = calculated  $V_n$  corresponding to second assumed value of  $V_u$ .

$V_{u, assumed}$  = assumed value of  $V_u$  equals  $V_n$ .

$V_{u1, assumed}$  = first assumed value of  $V_u$ .

$V_{u2, assumed}$  = second assumed value of  $V_u$ .

### Analysis of Predicted Results

This section discusses the test-to-prediction ratios for the LWC girder tests determined using the GP-equation method, the GP-table method, and the Simplified-PC/RC method.

Test-to-prediction ratios for the three procedures are given in table 23 with no modification for LWC (i.e.,  $\lambda$  taken as 1). The ratios are grouped by girder type and failure type. The ratios are shown graphically in figure 32 through figure 40 versus compressive strength ( $f'_c$ ), effective shear depth ( $d_v$ ), and stirrup strength ( $\rho_v f_{yt}$ ) for each procedure. The shear reinforcement ratio ( $\rho_v$ ) is given by equation 40. The ratios are shown in four groups: tests on type II girders resulting in shear failures, tests on type II girders resulting in flexural failures, tests on BT-54 girders resulting in shear failures, and tests on BT-54 girders resulting in flexural failures. A regression line is shown for the data in each group.

**Table 23. Test-to-prediction ratio of shear resistance for design expressions with no modification for LWC.**

Girder and Failure Types*	Design Expression	Mean	COV (Percent)	Maximum	Minimum	Percent Test-to-Prediction Ratio	
						<1.0	<0.8
Type II shear failure (4)	GP-equation	1.39	7.9	1.50	1.24	0.0	0.0

**Figure 40. Graph. Test-to-predicted shear resistance for Simplified-PC/RC with no LWC modification ( $\lambda$ -factor = 1) compared to stirrup strength.**

The test-to-prediction ratios in table 23 show that all three procedures gave conservative predictions (i.e.,  $V_{test}/V_n > 1$ ) for all of the tests failing in shear. The Simplified-PC/RC procedure had the smallest mean ratio for the type II girders and the largest mean ratio for the BT-54 girders. The mean ratios for GP-equation and GP-table were similar to each other for both girder sizes. The COV was between 4.4 and 9.5 percent for all three methods. The COV is an indication of how close the ratios are to the mean value, with a smaller COV value indicating that there is less scatter. The ratios for tests ending in a flexural failure are shown for informational purposes only. Table 23 also shows that the ratios for the both the GP-equation and the GP-table procedures are larger for the type II girders than the BT-54 girders. The opposite is shown for the Simplified-PC/RC procedure with the ratios for the BT-54 girders larger than the type II girders.

The ratios shown in figure 32 through figure 34 for the GP-equation procedure and in figure 35 through figure 37 for the GP-table procedure show similar trends. The main difference is the slight upward shift in the ratios for the GP-table procedure. The ratios shown in figure 38 through figure 40 for the Simplified-PC/RC procedure are comparable to those of either general procedure method. The most noticeable difference is the increase in test-to-prediction ratio given by the Simplified-PC/RC procedure for the BT-54 girders with compressive strengths near 12 ksi (82.7 MPa).

### **Analysis of Predicted Results Including Modification for LWC**

The test-to-prediction ratios for the LWC girder tests that did not include modification for LWC were compared to the ratios that do include modification for LWC (see table 24). The modification for LWC is based on the inclusion of a  $\lambda$ -factor in the expressions for determining the nominal shear resistance. The proposed expressions that include the  $\lambda$ -factor are described in chapter 5 of this report. Table 24 includes test-to-prediction ratios determined using a  $\lambda$ -factor based on  $w_c$  given by equation 36 through equation 38 and based on splitting tensile strength given by equation 39.

The ratios in table 24 are for tests that ended in a shear failure. The LWC girder tests used high-strength SDC. The  $\lambda$ -factor based on  $w_c$  was slightly less than 1.0 for the LWC girder tests and resulted in test-to-prediction ratios slightly higher than the ratios with a  $\lambda$ -factor of 1.0. The high-strength concrete also had a relatively high splitting tensile strength, and the  $\lambda$ -factor based on  $f_{ct}$  was equal to 1.0, resulting in identical ratios to those without modification for LWC.

**Table 24. Test-to-prediction ratio of shear resistance for design expressions with no modification for LWC, proposed expression for the  $\lambda$ -factor and modification for LWC based on splitting tensile strength.<sup>(3)</sup>**

## COMPARISON OF TEST RESULTS TO PREDICTED WEB-SHEAR CRACKING

The measured shear force at web-shear cracking and the web-shear crack inclination angle from the girder tests were compared to the shear force and angle predicted by the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The crack angles were measured directly using a crack protractor to determine the angle of the web cracks that crossed the midheight of the web. The measured crack angle values are given in table 19 and table 20.

The measured shear force at web cracking and inclination angle were compared to the predictions given by the GP-equation method, the GP-table method, and the Simplified-PC/RC procedure. The prediction of the shear force and inclination angle by GP-equation was taken as  $V_c$  and  $\theta$ , respectively. For the purpose of predicting the shear force at web-shear cracking, the value of  $\beta$  was calculated assuming that there were no stirrups because web-shear cracking is essentially the limiting shear resistance for members without shear reinforcement. The value of  $\beta$  was determined using equation 22 with the factor  $s_x$  taken as the effective  $d_v$  according to Article 5.8.3.4.2 in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The prediction by GP-table was also taken as  $V_c$  and  $\theta$  for the shear force and inclination angle, and the value of  $\beta$  was calculated assuming that there were no stirrups. The shear force and inclination angle predicted by the Simplified-PC/RC procedure was taken as  $V_{cw}$  and  $\theta$  determined from equation 35.

The test-to-prediction ratios for the shear force at web-shear cracking for the three procedures are given in table 25 with no modification for LWC (i.e., the  $\lambda$ -factor taken as 1). The ratios are grouped by girder type and failure type for comparison with the test-to-prediction ratios shown in previous tables. The ratios are also shown for all type II and all BT-54 girders. The table shows that the shear force at web-shear cracking for all of the LWC girder tests was conservatively predicted (i.e., test-to-prediction ratios greater than 1.0) by all three procedures.

**Table 25. Test-to-prediction ratio of the shear force at web-shear cracking for design expressions with no modification for LWC.<sup>(3)</sup>**

Girder Type and Failure Type*	Design Expression	Mean	COV (Percent)	Maximum	Minimum	Percent Test-to-Prediction Ratio	
						<1.0	<0.8
Type II shear failure (4)	GP-equation	2.62	11.7	2.92	2.32	0.0	0.0
Type II shear failure (4)	GP-table	2.17	6.9	2.31	2.02	0.0	0.0
Type II shear failure (4)	Simplified-PC/RC	1.37	7.6	1.51	1.26	0.0	0.0
Type II flexure failure (13)	GP-equation	2.29	17.5	2.96	1.81	0.0	0.0
Type II flexure failure (13)	GP-table	1.81	17.0	2.33	1.46	0.0	0.0
Type II flexure failure (13)	Simplified-PC/RC	1.34	8.0	1.46	1.07	0.0	0.0
BT-54 shear failure (6)	GP-equation	1.90	7.8	2.11	1.72	0.0	0.0
BT-54 shear failure (6)	GP-table	1.40	9.2	1.63	1.27	0.0	0.0

BT-54 flexure failure (6)	Simplified-PC/RC	1.29	8.4	1.47	1.18	0.0	0.0
Type II (17)	GP-equation	2.37	16.8	2.96	1.81	0.0	0.0
Type II (17)	GP-table	1.90	16.6	2.33	1.46	0.0	0.0
Type II (17)	Simplified-PC/RC	1.35	7.7	1.51	1.07	0.0	0.0
BT-54 (12)	GP-equation	2.16	15.4	2.60	1.72	0.0	0.0
BT-54 (12)	GP-table	1.62	16.9	1.98	1.27	0.0	0.0
BT-54 (12)	Simplified-PC/RC	1.24	10.0	1.47	1.06	0.0	0.0

\*The number of specimens is shown in parentheses.

Note: Test A7L failing in horizontal shear was included with type II flexural failures; however, shear force at web-shear cracking was not recorded for test A7L, and the test is not included in this table.

COV for the Simplified-PC/RC procedure was the lowest at 7.7 percent for the type II girders and 10 percent for the BT-54 girders. The variation in ratios was similar for both general procedure methods at a mean of 16.7 percent for the type II girders and 16.2 percent for the BT-54 girders. The Simplified-PC/RC procedure gave the lowest mean ratios at 1.35 for the type II girders and 1.24 for the BT-54 girders. The mean ratios given by the GP-equation procedure at 2.37 and 2.16 for the type II and BT-54 girders, respectively, were the highest.

All three procedures underestimated how much lower the shear force at web-shear cracking would be in the tests of the larger girders. The mean ratios for the BT-54 girders using the GP-equation, GP-table, and Simplified-PC/RC procedure were 21, 28, and 11 percent lower, respectively, than the mean ratios for the type II girders.

The test-to-prediction ratios for the angle of inclined web-shear cracking for the three procedures are given in table 26 with no modification for LWC (i.e., the  $\lambda$ -factor taken as 1). The ratios were grouped by girder type and failure type for comparison with the ratios shown in previous tables. The ratios are also shown for all type II girders and all BT-54 girders. A range of crack angles was measured along the girder web between the centerline of the support and a distance of two times the effective depth ( $2d_v$ ) from the centerline of the support. The mean of the measured crack angles in each test was used to determine the test-to-prediction ratios for each test. The mean of test-to-prediction ratios for all of the girder tests was based on the average measured crack angle. The average measured crack angle was also the basis for the COV, maximum value, and minimum value of the ratios for all of the girder tests. The predicted values were also compared to the largest and smallest measured crack angles in the range of angles measured along the girder web. The percent of predicted crack angles less than the range of measured angles and the percent of predicted crack angles greater than the range of measured angles are shown in table 26.

**Table 26. Test-to-prediction ratio of angle of inclination for web-shear cracks for design expressions with no modification for LWC.<sup>(3)</sup>**

Girder Type and Failure Type <sup>a</sup>	Design Expression	Mean	COV (Percent)	Maximum	Minimum	Percent of Predicted Angles	
						Less than Minimum Range <sup>b</sup>	Greater than Maximum Range <sup>c</sup>

Type II flexure failure (14)	Simplified-PC/RC	1.10	11.7	1.26	0.80	35.7	7.1
BT-54 shear failure (5)	GP-equation	0.96	3.0	0.99	0.92	0.0	20.0
BT-54 shear failure (5)	GP-table	0.68	2.9	0.70	0.65	0.0	100.0
BT-54 shear failure (5)	Simplified-PC/RC	0.91	4.1	0.96	0.87	0.0	60.0
BT-54 flexure failure (6)	GP-equation	1.01	3.0	1.06	0.97	0.0	0.0
BT-54 flexure failure (6)	GP-table	0.74	2.7	0.77	0.72	0.0	100.0
BT-54 flexure failure (6)	Simplified-PC/RC	0.99	5.8	1.04	0.88	0.0	16.7
Type II (18)	GP-equation	1.11	11.6	1.29	0.81	50.0	5.6
Type II (18)	GP-table	0.89	12.1	1.06	0.64	0.0	44.4
Type II (18)	Simplified-PC/RC	1.10	11.6	1.26	0.80	38.9	5.6
BT-54 (11)	GP-equation	0.99	4.1	1.06	0.92	0.0	9.1
BT-54 (11)	GP-table	0.71	5.3	0.77	0.65	0.0	100.0
BT-54 (11)	Simplified-PC/RC	0.95	6.7	1.04	0.87	0.0	36.4

<sup>a</sup>The number of specimens is shown in parentheses.

<sup>b</sup>The percent of predicted angles is less than the minimum value of the range of measured web cracking angles.

<sup>c</sup>The percent of predicted angles is greater than the maximum value of the range of measured web cracking angles.

Note: Test A7L failing in horizontal shear is included with type II flexural failures; however, crack angles were not recorded for test A9D, and the test is not included in this table.

The web crack–inclination angles predicted by the three procedures were close to the measured values for many of the tests. A test-to-prediction ratio greater than 1.0 indicates that the predicted angle was smaller than the measured angle (i.e., the crack predicted to be closer to horizontal). A smaller predicted angle will result in an increase in the predicted contribution of the stirrups to the nominal shear resistance (larger  $V_s$ ) and, for the GP-table procedure, a slight decrease in the predicted  $V_c$  (through the larger calculated  $\epsilon_s$ ).

The mean ratios closest to 1.0 were given by the Simplified-PC/RC procedure for the type II girders at 1.10 and by the GP-equation procedure for the BT-54 girders at 0.99. The GP-equation procedure had a mean ratio greater than 1.0 for the type II girders and underestimated the smallest measured inclination angle for 50 percent of the type II girder tests. An underestimation of the inclination angle will result in an increase in the predicted contribution of the stirrups to the nominal shear resistance (i.e., a larger  $V_s$ ). The GP-table procedure predicted inclination angles greater than the range of measured angles for all of the BT-54 girders. The mean COV for the predictions was low for the type II girders at 11.8 percent and even lower for the BT-54 girders at 5.4 percent. All three procedures had lower mean ratios for the BT-54 girders than for the type II girders, indicating that the procedures predicted larger cracking angles than the measured angles for the larger-sized BT-54 girders.

## SUMMARY OF EXPERIMENTAL RESULTS AND CONCLUDING REMARKS

The performance of 15 prestressed girders was evaluated in 30 tests to investigate the shear resistance of high-strength LWC. Key test parameters included the lightweight aggregate, the amount of shear reinforcement, the girder depth, and the use of straight or draped strands. Five girder designs were developed to evaluate the effect of the key parameters. The end of each girder had different amounts of shear reinforcement. Three different concrete-mixture designs using three different lightweight aggregates were used. The mix designs included two expanded shales and one expanded slate. The concrete mixtures used a blend of lightweight and normal-weight coarse aggregate and normal-weight sand. These mixes were prescriptively produced at the precaster's facility and used to produce the 15 prestressed girders. The design compressive strength ranged from 6 to 10 ksi (41 to 69 MPa), and the target unit weight ranged from 0.126 to 0.130 kcf (2,020 to 2,080 kg/m<sup>3</sup>). The resulting concrete had a range in 28-day compressive strength of 8.6 to 9.7 ksi (59.3 to 66.9 MPa) and an air-dry density range of 0.125 to 0.132 kcf (2,000 to 2,110 kg/m<sup>3</sup>).

The maximum applied shear force was compared to the shear resistance predicted by three design procedures in the *AASHTO LRFD Bridge Design Specifications*: the GP-equation method (see Article 5.8.3.4.1), the GP-table method (see appendix B5), and the Simplified-PC/RC method (see Article 5.8.3.4.2).<sup>(3)</sup> The measured shear force at web-shear cracking and the inclination angle of the web-shear cracks was also compared to the values predicted by the same three design procedures in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

One girder test failed in horizontal shear through the concrete deck. Four of the remaining tests on the type II girders failed in shear, and 13 girders failed in flexure. Six of the tests on the BT-54 girders failed in shear, and the remaining six girders failed in flexure.

As expected, the average shear stress at failure increased as the amount of transverse reinforcement increased. The mean shear stress at failure for the type II girders was larger than for the BT-54 girders. The effect of reduced shear strength with increased girder depth was observed for three separate groups of tests. Each group of tests had similar percentages of longitudinal and transverse reinforcement. The mean test-day compressive strength was near 10 ksi (68.9 MPa) for all three girder mixes. No dependency on aggregate was observed in the average shear stress at failure.

All three design procedures in the *AASHTO LRFD Bridge Design Specifications* gave conservative predictions of shear resistance for the tests failing in shear.<sup>(3)</sup> The two general procedure methods gave less conservative predictions of shear resistance for the BT-54 girders than the type II girders. The opposite was observed with the Simplified-PC/RC procedure, which gave more conservative predictions of shear resistance for the BT-54 girders than the type II girders. All of these predictions were made without modification for LWC. The high splitting tensile strength of most of the girders did not require modification for LWC according to Article 5.8.2.2 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

The shear force at web-shear cracking was conservatively predicted by all three design procedures in the *AASHTO LRFD Bridge Design Specifications* for all of the tests.<sup>(3)</sup> The GP-equation procedure and the Simplified-PC/RC procedure gave the most conservative and least conservative predictions of web-shear cracking for both the type II and BT-54 girders, respectively. All three design procedures gave less conservative predictions of web-shear cracking for the BT-54 girders than for the type II girders.

On average, the three design procedures in the *AASHTO LRFD Bridge Design Specifications* tended to underestimate the web-shear-crack-inclination angle of the type II girders (i.e., the observed crack angle was greater than the predicted angle) and overestimate the web-shear crack inclination angle of the BT-54 girders (i.e., observed crack angle was less than the predicted angle).<sup>(3)</sup> An underestimation of the inclination angle results in an increase in the predicted contribution of the stirrups to the nominal shear resistance (i.e., a larger  $V_s$ ).

## CHAPTER 4. TFHRC SHEAR DATABASE

### INTRODUCTION

This chapter describes the information available in the TFHRC shear database.<sup>1</sup> The type of information included in the database for each specimen is described. The number of each type of specimen and the types of concrete mixtures found for each specimen type is described. A large number of NWC specimens are available in a database collected by a joint ACI Committee 445 and Deutscher Ausschuss für Stahlbeton (i.e., the German Committee for Structural Concrete; DafStb).<sup>(44-47)</sup> The method used to select specimens from the ACI-DafStb database for comparison with LWC specimens in the TFHRC shear database is described.<sup>(44)</sup> This chapter also includes statistical information by concrete-mixture type and specimen type for the tests in the internal TFHRC shear database.

### TFHRC SHEAR DATABASE SUMMARY

A thorough literature review was performed to find published journal papers, conference papers, technical reports, and university dissertations that included tests, analysis, or discussions of LWC. Over 500 references were found in the literature that mentioned LWC. These references were reviewed for data from tests on beam and girder specimens. Tests included in the database were limited to data from RC and PC beams that culminated in a shear failure. (For sources, see Bibliography section LWC Sources for TFHRC Shear Database.) The details of the specimens in each reference are described in the following section. Only test data from published reports were included in the database.

There were 40 references with shear tests on LWC specimens that resulted in a shear failure. Table 27 shows the number of references per specimen type. The specimen types include tests on RC beams with and without shear reinforcement (i.e., specimens with and without  $A_v$ ) and PC beams with and without shear reinforcement. The tests on beams and girders with shear reinforcement included specimens that did not meet the requirements for minimum shear reinforcement in Article 5.8.2.5 or the requirements for maximum spacing of shear reinforcement in Article 5.8.2.7 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

Table 27 shows that the tests for each specimen type came from several different references. While some references had many more shear tests than other references, the mean number of tests from a reference was greater than or equal to five. This indicates that the test results from one reference are not likely to improperly bias the analysis of the test data.

---

<sup>1</sup>The TFHRC shear database is not publicly available. For a list of available sources, see Bibliography section LWC Sources for TFHRC Shear Database.

**Table 27. Summary of the source information for tests on LWC in the TFHRC shear database by specimen type.**

Specimen Type	Total Number of Sources	Source*	Number of Tests per Source

\*Source information can be found in the LWC Sources for TFHRC Shear Database section in the Bibliography.

The information collected for each test included its concrete mixture, associated concrete mechanical property tests, test specimen dimensions, and test results. The recorded concrete mechanical tests included compressive strength, modulus of elasticity, splitting tensile test, modulus of rupture, and Poisson's ratio. Up to two measures of concrete density were also recorded. Concrete-mixture information was recorded, including the type of coarse and fine aggregate, the use of chemical admixtures, and the use of supplementary cementitious materials. Information about the mechanical tests was recorded, including the specimen size, duration and type of curing, and specimen age.

Measured concrete and steel material properties were used when reported. When material properties were not reported, nominal values were used as appropriate (e.g., reinforcement yield strength) and predictions using expressions in the *AASHTO LRFD Bridge Design Specifications* were used as appropriate (e.g., for concrete modulus of elasticity).<sup>(3)</sup> The effective prestress was calculated using the approximate estimate of time-dependent losses in Article 5.9.5.3.

In addition to data from tests on LWC, a select number of tests on NWC were also included in the database for comparison. The ACI-DafStb database has data from 928 specimens. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.) A subset of the ACI-DafStb database was selected for comparison to the LWC specimens and included in the TFHRC shear database. The criteria used to select the NWC specimen from the ACI-DafStb database is described later in this chapter. A list of references for the tests of LWC in the TFHRC shear database and the selected NWC specimens in the ACI-DafStb Database is included in the Bibliography section.

## Test Specimens

This section describes the types of specimens included in the TFHRC shear database and the type of information collected for each specimen type. The data were limited to specimens that were determined to have failed in shear. If a failure mode was recorded in the literature, only specimens indicated as having failed in shear without bond failure were included. The moment caused by the ultimate force applied to the specimen was also compared to the nominal moment capacity determined using the *AASHTO LRFD Bridge Design Specifications* (see equation 9).<sup>(3)</sup> If the ultimate applied moment was larger than the moment capacity, the failure was considered to be potentially affected by a large longitudinal strain, and the specimen was excluded from the database.

Table 28 provides a summary of the number of tests for each concrete-mixture type relevant to each specimen type in the TFHRC database. The definitions of different types of LWC mixtures have been traditionally based on the use of lightweight or normal-weight constituent materials. The types of concrete mixtures used in the database included all-lightweight, sand-lightweight, specified density, and inverted mix. All-lightweight is defined as concrete with lightweight fine and coarse aggregate, while sand-lightweight is defined as concrete with lightweight coarse aggregate and either sand or a mixture of sand and lightweight fine aggregate. SDC is defined as concrete with a mixture of normal-weight and lightweight coarse aggregate and either sand or lightweight fine aggregate. An inverted mix has normal-weight coarse aggregate and lightweight fine aggregate. The tests indicated as "ACI-DafStb" are the selected tests from the ACI-DafStb database. These four databases, two for RC beams with and without shear reinforcement and two

for PC beams with and without shear reinforcement, are referred to in this report as the ACI-DafStb database. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.)

**Table 28. Number of tests in the TFHRC shear database by specimen type and concrete mixture.**

Specimen Type	Number of LWC Tests					Number of NWC ACI-DafStb Tests
	All-Lightweight	Sand-Lightweight	Specified Density	Inverted Mix	Total	
RC without $A_v$	151	156	0	0	307	648
RC with $A_v$	12	57	0	1	70	107
PC without $A_v$	14	9	7	0	30	100
PC with $A_v$	12	17	11	1	41	31
Total	189	239	18	2	448	886

A summary of the number of LWC tests in the TFHRC shear database is shown in table 29 by cross-sectional shape and presence of a cast-in-place (CIP) deck. The cross-sectional shapes in the database are rectangular, T-beams, and I-beams. The CIP decks were either LWC or NWC. A total of 81 percent of the RC specimens had a rectangular cross section, and none of the RC specimens had a CIP deck. Only 37 percent of the PC specimens had a rectangular cross section, and 35 percent had an LWC or NWC deck.

**Table 29. Number of tests on LWC in the TFHRC shear database by specimen type, cross section, and CIP deck.**

Specimen Type	Total LWC*	Cross-Section Shape			CIP Deck		
		Rectangular	T-Beam	I-Beam	No Deck	LWC Deck	NWC Deck
RC without $A_v$	307	255	43	9	307	0	0
RC with $A_v$	70	51	5	14	70	0	0
PC without $A_v$	30	22	0	8	28	0	2
PC with $A_v$	41	4	0	37	18	7	16
Total	448	332	48	68	423	7	18

\*Total LWC specimens includes all-lightweight, sand-lightweight, specified density, and inverted mix.

The tests performed as part of the research program at TFHRC on LWC as described previously in this report are included in the TFHRC shear database. The tests were PC specimens with an area of the shear reinforcement within the spacing ( $A_v$ ), using SDC with an I-shaped cross section and an LWC deck.

### **Distribution of Statistical Parameters for Specimens in the TFHRC Shear Database**

A series of tables and figures were created to give statistical information for the parameters that influence shear resistance for the specimens in the TFHRC shear database. The statistical information is given by type of concrete mixture and then given again by type of specimen.

The information for RC specimens and PC specimens is shown by concrete mixture in table 30 and table 31, respectively. Table 32 provides the information for all RC and PC specimens.

The statistical information in the tables includes the mean value and range of values (i.e., maximum and minimum values) for concrete material properties, specimen geometry parameters, and maximum shear stress values. The concrete material properties include the compressive strength ( $f'_c$ ), splitting tensile strength ( $f_{ct}$ ), and unit weight ( $w_c$ ). The specimen geometry parameters include the effective depth for shear ( $d_v$ ), the ratio of the shear span ( $a$ ) to effective shear depth ( $d_v$ ), the nonprestressed longitudinal reinforcement ratio ( $\rho_\ell$  or also referred to as  $A_s/bd_s$ ) for RC specimens or the prestressed longitudinal reinforcement ratio ( $\rho_p$  or also referred to as  $A_p/b_p s$ ) for PC specimens, and the stirrup strength ( $\rho_v f_{yt}$ ). The average shear stress ( $v_u$ ) and the ratio of  $v_u$  to  $f'_c$  are also given.

**Table 30. Distribution of properties for RC specimens failing in the shear in TFHRC shear database.**

Concrete-Mixture Type*	Property	Without Stirrups			With Stirrups		
		Mean	Maximum	Minimum	Mean	Maximum	Minimum
All-lightweight	$f'_c$ (ksi)	4.53	8.16	1.79	4.35	9.54	2.93
All-lightweight	$f_{ct}$ (ksi)	0.344	0.452	0.246	0.146	0.296	0.215

### **Selection of Specimens for Comparison from the ACI-DafStb Database**

The effect that lightweight aggregate has on shear resistance was evaluated by comparing LWC specimens to NWC specimens. ACI Committee 445 on shear and torsion and DafStb have collected a large number of NWC shear tests in four databases. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.) In order to determine the effect of LWC on shear resistance, the LWC specimens in the TFHRC shear database were compared to a subset of NWC specimens in the ACI-DafStb database that have similar parameters that are significant to shear resistance.

As shown in table 33, the 928 NWC specimens in the ACI-DafStb database had larger values for the two selected parameters of concrete compressive strength and specimen depth. The table gives the number of specimens in the ACI-DafStb database that exceed the maximum value for the parameter of the tests in the LWC database. The number of NWC prestressed specimens was limited to those that used pretensioning, and no post-tensioned specimens were included in the specimens selected from the ACI-DafStb database.

**Table 33. Properties of shear specimens in the ACI-DafStb database and the number of specimens in the ACI-DafStb database within the property limits of the TFHRC shear database.**

<b>Dataset<sup>a</sup></b>	<b>Specimen Type</b>	<b>Number Tests and Number within Limits</b>	<b>Limit</b>	<b><math>f'_c</math> (ksi)</b>	<b>Member Height (<math>h</math>) (Inches)</b>
ACI-DafStb	RC without $A_v$	684	Maximum	19.2	86.6
ACI-DafStb	RC with $A_v$	111	Maximum	17.3	49.2
ACI-DafStb	PC without $A_v$	100	Maximum	10.8	18.0
ACI-DafStb	PC with $A_v$	33	Maximum	14.1	54.0
TFHRC	RC without $A_v$	648	Maximum	13.0	42.0
TFHRC	RC without $A_v$	648	Number > Maximum <sup>b</sup>	21.0	15.0
TFHRC	RC with $A_v$	107	Maximum	13.0	42.0
TFHRC	RC with $A_v$	107	Number > Maximum <sup>b</sup>	3.0	1.0
TFHRC	PC without $A_v$	100	Maximum	13.0	62.0
TFHRC	PC without $A_v$	100	Number > Maximum <sup>b</sup>	0.0	0.0
TFHRC	PC with $A_v$	31	Maximum	13.0	62.0
TFHRC	PC with $A_v$	31	Number < Maximum <sup>c</sup>	2.0	0.0

1 inch = 25.4 mm.

1 ksi = 6.89 MPa.

<sup>a</sup>For ACI-DafStb, there were 928 specimens total that were all within the maximum limits of both parameters for the LWC datasets—784 without  $A_v$  and 144 with  $A_v$ . For TFHRC, there were 866 specimens total within limits—748 without  $A_v$  and 138 with  $A_v$ .

<sup>b</sup>The number of specimens in ACI-DafStb database were greater than the maximum parameter of the LWC dataset.

<sup>c</sup>The number of specimens in ACI-DafStb database were less than the number of specimens within limits of both parameters for the LWC datasets.

An NWC specimen in the ACI-DafStb database was assumed to be similar to the LWC specimens in the TFHRC shear database if both parameters (i.e.,  $f'_c$  and  $h$ ) were less than the maximum value of the parameters in the LWC database. One set of maximum values for the parameters were determined for the RC specimens, and another set of maximum values was determined for the PC specimens in the TFHRC shear database. There were 886 specimens from the ACI-DafStb database that were less than the maximum value of both parameters. In chapters 5–7 of this report, the specimens referred to as “NWC specimens” are the selected 886 NWC specimens from the ACI-DafStb database. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.)

Figures were created to show statistical information for three parameters that influence shear resistance for the selected NWC specimens from the ACI-DafStb database. Figure 51 through figure 53 show  $v_u$  compared to  $f'_c$ ,  $d_v$ , and  $a/d_v$ , respectively.

## CHAPTER 5. SHEAR-STRESS ANALYSIS AND SHEAR-RESISTANCE ANALYSIS OF SPECIMENS IN THE TFHRC SHEAR DATABASE

### INTRODUCTION

This chapter provides an analysis of the average shear stress at failure and the test-to-prediction ratios for LWC specimens in the TFHRC shear database. First, the average shear stress of LWC specimens is analyzed by specimen type and compared to NWC specimens. In this chapter, “specimen type” refers to the four combinations of RC and PC specimens with and without shear reinforcement. Next, the ratio of the maximum shear force ( $V_{test}$ ) to the nominal shear resistance predicted using the four methods in the *AASHTO LRFD Bridge Design Specifications* is analyzed.<sup>(3)</sup> Different methods for accounting for LWC are compared, and new design expressions are proposed that include a proposed  $\lambda$ -factor based on unit weight to account for LWC. The effect that the proposed expression for the  $\lambda$ -factor has on the test-to-prediction ratios is evaluated. After, the ratios for LWC specimens to NWC specimens are compared. The last two sections evaluate the ratios near two limits specified by *AASHTO LRFD Bridge Design Specifications*—the lower limit on shear reinforcement and the upper limit on shear resistance.<sup>(3)</sup>

The quality of the prediction is given by its test-to-prediction ratio and COV describing the distribution of the ratios. A test-to-prediction ratio that is greater than unity indicates that the expression has underestimated the measured value, while a ratio that is less than unity indicates an overestimated value. COV indicates the amount of scatter in the test-to-prediction ratio, and a small COV is preferred.

The specimens included in this chapter were limited to those failing in shear and having an appropriate ratio of shear span to effective depth. As described previously in chapter 4 of this report, only LWC specimen failing in shear were included in the TFHRC shear database. A specimen was determined to have failed in shear if that was the mode of failure recorded in the literature and if the applied moment at failure was less than the calculated moment capacity given by equation 9. The NWC specimens in the ACI-DafStb database were also limited to those specimens failing in shear. A limit of 2.5 was placed on the  $a/d_v$  ratio for the LWC specimens. The NWC specimens in the ACI-DafStb database were already limited to a minimum  $a/d_v$  ratio of 2.5. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.)

The average shear stress and nominal shear resistance of each specimen were determined at the critical section for shear. The critical section for shear is taken as the effective shear depth ( $d_v$ ) from the edge of the bearing plate. If the bearing plate width was not given, a value of 0.375 inch (9.5 mm) was assumed.

The shear resistance of the LWC and NWC specimens was determined following the procedure described in chapter 3 for the two methods of the general procedure and the Simplified-PC/RC method. The iterative process (also described in chapter 3) was followed to determine the shear resistance for the general procedures.

The term “proposed expression” in this report refers to a prediction expression that is being proposed to the AASHTO Subcommittee on Bridges and Structures (SCOBs) T-10 for

consideration as a design expression in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> Proposed expressions are also included in chapter 7 of this report.

## ANALYSIS OF NORMALIZED SHEAR STRESS

This section includes a comparison of the normalized shear stress at failure for the LWC and NWC specimens from the ACI-DafStb database. The purpose of the comparison is to examine the effect of different parameters on shear resistance. The parameters were evaluated by comparing normalized shear to one of the parameters.

The normalized shear stress was compared to parameters that are known to affect shear resistance. The average shear stress given by equation 15 can be simplified by taking the resistance factor ( $\phi$ ) as 1.0 because  $v_u$  is determined using a test result. The resulting expression is shown in equation 41. For specimens without shear reinforcement, the shear stress was normalized by the concrete compressive strength ( $f'_c$ ) and by two methods for determining  $\beta$ , which relates the effect of longitudinal strain to the shear resistance of the concrete. The normalized shear stress was compared to parameters that include the longitudinal reinforcement ratio (i.e.,  $A_s/bd_s$  (referred to as  $\rho_\ell$  previously) for RC and  $A_{ps}/bd_p$  (referred to as  $\rho_p$  previously) for PC), the net reinforcement strain ( $\epsilon_s$ ), the crack-spacing parameter ( $s_{xe}$ ), the effective shear depth ( $d_v$ ), and the shear span to effective shear depth ratio ( $a/d_v$ ). For specimens with shear reinforcement, the shear stress was normalized by  $f'_c$  and by the amount of shear reinforcement ( $b_v d_v / A_v f_y$ ). The normalized shear stress was compared to parameters that include the shear reinforcement ratio ( $\rho_v$ ; also referred to as  $A_v / b_v s$ ) multiplied by the stirrup yield strength ( $f_y$ ),  $\rho_v$  multiplied by the ratio of  $f_y$  to  $\sqrt{f'_c}$ , and the ratio of the stirrup spacing ( $s$ ) to  $d_v$ .

$$v_u = \frac{V_{test} - V_p}{b_v d_v} \quad (41)$$

The two methods for determining  $\beta$  from the shear tests are based on equation 21 and equation 22. The nominal shear resistance in equation 13 is taken as  $V_{test}$ . For tests of RC and PC members without shear reinforcement,  $V_s$  is zero. By combining equation 13, equation 16 for  $V_c$ , and equation 41, the resulting expression is given by equation 42, which can be simplified and solved for  $\beta$  to give equation 43. The expression for  $\beta$  in the *AASHTO LRFD Bridge Design Specifications* is given by equation 21 for members with shear reinforcement and by equation 22 for members without shear reinforcement.<sup>(3)</sup> The difference between equation 21 and equation 22 is a term that is a function of the crack-spacing parameter  $s_{xe}$ . The term with  $s_{xe}$  can be included with  $v_u$  in the determination of  $\beta$ , as given by equation 44. The net longitudinal strain at the centroid of the reinforcing ( $\epsilon_s$ ) can be determined using equation 18 and equation 19 with  $V_{test}$  substituted for  $V_u$  and the associated maximum moment at  $V_{test}$  substituted for  $M_u$ .

$$v_u = \frac{V_{test} - V_p}{b_v d_v} = 0.0316\beta \sqrt{f'_c} \quad (42)$$

$$\beta = \frac{v_u}{0.0316\sqrt{f'_c}} \quad (43)$$

$$\beta = \frac{v_u}{0.0316\sqrt{f'_c} \times 51/(39 + s_{xe})} \quad (44)$$

Three parameters were used to evaluate the normalized shear stress of RC and PC members with shear reinforcement. For the first parameter,  $V_s$  (see equation 17) is divided by the web area ( $b_v d_v$ ) and  $\cot \theta$  is taken as 1.0. After simplification, the resulting expression is given by equation 45. The expression given by equation 45 is in terms of  $\rho_v$  (see equation 40) multiplied by  $f_y$ . The expression for minimum shear reinforcement given by equation 10 can be rearranged as an expression in terms of  $\rho_v$  and the ratio of  $f_y$  to  $\sqrt{f'_c}$ . This rearranged expression is shown in equation 46 and is the second parameter. The third parameter is the ratio of the stirrup spacing to  $d_v$  (i.e., normalized stirrup spacing).

$$\frac{V_s}{b_v d_v} = \left(\frac{A_v}{b_v s}\right) f_y \quad (45)$$

$$\left(\frac{A_v}{b_v s}\right) \frac{f_y}{\sqrt{f'_c}} = 0.0316 \quad (46)$$

The shear stress normalized by the amount of shear reinforcement ( $b_v d_v / A_v f_y$ ) was also compared to the normalized stirrups spacing ( $s/d_v$ ), which is the basis for equation 11 and equation 12, which are the expressions in the *AASHTO LRFD Bridge Design Specifications* for maximum stirrup spacing.<sup>(3)</sup> The nominal shear resistance given in equation 13 can be rearranged to isolate the terms that comprise  $v_u$ , which results in equation 47 after  $\cot \theta$  is taken as 1.0. Both sides are divided by  $A_v f_y$ , which gives the expression in equation 48. The application of equation 48 allows  $v_u$  normalized by the force in the shear reinforcement to be compared with  $s/d_v$ .

$$\left(\frac{V_{test} - V_p}{b_v d_v}\right) b_v d_v = V_c + A_w f_y \left(\frac{d_v}{s}\right) \quad (47)$$

$$v_u \left(\frac{b_v d_v}{A_w f_y}\right) = \frac{V_c}{A_w f_y} + \frac{d_v}{s} \quad (48)$$

Normalized shear stress is compared to each parameter in pairs of figures. The first figure in each pair provides the comparison for LWC specimens that are grouped by unit weight ( $w_c$ ). The second figure in each pair gives the comparisons for the LWC specimens with a reported  $w_c$ , LWC specimens without a reported  $w_c$ , and NWC specimens. The first figure can be used to evaluate the effect of  $w_c$  on the parameter being compared, and the second figure can be used to evaluate the effect of the use of lightweight aggregate in general. The comparisons are grouped by specimen type: RC specimens without and with stirrups and PC specimens without and with stirrups. In the determination of the average shear stress, no modification for LWC was considered.

### RC Specimens Without Shear Reinforcement

Figure 54 and figure 55 show a comparison of  $v_u$  normalized by  $f'_c$  to the longitudinal reinforcement ratio ( $A_s/bd_s$ ) for RC specimens without shear reinforcement. Figure 54 gives the

data for specimens with a reported  $w_c$ . The data are given by ranges of  $w_c$ . Also shown in the figure is a least-squares linear-regression line for each range of  $w_c$ . All of the data in figure 54 are grouped together and shown in figure 55 as LWC data with a recorded  $w_c$  (i.e., LWC with  $w_c$ ). Additional LWC specimens that did not have a recorded  $w_c$  (i.e., LWC without  $w_c$ ) are also included in the figure. The large number of selected NWC specimens from the ACI-DafStb database is shown in figure 55. The number of data points in each group is shown in parentheses in the legend. The linear-regression lines in figure 54 show a trend of normalized shear stress increasing with longitudinal reinforcement ratio. There does not appear to be an obvious trend for the unit weight. The NWC data show a similar trend of normalized shear stress increasing with longitudinal reinforcement ratio. The linear-regression lines for the LWC with  $w_c$  regression line and the NWC data regression line intersect at a longitudinal reinforcement ratio of 0.034. If all of the LWC data are considered together, the regression lines for LWC and NWC intersect at a ratio of 0.030. This indicates that a small modification for LWC may be appropriate for most RC specimens without shear reinforcement.

**Figure 55. Graph. Normalized shear stress compared to the longitudinal reinforcement ratio for LWC and NWC RC members without shear reinforcement in the TFHRC shear database.**

Figure 56 and figure 57 show a comparison of  $v_u$  normalized by  $0.316\sqrt{f'_c}$  (i.e.,  $\beta$  given by equation 43) to the net reinforcement strain ( $\epsilon_s$ ). The shear specimen data are grouped in a similar manner as described previously for figure 54 and figure 55. Also shown in figure 56 and figure 57 is the prediction for  $\beta$  used by GP-equation in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> This expression for the prediction of  $\beta$  is given by equation 21.

A large number of LWC data points with an  $\epsilon_s$  less than 0.001 inch/inch (0.001 mm/mm) in figure 56 are below the predicted value for  $\beta$ . In figure 57, a large number of NWC data points with an  $\epsilon_s$  less than 0.0015 inch/inch (0.0015 mm/mm) are below the predicted value for  $\beta$ . In both figure 56 and figure 57, the regression lines for the LWC show an increase in the normalized shear stress with  $\epsilon_s$ . As discussed chapter 4, section Shear Span to Effective Depth Ratio for RC Specimens Without Shear Reinforcement, most of the LWC data points with an  $\epsilon_s$  greater than 0.001 inch/inch (0.001 mm/mm) and a high normalized shear stress have an  $a/d_v$  ratio between 2.5 and 3.0.

Figure 57. Graph. Normalized shear stress compared to net reinforcement strain for LWC and NWC RC members without shear reinforcement in the TFHRC shear database.

Figure 58 and figure 59 show a comparison of  $v_u$  normalized by  $0.316\sqrt{f'_c}$  and an additional term that is a function of the crack-spacing parameter  $s_{xe}$  (i.e.,  $\beta$  given by equation 44) to the net reinforcement strain ( $\epsilon_s$ ).  $s_{xe}$  is shown in figure 60 and figure 61 for LWC and NWC specimens. For most of the specimens,  $s_{xe}$  is at the lower limit of 12 inches (305 mm). The specimens with an  $s_{xe}$  greater than the lower limit will have a larger normalized  $v_u$ . A comparison of figure 56 and figure 58 shows that there is very little noticeable difference in the position of the LWC data. This is likely due to the limited amount of data with  $s_{xe}$  greater than the lower limit of 12 inches (305 mm) and almost no data greater than 25 inches (635 mm). There are a significant number of NWC data points in figure 61 that are greater than 12 inches (305 mm) and some data points with  $s_{xe}$  greater than 40 inches (1016 mm). As a result, a comparison of figure 57 and figure 59 shows a slight increase in the normalized shear stresses (see figure 59), as indicated by the slight upward shift of the data.

**Figure 61. Graph. Normalized shear stress compared to crack-spacing parameter for LWC and NWC RC members without shear reinforcement in the TFHRC shear database.**

Figure 62 and figure 63 show a comparison of  $v_u$  normalized by  $0.316\sqrt{f'_c}$  to the effective depth for shear. The purpose of these two figures is to investigate size effect for LWC specimens. Figure 62 does not indicate an obvious relationship between  $w_c$  and size effect. Both the regression lines for LWC and NWC indicate that normalized  $v_u$  decreases as the effective depth increases. The regression lines for LWC and NWC are nearly parallel with the LWC regression line slightly below the NWC line. There are only two LWC data points with  $d_v$  greater than 15 inches (381 mm), so it is difficult to come to a definitive conclusion on the size effect of LWC specimens.

### RC Specimens With Shear Reinforcement

Figure 64 and figure 65 show a comparison of  $v_u$  normalized by  $f'_c$  to stirrup strength ( $\rho_v f_{yt}$ ) for RC specimens with shear reinforcement. Figure 64 gives the data for specimens with a reported unit weight. Figure 65 shows the data from figure 64 and selected NWC specimens from the ACI-DafStb database.

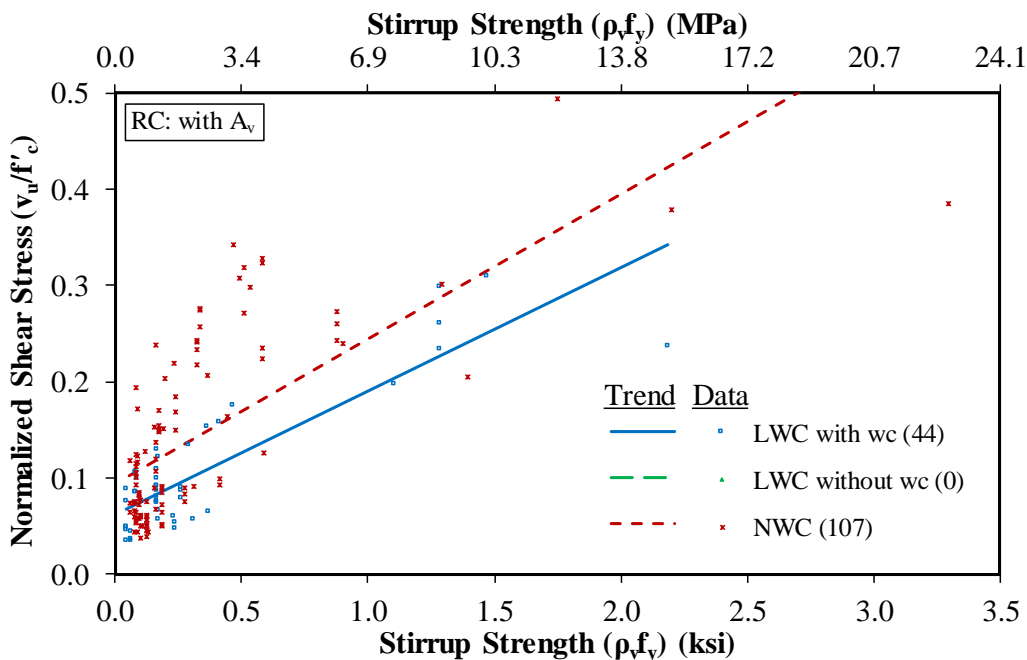

Source: FHWA.

1 ksi = 6.89 MPa.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 64. Graph. Normalized shear stress compared to stirrup strength for LWC RC members with shear reinforcement in the TFHRC shear database.**

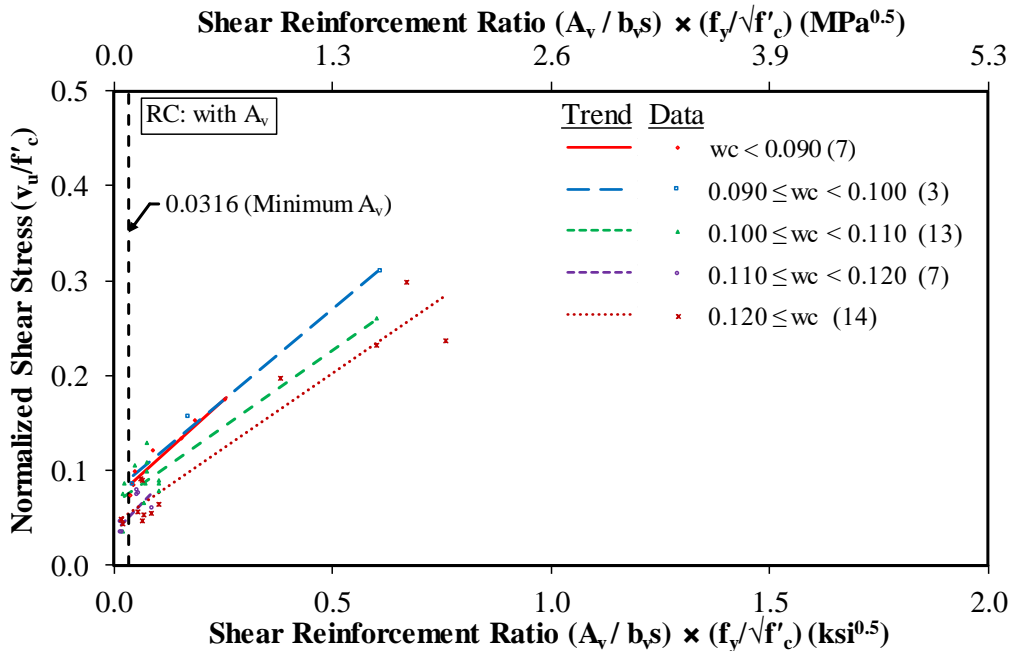

Source: FHWA.

1 ksi = 6.89 MPa.

**Figure 65. Graph. Normalized shear stress compared to stirrup strength for LWC and NWC RC members with shear reinforcement in the TFHRC shear database.**

Figure 64 appears to show a trend of normalized  $v_u$  decreasing as  $w_c$  increases. An additional comparison was made with the shear reinforcement ratio multiplied by the ratio of the stirrup yield strength to the square root of the concrete compressive strength ( $f_y/\sqrt{f'_c}$ ). This additional comparison is in the form of an expression for the minimum amount of shear reinforcement given by equation 46 and is shown in figure 66 and figure 67. A vertical line at a value of 0.0316 in figure 66 and figure 67 indicates the minimum amount of shear reinforcement required by the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The LWC data shown in figure 66 do not show an obvious dependence of normalized  $v_u$  on  $w_c$ .

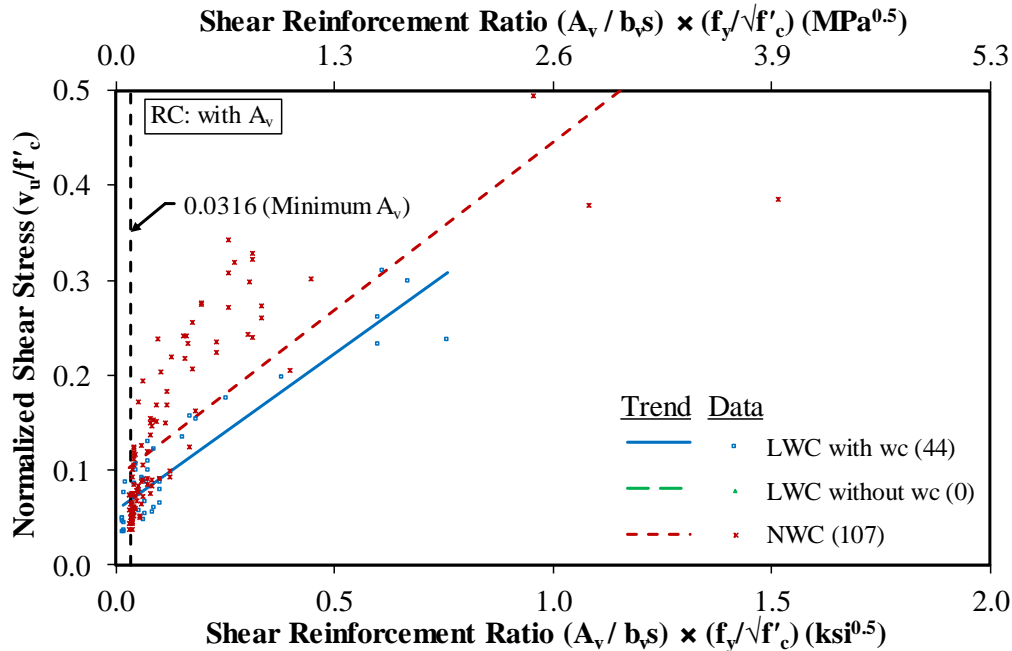

Source: FHWA.

1 ksi = 6.89 MPa.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 66. Graph. Normalized shear stress compared to shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for LWC RC members with shear reinforcement in the TFHRC shear database.**

Source: FHWA.  
1 ksi = 6.89 MPa.

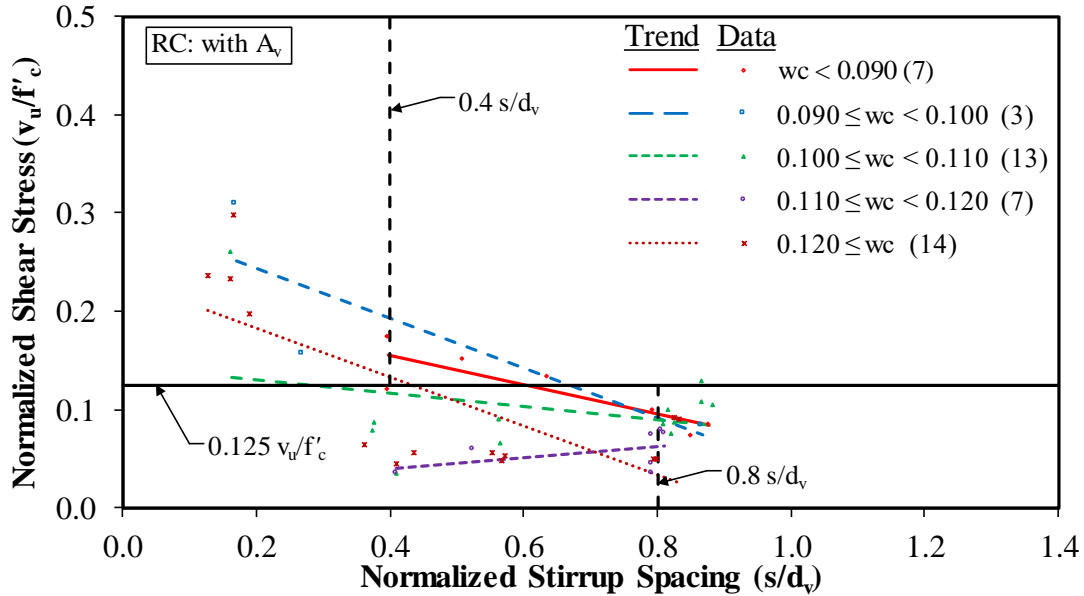

**Figure 67. Graph. Normalized shear stress compared to shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for LWC and NWC RC members with shear reinforcement in the TFHRC shear database.**

A comparison of the LWC and NWC in figure 65 and figure 67 shows that the regression lines for LWC and NWC are nearly parallel but that the line for the LWC data is much lower than the NWC line. It is interesting to observe that the difference between the LWC and NWC regression lines in figure 65 and figure 67 for RC specimens with shear reinforcement is much greater than the difference between the LWC and NWC regression lines in figure 55 for RC specimens without shear reinforcement. This suggests that the effect of lightweight aggregate on shear strength is more pronounced for members with shear reinforcement than for members without shear reinforcement.

Figure 68 and figure 69 show a comparison of  $v_u$  normalized by  $f'_c$  to the stirrup spacing ( $s$ ) normalized by the effective shear depth ( $d_v$ ) for RC specimens with shear reinforcement. These figures are intended to show the effect of stirrup spacing on  $v_u$ . A horizontal line is shown in the figures at  $0.125 v_u/f'_c$ . A normalized  $v_u$  below this line has a maximum stirrup spacing ( $s_{max}$ ) given by equation 11, and a normalized  $v_u$  above this line has an  $s_{max}$  given by equation 12. The vertical lines in the figures at  $0.4d_v$  and  $0.8d_v$  represent the limit on  $s_{max}$  given by equation 11 and equation 12. Data points that are below the horizontal line at  $0.125 v_u/f'_c$  and to the right of the vertical line at  $0.8d_v$  represent tests with stirrup spacings that exceed  $s_{max}$  given by equation 11. Similarly, stirrup spacing of the test with data points that are above the horizontal line at  $0.125 v_u/f'_c$  and to the right of the vertical line at  $0.4d_v$  exceed the  $s_{max}$  given by equation 12.

As shown in figure 68, most of the LWC tests satisfy the requirements in the *AASHTO LRFD Bridge Design Specifications* for maximum stirrup spacing.<sup>(3)</sup> There are only three data points

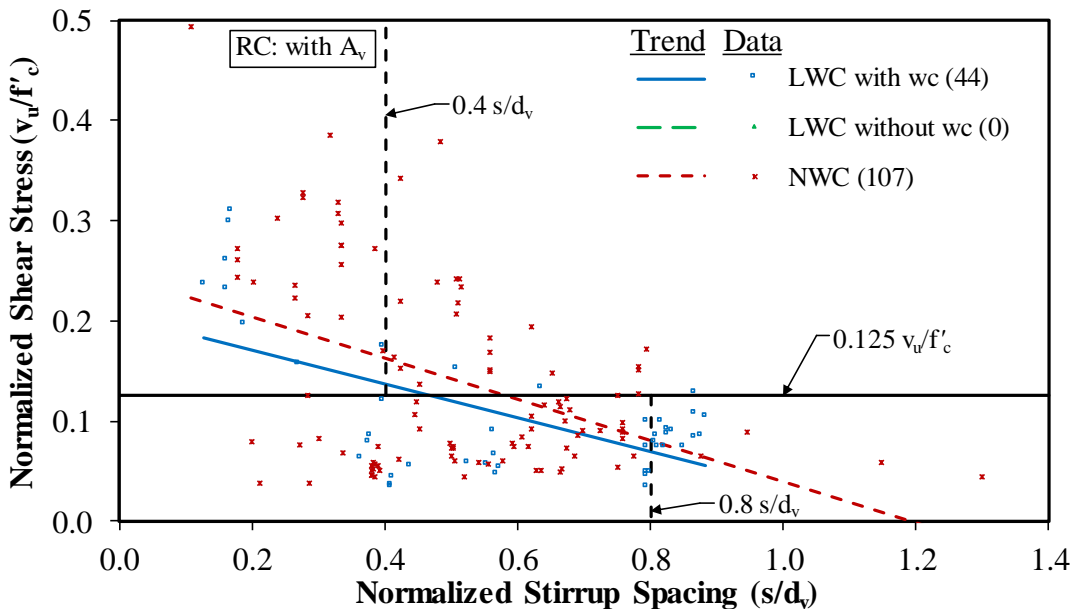

above the  $0.125 v_u/f'_c$  line that have a stirrup spacing greater than  $s_{max}$ . There are several tests over a range of  $w_c$  that are below the  $0.125 v_u/f'_c$  line and have a stirrup spacing greater than  $s_{max}$ . The stirrup spacing for all of these points is less than  $0.9 s/d_v$ . A large number of the NWC data points shown in figure 69 have stirrup spacings that exceed  $s_{max}$ .

Source: FHWA.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where  $1 \text{ kcf} = 16,020 \text{ kg/m}^3$ .

**Figure 68. Graph. Normalized shear stress compared to normalized stirrup spacing for LWC RC members with shear reinforcement in the TFHRC shear database.**

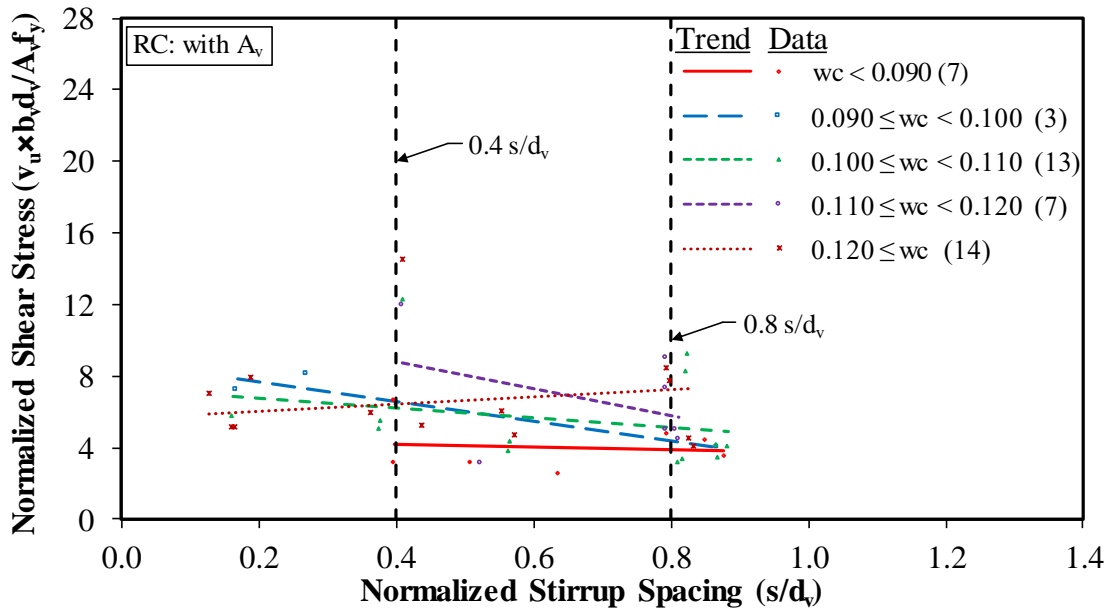

Source: FHWA.

**Figure 69. Graph. Normalized shear stress compared to normalized stirrup spacing for LWC and NWC RC members with shear reinforcement in the TFHRC shear database.**

The regression lines for the LWC and NWC data in figure 68 and figure 69 show a decrease in normalized  $v_u$  as the normalized stirrup spacing ( $s/d_v$ ) increases. However, the data are not independent of the area of shear reinforcement, and the downward trend may be due to a decrease in the amount of shear reinforcement for the tests with large stirrup spacing.

Alternatively,  $v_u$  can be normalized by the force in the shear reinforcement (see equation 48). The resulting data points are shown in figure 70 and figure 71. The trend line for the LWC data points in figure 71 shows a slight decrease in the normalized  $v_u$  as  $s/d_v$  increases. As shown in figure 70, there is not an obvious dependency of  $w_c$  on normalized  $v_u$ .

For  $s/d_v$  less than 0.8, the regression line for NWC data points is above the regression line for the LWC data points. However, the downward slope of the regression line for NWC data points in figure 71 is much greater than for the LWC regression line. At larger  $s/d_v$ , the shear reinforcement may be less effective at reducing the diagonal cracking.<sup>(14)</sup> Figure 71 indicates that, at larger  $s/d_v$ , the effectiveness of shear reinforcement in NWC behaves similarly to the effectiveness of shear reinforcement in LWC. The lower cracking strength of LWC appears to reduce the effectiveness of the shear reinforcement to reduce the propagation of the diagonal cracking.

### PC Specimens Without Shear Reinforcement

Figure 72 and figure 73 show a comparison of  $v_u$  normalized by  $f'_c$  to the longitudinal reinforcement ratio ( $A_{ps}/bd_p$ ) for PC specimens without shear reinforcement. The limited number of LWC data points in figure 72 does not give an obvious trend for the effect of  $w_c$  on normalized shear stress. The range of longitudinal reinforcement ratios for the test data is more limited for the NWC than for LWC. Over the range of ratios available for NWC, the trend line of the normalized shear stress for NWC is above the trend line for LWC, indicating a potential need for a reduction factor for LWC.

Source: FHWA.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 72. Graph. Normalized shear stress compared to longitudinal reinforcement ratio for LWC PC members without shear reinforcement in the TFHRC shear database.**

**Figure 73. Graph. Normalized shear stress compared to longitudinal reinforcement ratio for LWC and NWC PC members without shear reinforcement in the TFHRC shear database.**

Figure 74 and figure 75 show a comparison of  $v_u$  normalized by  $0.316\sqrt{f'_c}$  (i.e.,  $\beta$  in equation 43) to the net reinforcement strain ( $\epsilon_s$ ). Except for the data from a single source, the rest of the LWC was above the prediction for  $\beta$  in equation 21. All of the NWC data with a tensile net

reinforcement strain (i.e., positive  $\epsilon_s$ ) were above the prediction for  $\beta$ , and most of the data with a compressive net reinforcement strain (i.e., negative  $\epsilon_s$ ) were above the prediction for  $\beta$ .

**Figure 75. Graph. Normalized shear stress compared to net reinforcement strain for LWC and NWC PC members without shear reinforcement in the TFHRC shear database.**

Including the crack-spacing parameter ( $s_{xe}$ ) in the normalized shear stress did not cause a noticeable difference in the position of the LWC data or NWC data in figure 76 and figure 77 when compared to their relative positions in figure 74 and figure 75. This is due to nearly all of the LWC data shown in figure 78 and most of the NWC data shown in figure 79 having an  $s_{xe}$  equal to the lower limit of 12 inches (305 mm).

Source: FHWA.

1 ksi = 6.89 MPa.

1 inch = 25.4 mm.

**Figure 79. Graph. Normalized shear stress compared to crack-spacing parameter for LWC and NWC PC members without shear reinforcement in the TFHRC shear database.**

Normalized shear stress compared to effective depth for shear is shown in figure 80 and figure 81. There are only two LWC data points with a  $d_v$  greater than 10 inches (254 mm) and very few NWC data points with a  $d_v$  greater than or equal to 10 inches (254 mm). The effective depth for nearly all of the data was too small, and the number of data points available was too few to be used to determine the effect of  $d_v$  on normalized shear stress.

### PC Specimens With Shear Reinforcement

Figure 82 and figure 83 show a comparison of  $v_u$  normalized by  $f'_c$  to the shear reinforcement ratio ( $A_v/b_v s$ ) multiplied by stirrup yield strength ( $f_y$ ) for PC specimens with shear reinforcement. Figure 82 gives the data for specimens with a reported  $w_c$ . Figure 83 shows the data from figure 82 and selected NWC specimens from the ACI-DafStb database. Figure 82 for PC specimens with shear reinforcement appears to show a trend of normalized  $v_u$  decreasing as  $w_c$  increases, which was similar to the trend seen in figure 64 for RC specimens without shear reinforcement.

Source: FHWA.

1 ksi = 6.89 MPa.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

Source: FHWA.

1 ksi = 6.89 MPa.

**Figure 83. Graph. Normalized shear stress compared to stirrup strength for LWC and NWC PC members with shear reinforcement in the TFHRC shear database.**

Figure 84 and figure 85 show an additional comparison that was made with the shear reinforcement ratio multiplied by  $f_y/\sqrt{f'_c}$ . This additional comparison is in the form of an expression for the minimum amount of shear reinforcement given by equation 46, and the vertical line at a value of 0.0316 in figure 84 and figure 85 indicates the minimum amount of shear reinforcement required by the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The LWC data shown in figure 84 do not show an obvious dependence of normalized  $v_u$  on  $w_c$ . The LWC and NWC regression lines shown in figure 83 and figure 85 indicate that the line for the LWC data is lower than the NWC line. A similar trend was observed in figure 65 and figure 67 for RC specimens with shear reinforcement.

Source: FHWA.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 84. Graph. Normalized shear stress compared to shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for LWC PC members with shear reinforcement in the TFHRC shear database.**

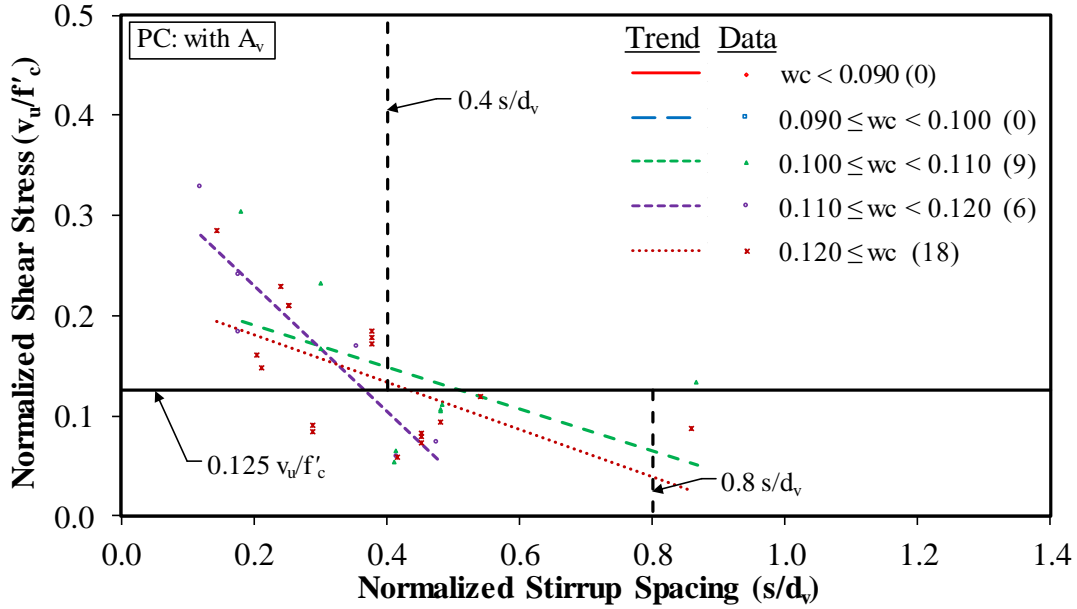

Source: FHWA.

**Figure 85. Graph. Normalized shear stress compared to shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for LWC and NWC PC members with shear reinforcement in the TFHRC shear database.**

Figure 86 and figure 87 show a comparison of  $v_u$  normalized by  $f'_c$  to the  $s/d_v$  ratio for PC specimens with shear reinforcement. These figures are intended to show the effect of stirrup spacing on  $v_u$ . A horizontal line is shown at  $0.125 v_u/f'_c$ . A normalized  $v_u$  below this line has a maximum stirrup spacing ( $s_{max}$ ) given by equation 11, and a normalized  $v_u$  above this line has an  $s_{max}$  given by equation 12. The vertical lines in the figures at  $0.4d_v$  and  $0.8d_v$  represent the limit on  $s_{max}$  given by equation 11 and equation 12. Data points that are below the horizontal line at  $0.125 v_u/f'_c$  and to the right of the vertical line at  $0.8d_v$  represent tests with stirrup spacings that exceed the  $s_{max}$  given by equation 11. Similarly, stirrup spacing of the test with data points that are above the horizontal line at  $0.125 v_u/f'_c$  and to the right of the vertical line at  $0.4d_v$  exceed  $s_{max}$  given by equation 12.

As shown in figure 86, all but two LWC tests satisfy the requirements in the *AASHTO LRFD Bridge Design Specifications* for maximum stirrup spacing.<sup>(3)</sup> The stirrup spacing for both of these points is less than  $0.9 s/d_v$ . Many of the NWC data points shown in figure 87 have stirrup spacings that exceed  $s_{max}$ .

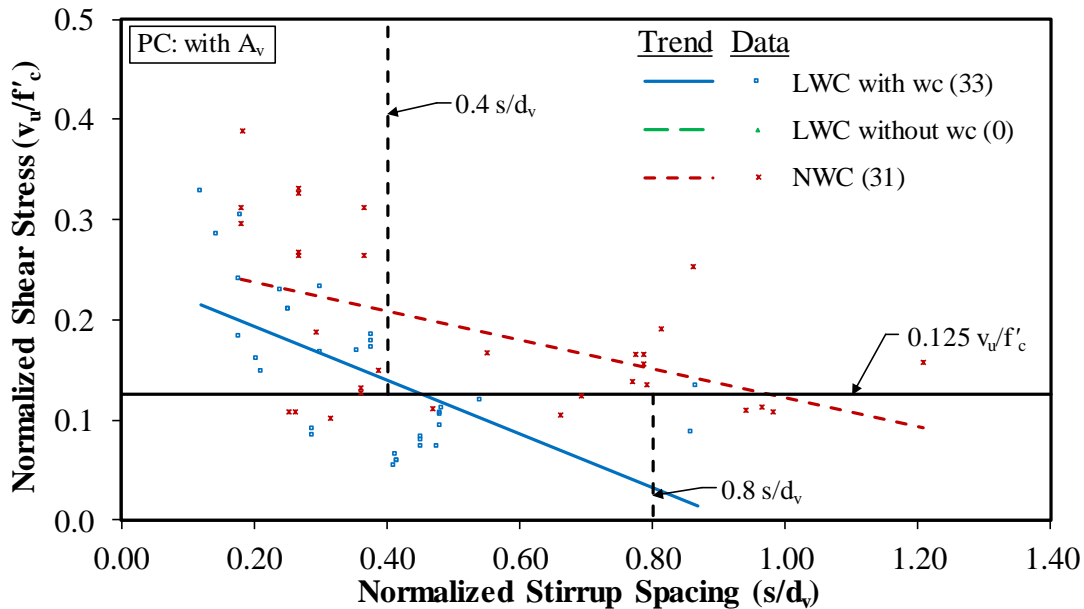

The regression lines for the LWC and NWC data shown in figure 86 and figure 87 show a decrease in normalized  $v_u$  as the normalized stirrup spacing increases. However, as described previously for the RC data shown in figure 68 and figure 69, the data in figure 86 and figure 87 are not independent of the area of shear reinforcement, and the downward trend may be due to a decrease in the amount of shear reinforcement for the tests with large stirrup spacing.

Source: FHWA.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 86. Graph. Normalized shear stress compared to normalized stirrup spacing for LWC PC members with shear reinforcement in the TFHRC shear database.**

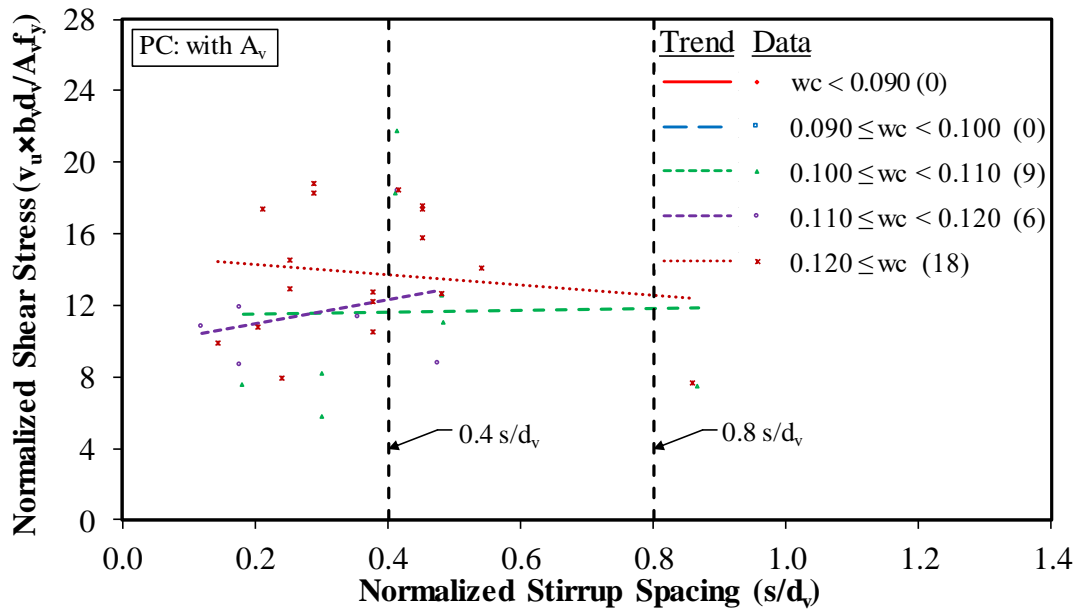

Source: FHWA.

**Figure 87. Graph. Normalized shear stress compared to normalized stirrup spacing for LWC and NWC PC members with shear reinforcement in the TFHRC shear database.**

Figure 88 and figure 89 show  $v_u$  normalized by the force in the shear reinforcement as given by equation 48. As shown in figure 88, there is not an obvious dependency of  $w_c$  on normalized  $v_u$ . The trend line for the LWC data points in figure 88 shows a slight decrease in the normalized  $v_u$  as  $s/d_v$  increases.

The location of the regression line for the NWC data in figure 89 for PC specimens is in a similar location to the regression line for the NWC data for RC specimens shown in figure 71. In both figures, the NWC regression line has a downward slope indicating a decrease in the normalized shear stress with increased normalized stirrup spacing. Interestingly, for LWC specimens with shear reinforcement, the regression line is above the NWC line for most of the data, while for RC specimens with shear reinforcement, the LWC regression line is below the NWC line for most of the data. The downward slope of the LWC regression line in both figure 71 and figure 89 is less than the slope of the regression line for NWC data, indicating a decreased dependence on the normalized stirrup spacing.

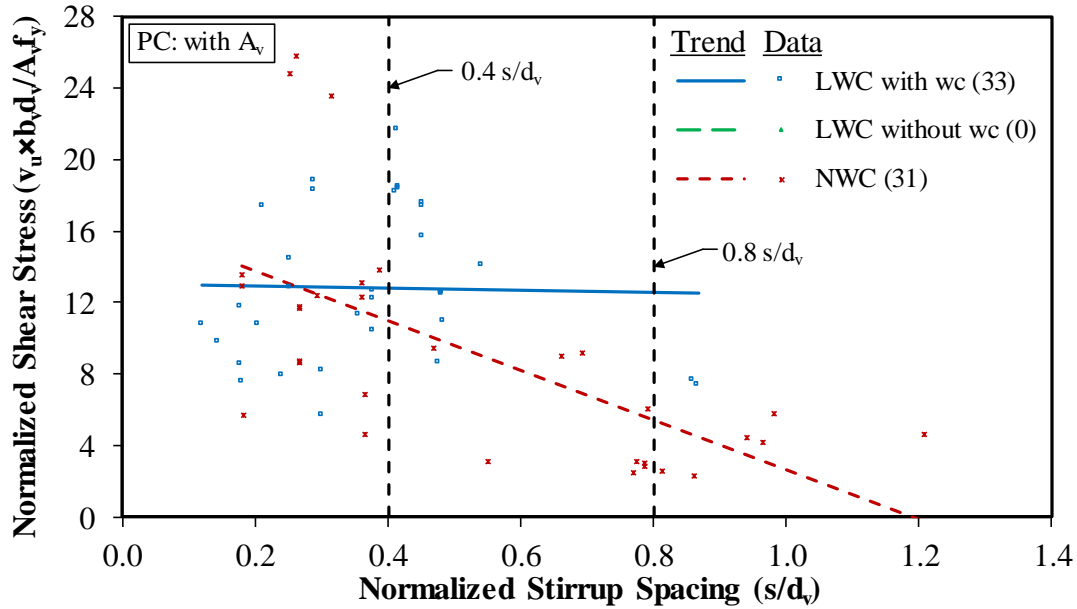

There are two explanations for why the LWC regression line is higher than the NWC regression line for PC specimens in figure 80 and why this trend was not observed in figure 71 for RC specimens. First, there are only two LWC data points in figure 89 with normalized stirrup spacing greater than 0.6, and in figure 71 for RC specimens, the data are more uniformly distributed across normalized stirrup spacings up to 0.9. Second, for the PC specimens, the mean compressive strength of the LWC specimens is 40 percent higher than the mean compressive strength of the NWC specimens, while for the RC specimens, the mean compressive strengths of the LWC and NWC specimens are nearly equal. The mean compressive strength of the LWC PC specimens is 9.5 ksi (65.5 MPa), while the mean compressive strength of the NWC PC specimens is 6.8 ksi (46.9 MPa). In contrast, the mean compressive strength of the LWC and NWC RC specimens is 6.3 ksi (43.4 MPa) and 6.2 ksi (42.7 MPa), respectively.

### Shear Span to Effective Depth Ratio for RC Specimens Without Shear Reinforcement

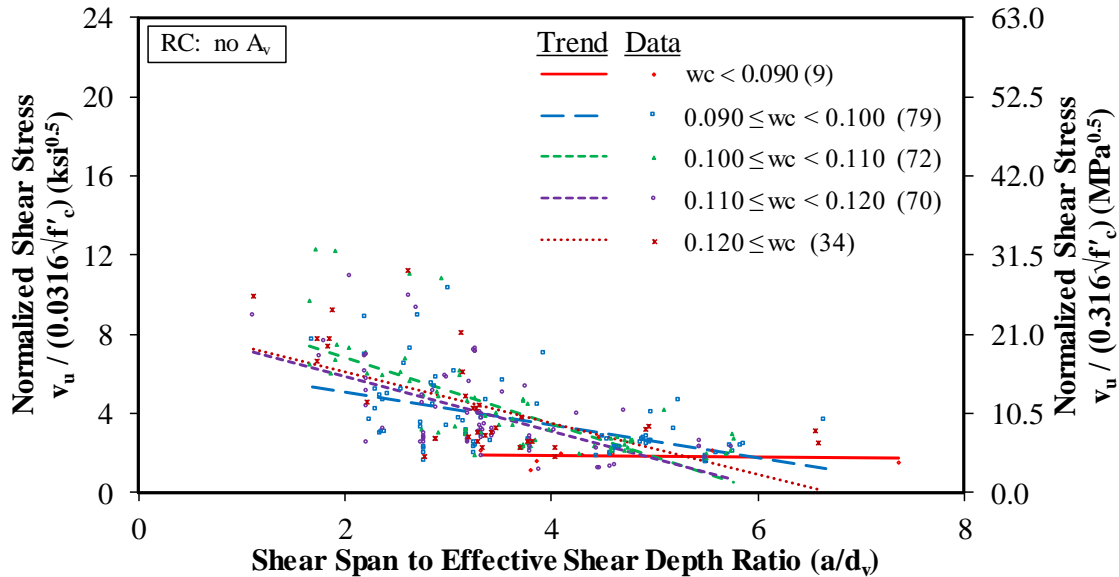

Figure 90 shows a comparison of  $v_u$  normalized  $0.316\sqrt{f'_c}$  (i.e.,  $\beta$  given by equation 43) to the net reinforcement strain ( $\epsilon_s$ ) for LWC RC specimens. The data are grouped by the shear span to effective depth ratio ( $a/d_v$ ). Only specimens with an  $a/d_v$  ratio greater than or equal to 2.5 were included in the analysis described previously in this chapter. Most of the data from specimens with an  $a/d_v$  ratio greater than or equal to 4.0 were below the prediction for  $\beta$  given by equation 21. The normalized shear stress for some specimens with an  $\epsilon_s$  greater than 0.001 inch/inch (0.001 mm/mm) and an  $a/d_v$  ratio between 2.5 and 3.0 were higher than specimens with a smaller  $a/d_v$  ratio. Overall, the regression lines show a clear trend of normalized shear stress increasing as the  $a/d_v$  ratio decreases.

 1 inch/inch = 1 mm/mm.

**Figure 90. Graph. Normalized shear stress compared to net reinforcement strain plotted by the ratio of shear span to the effective shear depth for LWC RC members without shear reinforcement in the TFHRC shear database.**

Figure 91 shows a comparison of  $v_u$  normalized  $0.316\sqrt{f'_c}$  (i.e.,  $\beta$  given by equation 43) to the  $a/d_v$  ratio for LWC RC specimens. The data are grouped by unit weight ( $w_c$ ). Nearly all of the regression lines for the different ranges of  $w_c$  are close to parallel and intersecting, indicating that the decrease in normalized  $v_u$  with increases in the  $a/d_v$  ratio is independent of  $w_c$ .

Source: FHWA.

1 ksi = 6.89 MPa.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

## COMPARISONS WITH PREDICTED SHEAR RESISTANCE

The following section discusses the test-to-prediction ratios for the specimens in the TFHRC shear database. The measured shear force at failure was compared to the predicted shear resistance determined using the GP-equation method, the GP-table method, and the Simplified-PC/RC method. Tests on RC specimens that satisfied the limits given in Article 5.8.3.4.1 of the *AASHTO LRFD Bridge Design Specifications* were also compared to the Simplified-RC method.<sup>(3)</sup>

The proposed expressions for shear resistance that include a  $\lambda$ -factor to account for LWC modification are presented. A proposed revision to the LWC modification of the expression for  $\cot \theta$  in the Simplified-PC/RC is described. The test-to-prediction ratios for the shear resistance of LWC specimens that included the proposed  $\lambda$ -factor based on  $w_c$  are discussed. Next, the test-to-prediction ratios determined using the proposed  $\lambda$ -factor based on  $w_c$  are compared to other methods for modification of shear resistance for LWC. Finally, the test-to-prediction ratios for LWC specimens are compared to the ratios for similar types of NWC specimens.

### Proposed Expressions for Shear Resistance Including Modification Factor for LWC

Article 5.8.2.2 in the *AASHTO LRFD Bridge Design Specifications* states that all expressions in Article 5.8.2 and Article 5.8.3 shall be modified for the effects of LWC.<sup>(3)</sup> The modification consists of replacing  $\sqrt{f'_c}$  with  $4.7f_{ct}$  when the splitting tensile strength is specified. When  $f_{ct}$  is not specified,  $\sqrt{f'_c}$  is replaced with  $0.75\sqrt{f'_c}$  when all-lightweight concrete is used or  $0.85\sqrt{f'_c}$  when sand-lightweight concrete is used.

A method to provide a more uniform treatment of LWC tensile strength has been proposed to section 5.4 of the *AASHTO LRFD Bridge Design Specifications* to add a definition of a modification factor for LWC, the  $\lambda$ -factor, which could then be referenced in other articles.<sup>(3,1)</sup> The  $\lambda$ -factor was previously developed from tests on LWC.<sup>(1)</sup> It is based on  $f_{ct}$  when available and  $w_c$  otherwise. The expression for the  $\lambda$ -factor based on  $w_c$  is given by equation 36 through equation 38, and equation 39 gives the expression for the  $\lambda$ -factor based on  $f_{ct}$ .

There are seven expressions in Article 5.8.2 and Article 5.8.3 with a  $\sqrt{f'_c}$ , and according to Article 5.8.2.2 of the *AASHTO LRFD Bridge Design Specifications*, each shall be modified for the effects of LWC.<sup>(3)</sup> A proposed expression that includes the  $\lambda$ -factor is described in this section for four of these current equations. The expression for the cracking torque given in Article 5.8.2.1 and the expression for the shear resistance provided by bent up bars given in Article 5.8.3.3 are beyond the scope of this report and will not be discussed. The expression for  $\cot \theta$  in the Simplified-PC/RC is intentionally not modified to include a  $\lambda$ -factor. The reason for the exclusion is described in the following section of this report.

The inclusion of the  $\lambda$ -factor is proposed for four expressions in Article 5.8.2 and Article 5.8.3 in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The minimum amount of shear reinforcement in the *AASHTO LRFD Bridge Design Specifications* is given by equation 10.<sup>(3)</sup> The proposed expression is given by equation 49 and includes the  $\lambda$ -factor. The expression for the shear resistance provided by the concrete contribution in Article 5.8.3.3 is given by equation 16, and the proposed expression that includes the  $\lambda$ -factor is given by equation 50. The expressions for  $V_{cw}$  and  $V_{ci}$  that are part of the Simplified-PC/RC are given by equation 28 and equation 29, and the proposed expressions are given by equation 51 and equation 52.

$$A_v \geq 0.0316\lambda\sqrt{f'_c} \frac{b_v s}{f_y} \quad (49)$$

$$V_c = 0.0316\beta\lambda\sqrt{f'_c} b_v d_v \quad (50)$$

$$V_{cw} = \left(0.06\lambda\sqrt{f'_c} + 0.3f_{pc}\right) b_v d_v + V_p \quad (51)$$

$$V_{ci} = 0.02\lambda\sqrt{f'_c} b_v d_v + V_d + \frac{V_i M_{cre}}{M_{max}} \geq 0.06\lambda\sqrt{f'_c} b_v d_v \quad (52)$$

### Removal of the Modification for LWC on Cot Theta of the Simplified-PC/RC Procedure

Article 5.8.2.2 of the *AASHTO LRFD Bridge Design Specifications* states that all expressions in Article 5.8.2 and Article 5.8.3 shall be modified for the effects of LWC.<sup>(3)</sup> This includes the expression for  $\cot \theta$ , given by equation 35, in the Simplified-PC/RC when  $V_{ci}$  is greater than  $V_{cw}$ . An expression for  $\cot \theta$  including the  $\lambda$ -factor is provided in equation 53.

$$\cot \theta = 1.0 + 3 \left( \frac{f_{pc}}{\lambda\sqrt{f'_c}} \right) \leq 1.8 \quad (53)$$

$\cot \theta$  determined using equation 35 or equation 53 will only affect the shear resistance determined for PC specimens with shear reinforcement.  $\cot \theta$  is used in  $V_s$  given by equation 17 to determine the contribution of the shear reinforcement.

The test-to-prediction ratios for the Simplified-PC/RC procedure are shown in table 34 for PC specimens with shear reinforcement. They compare the modification based on unit weight (i.e., the proposed  $\lambda$ -factor based on  $w_c$ ) (see equation 36 through equation 38), the modification based on concrete type (i.e., all-lightweight and sand-lightweight) currently used in the *AASHTO LRFD Bridge Design Specifications* (i.e., AASHTO modified), and modification based on  $f_{ct}$  (i.e., the proposed  $\lambda$ -factor based on  $f_{ct}$ ) (see equation 39).<sup>(3)</sup> The test-to-prediction ratios in table 34 are also compared by the shear resistance determined without modification for LWC concrete (i.e., no modification for the  $\lambda$ -factor taken as 1) and the shear resistance determined with modification for LWC concrete included in the determination of  $V_c$  (lesser of equation 51 and equation 52). Two cases were considered when modification for LWC concrete was included in the determination of  $V_c$ : modification of  $\cot \theta$  (i.e., modification of  $V_c$  and  $\cot \theta$  using equation 53) and no modification of  $\cot \theta$  (i.e., modification of  $V_c$  only using equation 35).

**Table 34. Test-to-prediction ratio of shear resistance for Simplified-PC/RC with and without LWC modification for LWC PC specimens with shear reinforcement in the TFHRC shear database.**

LWC Modification and Specimen Group*	Simplified-PC/RC Modification for LWC	Mean	COV (Percent)	Maximum	Minimum	Percent Test-to-Prediction Ratio	
						<1.0	<0.8
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ (33)	No modification	1.29	16.4	1.98	0.98	3.0	0.0
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ (33)	Modification of $V_c$ and $\cot \theta$	1.30	17.4	2.00	0.96	6.1	0.0
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ (33)	Modification of $V_c$ only	1.32	17.6	2.00	0.99	3.0	0.0
AASHTO modified PC with $A_v$ (21)	No modification	1.28	19.1	1.98	0.98	4.8	0.0
AASHTO modified PC with $A_v$ (21)	Modification of $V_c$ and $\cot \theta$	1.31	21.3	2.05	0.95	9.5	0.0
AASHTO modified PC with $A_v$ (21)	Modification of $V_c$ only	1.35	21.2	2.09	1.00	0.0	0.0
Proposed $\lambda$ -factor based on $f_{ct}$ , PC with $A_v$ (33)	No modification	1.29	16.4	1.98	0.98	3.0	0.0
Proposed $\lambda$ -factor based on $f_{ct}$ , PC with $A_v$ (33)	Modification of $V_c$ and $\cot \theta$	1.32	18.2	2.05	0.95	6.1	0.0
Proposed $\lambda$ -factor based on $f_{ct}$ , PC with $A_v$ (33)	Modification of $V_c$ only	1.35	18.6	2.09	1.00	3.0	0.0

\*The number of specimens is shown in parentheses.

A comparison of the test-to-prediction ratios in table 34 shows that the mean ratios determined with modification for LWC were higher than the ratios determined without modification for LWC. However, the minimum test-to-prediction ratios determined by including the  $\lambda$ -factor in the expression for  $\cot \theta$  were less than the minimum ratios determined without modification for LWC. The minimum ratio determined using the modification for LWC in the *AASHTO LRFD Bridge Design Specifications* (AASHTO modified) and by including the LWC modification in the term for  $\cot \theta$  (modification of  $V_c$  and  $\cot \theta$ ) was 0.95, which was less than the minimum ratio of 0.98 determined without modification for LWC. This indicates that  $V_n$  determined for an LWC PC girder using the Simplified-PC/RC procedure in the current *AASHTO LRFD Bridge Design Specifications* could be higher than the shear resistance determined for an identical NWC girder.<sup>(3)</sup> An identical girder would have the same cross section ( $b_v$ ,  $d_v$ ), design material properties ( $f'_c$  and  $f_y$ ), reinforcement ( $A_v/s$  and  $f_{pc}$ ), and internal forces ( $V_d$  and  $V_i M_{cre}/M_{max}$ ).

The effect of including the modification for LWC in  $\cot \theta$  was evaluated by examining the ratio  $V_c$ ,  $\theta$ ,  $V_s$ , and  $V_n$  determined by including the  $\lambda$ -factor in the expressions for  $V_c$  and the expression for  $\cot \theta$  to the same terms determined without modification for LWC. The ratio of these four terms are given in table 35 and were determined using the  $\lambda$ -factor based on  $w_c$  (see equation 36 through equation 38). All 33 PC specimens with shear reinforcement (PC with  $A_v$ ) in the TFHRC shear database had a calculated  $V_{ci}$  greater than its calculated  $V_{cw}$ , and as a result,  $\cot \theta$  was determined using equation 35 or equation 53. The ratio of  $V_c$  was equal to the  $\lambda$ -factor itself and was slightly less than 1.0 for all values. The ratio of  $\theta$  was less than or equal to 1.0, indicating that the predicted angle of compressive stresses was smaller if  $\cot \theta$  included the  $\lambda$ -factor (i.e., a predicted angle closer to horizontal). A smaller predicted angle results in an increase in the predicted contribution of the stirrups to the nominal shear resistance (i.e., larger  $V_s$ ), as shown by the ratio of  $V_s$  in table 35. The ratio of  $V_s$  had a mean value of 1.03 and a maximum value of 1.09.  $V_s$  for nearly 70 percent of the LWC PC specimens with shear reinforcement in the TFHRC shear database determined by including the modification for LWC in the expression for  $\cot \theta$  were larger than if no modification for LWC had been included. The remaining LWC PC specimens with shear reinforcement had a ratio of  $V_s$  equal to 1.0 (i.e., the same  $V_s$  determined for both).

**Table 35. Ratio of terms for shear resistance determined using Simplified-PC/RC with and without LWC modification included in the expression for  $\cot \theta$  for LWC PC specimens with shear reinforcement in the TFHRC shear database.**

<b>Specimen Group<sup>a</sup></b>	<b>Simplified-PC/RC Ratio of Predictions</b>	<b>Term<sup>b</sup></b>	<b>Mean</b>	<b>Maximum</b>	<b>Minimum</b>	<b>Percent Test-to-Prediction Ratio &gt;1.0</b>
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ where $V_{ci} > V_{cw}$ (33)	Modification of $V_c$ and $\cot \theta$ /no modification	$V_c (\lambda)$	0.95	0.99	0.86	0.0
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ where $V_{ci} > V_{cw}$ (33)	Modification of $V_c$ and $\cot \theta$ /no modification	$\theta$	0.98	1.00	0.93	0.0
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ where $V_{ci} > V_{cw}$ (33)	Modification of $V_c$ and $\cot \theta$ /no modification	$V_s$	1.03	1.09	1.00	69.7
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ where $V_{ci} > V_{cw}$ (33)	Modification of $V_c$ and $\cot \theta$ /no modification	$V_n$	0.99	1.05	0.94	18.2
Proposed $\lambda$ -factor based on $w_c$ , PC with $A_v$ where $V_{ci} > V_{cw}$ (33)	Modification of $V_c$ only/no modification	$V_n$	0.98	1.00	0.91	0.0

<sup>a</sup>The number of specimens is shown in parentheses.

<sup>b</sup>The ratio for  $V_c$  is equal to the  $\lambda$ -factor.

Similar ratios for  $\theta$  and  $V_s$  determined by including the  $\lambda$ -factor in the expressions for  $V_c$  but not in the expression for  $\cot \theta$  to the same  $\theta$  and  $V_s$  determined without modification for LWC would all be 1.0 and are not given in table 35. The maximum ratio for shear resistance is 1.0, indicating that by using equation 35 to determine  $\cot \theta$ ,  $V_n$  was always less than or equal to  $V_n$  determined without modification for LWC. The test-to-prediction ratios for the Simplified-PC/RC procedure in the remainder of this chapter all include  $\cot \theta$  determined using equation 35.

### **Test-to-Prediction Ratios for Shear Resistance Including Proposed LWC Modification Factor**

This section includes several tables with the test-to-prediction ratios for the proposed  $\lambda$ -factor based on  $w_c$  given by equation 36 through equation 38. The ratios are given by the method used to determine shear resistance, specimen type,  $w_c$ , by concrete-mixture type.

The test-to-prediction ratios are shown in table 36 for all LWC specimens and by specimen type. For all of the specimens, the GP-equation and GP-table methods had similar ratios at 1.32 and 1.39, respectively. The Simplified-PC/RC procedure gave a more conservative prediction at 2.07. The COV for the three methods was high at nearly 50 percent for the general procedure methods and nearly 60 percent for the Simplified-PC/RC procedure. All three methods had more conservative predictions for the RC specimens without shear reinforcement (i.e., RC specimens without  $A_v$ ) than for RC specimens with shear reinforcement (i.e., RC specimens with  $A_v$ ). A similar trend was observed for PC specimens with and without shear reinforcement. All three methods gave more conservative predictions for PC specimens without shear reinforcement (i.e., PC specimens without  $A_v$ ) than for RC specimens without shear reinforcement. The two general procedure methods also gave more conservative predictions for PC specimens with shear reinforcement (i.e., PC specimens with  $A_v$ ) than for RC specimens with shear reinforcement. For the Simplified-PC/RC procedure, however, the prediction of RC specimens with shear reinforcement was more conservative than for PC specimens with shear reinforcement.

**Table 36. Test-to-prediction ratio of shear resistance for design expressions with proposed expression for the  $\lambda$ -factor for LWC specimens in the TFHRC shear database.**

Specimen Group*	Design Expression	Mean	COV (Percent)	Maximum	Minimum	Percent Test-to-Prediction Ratio	
						<1.0	<0.8

Proposed $\lambda$ -factor based on $w_c$ , PC specimens with $A_v$ (33)	GP-table	1.24	11.5	1.52	0.98	3.0	0.0
Proposed $\lambda$ -factor based on $w_c$ , PC specimens with $A_v$ (33)	Simplified-PC/RC	1.32	17.6	2.00	0.99	3.0	0.0

\*The number of specimens is shown in parentheses.

Table 37 through table 40 provide the test-to-prediction ratios for a particular specimen type. The ratios are given in groups by ranges of  $w_c$  and then by concrete-mixture type. Table 37 and table 38 shows ratios for RC specimens without and with shear reinforcement, respectively. The ratios for PC specimens without and with shear reinforcement are shown in table 39 and table 40. The test-to-prediction ratios in these tables give the same trend as for the specimens as a whole: the two general procedure methods give similar ratios, and the ratio for the Simplified-PC/RC procedure is higher. The most obvious exception is the ratios for the seven SDC PC specimens without shear reinforcement in table 39. All seven of these specimens were from the same study, and the low ratios for these specimens are observed throughout the tables and figures in this section.

**Table 37. Test-to-prediction ratio of shear resistance for design expressions with proposed expression for the  $\lambda$ -factor for LWC RC specimens without stirrups in the TFHRC shear database.**

## Comparison of the Basis for the LWC Modification Factor on Test-to-Prediction Ratio for Shear Resistance

This section includes figures and tables that provide comparisons of the method used to determine the LWC modification factor on the predicted shear resistance. Test-to-prediction ratios were determined for the specimens based on four different methods to account for LWC. These methods include no modification for LWC, the modification given in the current *AASHTO LRFD Bridge Design Specifications* based on mixture type, the proposed  $\lambda$ -factor based on  $w_c$ , and the proposed  $\lambda$ -factor based on splitting tensile strength.<sup>(3)</sup> The effect that the four methods of LWC modification have on the test-to-prediction ratios is given for each of the four design procedures in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

The number of specimens given in each comparison depended on the information reported. The number of specimens in all of the figures and tables in this section was limited to the specimens with a  $w_c$ . The ratios determined using the method in the *AASHTO LRFD Bridge Design Specifications* were further limited to the specimens with all-lightweight or sand-lightweight concrete.<sup>(3)</sup> The ratios determined using the proposed  $\lambda$ -factor based on splitting tensile strength were limited to specimens with a reported splitting tensile strength.

Figure 92 and figure 93 show the ratios for the Simplified-RC procedure. In each figure, the ratios are compared to  $w_c$ , shown in groups by specimen type, and limited to RC specimens without and with shear reinforcement. Least squares regression lines are shown for the specimens in each group. Figure 92 shows the ratios determined without modification for LWC (i.e., no modification), and figure 93 shows the ratios determined using  $\lambda$  based on  $w_c$ . Note that the number of specimens is shown in parentheses in the legends for all remaining graphs found in this chapter (i.e., figure 92 through figure 165).

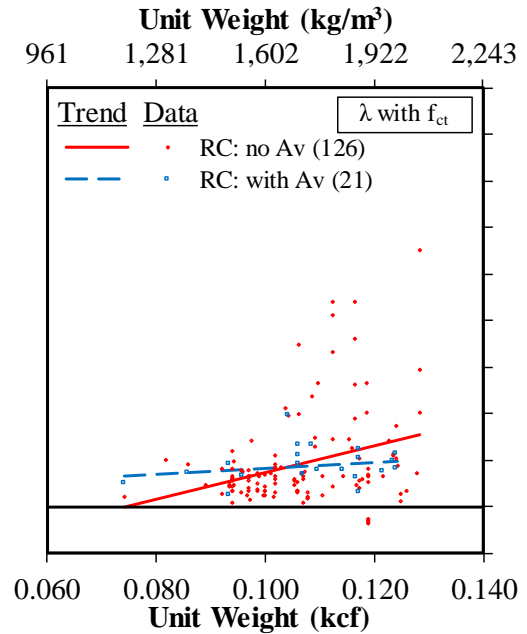

**Figure 93. Graph. Test-to-predicted shear resistance compared to unit weight for Simplified-RC with modification determined using proposed expression for the λ-factor based on  $w_c$ .**

Figure 94 shows the ratios determined using the modification given in the *AASHTO LRFD Bridge Design Specifications* (i.e., AASHTO modified), and figure 95 shows the ratios determined using the  $\lambda$ -factor based on  $f_{ct}$ .<sup>(3)</sup> The ratios shown in figure 93 and figure 94 for the proposed  $\lambda$ -factor based on  $w_c$  and AASHTO modified appear similar and are shifted slightly higher than the ratios determined without modification. There were fewer specimens reported with a splitting tensile strength. The ratios shown for the proposed  $\lambda$ -factor based on  $f_{ct}$  appeared more scattered than the other methods for determining LWC modification, but most of the ratios were still greater than 1.0, indicating a conservative prediction. The trend line for the RC specimens with shear reinforcement was greater than 1.0 and nearly horizontal, indicating that there was no obvious trend in the test-to-prediction ratios with increasing unit weight. For the RC specimens without shear reinforcement, the trend line was greater than 1.0 and inclined slightly upward, indicating that the ratios increased as  $w_c$  increased. This increase is observed in the figures for all three methods of accounting for LWC and in the figure for no modification for LWC.

**Figure 95. Graph. Test-to-predicted shear resistance compared to unit weight for Simplified-RC with proposed expression for the  $\lambda$ -factor based on  $f_{ct}$ .**

Figure 96 through figure 99 show the ratios for the GP-equation method in a similar format. The ratios are shown for all four groups of specimen type: RC specimens without and with shear reinforcement and PC specimens without and with shear reinforcement. Similar to figure 94 and figure 95, the ratios shown for the proposed  $\lambda$ -factor based on  $w_c$  and AASHTO modified appeared similar and were shifted slightly higher than the ratios determined without modification. The trend lines for all groups of specimens except for PC specimens without shear reinforcement were nearly horizontal and greater than 1.0. The trend line for the PC specimens without shear reinforcement had a downward trend both figure 96 and figure 97. Both figures include the seven SDC specimens with low test-to-prediction ratios. The ratios for these specimens were not included in either figure 98 or figure 99 because the specimens were not all-lightweight or sand-LWC, and splitting tensile strength values were not reported. In figure 98, the trend line for PC specimens without shear reinforcement did not include these seven points and was inclined slightly upward, indicating an increase in the test-to-prediction ratio as  $w_c$  increased.

Figure 100 through figure 103 show the ratios for the GP-table method. The method tends to produce similar test-to-prediction ratios, so although the ratios of individual specimens are in slightly different locations in figure 100 through figure 103 when compared to figure 96 through figure 99, the observed trends are similar.

**Figure 103. Graph. Test-to-predicted shear resistance compared to unit weight for GP-table method with LWC modification determined using proposed expression for the  $\lambda$ -factor based on  $f_{ct}$ .**

The ratios for the Simplified-PC/RC method are shown in figure 104 through figure 107. There is much more scatter observed in the ratios shown in these figures. The trend lines for RC and PC specimens with shear reinforcement are nearly horizontal and slightly greater than 1.0. The trend line for RC specimens without shear reinforcement is noticeably higher than the trend line for specimens with shear reinforcement, and the data points have much greater scatter. The trend line for the few PC specimens without shear reinforcement is much higher than the other three lines. The same seven SDC specimens caused a sharp downward trend in the regression lines shown in figure 104 and figure 105. Only a slight downward trend for the PC specimens without shear reinforcement is observed in figure 106 and figure 107 when the seven specimens are not included.

**Figure 107. Graph. Test-to-predicted shear resistance compared to unit weight for Simplified-PC/RC with LWC modification determined using proposed expression for the  $\lambda$ -factor based on  $f_{ct}$ .**

The test-to-prediction ratios determined using the proposed  $\lambda$ -factor based on  $w_c$  were compared to the ratios determined without modification for LWC (see table 41), the ratios determined using AASHTO modified (see table), and the ratios determined using the proposed  $\lambda$ -factor based on  $f_{ct}$  (see table 43). The ratios in table 41 through table 43 were calculated for both methods of the general procedure and the Simplified-PC/RC procedure. The ratios for RC specimens determined using AASHTO modified and the proposed  $\lambda$ -factor based on  $w_c$  are provided in table 44 and also include calculations using the Simplified-RC procedure. The ratios in each table are given for all specimens. Additional ratios are given in groups to compare the ratios of specimens without and with shear reinforcement and to compare the ratios of RC and PC specimens.

The mean ratios in table 41 that were determined using the proposed  $\lambda$ -factor based on  $w_c$  were all greater than the mean ratios determined without modification for LWC. The ratios determined using the GP-equation and GP-table methods without modification for LWC were less than 1.0 for 48 and 41 percent of the specimens, respectively. Determining the shear resistance using the proposed  $\lambda$ -factor based on  $w_c$  reduced the number of specimens with ratios less than 1.0 to 35 and 26 percent for the two general procedure methods, respectively. By comparison, the number of specimens with a ratio less than 1.0 for shear resistance determined using the Simplified-PC/RC procedure was 12 percent with no modification for LWC and 6 percent with modification based on unit weight. The COV for a design method was similar regardless of the method of LWC modification.

**Table 41. Test-to-predicted shear resistance for design expressions with no modification for LWC ( $\lambda$ -factor = 1) and modification determined using proposed expression for the  $\lambda$ -factor based on  $w_c$ .**

\*The number of specimens is shown in parentheses.

The ratios determined for specimens with all-lightweight and sand-lightweight concrete that satisfied the limits for using the Simplified-RC procedure are included in table 44. The mean ratios for all of the specimens determined using the modification for LWC AASHTO modified method were 2 percent larger than the ratios determined using the proposed  $\lambda$ -factor based on  $w_c$ . The mean ratios determined using the Simplified-RC procedure were considerably larger than the ratios determined using either of the two general procedure methods, but the ratios were not quite as large as the ratios determined using the Simplified-PC/RC method. The COV for a design method was similar regardless of the method of LWC modification.

## COMPARISON OF LWC AND NWC ON TEST-TO-PREDICTION RATIO FOR SHEAR RESISTANCE

The following section compares the test-to-prediction ratios for the LWC specimens to the ratios for the selected NWC specimens from the ACI-DafStb database. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.) The ratios for the LWC specimens were determined using only the proposed  $\lambda$ -factor based on  $w_c$  to account for LWC. Shear resistance was determined for each of the four design procedures in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup>

A comparison of test-to-prediction ratios for LWC and NWC specimens is provided. Specifically, the ratios are given in tables for the two methods of the general procedure and the Simplified-PC/RC procedure. Figures are presented for each specimen type that compare the ratios for the GP-equation method and the Simplified-PC/RC method. Additional figures for the GP-table method were not shown because of their similarity to the figures showing the GP-equation method. Figures showing the ratios for the Simplified-RC method are included for the RC specimens that satisfy the limitations of the method.

Table 45 provides the ratios for all LWC and NWC in the TFHRC shear database. The ratios are also given for all RC specimens and all PC specimens. The ratios are shown in table 46 by specimen type. The mean ratios for the LWC specimens were 9 to 10 percent larger than the ratios of the NWC specimens depending on the design procedure. The COV of the ratios for the LWC specimens was much larger than the COV of the NWC specimens. A similar trend was observed for all of the RC and PC specimens.

**Table 45. Test-to-predicted shear resistance for design expressions with LWC modification determined using proposed expression for the  $\lambda$ -factor based on  $w_c$  for LWC and NWC specimens by reinforcement type.**

LWC, $\lambda$ -factor based on $w_c$ , all PC specimens (60)	Simplified-PC/RC	2.04	77.9	6.80	0.43	13.3	11.7

\*The number of specimens is shown in parentheses.

Note: NWC specimens are from the ACI-DafStb database.

The same trend of the LWC specimens having a larger mean ratio was not observed for each specimen type, as shown in table 46. For RC and PC specimens without shear reinforcement, the LWC specimens had larger ratios than the NWC specimens. The ratios for RC specimens with shear reinforcement were 12 to 19 percent smaller than the ratios for the NWC specimens depending on the design procedure. For the PC specimens with shear reinforcement, the ratios for the LWC were similar to the ratios for the NWC specimens and ranged from 2 percent smaller to 6 percent larger than the ratios for the NWC specimens.

**Table 46. Test-to-predicted shear resistance for design expressions with LWC modification determined using proposed expression for the  $\lambda$ -factor based on  $w_c$  for LWC and NWC specimens by specimen type.**

## RC Specimens Without Shear Reinforcement

The test-to-prediction ratios determined for the Simplified-RC procedure for RC specimens without shear reinforcement are compared to concrete compressive strength ( $f'_c$ ) and effective shear depth ( $d_v$ ) in figure 108 through figure 111. The ratios in figure 108 and figure 109 for LWC specimens are grouped by ranges of  $w_c$ . The ratios in figure 110 and figure 111 are grouped by all of the LWC specimens and all of the NWC specimens. Least-squares linear-regression lines are shown for each group of specimens. Figure 108 and figure 110 compare the ratios to  $f'_c$ , while figure 109 and figure 111 compare the ratios to  $d_v$ .

Source: FHWA.

1 ksi = 6.89 MPa.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

Source: FHWA.  
1 inch = 25.4 mm.

**Figure 111. Graph. Test-to-predicted shear resistance compared to effective shear depth for Simplified-RC for LWC and NWC RC members without shear reinforcement.**

Figure 108 shows that most of the LWC specimens had a compressive strength of approximately 6 ksi (41 MPa) or less. In figure 110, the regression line for the LWC specimens with a compressive strength less than 6 ksi (41 MPa) was below the regression line for the NWC specimens, indicating a less-conservative prediction of shear resistance using the Simplified-RC procedure. For the smaller number of LWC specimens with an  $f'_c$  greater than 6 ksi (41 MPa), the trend line indicates that the prediction of shear resistance was more conservative than for the NWC specimens. There was no noticeable difference between LWC and NWC specimens with regard to effective shear depth over the limited range of  $d_v$  for the specimens that satisfied the limitations of the Simplified-RC procedure.

Figure 112 through figure 115 show similar information for the ratios determined using the GP-equation method. The trend line for the LWC specimens is above the NWC trend line in figure 114 over the entire range of compressive strengths for the specimens. The trend lines for the LWC and NWC specimens show a uniform ratio with increases in  $d_v$ , although the number of specimens with an effective depth greater than 15 inches (381 mm) is limited.

1 inch = 25.4 mm.

**Figure 115. Graph. Test-to-predicted shear resistance compared to effective shear depth for GP-equation method for LWC and NWC RC members without shear reinforcement.**

The ratios determined using the Simplified-PC/RC method are shown in figure 116 through figure 119. The trend line for the LWC is inclined slightly upward, indicating that the predicted shear resistance became more conservative with increasing compressive strength. The opposite trend is observed for the NWC specimens, where the predicted shear resistance became slightly less conservative as compressive strength increased. The trend line for the ratios compared to  $d_v$  shows that, for the limited number of specimens with a  $d_v$  above 15 inches (381 mm), the shear resistance rapidly became less conservative as effective depth increased. The ratios were less than 1.0 for most of the NWC specimens with a  $d_v$  greater than 30 inches (762 mm).

### RC Specimens With Shear Reinforcement

The test-to-prediction ratios are shown in figure 120 through figure 123 for RC specimens with shear reinforcement determined using the Simplified-RC method. The trend line for the LWC specimens is below the NWC trend line over the entire range of  $f'_c$  and  $d_v$  shown in figure 122.

### PC Specimens Without Shear Reinforcement

The ratios for the limited number of LWC PC specimens without shear reinforcement are shown in figure 132 through figure 135 for shear resistance determined by the GP-equation procedure and in figure 136 through figure 139 for shear resistance determined by the Simplified-PC/RC procedure. The low  $V_{test}$  for the seven specimens described previously in this report has resulted in low test-to-prediction ratios for both procedures. The low ratios for these seven specimens, which have compressive strengths of approximately 8 and 12 ksi (55 and 83 MPa), had a large effect on the trend line for the LWC specimens. Excluding these seven tests, the trend line for the LWC specimens would be above the trend line for the NWC for both design procedures.

### PC Specimens With Shear Reinforcement

The ratios for the PC specimens with shear reinforcement are shown in figure 140 through figure 147. Figure 140 through figure 143 show the ratios for shear resistance determined using the GP-equation method, and figure 144 through figure 147 show the ratios for shear resistance determined using the Simplified-PC/RC procedure. The similar prediction of shear resistance for the LWC and NWC specimens is shown by their nearly overlapping trend lines in figure 142 and figure 143 as well as figure 146 and figure 147.

The 10 SDC specimens that are a part of the experimental research described in chapter 3 of this report can be seen in figure 140 through figure 147. The effective depth for these specimens was slightly greater than 30 inches (762 mm) and slightly less than 50 inches (1,270 mm). The trend lines for LWC that include these 10 specimens was parallel to the line, indicating a ratio of 1.0 in figure 142 and figure 143 as well as figure 146 and figure 147. This indicates that the ratios determined for both the GP-equation procedure and the Simplified-PC/RC procedure were independent of effective shear depth.

### Lower Limit on Shear Reinforcement in RC and PC Specimens

In this section, test-to-prediction ratios for shear resistance were used to evaluate the expression for minimum shear reinforcement. The expression for the minimum shear reinforcement in the *AASHTO LRFD Bridge Design Specifications* is provided in equation 10.<sup>(3)</sup> As specified in Article 5.8.2.2, this expression shall be modified for the effects of LWC. The proposed expression, including the  $\lambda$ -factor, is provided in equation 49. As a result of modifying the expression for LWC, the minimum amount of shear reinforcement determined for an LWC member was up to 25 percent less than the amount determined for a similar NWC member.

Figure 148 through figure 157 compare the test-to-prediction ratios to the amount of shear reinforcement. The ratios for the RC specimens were determined using the Simplified-RC procedure (see figure 148 and figure 149), the GP-equation method (see figure 150 and figure 151), and the Simplified-PC/RC procedure (see figure 152 and figure 153). Four figures give the ratios for PC members with shear reinforcement, which were determined using the GP-equation method (see figure 154 and figure 155) and the Simplified-PC/RC procedure (see figure 156 and figure 157). The amount of shear reinforcement is given as the reinforcement ratio ( $A_v/b_v s$ ) multiplied by the ratio  $f_y/\sqrt{f'_c}$ . The amount of shear reinforcement expressed in this manner is based on the rearrangement of the equation for minimum shear reinforcement as shown in equation 46.

Figure 148 and figure 149 show the ratios determined using the Simplified-RC procedure for the RC specimens that satisfied the limits of the procedure. In figure 148, the ratios are shown in groups by  $w_c$ . The ratios for LWC and NWC specimens are shown in figure 149. The graph on the left in figure 148 and figure 149 shows the ratios over the full range of the horizontal axis, while the graph on the right shows the data for specimens over a range of shear reinforcement ratios closer to the minimum amount of shear reinforcement given by equation 10. The minimum amount of reinforcement is indicated by the vertical line at 0.0316.

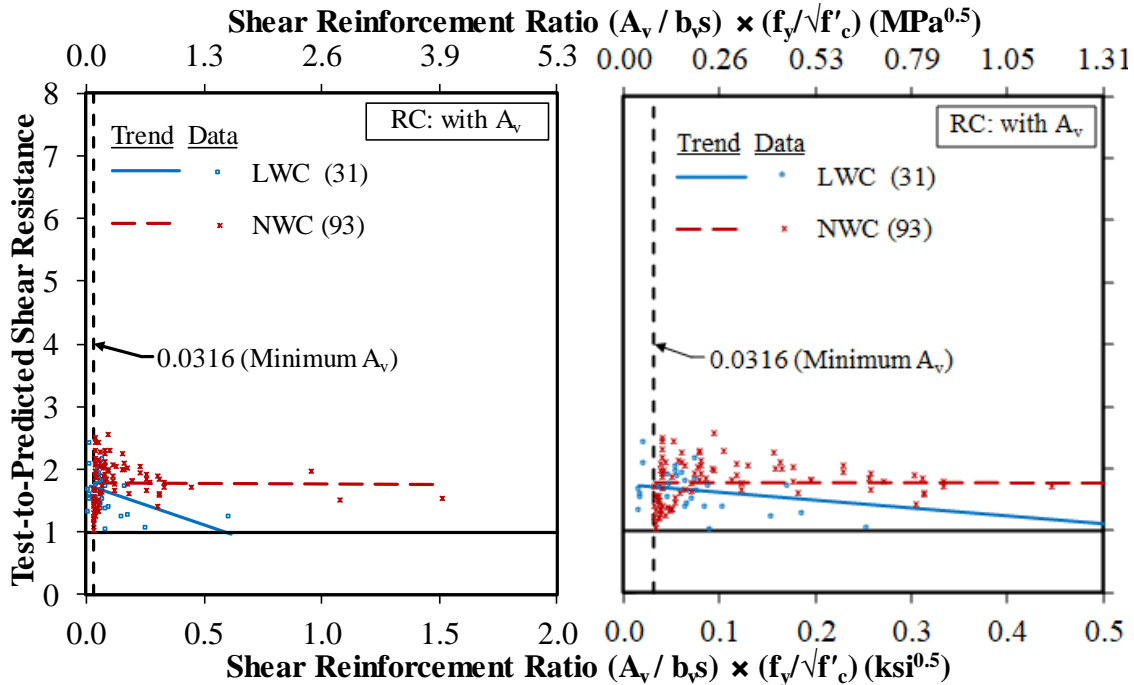

Source: FHWA.

1 ksi = 6.89 MPa.

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 148. Graphs. Test-to-predicted shear resistance compared to shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for Simplified-RC for LWC RC members with shear reinforcement.**

1 ksi = 6.89 MPa.

**Figure 149. Graphs. Test-to-predicted shear resistance compared to shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for Simplified-RC for LWC and NWC RC members with shear reinforcement.**

A  $\lambda$ -factor of 0.75 is the smallest modification factor possible for the proposed LWC modification factor using equation 36 through equation 38 and the smallest for all-lightweight concrete in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> Using the proposed equation 49 for the minimum amount of shear reinforcement with a  $\lambda$ -factor of 0.75 is shown by the vertical line at 0.0237 (i.e., a line slightly to the left of the one shown at 0.0316) in figure 148 and figure 149. There are six specimens with an amount of shear reinforcement less than the minimum given by equation 10 (i.e., shown on the left side of the vertical line at 0.0316). They have an amount of shear reinforcement that is also less than that given by equation 49 using a  $\lambda$ -factor of 0.75. As shown in figure 148, the test-to-prediction ratios for these six specimens appear to have similar values to the specimens with an amount of shear reinforcement slightly greater than the minimum amount given by equation 10. This is also indicated by the regression line for the LWC specimens in figure 149 that is slightly higher for the specimens with shear reinforcement less than the minimum amount.

The ratios determined using the GP-equation method are shown in figure 150 and figure 151, and the ratios determined using the Simplified-PC/RC procedure are shown in figure 152 and figure 153. Note that these four figures present the ratios in a similar manner as in figure 148 and figure 149. In each of these figures, the left-hand graph shows the ratios over the full range of the horizontal axis. The right-hand graph shows the data for specimens over a range of shear reinforcement ratios closer to the minimum amount of shear reinforcement given by equation 10.

There are nine specimens shown in figure 150 through figure 153 with an amount of shear reinforcement less than the minimum amount given by equation 10, as indicated by their position to the left of the vertical line at 0.0316. For all nine of these specimens, their amount of shear reinforcement is also less than that given by equation 49 using a  $\lambda$ -factor of 0.75. The test-to-prediction ratios for these nine specimens is similar to the ratios at slightly larger shear reinforcement values (i.e., slightly to the right of the line at 0.0316).

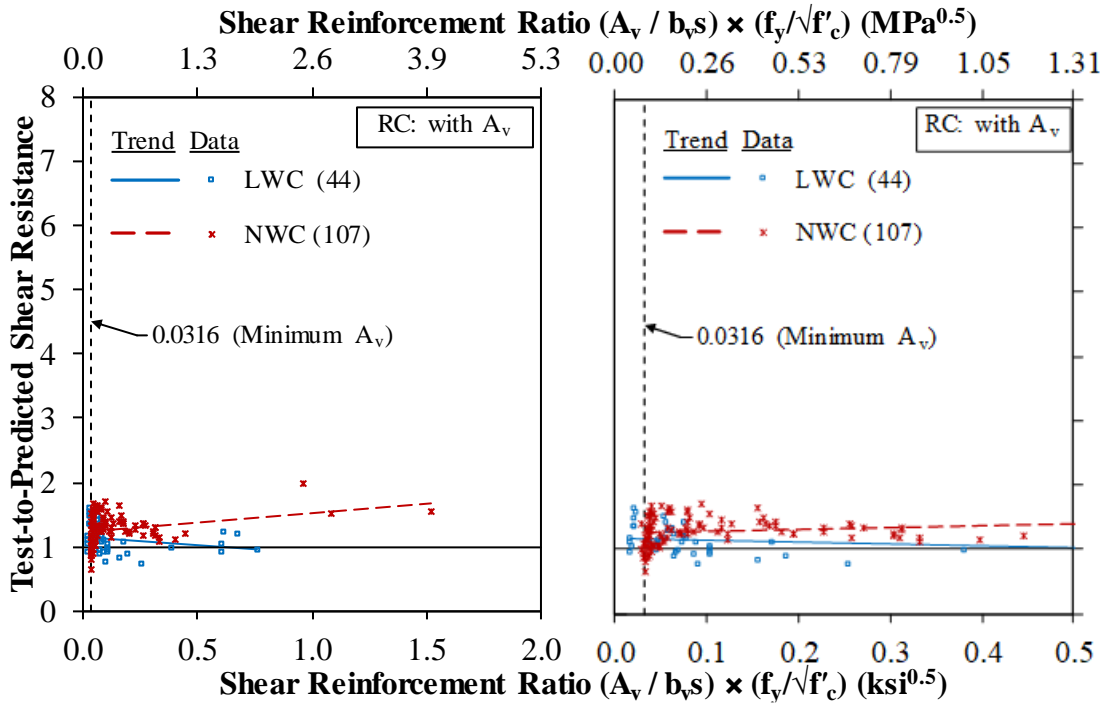

Source: FHWA.

1 ksi = 6.89 MPa.

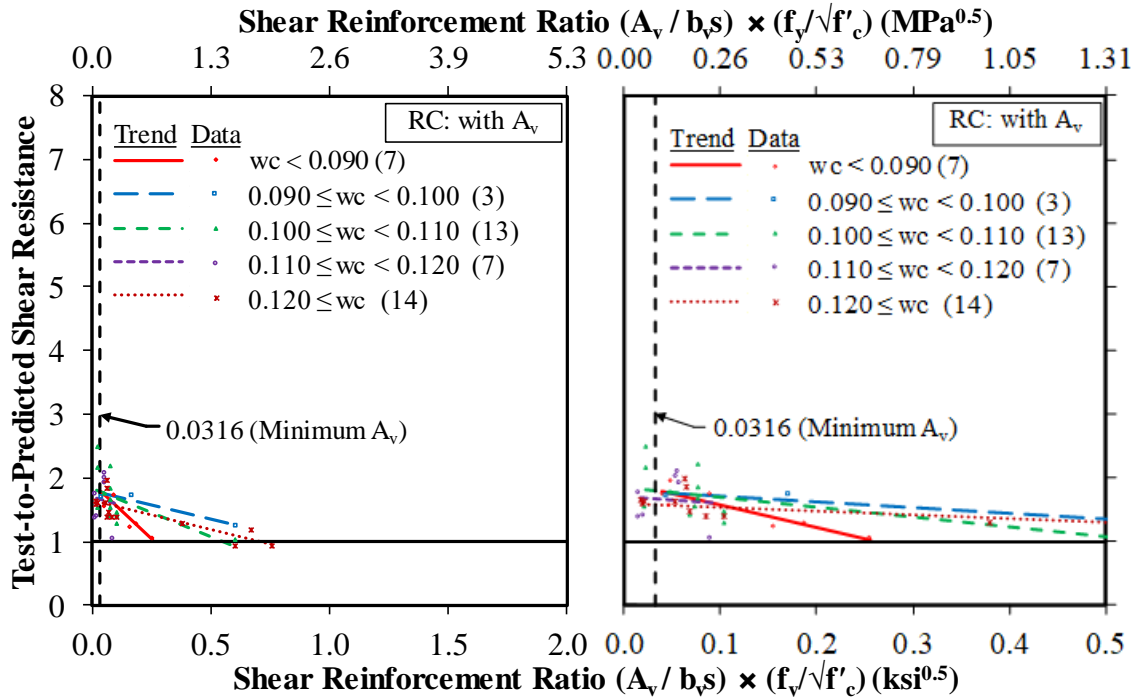

Note: Unit weight ( $w_c$ ) in the legend is measured in kcf where 1 kcf = 16,020 kg/m<sup>3</sup>.

**Figure 153. Graphs. Test-to-predicted shear resistance compared to the shear reinforcement ratio multiplied by the ratio of stirrup yield strength to the square root of concrete compressive strength for Simplified-PC/RC for LWC and NWC RC members with shear reinforcement.**

Similar trends were observed in the figures for PC specimens with shear reinforcement. Figure 154 and figure 155 show the ratios determined using the GP-equation method, and figure 156 and figure 157 show the ratios determined using the Simplified-PC/RC procedure. The four specimens with less shear reinforcement than the minimum given by equation 10 were also less than the minimum given by equation 49 using a  $\lambda$ -factor of 0.75. Similar to the RC specimens, these four PC specimens had similar test-to-prediction ratios as the specimens with slightly more shear reinforcement. Note that the four figures also present the ratios in a similar manner as in figure 148 and figure 149. In each of these figures, the left-hand graph shows the ratios over the full range of the horizontal axis, and the right-hand graph shows the data for specimens over a range of shear reinforcement ratios closer to the minimum amount of shear reinforcement given by equation 10.

For both RC and PC specimens in the TFHRC shear database, the test-to-prediction ratios for LWC specimens with less shear reinforcement than the minimums given by equation 10 and equation 49 are similar to the ratios for specimens with slightly more shear reinforcement. Also, nearly all of the LWC specimens with an amount of shear reinforcement near the minimum had ratios that were greater than 1.0 regardless of the method used to determine shear resistance.

### Upper Limit on Shear Resistance for RC and PC Specimens

In this section, test-to-prediction ratios for shear resistance were used to evaluate the upper limit on the average shear stress given by Article 5.8.3.3 in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The expression for the upper limit is given by equation 14, which limits average stress equal to 25 percent of the concrete compressive strength.

Figure 158 through figure 165 compare the test-to-prediction ratios to the normalized average shear stress. Normalized shear stress is given as the ratio of average shear stress to  $f'_c$ . Average shear stress was determined using equation 39. Note that in each set of the following eight figures (see figure 158 through figure 165), the graph on the left shows the full range of shear stress on the horizontal axis, while the graph on the right shows the same graph over a limited range of shear stress near the upper limit of  $0.25 f'_c$  on the horizontal axis. In each figure, a vertical line at 0.25 is shown to indicate the upper limit on shear stress. Two sets of figures are shown for RC specimens, and two more sets of figures are shown for PC specimens with shear reinforcement. The ratios were determined using the GP-equation and Simplified-PC/RC procedure for the both RC and PC specimens. Figures are not shown for the Simplified-RC procedure because only one specimen satisfied the limitations of the procedure that had a  $v_u$  greater than  $0.25 f'_c$ .

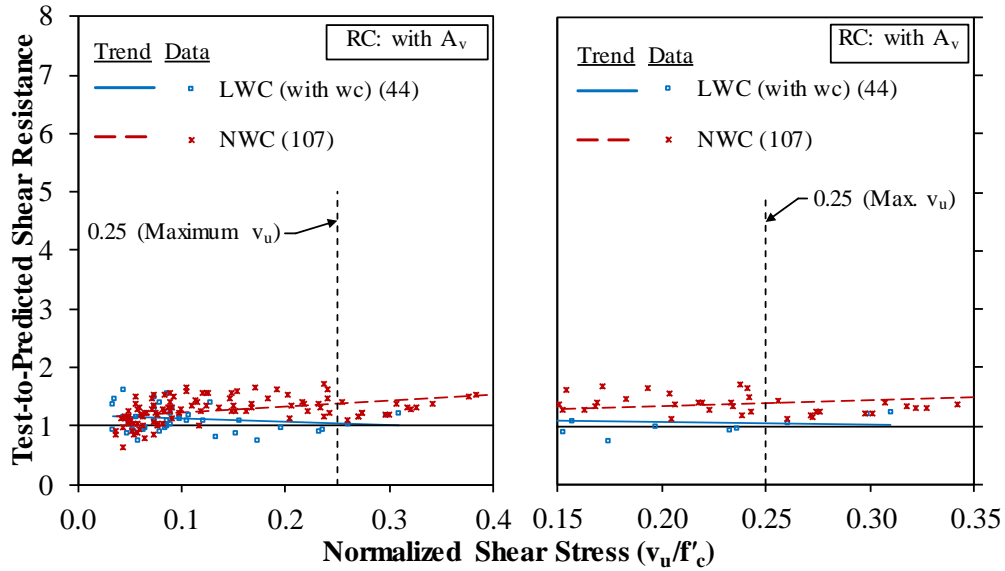

The ratios for RC specimens determined using the GP-equation method are shown in figure 158 and figure 159, while figure 160 and figure 161 show the ratios determined using the Simplified-PC/RC procedure. These figures show that, for specimens with a normalized stress greater than the limit, there were no ratios less than 1.0. Also, the trend lines are nearly horizontal, indicating that ratios above and below the limit were similar. A similar trend is observed for the ratios of PC specimens. Figure 160 and figure 163 show the ratios determined using the GP-equation method. The ratios determined using the Simplified-PC/RC procedure are shown in figure 164 and figure 165.

## SUMMARY OF SHEAR STRESS AND SHEAR RESISTANCE ANALYSES

The average shear stress at failure and predicted shear resistance was evaluated on tests of LWC beams. The results of LWC beam tests were compared to NWC beam tests to determine the effect of using lightweight aggregate.

### Normalized Shear Stress

The regression line for the normalized shear stress of LWC specimens without shear reinforcement was slightly less than the normalized stress of NWC specimens, indicating a modification for LWC may be appropriate. A dependence of normalized shear strength on  $w_c$  was not observed for RC specimens without shear reinforcement. Although the data on LWC specimens with an effective depth greater than 15 inches (381 mm) was limited, the regression lines for both LWC and NWC showed a decrease in normalized stress as the effective depth increased. This indicates that there was some dependence of shear strength on the effective depth of RC beams without shear reinforcement.

The difference between the LWC and NWC regression lines indicating normalized shear stress was greater for specimens with shear reinforcement than for specimens without shear reinforcement. This suggests that the effect of lightweight aggregate on shear strength was more pronounced for members with shear reinforcement than for members without shear reinforcement. A dependence of normalized shear strength on  $w_c$  was not observed for RC specimens with shear reinforcement. The regression lines for both LWC and NWC showed a slight decrease in normalized shear stress as the normalized spacing of shear reinforcement increased.

There were a limited number of tests on PC specimens without shear reinforcement. The regression line for the normalized shear stress of the LWC data was below the regression line of the NWC data, indicating a potential need for a reduction factor for LWC. The limited LWC data did not allow a comparison of normalized shear strength with concrete unit weight for PC specimens without shear reinforcement.

Similar to the trend observed for RC specimens, the regression line for the normalized shear stress of LWC PC specimens with shear reinforcement was below the NWC regression line. A dependence of normalized shear strength on concrete unit weight was not observed for PC specimens with shear reinforcement. The regression lines for both LWC and NWC showed a decrease in normalized shear stress as the normalized spacing of shear reinforcement increased, although the slope of the LWC line was much less (i.e., closer to horizontal) than the NWC line.

A clear trend was shown of the normalized shear stress increasing for LWC specimens as the ratio of shear span-to-effective  $a/d_v$  decreased. This trend did not appear to be dependent on  $w_c$ .

### **Predicted Shear Resistance—Comparisons of Design Methodologies and LWC Modification Factor**

In the *AASHTO LRFD Bridge Design Specifications*, the modification factor for LWC is applied to  $\cot \theta$  in the Simplified-PC/RC procedure.<sup>(3)</sup> For PC members with shear reinforcement, this can result in the predicted shear resistance of an LWC member being greater than the predicted resistance of a NWC member with similar dimensions and material strengths.

Test-to-prediction ratios were determined for the design methodologies in the *AASHTO LRFD Bridge Design Specifications* using the proposed expression for the  $\lambda$ -factor.<sup>(3)</sup> The mean test-to-prediction ratios for all specimens determined using the GP-equation and GP-table methods were similar with values of 1.32 and 1.39, respectively, and had a COV of nearly 50 percent. The mean ratio determined using the Simplified-PC/RC procedure was larger with a value of 2.07 and a COV of nearly 60 percent.

Test-to-prediction ratios were determined to compare the proposed  $\lambda$ -factor based on  $w_c$  and the modification for LWC in the *AASHTO LRFD Bridge Design Specifications* based on concrete constituents (i.e., all-lightweight and sand-lightweight).<sup>(3)</sup> The ratios were determined for specimens with either all-lightweight or sand-lightweight concrete. The mean ratios determined using the modification for LWC in the AASHTO modified method were 1 to 2 percent larger than the ratios determined using the proposed  $\lambda$ -factor based on  $w_c$ . The COV for a design method was nearly the same regardless of the method of LWC modification.

The test-to-prediction ratios for LWC specimens with less shear reinforcement than the minimum amount given by the *AASHTO LRFD Bridge Design Specifications* were similar to the ratios for specimens with slightly more shear reinforcement.<sup>(3)</sup> This trend was observed for both RC and PC specimens. Nearly all of the LWC specimens with an amount of shear reinforcement near the minimum had ratios that were greater than 1.0. This trend was observed regardless of the method used to determine shear resistance.

The mean test-to-prediction ratios for both RC and PC LWC specimens with a normalized stress greater than the upper limit given in the *AASHTO LRFD Bridge Design Specifications* were all

greater than 1.0.<sup>(3)</sup> The ratios for specimens slightly above and slightly below the limit were similar.

### **Predicted Shear Resistance—Comparison of LWC and NWC**

The mean ratios determined for all of the LWC specimens in the TFHRC shear database were compared to the ratios determined for all of the NWC specimens in the ACI-DafStb database. (For sources, see both Bibliography sections.) The ratios of the LWC specimens were determined using the proposed  $\lambda$ -factor. The mean ratios for the LWC specimens were 9 to 10 percent larger than the ratios of the NWC specimens depending on the design procedure; however, the COVs determined for the LWC specimens were much larger than the COVs of the NWC specimens.

A comparison of the mean ratios for LWC specimens and the NWC specimens was also made by specimen type. The mean ratios for RC and PC LWC specimens without shear reinforcement were greater than the mean ratios for the NWC specimens. For the RC specimens with shear reinforcement, the mean ratios for the LWC specimens were less than for the NWC specimens but still greater than 1.0. The LWC and NWC PC specimens with shear reinforcement had similar mean test-to-prediction ratios and COVs. The COVs for the other three types of LWC specimens were nearly twice the COVs of the NWC specimens.

## CHAPTER 6. REDUCTION FACTOR FOR LWC IN SHEAR

### INTRODUCTION

The resistance factor ( $\phi$ ) for LWC in shear was determined by calculating the reliability index for LWC ( $\beta_{LWC}$ ) and comparing the calculated  $\beta_{LWC}$  to a target reliability index of 3.5 and the reliability index for NWC ( $\beta_{NWC}$ ) in shear.

The nominal unfactored load effects (i.e., dead loads and vehicular loads) used for design are given in Articles 3.5.1 and 3.6.1 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The total sum of these nominal unfactored loads ( $\Sigma Q_i$ ) is given by equation 54. The dead load effects in the equation include the dead load of structural components ( $Q_{DC}$ ) and the dead load of the wearing surface ( $Q_{DW}$ ). The vehicular live load ( $Q_{LL}$ ) and vehicular dynamic load allowance ( $Q_{IM}$ ) are also included. The effect of the vehicular live load and dynamic load allowance are given together as the term  $Q_{LL+IM}$ . For design by LFRD, the nominal loads are factored. The total factored loads ( $Q$ ) used for design are given by equation 55, where the nominal design loads are given by the unfactored load effects ( $Q_i$ ), and the load factors are given by  $\gamma_i$ . In this chapter, the subscript  $i$  is used to denote the individual unfactored design loads (i.e.,  $Q_{DC}$ ,  $Q_{DW}$ ,  $Q_{LL}$ , and  $Q_{IM}$ ).

$$\Sigma Q_i = Q_{DC} + Q_{DW} + Q_{LL+IM} \quad (54)$$

$$Q = \Sigma \gamma_i Q_i \quad (55)$$

The load effects can be assumed to be normally distributed, as shown in figure 166.  $\Sigma Q_i$  and  $Q$  are shown in the figure as is the most frequent actual load effect, which is the mean load effect ( $m_Q$ ). The ratio of a mean value to the nominal value used for design is known as the bias factor. The bias factor for the load effects ( $\lambda_{Q_i}$ ) is the ratio of the mean load effects to the unfactored load effects (see equation 56). The total mean load effect can then be determined as a sum of the individual mean load effects (see equation 57).

Source: FHWA.

**Figure 166. Graph. Nominal, mean, and factored load effects and resistance.**

Where:

$\phi R_n$  = factored nominal resistance.

$R_n$  = nominal resistance.

$m_R$  = mean resistance.

$\beta_{RQ}$  = reliability index.

$$\lambda_{Qi} = \frac{m_i}{Q_i} \quad (56)$$

Where  $m_i$  is the mean load effect of an individual load.

$$m_Q = \Sigma(Q_i \lambda_{Qi}) \quad (57)$$

Member resistance can also be assumed to be normally distributed, as shown in figure 166. The nominal resistance ( $R_n$ ) is the calculated strength of a member. The mean resistance ( $m_R$ ) is given by equation 58, where  $\lambda_R$  is the bias factor for resistance. Mean resistance is commonly assumed to be the product of the nominal resistance and three parameters that account for uncertainty in the actual member resistance. The product of  $\phi$  and  $R_n$  is the factored nominal resistance ( $\phi R_n$ ).  $R_n$ ,  $m_R$ , and  $\phi R_n$  are all shown in figure 166. The determination of  $\phi$  for LWC in shear is described in this chapter.

$$m_R = R_n \lambda_R \quad (58)$$

The three parameters that account for uncertainty in the actual member resistance are fabrication, material, and analysis.<sup>(48,49)</sup> The uncertainty in fabrication is due to differences between the nominal and actual overall cross-section dimensions. Material uncertainty is due to differences between the nominal and actual material properties of the concrete and reinforcement. The analysis uncertainty is a result of the approximate methods used to predict resistance.  $\lambda_R$  is assumed to be the product of the bias factors for uncertainty in the fabrication ( $\lambda_F$ ), uncertainty in the material ( $\lambda_M$ ), and uncertainty in the analysis ( $\lambda_P$ ) (also referred to as the professional factor) (see equation 59). The COV for resistance ( $V_R$ ) is given by equation 60, where  $V_F$ ,  $V_M$ , and  $V_P$  are the COV of the uncertainty of the fabrication, material, and analysis parameters, respectively.

$$\lambda_R = \lambda_F \lambda_M \lambda_P \quad (59)$$

$$V_R = \sqrt{V_F^2 + V_M^2 + V_P^2} \quad (60)$$

The LRFD method of design is based on  $Q$  being less than  $\phi R_n$ , as given by equation 61. A failure is assumed in the event that  $Q$  exceeds  $\phi R_n$ . The probability of failure is then the area under the overlap of the distributions for load effects and resistance, as illustrated by the red shaded area in figure 166 labeled “overlap.”

$$Q \leq \phi R_n \quad (61)$$

The probability of failure (i.e., when  $\phi R_n - Q < 0$ ) is related to  $\beta_{RQ}$ . The expression for  $\beta_{RQ}$  in equation 62 has been recently used to evaluate  $\phi$  for structural concrete buildings.<sup>(48,50,51)</sup> In equation 62,  $\sigma_R$  and  $\sigma_Q$  are the standard deviation of the resistance and total load effect, respectively. In the evaluation, a resistance factor was selected, and then  $\beta_{RQ}$  was determined using equation 62 over a range of dead-to-total load ratios. The resulting  $\beta_{RQ}$  for LWC in shear was then compared to a target reliability index ( $\beta_{target}$ ) and the  $\beta_{NWC}$  in shear to determine whether the selected resistance factor was adequate.

$$\beta_{RQ} = \frac{m_R - m_Q}{\sqrt{\sigma_R^2 + \sigma_Q^2}} \quad (62)$$

Where:

$\sigma_R^2$  = variance of the resistance.

$\sigma_Q^2$  = variance of the mean unfactored load effects.

## METHOD TO DETERMINE THE RELIABILITY INDEX

The introduction to this chapter gave definitions for the important terms that are used to perform a reliability analysis to evaluate a selected  $\phi$ . This section describes the method used to determine the mean and standard deviation of resistance and load effect that are needed to determine  $\beta_{RQ}$  using equation 62.

The three basic steps to determine  $\beta_{RQ}$  are described. The first step is to determine a relationship between  $R_n$  and the total nominal unfactored load effects ( $\Sigma Q_i$ ). The next step is to determine the mean and standard deviation of the load effects (i.e.,  $m_Q$  and  $\sigma_Q$ ). The third step is to determine the mean of resistance ( $m_R$ ) and the standard deviation of resistance ( $\sigma_R$ ). Then, equation 62 can be used to determine  $\beta_{RQ}$ .

### Relationship Between Nominal Resistance and Unfactored Loads

The nominal resistance and unfactored loads are related by considering the largest factored loads that can be used for design. The largest loads for design occur for the case of the factored loads equaling the factored nominal resistance as given by equation 63. An expression that relates the sum of  $\Sigma Q_i$  to the total factored load effects ( $Q$ ) is needed.

$$Q = \phi R_n \quad (63)$$

The individual load effects due to dead load and vehicle live loads are given by the load combinations in Article 3.4.1 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The individual loads are multiplied by load factors ( $\gamma_i$ ) in each load combination. Considering the effects of dead load and vehicular live load, the total factored loads are shown in equation 64. According to the *AASHTO LRFD Bridge Design Specifications*, the strength I load combination is used for the normal operational use of a bridge.<sup>(3)</sup> It has also been previously used to evaluate the structural reliability of bridges.<sup>(52)</sup> The load factors for the strength I load combination are load factor for load effects due to dead load of structural components ( $\gamma_{DC}$ ) = 1.25, load factor for

load effects due to dead load of the wearing surface ( $\gamma_{DW}$ ) = 1.50, and load factor for load effects due to combined vehicular live load and dynamic load allowance ( $\gamma_{LL+IM}$ ) = 1.75.

$$Q = \gamma_{DC}Q_{DC} + \gamma_{DW}Q_{DW} + \gamma_{LL+IM}Q_{LL+IM} \quad (64)$$

$r_Q$  is the ratio of the unfactored permanent loads (i.e.,  $Q_{DC}$  and  $Q_{DW}$ ) to the total unfactored force effect ( $\Sigma Q_i$ ) (see equation 65). This is analogous to the ratio of dead load to the sum of dead and live loads previously used in the reliability analysis of buildings.<sup>(51,53)</sup>

$$r_Q = \frac{Q_{DC} + Q_{DW}}{\Sigma Q_i} \quad (65)$$

$r_{DW}$  is the ratio of the dead load of the wearing surface ( $Q_{DW}$ ) to the dead load of structural components ( $Q_{DC}$ ) (see equation 66).

$$r_{DW} = \frac{Q_{DW}}{Q_{DC}} \quad (66)$$

The unfactored load effects can be expressed in terms  $\Sigma Q_i$  and the ratios  $r_Q$  and  $r_{DW}$ .  $Q_{DC}$  and  $Q_{DW}$  are provided in equation 67 and equation 68, respectively. The expression for the combined vehicular live load and dynamic load allowance ( $Q_{LL+IM}$ ) is solved using equation 69. A more detailed explanation of the derivation of equation 67 through equation 69 is given in appendix D.

$$Q_{DC} = \left( \frac{r_Q}{1 + r_{DW}} \right) \Sigma Q_i \quad (67)$$

$$Q_{DW} = \left( \frac{r_{DW}r_Q}{1 + r_{DW}} \right) \Sigma Q_i \quad (68)$$

$$Q_{LL+IM} = (1 - r_Q) \Sigma Q_i \quad (69)$$

The nominal dynamic load allowance ( $IM$ ) in the *AASHTO LRFD Bridge Design Specifications* is 0.33.<sup>(3)</sup>  $Q_{LL}$  can be separated from  $Q_{LL+IM}$  using  $IM$ , as shown in equation 70.

$$Q_{LL} = \frac{Q_{LL+IM}}{1 + IM} \quad (70)$$

The expressions for the individual load effects in equation 67 through equation 69 are then substituted into equation 64. After simplification, the resulting expression is in equation 71. The right-hand term of equation 71 is only a function of the load factors ( $\gamma_i$ ) and the ratios  $r_Q$  and  $r_{DW}$ .  $Q$  can be expressed as  $\Sigma Q_i$  multiplied by the function of  $\gamma_i$ ,  $r_Q$ , and  $r_{DW}$  (see equation 72).

$$Q = \Sigma Q_i \left[ \left( \frac{r_Q}{1 + r_{DW}} \right) (\gamma_{DC} + \gamma_{DW}r_{DW}) + \gamma_{LL+IM}(1 - r_Q) \right] \quad (71)$$

$$Q = \Sigma Q_i f(\gamma_i, r_Q, r_{DW}) \quad (72)$$

After substituting equation 72 into equation 63 and rearranging, an expression for the relationship between  $\Sigma Q_i$  and  $R_n$  is created (see equation 73). A more detailed explanation of the derivation of equation 67 through equation 73 is provided in appendix D.

$$\Sigma Q_i = \frac{\phi R_n}{f(\gamma_i, r_Q, r_{DW})} \quad (73)$$

### Mean and Standard Deviation of Unfactored Load Effects

The general expression for  $m_Q$  was previously provided in equation 57. For the case of load effects due to dead loads and vehicular live loads,  $m_Q$  is solved for using equation 74. The effects of  $Q_{LL}$  and  $Q_{IM}$  are considered separately in equation 74. This implies that  $Q_{LL}$  and  $Q_{IM}$  are uncorrelated, which is the assumption made in previous reliability analyses of bridges.<sup>(49,52)</sup>  $IM$  in equation 74 is a factor multiplied by  $Q_{LL}$ . The individual load effects in equation 74 are multiplied by bias factors.

$$m_Q = Q_{DC}\lambda_{DC} + Q_{DW}\lambda_{DW} + Q_{LL}\lambda_{LL} + (Q_{LL}IM)\lambda_{IM} \quad (74)$$

Where:

$\lambda_{DC}$  = bias factor for the load effects due to dead load of structural components.

$\lambda_{DW}$  = bias factor for the load effects due to dead load of the wearing surface.

$\lambda_{LL}$  = bias factor for the load effects due to vehicular live load.

$\lambda_{IM}$  = bias factor for the load effects due to vehicular dynamic load allowance.

Variation of the mean unfactored load effects ( $\sigma_Q^2$ ) is the sum of the variation of the individual loads.<sup>(49,54)</sup> The definition of standard deviation is the square root of variance. The COV is the ratio of the standard deviation to the mean. The definition of the bias factor is the ratio of the mean to the nominal value. The general expression for  $\sigma_Q^2$  is found in equation 75 and includes the progressive derivation by substituting the definitions of COV and bias factor. The expression for variance that includes the dead load and vehicular live load effects is solved for in equation 76. A more detailed explanation of the derivation of equation 74 and equation 76 is provided in appendix D.

$$\sigma_Q^2 = \Sigma(\sigma_{Q_i})^2 = \Sigma(V_{Q_i}m_{Q_i})^2 = \Sigma[V_{Q_i}(Q_i\lambda_{Q_i})]^2 \quad (75)$$

Where:

$\sigma_{Q_i}$  = standard deviation of the individual load effects.

$V_{Q_i}$  = COV of the unfactored load effect.

$m_{Q_i}$  = mean of the individual load effects.

$$\sigma_Q^2 = (V_{DC}Q_{DC}\lambda_{DC})^2 + (V_{DW}Q_{DW}\lambda_{DW})^2 + (V_{LL}Q_{LL}\lambda_{LL})^2 + (V_{IM}Q_{IM}IM\lambda_{IM})^2 \quad (76)$$

Where:

$V_{DC}$  = COV for the dead load of structural components.

$V_{DW}$  = COV for the dead load of the wearing surface.

$V_{LL}$  = COV for the vehicular live load.

$V_{IM}$  = COV for the vehicular dynamic load allowance.

### Mean and Standard Deviation of Resistance

The general expression for the mean of the resistance ( $m_R$ ) was solved for in equation 58. The uncertainties due to fabrication and materials were determined together using a numerical technique known as Monte Carlo simulation.<sup>(55)</sup> The bias factor and COV for the combined uncertainty of the fabrication and materials are  $\lambda_{FM}$  and  $V_{FM}$ , respectively.<sup>(49,52)</sup> The expression for mean resistance that includes  $\lambda_{FM}$  is given by equation 77. The general expression given by equation 60 for the COV of the resistance ( $V_R$ ) was modified to include  $V_{FM}$  (see equation 78). The expression for  $\sigma_R^2$  (see equation 79) was determined by substituting equation 78 into the definition of standard deviation. A more detailed explanation of the derivation of equation 79 is provided in appendix D.

$$m_R = R_n \lambda_{FM} \lambda_P \quad (77)$$

$$V_R = \sqrt{V_{FM}^2 + V_P^2} \quad (78)$$

$$\sigma_R^2 = m_R^2 (V_{FM}^2 + V_P^2) \quad (79)$$

### Summary of the Solution Procedure

The following section summarizes the solution procedure used to determine  $\beta_{RQ}$ . A value of 1.0 was selected for  $R_n$ . The magnitude of  $R_n$  is not important because the nominal loads are determined as a fraction of  $R_n$  in the analysis. A trial value for  $\phi$  was selected, and values for  $r_Q$  and  $r_{DW}$  were selected.  $\Sigma Q_i$  is determined using equation 73. The individual unfactored dead loads (i.e.,  $Q_{DC}$  and  $Q_{DW}$ ) are determined using equation 67 and equation 68.  $Q_{LL+IM}$  is determined using equation 69, and  $Q_{LL}$  is separated from  $Q_{LL+IM}$  using equation 70.

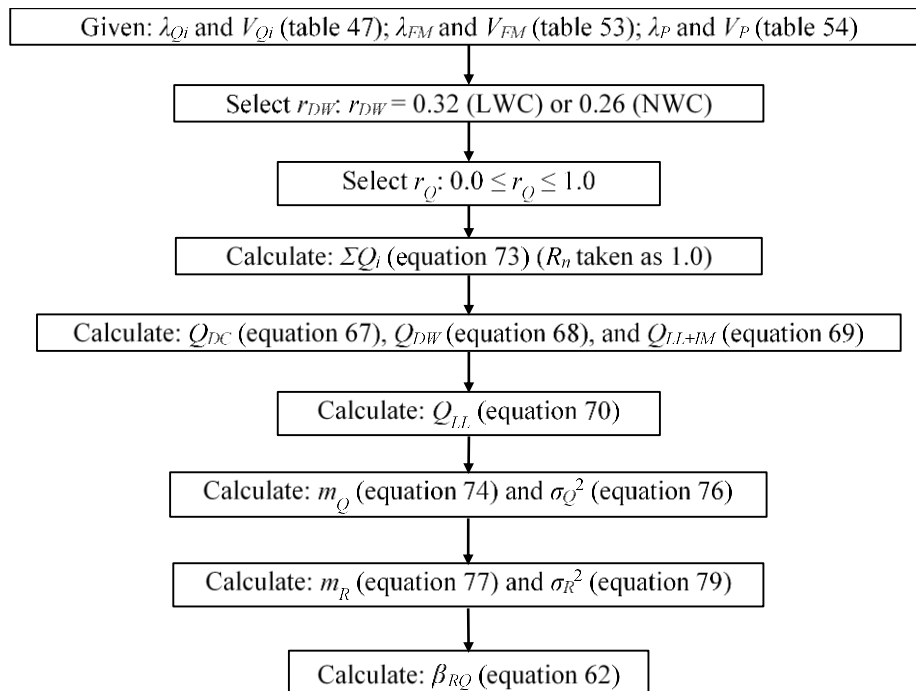

The mean unfactored load and the variance of the loads are determined using the statistical parameters  $\lambda_{Q_i}$  and  $V_{Q_i}$ . The bias factor ( $\lambda_{Q_i}$ ) and COV ( $V_{Q_i}$ ) for the individual loads were found in the literature and are described in the following section.<sup>(50,52)</sup>  $m_Q$  was determined using equation 74, and  $\sigma_Q^2$  was determined using equation 76.

The mean resistance ( $m_R$ ) and the variance of the resistance ( $\sigma_R^2$ ) were determined using the bias factors and COV for the uncertainty in the fabrication, materials, and analysis. The bias factors and COVs for the fabrication and material parameters (i.e.,  $\lambda_{FM}$  and  $V_{FM}$ ) were determined using Monte Carlo simulations that are described in the following section. The bias factor and COV for the analysis factor (i.e.,  $\lambda_P$  and  $V_P$ ) were determined using the specimens in the TFHRC shear database for shear described previously in this report. The statistical parameters for the analysis factor (i.e., professional factor) are also summarized in the following section and depend on the

type of specimen and analysis method for determining  $R_n$ .  $m_R$  and  $\sigma_R^2$  were determined using equation 77 and equation 79, respectively.

$\beta_{RQ}$  was determined using equation 62 for given values for  $r_Q$  and  $r_{DW}$ , a specific specimen type, and a specific analysis method for determining  $R_n$ . The values of  $r_Q$  were varied between 0 and 1.0 to produce a set of  $\beta_{RQ}$  values. Values for  $r_{DW}$  were determined as described in the following section. Separate calculations were made for three of the analysis methods used to determine  $R_n$  in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> Separate calculations were also made for an RC cross section and two different PC cross sections. A flowchart showing the method for determining  $\beta_{RQ}$  is given in figure 167. Figures showing the  $\beta_{RQ}$  values determined using this procedure and an analysis of results are included later in this chapter in the Reliability Index for RC and PC LWC Members in Shear section.

## STATISTICAL PARAMETERS FOR LOAD EFFECTS AND RESISTANCE

This section describes the statistical parameters for load effects and resistance that are used in the reliability analysis described in this report. The mean, bias, and COV of the load effects are described as well as the numerical method used to determine the statistical parameters for the uncertainty in fabrication and materials. This section also provides the method used to determine the uncertainty in the analysis by analyzing databases of shear tests on LWC and NWC.

## Load Effect Factors

The load factors for the dead load of structural components ( $Q_{DC}$ ), dead load of the wearing surface ( $Q_{DW}$ ), vehicular live load ( $Q_{LL}$ ), and vehicular dynamic load allowance ( $Q_{IM}$ ) specified for load combination strength I in the *AASHTO Bridge Design Specifications* are provided in table 47.<sup>(3)</sup> The bias factors and COV for the load effects that were determined in previous studies are also given in table 47.

**Table 47. Statistical parameters for load effects.**

Force Effect	$\gamma_i$	$\lambda_{Qi}$	$V_{Qi}$ (Percent)	Reference
$Q_{DC}$	1.25	1.05	8.0	52
$Q_{DW}$	1.50	1.00	25.0	52
$Q_{LL}$	1.75	1.28	12.0	50 and 52
$Q_{IM}$	1.75	0.303	80.0	50 and 52

The term  $r_{DW}$  is used to define the ratio of  $Q_{DW}$  to  $Q_{DC}$  in this report. The ratio was estimated using four sets of assumed girder spacings and girder sizes. It was then determined for each case using equation 80.  $r_{DW}$  was determined for a bridge with LWC girders and deck and also for a bridge with NWC girders and deck. The assumed girder spacing, girder sizes, and calculated values of  $r_{DW}$  for an LWC bridge and an NWC bridge are provided in table 48. Based on the range values determined for the four cases, a value of 0.32 was selected for the  $r_{DW}$  for LWC bridges, and a value of 0.26 was selected for the value of  $r_{DW}$  for NWC bridges.

$$r_{DW} = \frac{Q_{DW}}{Q_{DC}} = \frac{\left[\left(\frac{t_{ws}}{12}\right)\left(\frac{s_{beam}}{12}\right)\right] w_{ws}}{\left[\left(\frac{t_{slab}}{12}\right)\left(\frac{s_{beam}}{12}\right)\right] w_{slab} + \left(\frac{A_{beam}}{144}\right) w_{beam}} \quad (80)$$

Where:

$t_{ws}$  = wearing surface thickness.

$s_{beam}$  = beam spacing.

$w_{ws}$  = wearing surface unit weight.

$t_{slab}$  = concrete slab thickness.

$w_{slab}$  = slab unit weight.

$A_{beam}$  = beam cross-sectional area.

$w_{beam}$  = beam unit weight.

**Table 48. Ratio of structural component dead load to wearing surface dead load ( $r_{DW}$ ) determined using equation 80 for modeled bridge geometries.**

Parameter	Case 1: Type I Girder With 4-ft Spacing	Case 2: Type VI Girder With 12-ft Spacing	Case 3: Type IV Girder With 12-ft Spacing	Case 4: Type IV Girder With 14-ft Spacing
Beam spacing, $s_{beam}$ (inches)	48	144	144	168
Wearing surface thickness, $t_{ws}$ (inches)	3.5	3.5	3.5	3.5
Wearing surface unit weight, $w_{ws}$ (kcf)	0.140	0.140	0.140	0.140
Concrete slab thickness, $t_{slab}$ (inches)	8.0	8.0	8.0	8.0
Slab unit weight, $w_{slab}$ (kcf)	0.120	0.120	0.120	0.120
Beam cross-sectional area, $A_{beam}$ (inches <sup>2</sup> )	276	1085	789	789
Beam unit weight (LWC), $w_{beam}$ (kcf)	0.120	0.120	0.120	0.120

### Fabrication and Material Factors for Resistance

The bias and COV due to the uncertainty in fabrication and materials (i.e.,  $\lambda_{FM}$  and  $V_{FM}$ ) were determined using the Monte Carlo simulation of statistical sampling.<sup>(49,50,55)</sup> Three different LWC and NWC cross sections were simulated to determine  $\lambda_{FM}$  and  $V_{FM}$ . Separate simulations were made of each cross section without and with shear reinforcement. Nominal geometric and material parameters for each simulated cross section are assumed to be normally distributed. The bias and COV were determined using 100,000 simulations for each cross section.

The uncertainty in fabrication and materials was evaluated by determining the nominal resistance for simulated cross sections. The cross sections had geometric and material properties that were assumed to be normally distributed. An RC cross section was simulated with the nominal parameters given in table 49. The geometric parameters are illustrated in figure 168. AASHTO type II and type IV prestressed girder cross sections were also simulated with the nominal parameters (see table 50 and table 51, respectively). Figure 169 illustrates the geometric parameters for the prestressed cross sections. The thickness of the flanges was taken as the thickness of the actual flange plus one-third the thickness of the chamfer. The nominal resistance was determined for two versions of each cross section: one without shear reinforcement and the other with shear reinforcement.

B. Idealized PC cross section.

**Figure 169. Illustrations. Geometric parameters for cross section and idealized PC sections.**

For each simulation, a uniformly distributed random number was generated for each geometric and material parameter. The random number was used as the probability of a value in the normal cumulative distribution and was used to determine a simulated sample value of the parameter

with a given mean and standard deviation. After the geometric and material parameters were simulated, the nominal resistance was determined using the Simplified-RC procedure, the GP-equation method, and the Simplified-PC/RC procedure. The bias for each simulation was determined as the ratio of the nominal resistance using the simulated parameters to the nominal resistance determined using nominal values for the parameters. The mean and COV of the bias factors for all of simulations on a cross section is taken as  $\lambda_{FM}$  and  $V_{FM}$ , respectively.

The effect that the number of simulations has on the bias and COV of the RC section is given in table 52. The bias of the load effects was reported to three significant figures, as given in table 47. The COV of the load effects was reported to only two significant figures. The statistical parameters for geometry and materials were reported to a similar level of precision. As shown in table 52,  $\lambda_{FM}$  and  $V_{FM}$  obtained this level of precision for the RC cross section after 100,000 simulations. Fewer numbers of simulations were needed to obtain a similar level of accuracy for the type II and type IV cross sections.

**Table 52. Effect of the number of simulations on the statistical parameters for the RC cross section determined using the Monte Carlo simulation for LWC.**

Concrete Type and Specimen Group	Design Expression	Statistical Parameter	Number of Simulations			
			1,000	10,000	100,000	1 Million
RC cross section without $A_v$	Simplified-RC	$\lambda_{FM}$	1.1570	1.1540	1.1555	1.1554
	Simplified-RC	$V_{FM}$ (percent)	9.750	9.454	9.523	9.568
RC cross section without $A_v$	GP-equation	$\lambda_{FM}$	1.1549	1.1531	1.1541	1.1540
	GP-equation	$V_{FM}$ (percent)	7.284	7.081	7.140	7.178
RC cross section without $A_v$	Simplified-PC/RC	$\lambda_{FM}$	1.1570	1.1540	1.1555	1.1554
	Simplified-PC/RC	$V_{FM}$ (percent)	9.750	9.454	9.523	9.568
RC cross section with $A_v$	Simplified-RC	$\lambda_{FM}$	1.2466	1.2455	1.2442	1.2442
	Simplified-RC	$V_{FM}$ (percent)	6.728	6.934	6.900	6.904
RC cross section with $A_v$	GP-equation	$\lambda_{FM}$	1.2156	1.2150	1.2139	1.2139
	GP-equation	$V_{FM}$ (percent)	5.775	5.888	5.874	5.858
RC cross section with $A_v$	Simplified-PC/RC	$\lambda_{FM}$	1.2475	1.2463	1.2451	1.2450
	Simplified-PC/RC	$V_{FM}$ (percent)	6.741	6.948	6.915	6.919

In table 52, the bias and COV for the Simplified-RC and Simplified-PC/RC procedures are the same values for the RC cross section without shear reinforcement.  $V_{cw}$  (see equation 30) controlled the shear resistance for this cross section, so both design expressions for  $V_c$  are a function of  $\sqrt{f'_c}b_vd_v$ . The mean  $V_c$  values determined using the two procedures are different, but the simulated normal distributions of  $f'_c$ ,  $b_v$ , and  $d_v$  will cause proportional changes in  $V_c$ , resulting in the same bias and COV for the two methods.

The bias and COV (i.e.,  $\lambda_{FM}$  and  $V_{FM}$ ) for the three LWC and NWC cross sections after 100,000 simulations are given in table 53. The statistical parameters in the table are the result of 1.2 million simulations. The calculation of nominal resistance by the GP-equation method required iterations, so the total time required for each simulation ranged from between 2 to 3 s. Simulations on the LWC RC cross sections were increased to 1 million simulations for a total of 3 million simulations completed for this research effort.

**Table 53. Statistical parameters for fabrication and material factor determined using Monte Carlo simulation for LWC and NWC cross sections.**

Concrete Type and Specimen Group	Design Expression	LWC (100,000 Simulations)		NWC (100,000 Simulations)

Note: NWC specimens were from the ACI-DafStb database.

### Professional Factors for Resistance

The bias and COV due to uncertainty in the analysis (i.e.,  $\lambda_P$  and  $V_P$ ) were determined by analyzing the LWC and NWC shear test databases described and analyzed in a previous chapter of this report. The ratio of test-to-predicted shear resistance for each specimen type was analyzed separately. The test-to-prediction ratios were plotted on normal probability paper, and the bias and COV were determined from the tail of the data.

The bias and COV were determined by plotting the test-to-prediction ratios on normal probability paper. The ratios from a database were arranged in increasing order. The ratios were assigned a cumulative probability ( $p_n$ ) determined using equation 81, where  $n$  was the smallest ratio of test-to-predicted shear resistance, and  $N$  was the total number of ratios of test-to-predicted shear resistance. The smallest ratio was assigned  $n = 1$ , and the largest ratio was assigned  $n = N$ . For each test-to-prediction ratio, the value of the ratio was plotted on the x-axis, and the standard normal variable was plotted on the y-axis. The standard normal variable was equal to the inverse of the cumulative probability. The mean value had a standard normal variable equal to zero, and the distance from the mean value was given in terms of the number of standard deviations. Data that followed a “perfect” normal distribution were arranged along a straight line on normal probability paper.<sup>(50)</sup>

$$P_n = \frac{n}{N+1} \quad (81)$$

The bias and COV were determined from the lower tail of the data. The mean test-to-prediction ratio was the bias factor ( $\lambda_P$ ). The test-to-prediction ratios with a standard normal variable less than or equal to zero were defined as the “lower tail.” A least-squares linear regression was determined for the data in the lower tail. The slope of the regression line was the reciprocal of the standard deviation. By definition, the COV ( $V_P$ ) is the standard deviation divided by the mean test-to-prediction ratio. The data in the lower tail were used to determine the standard deviation because, in the event of a failure, they were due to the resistance being lower than the associated load effects. This is shown in figure 166 as the distribution representing load effects exceeding the lower tail of the distribution representing resistance.

The bias and COV were determined for each specimen type, concrete type, and method of determining nominal resistance. The four specimen types included RC specimens without and with shear reinforcement and PC specimens without and with shear reinforcement. The concrete types included LWC and NWC. The nominal resistance was determined using the Simplified-RC procedure, the GP-equation method, and the Simplified-PC/RC procedure. The bias and COV (i.e.,  $\lambda_P$  and  $V_P$ ) determined for each specimen type, concrete type, and calculation method is given in table 54.

**Table 54. Statistical parameters for professional factor determined using the linear regression of the tail of the cumulative distribution function (CDF) for test-to-predicted resistance of LWC and NWC specimens.**

Concrete Type and Specimen Group	Design Expression	Number of Specimens	$\lambda_P$	$V_P$ (Percent)

NWC, PC specimens with $A_v$	Simplified-PC/RC	100	2.05	25.4

Figure 170 through figure 175 show the CDF for the test-to-prediction ratios. Figure 170 and figure 171 show the CDF for LWC and NWC specimens determined using the Simplified-RC procedure. The CDF for LWC and NWC specimens determined using the GP-equation method is shown in figure 172 and figure 173. The CDF determined using the Simplified-PC/RC procedure is shown in figure 174 and figure 175 for LWC and NWC specimens, respectively. The data in each figure are grouped by specimen type with the number of specimens shown in parentheses. In each figure, the linear regression of lower tail is shown. A vertical line at a ratio of 1.0 is shown. Also shown in each figure are horizontal lines at standard normal variables of 0 and  $-1$ . The standard deviation is the horizontal distance from the intersection of the regression line with the standard normal variable at 0 and at  $-1$ .

The test-to-prediction ratios for a limited number of LWC specimens were not included in the CDF to determine  $\lambda_P$  and  $V_P$ . A total of 11 tests were removed from the databases of RC specimens without stirrups (4 tests) and PC without stirrups (7 tests). For each specimen type, all the tests from only one reference were removed because they had a tested shear strength that was considerably lower than the shear strength of specimens with a similar size and material strengths. Including the test-to-prediction ratios from these few tests resulted in considerably higher values of  $V_P$ . More information about the excluded tests, including figures showing the CDFs,  $\lambda_P$ , and  $V_P$  of the data with the tests included, is given in appendix E.

### RELIABILITY INDEX FOR RC AND PC LWC MEMBERS IN SHEAR

The mean  $\beta_{RQ}$  was determined for the shear resistance of LWC cross sections and compared to  $\beta_{target}$  and the mean reliability index for NWC cross sections. The uncertainty due to the loads was evaluated using data from previous studies to determine the mean and variation of the load.<sup>(50,52)</sup> The uncertainties due to fabrication, material, and analysis were evaluated using numerical simulation and evaluation of shear test results to determine the mean and variance of resistance.  $\beta_{RQ}$  for LWC and NWC in shear was then determined over a range of dead-to-total load ratios.  $\beta_{RQ}$  for LWC was compared to  $\beta_{target}$  and  $\beta_{RQ}$  for NWC.

## Method of Determining Reliability Index

The *AASHTO LRFD Bridge Design Specifications* gives  $\phi$  for LWC in shear as 0.80 and for NWC as 0.90.<sup>(3)</sup>  $\beta_{RQ}$  was evaluated at a resistance factor for LWC 0.75, 0.80, 0.85, and 0.90. These resistance factors were used to determine the mean and variation of the load (i.e.,  $m_Q$  and  $\sigma_Q^2$ ) using equation 74 and equation 76.

The uncertainties due to fabrication, material, and analysis were evaluated using numerical simulation and evaluation of shear test results. The bias and COV due to the uncertainty in the fabrication and materials (i.e.,  $\lambda_{FM}$  and  $V_{FM}$ ) were determined using Monte Carlo simulations on one RC and two PC cross sections. Each cross section was evaluated without and with shear reinforcement. The uncertainty in the analysis was evaluated using the LWC and NWC shear test databases to determine the bias and COV for the professional factor (i.e.,  $\lambda_P$  and  $V_P$ ). The mean and variance of resistance were determined using equation 77 and equation 79, which combine the bias and COV from the fabrication, material, and analysis uncertainty.

$\beta_{RQ}$  was then determined using equation 62 for a range of  $r_Q$  values between 0 and 1.0 in increments of 0.05. The most probable values of  $r_Q$  are assumed to be between 0.3 and 0.7. This is the assumption used by a previous evaluation that determined  $\beta_{RQ}$  for beams over a range of dead-to-total load ratios.<sup>(51)</sup> The mean  $\beta_{RQ}$  was taken as the mean of  $\beta_{RQ}$  determined for  $0.3 \leq r_Q \leq 0.7$ .

A similar method was used to determine  $\beta_{RQ}$  for NWC beams in shear. The resistance factor of 0.9 that is given in the *AASHTO LRFD Bridge Design Specifications* was used to determine the mean and variation of the load.<sup>(3)</sup> Monte Carlo simulations were used on similar cross sections, and the shear test database for NWC described in a previous chapter was used to determine the mean and variation of the resistance. The mean  $\beta_{RQ}$  was determined for  $r_Q$  between 0.3 and 0.7.

## Analysis of Reliability Index for LWC in Shear

$\beta_{RQ}$  determined for each cross section, design expression, resistance factor, and concrete type is given in table 55. The purpose of this table is to compare  $\beta_{RQ}$  for LWC ( $\beta_{LWC}$ ) determined using different resistance factors to the  $\beta_{RQ}$  for NWC ( $\beta_{NWC}$ ). As shown in table 55, for the resistance factors evaluated (0.75, 0.80, 0.85, and 0.90),  $\beta_{LWC}$  was either less than or greater than  $\beta_{NWC}$  regardless of resistance factor or the design expression. The resistance factor of 0.75 is 0.05 less than the value for LWC used in the *AASHTO LRFD Bridge Design Specifications*, while resistance factors of 0.85 and 0.90 are 0.05 and 0.10 more, respectively.<sup>(3)</sup>

**Table 55. Mean reliability index for LWC and NWC with varying resistance factor.**

Specimen Group	Design Expression	Mean Reliability Index ( $\beta_{RQ}$ )				
		LWC Resistance Factor				NWC Resistance Factor of 0.90
		0.75 (AASHTO - 0.05)	0.80 (AASHTO)	0.85 (AASHTO + 0.05)	0.90 (AASHTO + 0.10)

Type IV without $A_v$	GP-equation	2.08	2.05	2.02	2.00	1.83
Type IV without $A_v$	Simplified-PC/RC	1.57	1.56	1.55	1.54	3.02
Type IV with $A_v$	GP-equation	5.38	5.17	4.96	4.75	3.16
Type IV with $A_v$	Simplified-PC/RC	4.58	4.42	4.26	4.10	2.81

Table 55 provides a comparison of the reliability index for the RC cross section. For RC beams without shear reinforcement,  $\beta_{LWC}$  was greater than the  $\beta_{NWC}$  regardless of the design expression. For RC beams with shear reinforcement,  $\beta_{LWC}$  determined using the GP-equation method was greater than the  $\beta_{NWC}$ . For the Simplified-RC and Simplified-PC/RC procedures,  $\beta_{NWC}$  was greater than  $\beta_{LWC}$ .

The reliability indexes determined for the type II cross section are also shown in table 55.  $\beta_{LWC}$  determined using the GP-equation method was greater than  $\beta_{NWC}$  for the cross section without and with shear reinforcement. For the Simplified-PC/RC procedure,  $\beta_{LWC}$  was considerably lower than  $\beta_{NWC}$  for the cross section without shear reinforcement and considerably higher than  $\beta_{NWC}$  for the cross section with shear reinforcement. The same trends were observed for the type IV cross section. The reason for the low  $\beta_{LWC}$  for the PC cross section without stirrups is the low COV ( $V_P$ ) determined from the analysis of the shear database. This is observed as the much lower slope (i.e., PC no  $A_v$ ) data plotted in figure 172 and figure 174.

The reliability index determined for LWC using a resistance factor of 0.90 ( $\beta_{LWC, \phi = 0.90}$ ) was compared to  $\beta_{NWC}$  and the target reliability index ( $\beta_{target}$ ) in table 56. The purpose of this table is to compare  $\beta_{LWC}$  and  $\beta_{NWC}$  to  $\beta_{target}$ . It provides the ratio of  $\beta_{LWC, \phi = 0.90}$  to  $\beta_{NWC}$ ,  $\beta_{LWC, \phi = 0.90}$  to  $\beta_{target}$ , and  $\beta_{NWC}$  to  $\beta_{target}$ . The ratios for the two PC cross sections are combined by taking the lower reliability index ratios.  $\beta_{LWC}$  was less than the  $\beta_{target}$  of 3.5 for all RC specimens, regardless of design expression.  $\beta_{NWC}$  was also less than  $\beta_{target}$  for all RC specimens except for specimens with shear reinforcement determined using the Simplified-PC/RC procedure. For PC specimens without shear reinforcement, both  $\beta_{LWC}$  and  $\beta_{NWC}$  were less than  $\beta_{target}$ .  $\beta_{LWC}$  was greater than  $\beta_{target}$  for PC specimens with shear reinforcement, regardless of the design expression, but  $\beta_{NWC}$  was less than  $\beta_{target}$ . The mean of reliability index was determined between  $r_Q$  values of 0.3 to 0.7, with a target reliability index of 3.5.

**Table 56. Ratio of mean reliability index for LWC to NWC and both LWC and NWC to target reliability index.**

Specimen Group	Design Expression	Ratio of $\beta_{LWC, \phi = 0.90}$ to $\beta_{NWC}$	Ratio of $\beta_{LWC, \phi = 0.90}$ to $\beta_{target}$	Ratio of $\beta_{NWC}$ to $\beta_{target}$
RC beam without $A_v$	Simplified-RC	1.09	0.85	0.78
RC beam without $A_v$	GP-equation	1.11	0.77	0.69
RC beam without $A_v$	Simplified-PC/RC	1.21	0.83	0.69
RC beam with $A_v$	Simplified-RC	0.89	0.88	0.98
RC beam with $A_v$	GP-equation	1.10	0.88	0.80
RC beam with $A_v$	Simplified-PC/RC	0.79	0.83	1.06
Minimum PC without $A_v$	GP-equation	1.08	0.57	0.52
Minimum PC without $A_v$	Simplified-PC/RC	0.50	0.44	0.86
Minimum PC with $A_v$	GP-equation	1.50	1.36	0.90
Minimum PC with $A_v$	Simplified-PC/RC	1.40	1.12	0.80

$\beta_{LWC}$  and  $\beta_{NWC}$  are shown graphically in figure 176 through figure 189. The resistance factors were compared to a range of  $r_Q$  between 0 and 1.0. Each figure shows  $\beta_{NWC}$  and the  $\beta_{LWC}$  for resistance factors of 0.75, 0.80, 0.85, and 0.90. A horizontal line is shown at 3.5 to indicate  $\beta_{target}$ . Vertical lines are shown at  $r_Q$  values of 0.3 and 0.7 to indicate the range over which the mean  $\beta_{RQ}$  was determined. The reliability indexes for RC cross sections without shear reinforcement are shown in figure 176 through figure 178 for the Simplified-RC procedure, the GP-equation method, and the Simplified-PC/RC procedure, respectively. The reliability indexes determined using the same three design expressions are shown in figure 179 through figure 181 for RC cross sections with shear reinforcement. The reliability indexes for PC cross sections were determined using the GP-equation method and the Simplified-PC/RC procedure. The reliability indexes for the type II cross section are shown in figure 182 through figure 185. Figure 186 through figure 189 show the reliability indexes for the type IV cross section.

## RELIABILITY INDEX FOR SHEAR FROM THE LITERATURE

The reliability index for LWC and NWC in shear has been determined in previous studies. (See references 49, 50, 52, 11, and 60.) The following summarizes the results from these previous studies and describes the differences in the methods of calculating the reliability index.

### Studies on LWC

The reliability index for RC cross sections in shear was studied by Paczkowski and Nowak.<sup>(52)</sup> Shear test data from three previous studies that performed shear tests on both LWC and NWC were evaluated.<sup>(52)</sup> A total of 13 LWC and 13 NWC specimens were compared. The GP-equation method was used to determine nominal shear resistance. The study found that the mean test-to-predicted nominal shear resistance was 15 percent less for LWC specimens. Assumed values of  $\lambda_P$  and  $V_P$  of 1.075 and 10 percent, respectively, were used in the study for NWC. For the determination of the reliability index,  $\lambda_P$  for LWC was assumed to be 15 percent less than for NWC, and the same COV ( $V_P$ ) was used. The reliability index was evaluated over a range of span lengths. The study concluded that a resistance factor of 0.80 for LWC gave a reliability index that was greater than the reliability index for NWC and the target reliability index of 3.5.

NCHRP Report 733 describes the testing and evaluation of high-strength LWC prestressed girders in shear.<sup>(11)</sup> The report also describes the evaluation of a database of LWC shear tests on prestressed girders that included tests from three previous studies. The report includes an evaluation of test-to-predicted shear resistance for LWC specimens using a resistance factor

of 0.85 to test-to-predicted shear resistance for NWC specimens using a resistance factor of 0.90. The recommended resistance factor in NCHRP Report 733 is 0.85 for LWC in shear.

After NCHRP Report 733 was submitted for publication, additional evaluation of the LWC database was performed that included a reliability analysis.<sup>(60)</sup> The LWC database used in the study included 154 RC beams and 22 PC beams. The average shear span to effective depth ratio of the RC specimens in the study was 2.81, and the average ratio for the PC specimens in the study was 2.32. The Rackwitz-Fiessler procedure was used to determine reliability index.<sup>(50,60)</sup> The study evaluated the reliability index for PC girders with shear reinforcement. The study found that a resistance factor of 1.0 for LWC in shear determined using the two methods of the general procedure would have a reliability index greater than the target reliability index of 3.5. For the Simplified-PC/RC procedure, a resistance factor of 0.95 was needed to have a reliability index greater than the target reliability index of 3.5.

The present research effort described in this report also found that the reliability index of prestressed cross sections with shear reinforcement was greater than the target reliability index of 3.5. The present research effort also found that the reliability index determined using the GP-equation method was greater than the reliability index determined using the Simplified-PC/RC procedure for prestressed cross sections with shear reinforcement.

### **Studies on NWC**

NCHRP Report 368 describes the calibration of the LRFD bridge design code.<sup>(49)</sup> The reliability index was determined using the bias and COV of the professional factor ( $\lambda_P$  and  $V_P$ ) for NWC in shear for RC and PC cross sections from another study.<sup>(56)</sup>  $\lambda_P$  and  $V_P$  used in the study for sections with shear reinforcement were 1.075 and 10 percent, respectively, and were assumptions. The bias and COV due to materials and fabrication were determined using MCFT, which is the basis for the general procedure in the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The expression for the reliability index was also different. It included a two-standard deviation offset for the mean and variance of the resistance. The resistance factor for shear recommended in the study was 0.90. The report showed a reliability index for RC and PC sections that was less than 3.5 for nearly all span lengths and girder spacings.

NCHRP Report 549 describes the development and evaluation of the Simplified-PC/RC procedure.<sup>(32)</sup> A reliability index was not determined as part of the study. Instead, a fractile level was calculated as the percentage of the test data less than a test-to-predicted shear resistance of 1.0. The result reported in NCHRP Report 549 for fractile level was 20.5 percent.<sup>(32)</sup>

### **SUMMARY OF THE ANALYSIS OF RELIABILITY INDEX FOR LWC IN SHEAR**

The mean  $\beta_{RQ}$  was determined for the shear resistance of LWC cross sections.  $\beta_{RQ}$  for LWC was compared to the target reliability index and the mean reliability index for NWC cross sections. The uncertainty due to the loads was evaluated using data from previous studies to determine the mean and variation of the load. The uncertainty due to fabrication and materials was evaluated using the Monte Carlo simulation. One RC cross section and two PC cross sections were simulated. The uncertainty due to analysis was evaluated using LWC specimens and NWC specimens. The combined uncertainty was used to determine the mean and variance of

resistance. The reliability index was evaluated at a resistance factor for LWC of 0.75, 0.80, 0.85, and 0.90.  $\beta_{RQ}$  for LWC and NWC in shear was then determined over a range of dead-to-total load ratios. The reliability index for LWC was compared to the target reliability index and the reliability index for NWC.

$\beta_{RQ}$  for LWC and NWC was compared to  $\beta_{target}$ . The reliability indexes determined for LWC were less than  $\beta_{target}$  for all cross sections except PC specimens with shear reinforcement, regardless of the resistance factor (up to  $\phi = 0.90$ ) or the design expression used to determine nominal shear resistance. The reliability indexes determined for NWC were less than  $\beta_{target}$  for all cross sections except RC specimens with shear reinforcement determined using the Simplified-PC/RC procedure.

$\beta_{LWC}$  was also compared to  $\beta_{NWC}$ .  $\beta_{LWC}$  determined using the GP-equation method was greater than the  $\beta_{NWC}$  for all cross sections. The Simplified-RC and Simplified-PC/RC procedures had  $\beta_{LWC}$  greater than  $\beta_{NWC}$  for RC specimens without shear reinforcement and had  $\beta_{NWC}$  greater than  $\beta_{LWC}$  for RC specimens with shear reinforcement. For PC specimens without shear reinforcement, the Simplified-PC/RC procedure had  $\beta_{NWC}$  greater than  $\beta_{LWC}$ . For PC specimens with shear reinforcement,  $\beta_{LWC}$  determined using the Simplified-PC/RC procedure was greater than  $\beta_{NWC}$ .

## CHAPTER 7. PRELIMINARY RECOMMENDATIONS FOR AASHTO LRFD BRIDGE DESIGN SPECIFICATIONS<sup>(3)</sup>

### INTRODUCTION

This chapter summarizes several preliminary recommended changes to the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> The existing and recommended language is presented as it would appear in these specifications. The first two recommended changes regarding the definition of LWC and the introduction of an LWC modification factor ( $\lambda$ -factor) were previously described in a related document concerning the mechanical properties of LWC and are presented again for clarity.<sup>(1)</sup> Additional recommended changes are presented in this chapter that are based on the analysis described in this report. These additional recommendations are built on the two previous recommendations.

The recommended changes described in this chapter include the recommended new expression for the  $\lambda$ -factor. The  $\lambda$ -factor is not based on the proportions of constituent materials and includes tests from types of mix designs that are not explicitly permitted by the current edition of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> These mix types include specified density LWC (typically a blend of lightweight and normal-weight coarse aggregate) and inverted mixes (normal-weight coarse and lightweight fine aggregate). The recommended new expression for the  $\lambda$ -factor is instead based on unit weight ( $w_c$ ) and splitting tensile strength ( $f_{ct}$ ), and as a result, the definitions of sand-lightweight concrete and all-lightweight concrete would no longer be needed.

The changes to the *AASHTO LRFD Bridge Design Specifications* recommended in this chapter are in regard to the performance of LWC in shear. The first three recommended changes involve adding the new expression for the  $\lambda$ -factor to design expressions for nominal shear resistance. Another change involves adding the  $\lambda$ -factor to the design expression for minimum shear reinforcement. The final recommended change involves the reduction factor for LWC in shear and torsion.

This report previously described the shear performance of 15 LWC prestress girders tested at TFHRC. Additional shear tests on LWC specimens were found in the literature. (For sources, see Bibliography section LWC Sources for TFHRC Shear Database.) These tests on LWC were added to selected tests on NWC specimens found in the ACI-DafStb database. (For sources, see Bibliography section NWC Sources for ACI-DafStb Database.) The NWC specimens that were selected had parameters that are important to shear resistance that were similar to the LWC specimens. The recommended changes to the *AASHTO LRFD Bridge Design Specifications* were validated using the specimens from the TFHRC shear database and the ACI-DafStb database.

### PROPOSED DEFINITION FOR LWC

The definition for LWC in the *AASHTO LRFD Bridge Design Specifications* is in Article 5.2 and states the following:

*Lightweight Concrete* – Concrete containing lightweight aggregate and having an air-dry unit weight not exceeding 0.120 kcf, as determined by ASTM C567. Lightweight Concrete without natural sand is termed “all-lightweight concrete” and lightweight concrete in which all of the fine aggregate consists of normal weight sand is termed “sand-lightweight concrete.” (p. 5-3)<sup>(3)</sup>

This definition limits the unit weight for LWC to 0.120 kcf (1,920 kg/m<sup>3</sup>) and includes definitions for sand-lightweight and all-lightweight concretes. The proposed definition for LWC expands the range of  $w_c$  and eliminates the definitions for terms relating to the constituent materials in LWC. The proposed definition for LWC is as follows:

*Lightweight Concrete* – Concrete containing lightweight aggregate and having an equilibrium density not exceeding 0.135 kcf, as determined by ASTM C567.

The term “air-dry unit weight” is used in the existing definition; however, this term is not found in ASTM C567.<sup>(61)</sup> The term is interpreted to be equivalent to the ASTM C567 term “equilibrium density.” A statement could be added to the commentary to clarify the term “air-dry unit weight,” or the term “equilibrium density” could be used in the definition for LWC.

## **PROPOSED EXPRESSION FOR LWC MODIFICATION FACTOR**

The concept of including a modification factor for LWC in expressions for predicting nominal resistance is included in many articles of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> However, a single unified expression or LWC modification factor is not specified. This section proposes a new term, the  $\lambda$ -factor, to quantify the reduction in nominal resistance that could be included in any expression for nominal resistance. The language for the  $\lambda$ -factor could be based on the existing language for the modification factor for shear in Article 5.8.2.2 that states the following:

Where lightweight aggregate concretes are used, the following modifications shall apply in determining resistance to torsion and shear:

Where the average splitting tensile strength of lightweight concrete,  $f_{ct}$ , is specified, the term,  $\sqrt{f'_c}$  in the expressions given in Articles 5.8.2 and 5.8.3 shall be replaced by:  $4.7 f_{ct} < \sqrt{f'_c}$ .

Where  $f_{ct}$  is not specified, the term  $0.75 \sqrt{f'_c}$  for all lightweight concrete, and  $0.85 \sqrt{f'_c}$  for sand-lightweight concrete shall be substituted for  $\sqrt{f'_c}$  in the expressions given in Articles 5.8.2 and 5.8.3.

Linear interpolation may be employed when partial sand replacement is used. (p. 5-59)<sup>(3)</sup>

Article 5.8.2.2 specifically relates to torsion and shear, so a general  $\lambda$ -factor would not specifically reference those actions in its definition. The terms “sand-lightweight concrete” and “all-lightweight concrete” would not be used because the proposed new definition for LWC does not include them. The  $\lambda$ -factor relates to the material properties of structural LWC, so the new

article for the definition for the  $\lambda$ -factor could be located in Article 5.4.2. The  $\lambda$ -factor is referred to as Article 5.4.2.8 in this report. The proposed text for the  $\lambda$ -factor is as follows:

Where lightweight aggregate concretes are used, the lightweight concrete modification factor,  $\lambda$ , shall be determined as:

Where the average splitting tensile strength of lightweight concrete,  $f_{ct}$ , is specified,  $\lambda$  may be taken as:  $4.7 f_{ct} / \sqrt{f'_c} \leq 1.0$ .

Where  $f_{ct}$  is not specified,  $\lambda$  may be taken as:

$$0.75 \leq \lambda = 7.5 w_c \leq 1.0 \quad (5.4.2.8-1)$$

The language for the  $\lambda$ -factor expression when  $f_{ct}$  is not specified follows the format of the  $\phi$ -factor for flexure for prestressed and nonprestressed members in Article 5.5.4.2.1.

The effect of using the  $\lambda$ -factor in expressions for the development length of mild steel is evaluated in this report. The effect of using the  $\lambda$ -factor, in additional expressions for nominal resistance, still needs to be evaluated. The proposed  $\lambda$ -factor could then be included in additional expressions for nominal resistance in the *ASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> For example, the  $\lambda$ -factor could be added directly to design expressions for nominal shear resistance in Articles 5.8.2 and 5.8.3 and would replace the existing modification factor for LWC.

## PROPOSED DESIGN EXPRESSIONS FOR NOMINAL SHEAR RESISTANCE

Three recommended changes to the *AASHTO LRFD Bridge Design Specifications* involve adding the  $\lambda$ -factor to the three terms for the nominal shear resistance provided by the concrete (i.e.,  $V_c$ ,  $V_{ci}$ , and  $V_{cw}$ ). The change to the  $V_c$  term is described first and includes language for the nominal shear resistance ( $V_n$ ). The changes to  $V_{ci}$  and  $V_{cw}$  are presented after the expression for  $V_c$ .

The proposed design expression for nominal shear resistance provided by tensile stresses in the concrete ( $V_c$ ) is as follows:

The nominal shear resistance,  $V_n$ , shall be determined as the lesser of:

$$V_n = V_c + V_s + V_p$$

$$V_n = 0.25 f'_c b_v d_v + V_p$$

In which:

$V_c = 0.0316 \beta \lambda \sqrt{f'_c} b_v d_v$ , if the procedures of Articles 5.8.3.4.1 or 5.8.3.4.2 are used.

$V_c =$  The lesser of  $V_{ci}$  and  $V_{cw}$ , if the procedures of Article 5.8.3.4.3 are used.

The proposed design expression for nominal shear resistance provided by concrete when inclined cracking results from combined shear and moment ( $V_{ci}$ ) is as follows:

$V_{ci}$  shall be determined as:

$$V_{ci} = 0.02 \lambda \sqrt{f'_c} b_v d_v + V_d + V_i M_{cre} / M_{max} \geq 0.06 \lambda \sqrt{f'_c} b_v d_v$$

Where:

$V_i$  = factored shear force at the section due to externally applied loads occurring simultaneously with the maximum factored moment at the section due to externally applied loads ( $M_{max}$ ).

$M_{cre}$  = moment causing flexural cracking at the section due to externally applied loads.

The proposed design expression for nominal shear resistance provided by concrete when inclined cracking results from excessive principal tensions in the web ( $V_{cw}$ ) is as follows:

$V_{cw}$  shall be determined as:

$$V_{cw} = (0.02 \lambda \sqrt{f'_c} + 0.30 f_{pc}) b_v d_v + V_p$$

The ratio of test-to-predicted shear resistance for LWC specimens in the TFHRC shear database was compared to compressive strength in figure 190 and figure 191. Figure 190 shows the ratios for RC specimens without shear reinforcement, and figure 191 shows the ratios for PC specimens with shear reinforcement. For comparison, the ratios for NWC specimens in the ACI-DafStb database are also shown in each figure. The nominal shear resistance was determined using the GP-equations method for  $\beta$  and  $\theta$  given in Article 5.8.3.4.2 and the new expression  $\lambda$ -factor.<sup>3)</sup> Regression lines are shown for the LWC specimens and NWC specimens. The regression line for the LWC specimens is slightly greater than the regression line for NWC specimens for nearly all values of compressive strength. For both figures, the number of specimens is in parentheses in the legends.

**Figure 190. Graph. Test-to-predicted shear resistance using GP-equation method for RC members without shear reinforcement.**

Source: FHWA.  
1 ksi = 6.89 MPa.

**Figure 191. Graph. Test-to-predicted shear resistance using GP-equation method for PC members with shear reinforcement.**

## PROPOSED DESIGN EXPRESSION FOR MINIMUM SHEAR REINFORCEMENT

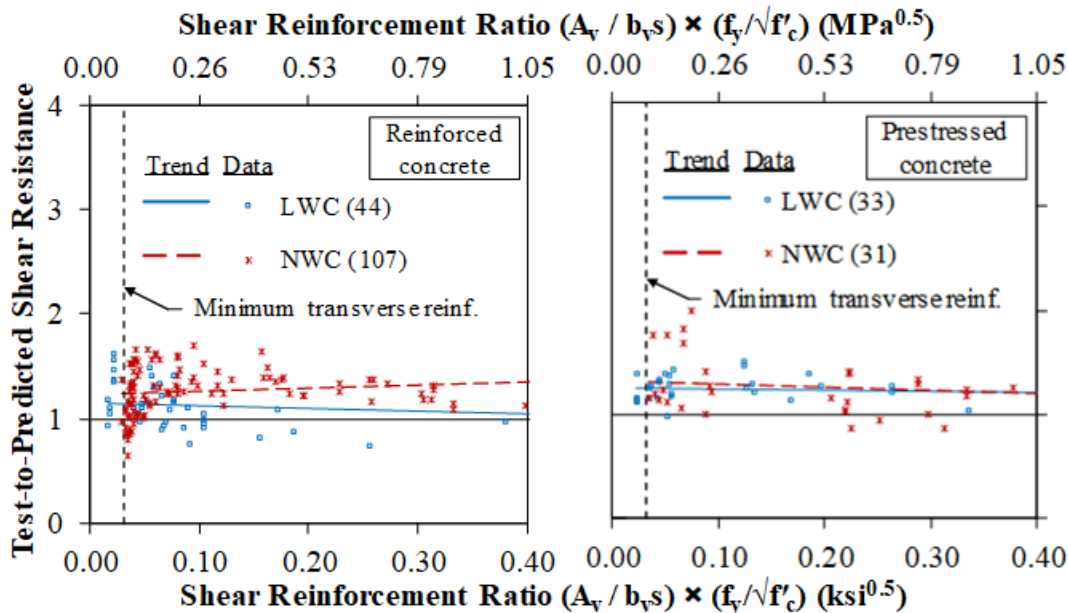

A recommended change to the *AASHTO LRFD Bridge Design Specifications* involves adding the new expression for the  $\lambda$ -factor to the design expression for minimum shear reinforcement (i.e., transverse reinforcement). The proposed design expression for the minimum shear reinforcement is as follows:

Except for segmental post-tensioned concrete box girder bridges, where transverse reinforcement is required, as specified in Article 5.8.2.4, the area of steel shall satisfy:

$$A_v \geq 0.0316 \lambda v f'_c b_v s / f_y$$

The ratio of test-to-predicted shear resistance for LWC specimens in the TFHRC shear database is compared to the shear reinforcement ratio in figure 192 for RC specimens and figure 193 for PC specimens. The nominal shear resistance was determined using the GP-equation method for  $\beta$  and  $\theta$  given in Article 5.8.3.4.2 and the new expression for the  $\lambda$ -factor. A vertical line indicates the minimum amount of shear reinforcement specified by Article 5.8.2.5. The ratios of test-to-predicted shear resistance for the few specimens with less shear reinforcement than the required amount was similar to the ratios for specimens with slightly greater than the required amount. For comparison, NWC specimens in the ACI-DafStb database are also shown in the figure. For both figures, the number of specimens is in parentheses in the legends.

### PROPOSED RESISTANCE FACTOR FOR SHEAR AND TORSION OF LWC

A reliability analysis was performed to evaluate the resistance factor for LWC in shear. Based on the analysis, a change to the reduction factor for LWC in shear and torsion is recommended. The proposed resistance factor for LWC in shear and torsion is as follows:

Resistance factor  $\phi$  shall be taken as:

For shear and torsion:

Normal weight concrete.....0.90

Lightweight concrete.....0.90

Table 57 shows a comparison of the reliability index ( $\beta_{RQ}$ ) for LWC using a resistance factor of 0.90 to  $\beta_{RQ}$  for NWC using a resistance factor of 0.90, as specified in Article 5.5.4.2.1.  $\beta_{RQ}$  were determined using the three different methods for calculating shear resistance in Article 5.8.3 and the new expression for the  $\lambda$ -factor. Table 57 shows that, for nominal resistance determined using

the GP-equation procedure,  $\beta_{RQ}$  for LWC with a resistance factor of 0.90 was greater than  $\beta_{RQ}$  for NWC.

**Table 57. Reliability index for LWC and NWC in shear.**

Specimen Group	Design Expression	$\beta_{RQ}$	
		LWC ( $\phi = 0.90$ )	NWC ( $\phi = 0.90$ )
RC beam without shear reinforcement	Simplified-RC	2.99	2.73
RC beam without shear reinforcement	GP-equation	2.69	2.43
RC beam without shear reinforcement	Simplified-PC/RC	2.91	2.41
RC beam with shear reinforcement	Simplified-RC	3.07	3.43
RC beam with shear reinforcement	GP-equation	3.07	2.79
RC beam with shear reinforcement	Simplified-PC/RC	2.92	3.70
PC girder without shear reinforcement	GP-equation	2.00	1.83
PC girder without shear reinforcement	Simplified-PC/RC	1.54	3.02
PC girder with shear reinforcement	GP-equation	4.75	3.16
PC girder with shear reinforcement	Simplified-PC/RC	4.10	2.81

## CHAPTER 8. CONCLUSION

This report presented and described 30 shear tests on 15 LWC prestressed girders, a shear strength database, a reliability analysis, and potential revisions to the *AASHTO LRFD Bridge Design Specifications* relating to the shear resistance of LWC.<sup>(3)</sup> The proposed design expressions for shear resistance were compared to tested values in a database including over 400 tests on LWC that was collected as part of this research effort. A description of the database and the development and evaluation of prediction expressions was included in this report.

Future phases of this research compilation and analysis effort will include a synthesis of past work on structural performance of LWC. The test results will be compared to the prediction expressions for nominal resistance in the *AASHTO LRFD Bridge Design Specifications*, incorporating appropriate proposed revisions for LWC mechanical properties.<sup>(3)</sup>

## APPENDIX A. REINFORCING BAR MATERIAL PROPERTIES

This appendix contains a table (see table 58) and figures (see figure 194 through figure 207) with material test data from the reinforcing bars used in the shear tests of LWC girders tested at TFHRC. The tensile data include yield strength (calculated using 0.2 percent offset method), ultimate strength, and stress–strain relationships of the mechanical tests.

**Table 58. Reinforcing bar mechanical properties.**

<b>Tensile Test</b>	<b>Girder Design No.</b>	<b>Coupon</b>	<b>Bar Type</b>	<b>Bar Size</b>	<b>Yield Strength (ksi)</b>	<b>Ultimate Strength (ksi)</b>
3-5A	5	1	Stirrup	3	69.1	112.1
3-5B	5	2	Stirrup	3	72.4	112.3
3-8A	8	1	Stirrup	3	70.5	109.3
3-8B	8	2	Stirrup	3	59.7	94.5

## APPENDIX B. LWC SPECIMENS IN TFHRC SHEAR DATABASE

This appendix contains a list of the LWC specimens in the TFHRC shear database (see table 59). These specimens include tests that failed in shear and tests that did not fail in shear.

**Table 59. List of LWC shear test specimens in the TFHRC shear database.**

## APPENDIX C. NWC SPECIMENS IN ACI-DAFSTB DATABASE

To determine the effect of LWC on shear resistance, the LWC specimens in the TFHRC shear database were compared to a subset of NWC specimens in the ACI-DafStb database that had similar parameters that were significant to shear resistance. This appendix contains a list of those selected specimens from the ACI-DafStb database that were compared to the TFHRC shear database (see table 60 through table 63).

**Table 60. Selected NWC shear test specimens from the ACI-DafStb database—RC members without shear reinforcement.**

Source*	Specimen Name
Adebar (1989)	ST1, ST2, ST3, ST8, ST16, ST23
Ahmad, Khaloo, and Poveda (1986)	A1, A2, A3, A7, A8, B1, B2, B3, B7, B8, B9, C1, C2, C3, C7, C8, C9
Ahmad, Park, and El-Dash (1995)	B7N, B7H, B8H
Al-Alusi (1957)	12, 11, 2, 21, 15, 10, 4, 13, 18, 7, 24, 16, 17, 8, 19, 25, 9, 20, 14, 23

## APPENDIX D. EQUATION DERIVATIONS FOR RELIABILITY ANALYSIS

This appendix contains derivations of the equations used in the reliability analysis. The first section contains the derivations of expressions for the unfactored load effects and the mean load effects. The second section contains the derivations of expressions for the variation of the unfactored load effects and resistance.

### UNFACTORED LOAD EFFECTS AND MEAN LOAD EFFECTS

The load effects due to dead load and vehicular live load are considered in the reliability analysis in this report. The load effects include the dead load of structural components ( $Q_{DC}$ ), the dead load of the wearing surface ( $Q_{DW}$ ), the vehicular live load ( $Q_{LL}$ ), and the dynamic load allowance ( $Q_{IM}$ ). The *AASHTO LRFD Bridge Design Specifications* applies different load factors to these load effects.<sup>(3)</sup> Also, the statistical parameters are different for these load effects, so an expression is needed to determine the individual unfactored load effects given the total factored load effects ( $Q$ ).

The term  $r_Q$  is defined as the ratio of the unfactored permanent loads (i.e.,  $Q_{DC}$  and  $Q_{DW}$ ) to the total unfactored force effect ( $\Sigma Q_i$ ) (see equation 65). The term  $r_{DW}$  is defined as the ratio of  $Q_{DW}$  to  $Q_{DC}$  (see equation 66). Equation 64 relates  $\Sigma Q_i$  to  $Q$ . This section shows the derivations of expressions for the unfactored load effects that are functions of only the load factors ( $\gamma_i$ ), the  $r_Q$  term, the  $r_{DW}$  term, and  $\Sigma Q_i$ .

$Q_{DW}$  for the load effects due to dead load of the wearing surface is removed from the definition of  $r_Q$  (see equation 82). The definition of  $r_{DW}$  given by equation 66 is substituted for  $Q_{DW}$  in the definition for  $r_Q$  in equation 65. The expression is then simplified.

$$r_Q = \frac{Q_{DC} + Q_{DW}}{\Sigma Q_i} = \frac{Q_{DC} + r_{DW}Q_{DC}}{\Sigma Q_i} = \frac{Q_{DC}(1 + r_{DW})}{\Sigma Q_i} \quad (82)$$

The expression for  $Q_{DC}$  given by equation 83 is obtained by rearranging equation 82 as follows:

$$Q_{DC} = \frac{r_Q \Sigma Q_i}{(1 + r_{DW})} \quad (83)$$

The expression for  $Q_{DC}$  given by equation 83 is then substituted into the definition of  $r_{DW}$  given by equation 66 to obtain the expression for  $Q_{DW}$  given by equation 84 as follows:

$$Q_{DW} = r_{DW}Q_{DC} = \frac{r_{DW}r_Q \Sigma Q_i}{(1 + r_{DW})} \quad (84)$$

The derivation of the expression for  $Q_{LL+IM}$  requires several steps. In the expression for  $r_Q$  given by equation 65,  $\Sigma Q_i$  is multiplied by both sides to obtain equation 85.  $\Sigma Q_i$  is subtracted from both sides of equation 85 to obtain equation 86. In equation 87,  $\Sigma Q_i$  on the right-hand side is replaced by the expression for  $\Sigma Q_i$  given by equation 54. The expression is then simplified to give equation 88 and simplified further to give equation 89.

$$r_Q \Sigma Q_i = Q_{DC} + Q_{DW} \quad (85)$$

$$r_Q \Sigma Q_i - \Sigma Q_i = Q_{DC} + Q_{DW} - \Sigma Q_i \quad (86)$$

$$r_Q \Sigma Q_i - \Sigma Q_i = Q_{DC} + Q_{DW} - (Q_{DC} + Q_{DW} + Q_{LL+IM}) \quad (87)$$

$$r_Q \Sigma Q_i - \Sigma Q_i = -Q_{LL+IM} \quad (88)$$

$$Q_{LL+IM} = \Sigma Q_i - r_Q \Sigma Q_i = (1 - r_Q) \Sigma Q_i \quad (89)$$

The expressions for  $Q_{DC}$ ,  $Q_{DW}$ , and  $Q_{LL+IM}$  in equation 83, equation 84, and equation 89, respectively, are substituted into the expression for total factored loads given by equation 64 to obtain equation 90. The expression is simplified to obtain equation 91 and further simplified to obtain equation 92. The term in brackets is restated as equation 93 and is a function of only the load factors ( $\gamma_i$ ),  $r_Q$ , and  $r_{DW}$ .

$$Q = \gamma_{DC} \left( \frac{r_Q}{1 + r_{DW}} \right) \Sigma Q_i + \gamma_{DW} \left( \frac{r_{DW} r_Q}{1 + r_{DW}} \right) \Sigma Q_i + \gamma_{LL+IM} (1 - r_Q) \Sigma Q_i \quad (90)$$

$$Q = \Sigma Q_i \left[ \gamma_{DC} \left( \frac{r_Q}{1 + r_{DW}} \right) + \gamma_{DW} \left( \frac{r_{DW} r_Q}{1 + r_{DW}} \right) + \gamma_{LL+IM} (1 - r_Q) \right] \quad (91)$$

$$Q = \Sigma Q_i \left[ \left( \frac{r_Q}{1 + r_{DW}} \right) (\gamma_{DC} + \gamma_{DW} r_{DW}) + \gamma_{LL+IM} (1 - r_Q) \right] \quad (92)$$

$$f(\gamma_i, r_Q, r_{DW}) = \left[ \left( \frac{r_Q}{1 + r_{DW}} \right) (\gamma_{DC} + \gamma_{DW} r_{DW}) + \gamma_{LL+IM} (1 - r_Q) \right] \quad (93)$$

The expression for vehicular live load effects given by equation 70 can be simplified as shown in equation 94. The expression for unfactored load effects given by equation 54 is substituted into the definition of mean load effects given by equation 56. The separation of the vehicular live load effects and the dynamic load allowance ( $IM$ ) given by equation 94 are included to obtain equation 95 for the mean load effects.

$$Q_{LL+IM} = Q_{LL} (1 + IM) = Q_{LL} + Q_{LL} IM \quad (94)$$

$$m_Q = \Sigma(Q_i \lambda_i) = Q_{DC} \lambda_{DC} + Q_{DW} \lambda_{DW} + Q_{LL} \lambda_{LL} + (Q_{LL} IM) \lambda_{IM} \quad (95)$$

## VARIATION OF UNFACTORED LOAD EFFECTS AND RESISTANCES

COV is defined as the ratio of the standard deviation to the mean value. The variation is the COV squared. The standard deviation of an unfactored load effect ( $\sigma_{Qi}$ ) is then equal to the COV of the unfactored load effect ( $V_{Qi}$ ) multiplied by the mean of the load effect ( $m_{Qi}$ ), as given by equation 96. The definition of the bias factor for the load effects ( $\lambda_{Qi}$ ) given by equation 56 is also included in equation 96. The variation of the total load effects is then the sum of the squares

of the standard deviation of the unfactored load effects, as given by equation 97. The individual load effects are substituted into equation 97 to obtain equation 98.

$$\sigma_{Q_i} = V_{Q_i} m_{Q_i} = V_{Q_i} (Q_i \lambda_{Q_i}) \quad (96)$$

$$\sigma_Q^2 = \Sigma(\sigma_{Q_i}^2) = \Sigma[V_{Q_i} (Q_i \lambda_{Q_i})]^2 \quad (97)$$

$$\sigma_Q^2 = (V_{DC} Q_{DC} \lambda_{DC})^2 + (V_{DW} Q_{DW} \lambda_{DW})^2 + (V_{LL} Q_{LL} \lambda_{LL})^2 + (V_{IM} Q_{IM} \lambda_{IM})^2 \quad (98)$$

The variation in the resistance ( $\sigma_R^2$ ) is due to the combined uncertainty in the fabrication and materials and the uncertainty in the analysis. The expression for  $\sigma_R^2$  is given by equation 99 and COV of the combined fabrication and materials uncertainty ( $V_{FM}$ ).

$$\sigma_R^2 = m_R^2 V_R^2 = m_R^2 (V_{FM}^2 + V_P^2) \quad (99)$$

## APPENDIX E. STATISTICAL PARAMETERS FOR EXCLUDED TESTS

The reliability analysis performed as part of the analysis described in this report excluded 15 shear tests from the TFHRC shear database. The tests were removed for the determination of the statistical parameters for the uncertainty in the analysis (i.e.,  $\lambda_P$  and  $V_P$ ). This appendix provides the bias, COV, and CDF with the 11 shear tests included.

A total of 11 tests were removed from the databases of RC specimens without stirrups (4 tests) and PC without stirrups (7 tests). For each specimen type, all the tests from only one reference were removed because they had a tested shear strength that was considerably lower than the shear strength of specimens with a similar size and material strengths.

The bias and COV (i.e.,  $\lambda_P$  and  $V_P$ ) determined for each specimen type, concrete type, and calculation method is shown in table 64 for the 11 shear tests included. The bias and COV in table 64 can be compared to those in table 54 with the 11 tests excluded.

**Table 64. Statistical parameters for professional factor determined using linear regression of the tail of the CDF for test-to-predicted resistance of all LWC specimens.**

Concrete Type and Specimen Group	Design Expression	Number of Specimens	Bias	COV (Percent)
LWC RC specimens without $A_v$	Simplified-RC	173	1.63	24.5
LWC RC specimens without $A_v$	GP-equation	222	1.07	21.3
LWC RC specimens without $A_v$	Simplified-PC/RC	222	1.78	25.1
LWC RC specimens with $A_v$	Simplified-RC	31	1.63	21.7
LWC RC specimens with $A_v$	GP-equation	44	1.08	16.2
LWC RC specimens with $A_v$	Simplified-PC/RC	44	1.55	22.3
LWC PC specimens without $A_v$	GP-equation	27	1.96	59.9
LWC PC specimens without $A_v$	Simplified-PC/RC	27	2.31	72.2
LWC PC specimens with $A_v$	GP-equation	33	1.24	10.3
LWC PC specimens with $A_v$	Simplified-PC/RC	33	1.27	11.8

For the RC specimens without shear reinforcement, the addition of the four tests resulted in a slightly higher bias and COV. These tests are shown in figure 208 through figure 210 and are shifted to the left (i.e., lower test-to-prediction ratio) of the line formed by the rest of the data in the tail of the CDF.

For the RC specimens with shear reinforcements, the four additional tests caused a bias factor reduction of 0.20 and the COV to more than double. Figure 208 through figure 210 show that these four tests were also shifted significantly to the left of the line formed by the rest of the data in the tail.

The COV of the PC specimens without shear reinforcement is high, even after excluding the seven tests. The bias factor with the seven tests included caused a small reduction in the bias for the test-to-prediction ratios determined using the GP-equation method. The inclusion of the seven points caused a 44 percent reduction of the bias factor determined using the Simplified-PC/RC procedure. An increase in the COV of more than 20 percent was observed by including

the seven points. The seven tests are shown in figure 209 and figure 210 and are also shifted to the left of the rest of the data. For each figure, the number of specimens is in parentheses in the legends.

## **APPENDIX G. OBTAINING A DRAFT OF THE RESEARCH DATA**

A hardcopy draft of the research data is available from Benjamin Graybeal, who can be contacted at Benjamin.Graybeal@dot.gov. The draft contains the detailed results of the 30 shear tests on high-strength LWC prestressed girders that were tested at TFHRC. Tables for each test give information about the girder geometry and reinforcement, material properties, and test setup. The tables also give the applied load, internal shear force, measured deflection, and measured reinforcement strain, strand slip, deck strain, and FRP strain. Figures show the applied load versus measured deflection and applied average shear stress versus measured average shear strain. Additional figures show the measured strain in the girder end reinforcement, measured longitudinal strain, measured transverse strain, and measured crack angles. Photographs show the girder before ultimate and after ultimate as well as the failure mode.

## ACKNOWLEDGEMENTS

This report presents results from the FHWA LWC research program and is intended to both facilitate a broader understanding of the performance of LWC and to assist AASHTO SCOBS T-10 as it considers relevant revisions to section 5 of the *AASHTO LRFD Bridge Design Specifications*.<sup>(3)</sup> It does not constitute a policy statement or a recommendation from FHWA. Additionally, the publication of this report does not necessarily indicate approval or endorsement of the findings, opinions, conclusions, or recommendations either inferred or specifically expressed herein by FHWA or the U.S. Government. This report was created on behalf of FHWA as part of contract DTFH61-10-D-00017.

The authors would like to acknowledge the work of the T-10 Ad-hoc Group on LWC revisions to *AASHTO LRFD Bridge Design Specifications* for their assistance, helpful comments, and suggestions during the analysis and compilation of these results.<sup>(3)</sup> The work of Matthew Swenty, who assisted with the reliability analysis, is gratefully acknowledged by the authors. The authors would also like to gratefully acknowledge the work of the FHWA Research Library staff, who have been assisting in the collection of hundreds of articles relating to LWC, as well as the contribution of Dr. Karl-Heinz Reineck of the University of Stuttgart, Germany, who supplied the digital files of the ACI-DafStb database.

## BIBLIOGRAPHY

### INTRODUCTION

The bibliography for this report has been organized in two parts. The first part consists of source information for shear tests on LWC specimens included in the TFHRC shear database. The second part consists of source information for shear tests on NWC specimens in the ACI-DafStb database.
