16. Abstract A side-mounted bridge railing consisting of wide-flange posts and tubular steel rail elements was designed and tested to performance level two of the 1989 <i>Guide Specifications for Bridge Railings</i>. The posts are blocked out from the edge of the deck to provide maximum useable space on the bridge. Acceptable performance was demonstrated in full-scale crash tests. This volume is the ninth in a series. The other volumes in the series are: Volume I: Technical Report; Volume II: Appendix A, "Oregon Side Mounted Bridge Railing;" Volume III: Appendix B, "BR27D Bridge Railing;" Volume IV: Appendix C, "Illinois 2399-1 Bridge Railing;" Volume V: Appendix D, "32-in (813-mm) Concrete Parapet Bridge Railing;" Volume VI: Appendix E, "32-in (813-mm) New Jersey Safety Shape;" Volume VII: Appendix F, "32-in (813-mm) F-Shape Bridge Railing;" Volume VIII: Appendix G, "BR27C Bridge Railing;" Volume X: Appendix I, "42-in (1.07-m) Concrete Parapet Bridge Railing;" Volume XI: Appendix J, "42-in (1.07-m) F-Shape Bridge Railing;" Volume XII: Appendix K, "Oregon Transition;" Volume XIII: Appendix L, "32-in (813-mm) Thrie-Beam Transition;" and Volume XIV: Appendix M, "Axial Tensile Strength of Thrie and W-Beam Terminal Connectors."

CHAPTER 1. DESIGN OF RAILING

A cross section of the prototype installation is shown in figure 1. The Illinois side mount railing design consists of W6x25 posts spaced at 6 ft-3 in (1.9 m) with a TS 8 by 4 by 5/16-in (203 by 102 by 8-mm) top rail element and a TS 6 by 4 by 1/4-in (152 by 102 by 6-mm) bottom rail element. The height of the metal railing above the asphalt surface is 32 in (813 mm).

At the time the railing was designed, the proposed strength test conditions for performance level two was 18,000 lb (8 172 kg) | 50 mi/h (80.5 km/h) | 15 degrees.⁽¹⁾ The design force for this test condition is a line force of 56 kips (249 kN) uniformly distributed over a longitudinal distance of 42 in (1.07 m) at 29 in (737 mm) above the asphalt surface. Computations of the strength of the railing system indicate that it will resist approximately 69 kips (3-8 kN) at 22.9 in (582 mm) above the asphalt surface.

1 in = 25.4 mm

Figure 1. Cross section of Illinois side mount bridge railing.

CHAPTER 2. CRASH TEST PROCEDURES

The Illinois side mount bridge railing was tested to performance level two requirements.⁽¹⁾ The following nominal test conditions were used:

1,800-lb (817-kg) passenger car | 60 mi/hr (96.6 km/h) | 20 degrees (test 7069-35)
5,400-lb (2 452-kg) passenger car | 60 mi/hr (96.6 km/h) | 20 degrees (test 7069-36)
18,000-lb (8 172-kg) single-unit truck | 50 mi/h (80.5 km/h) | 15 degrees (test 7069-37)

Each vehicle was instrumented with three solid-state angular rate transducers to measure yaw, pitch and roll rates; a triaxial accelerometer at the vehicle center-of-gravity to measure longitudinal, lateral, and vertical acceleration levels, and a biaxial accelerometer in the rear of the vehicle to measure longitudinal and lateral acceleration levels. In addition, another biaxial accelerometer was mounted forward of the center-of-gravity in the pickup and truck tests. The accelerometers were strain gauge type with a linear millivolt output proportional to acceleration. The electronic signals from the accelerometers and transducers were transmitted to a base station by means of constant bandwidth FM/FM telemetry link for recording on magnetic tape and for display on a real-time strip chart. Provision was made for the transmission of calibration signals before and after the test, and an accurate time reference signal was simultaneously recorded with the data.

Pressure sensitive contact switches on the bumper were actuated just prior to impact by wooden dowels to indicate the elapsed time over a known distance to provide a measurement of impact velocity. The initial contact also produced an "event" mark on the data record to establish the exact instant of contact with the bridge railing.

The multiplex of data channels transmitted on one radio frequency was received at a data acquisition station and demultiplexed into separate tracks of Intermediate Range Instrumentation Group (I.R.I.G.) tape recorders. After the test, the data were played back from the tape machines, filtered with an SAE J211 Class 180 filter, and digitized using a microcomputer for analysis and evaluation of impact performance.

The passenger car and pickup were equipped with one Alderson Research Laboratories Hybrid II, 50th percentile anthropomorphic dummy. The uninstrumented dummy was placed in the driver seat and was restrained with standard restraint equipment. The 18,000-lb (8 172-kg) truck carried no dummy.

The digitized data from the electronic transducers were then processed using two computer programs: DIGITIZE and PLOTANGLE. Brief descriptions on the functions of these two computer programs are as follows.

The DIGITIZE program uses digitized data from vehicle-mounted linear accelerometers to compute occupant/compartiment impact velocities, time of occupant/compartiment impact after vehicle impact, and the highest 0.010-s average ridedown acceleration. The DIGITIZE program also calculates a vehicle impact velocity and the change

in vehicle velocity at the end of a given impulse period. In addition, maximum average accelerations over 0.050-s intervals in each of the three directions are computed. Acceleration versus time curves for the longitudinal, lateral, and vertical directions are then plotted from the digitized data of the vehicle-mounted linear accelerometers using a commercially available software package (QUATTRO PRO). For each of these graphs, a 0.050-s average window was calculated at the center of the 0.050-s interval and plotted with the first 0.050-s average plotted at 0.026 s.

The PLOTANGLE program uses the digitized data from the yaw, pitch, and roll rate charts to compute angular displacement in degrees at 0.00067-s intervals and then instructs a plotter to draw a reproducible plot: yaw, pitch, and roll versus time. It should be noted that these angular displacements are sequence dependent with the sequence being yaw-pitch-roll for the data presented herein. These displacements are in reference to the vehicle-fixed coordinate system with the initial position and orientation of the vehicle-fixed coordinate system being that which existed at initial impact.

Photographic coverage of the test included three high-speed cameras: one over head with a field of view perpendicular to the ground and directly over the impact point, one placed to have a field of view parallel to and aligned with the bridge railing system at the downstream end, and a third placed perpendicular to the front of the bridge railing. A high-speed camera was also placed onboard the passenger car and the pickup to record the motions of the dummy placed in the driver seat during the test sequence. A flash bulb activated by pressure sensitive tape switches was positioned on the impacting vehicle to indicate the instant of contact with the bridge railing and was visible from each camera. The films from these high-speed cameras were analyzed on a computer-linked motion analyzer to observe phenomena occurring during the collision and to obtain time-event, displacement, and angular data. A 16-mm movie cine, a professional video camera, and a 3/4-in (19-mm) video recorder along with 35-mm still cameras were used for documentary purposes and to record conditions of the test vehicle and bridge railing system before and after the test.

The test vehicles were towed into the test installation using a steel cable guidance and reverse tow system. A steel cable for guiding the test vehicle was stretched along the path, anchored at each end, and threaded through an attachment to the front wheel of the test vehicle. Another steel cable was connected to the test vehicle, passed around a pulley near the impact point, through a pulley on the tow vehicle, and then anchored to the ground such that the tow vehicle moved away from the test site. A 2-to-1 speed ratio between the test and tow vehicle existed with this system. Immediately prior to impact with the bridge rail system, the test vehicle was released to be free-wheeling and unrestrained. The vehicle remained free-wheeling, i.e., no steering or braking inputs, until the vehicle cleared the immediate area of the test site. At this time brakes on the vehicle were activated to bring the vehicle to a safe and controlled stop.

CHAPTER 3. FULL-SCALE CRASH TESTS

TEST 7069-35

Test Description

A 1981 Honda Civic (figures 2 and 3) was used for the crash test. Test inertia mass of the vehicle was 1,800 lb (817 kg) and its gross static mass was 1,970 lb (894 kg). The height to the lower edge of the vehicle bumper was 13.6 in (345 mm) and it was 19.1 in (485 mm) to the top of the bumper. Additional dimensions and information on the test vehicle are given in figure 4. The vehicle was directed into the Illinois side mount bridge railing system (figure 5) using the cable reverse tow and guidance system and was released to be free-wheeling and unrestrained just prior to impact. The vehicle impacted the bridge railing 3.0 ft (914 mm) downstream from post 4 at a speed of 59.9 mi/h (96.4 km/h) and the angle of impact was 20.1 degrees.

Upon impact the front bumper was pushed toward the passenger side of the vehicle and the bumper then separated from the vehicle on the passenger side. At 0.044 s after impact, the vehicle began to redirect, and at 0.065 s the windshield began to crack at the lower corner on the driver side. The lower edge of the left front tire began to ride down the slope of the asphalt between the lower rail element and deck, and by 0.113 s the tire reached the lowest point under the rail element. By 0.136 s the vehicle was traveling parallel to the bridge railing at a speed of 51.1 mi/h (86.2 km/h), and at 0.148 s the rear of the vehicle impacted the bridge railing. By this time the left front tire was returning to the asphalt surface. The vehicle lost contact with the bridge railing at 0.190 s traveling at 50.8 mi/h (81.7 km/h) and 6.4 degrees. The brakes on the vehicle were applied at 1.65 s after impact, the vehicle yawed clockwise, and subsequently came to rest 150 ft (46 m) down from and 114 ft (35 m) in front of the point of impact.

As can be seen in figure 6, the bridge railing received minimal damage. There was no deformation to the metal rail element. The vehicle was in contact with the bridge railing for 8.4 ft (2.6 m).

The vehicle sustained damage to the left side as shown in figure 7. Maximum crush at the left front corner at bumper height was 7.5 in (190 mm) and there was a 1.3 in (32 mm) dent into the occupant compartment at the firewall. The driver door was deformed outward approximately 4.1 in (105 mm) and there was a small dent in the roof just above the B-pillar. The left front strut and sway bar were damaged, the instrument panel was bent, the windshield cracked, and the A-pillar was bent on the driver side. Also, damage was done to the front bumper, hood, grill, left front and rear quarter panel, left front and rear rim, and left door.

Test Results

Impact speed was 59.9 mi/h (96.4 km/h) and the angle of impact was 20.1 degrees. The speed of the vehicle at time of parallel was 51.1 mi/h (82.2 km/h) and the coefficient of friction was 0.25. The vehicle lost contact with the bridge railing traveling at 50.8 mi/h (81.7 km/h) and the exit angle between the vehicle path and the bridge railing was 6.4 degrees. Data from the accelerometer located at the center-of-gravity were digitized for evaluation and occupant risk factors were computed as follows. In the longitudinal direction, occupant impact velocity was 15.9 ft/s (4.8 m/s) at 0.200 s, the highest 0.010-s average ridedown acceleration was -1.7 g between 0.909 and 0.919 s, and the maximum 0.050-s average acceleration was -6.4 g between 0.034 and 0.084 s. Lateral occupant impact velocity was 25.8 ft/s (7.9 m/s) at 0.093 s, the highest 0.010-s occupant ridedown acceleration was -6.6 g between 0.143 and 0.153 s, and the maximum 0.050-s average acceleration was -14.8 g between 0.035 and 0.085 s. The change in vehicle velocity at loss of contact was 9.1 mi/h (14.6 km/h) and the change in momentum was 746 lb-sec (3,319 N-s). These data and other pertinent information from the test are summarized in figure 8 and table 1. Sequential photographs of the test sequence are shown in figures 9 and 10. Vehicular angular displacements are displayed in figure 11. Vehicular accelerations versus time traces filtered at SAE J211 (Class 180) are presented in figures 12 through 14.

Conclusions

The bridge railing contained the test vehicle with no lateral movement of the bridge railing. There was no intrusion of railing components into the occupant compartment although there was a 1.3-in (32-mm) dent into the occupant compartment at the firewall. The vehicle remained upright and relatively stable during the collision. The bridge railing redirected the vehicle and the effective coefficient of friction was considered good. Velocity change of the vehicle during the collision was 9.1 mi/h (14.6 km/h).

The 1989 American Association for State Highway and Transportation Officials (AASHTO) *Guide Specifications For Bridge Railings* sets forth required limits for occupant risk factors for tests with the 1800-lb (817-kg) vehicle.⁽¹⁾ The AASHTO specifications recommends a limit of 30 ft/s (9.1 m/s) for longitudinal occupant impact velocity and 25 ft/s (7.6 m/s) for the lateral occupant impact velocity. The longitudinal occupant impact velocity and the occupant ridedown accelerations were within the limits; however, the lateral impact velocity of 25.8 ft/s (7.9 m/s) was considered marginal. The vehicle trajectory at loss of contact indicated minimum intrusion into adjacent traffic lanes. See figure 8 and table 1 for more details.

	Desirable ⁵	e, f, h	e, f, g, h	d, e, f, h	d, e, f, h

Notes:

- Except as noted, all full-scale tests shall be conducted and reported in accordance with the requirements in NCHRP Report No. 230. In addition, the maximum loads that can be transmitted from the bridge railing to the bridge deck are to be determined from static force measurements or ultimate strength analysis and reported.
- Permissible tolerances on the test speeds and angles are as follows:

Speed	-1.0 mph	+2.5 mph
Angle	-1.0 deg.	+2.5 deg.

Tests that indicate acceptable railing performance but that exceed the allowable upper tolerances will be accepted.

- Criteria for evaluating bridge railing crash test results are as follows:
 - The test article shall contain the vehicle; neither the vehicle nor its cargo shall penetrate or go over the installation. Controlled lateral deflection of the test article is acceptable.
 - Detached elements, fragments, or other debris from the test article shall not penetrate or show potential for penetrating the passenger compartment or present undue hazard to other traffic.
 - Integrity of the passenger compartment must be maintained with no intrusion and essentially no deformation.
 - The vehicle shall remain upright during and after collision.
 - The test article shall smoothly redirect the vehicle. A redirection is deemed smooth if the rear of the vehicle or, in the case of a combination vehicle, the rear of the tractor or trailer does not yaw more than 5 degrees away from the railing from time of impact until the vehicle separates from the railing.
 - The smoothness of the vehicle-railing interaction is further assessed by the effective coefficient of friction, μ :

μ	Assessment
0-0.25	Good
0.26-0.35	Fair
>0.35	Marginal

where $\mu = (\cos\theta - V_p/V)/\sin\theta$

Table 2. Bridge railing performance levels and crash test criteria.
 (Exerpt from 1989 AASHTO *Guide Specifications for Bridge Railings*)⁽¹⁾
 (continued)

- g. The impact velocity of a hypothetical front-seat passenger against the vehicle interior, calculated from vehicle accelerations and 2.0-ft. longitudinal and 1.0-ft. lateral displacements, shall be less than:

Occupant Impact Velocity—fps	
Longitudinal	Lateral
30	25

and the vehicle highest 10-ms average accelerations subsequent to the instant of hypothetical passenger impact should be less than:

Occupant Ridedown Acceleration—g's	
Longitudinal	Lateral
15	15

- h. Vehicle exit angle from the barrier shall not be more than 12 degrees. Within 100 ft. plus the length of the test vehicle from the point of initial impact with the railing, the railing side of the vehicle shall move no more than 20-ft. from the line of the traffic face of the railing. The brakes shall not be applied until the vehicle has traveled at least 100-ft. plus the length of the test vehicle from the point of initial impact.
4. Values A and R are estimated values describing the test vehicle and its loading. Values of A and R are described in the figure below and calculated as follows:

Min. Load = 20.5 Kips

$$L_1 = 30'' \pm 1''$$

$$L_2 + \frac{L_3}{2} = 169'' \pm 4''$$

$$A = L_1 + \frac{W_2 L_2 + W_3 (L_2 + L_3)}{W_1 + W_2 + W_3}$$

$$R = \frac{W_1 + W_2 + W_3}{W}$$

$$W = W_1 + W_2 + W_3 + W_4 + W_5$$

= total vehicle weight.

5. Test articles that do not meet the desirable evaluation criteria shall have their performance evaluated by a designated authority that will decide whether the test article is likely to meet its intended use requirements.

TEST 7069-36

Test Description

A 1986 Chevrolet C20 Custom Deluxe pickup (figures 15 and 16) was used for the crash test. Test inertia mass of the vehicle was 5,400 lb (2 452 kg) and its gross static mass was 5,565 lb (2 526 kg). The height to the lower edge of the vehicle bumper was 17.2 in (436 mm) and it was 26.1 in (662 mm) to the top of the bumper. Additional dimensions and information on the test vehicle are given in figure 17. The vehicle was directed into the Illinois side mount bridge railing system (shown in figure 18) using the cable reverse tow and guidance system and was released to be free-wheeling and unrestrained just prior to impact. The vehicle impacted the bridge railing system 1.0 ft (305 mm) downstream from post 4 at a speed of 60.4 mi/h (97.2 km/h) and the angle of impact was 20.4 degrees.

At 0.017 s after impact the left front tire contacted the lower rail element, and at 0.027 s the vehicle began to redirect. At 0.036 s the left front wheel redirected and the tire began to ride along the edge of the asphalt slope on the bridge deck. The shoulder of the dummy impacted the door of the vehicle at 0.080 s and the door glass shattered at 0.107 s. By 0.182 s the vehicle was traveling parallel to the bridge railing at a speed of 56.6 mi/h (91.1 km/h), and at 0.189 s the rear of the vehicle contacted the bridge railing. The vehicle lost contact with the bridge railing at 0.291 s traveling at 55.6 mi/h (89.5 km/h) and 9.0 degrees. The brakes on the vehicle were applied at 1.4 s after impact. One of the two rear wheel brakes locked up causing the vehicle to yaw counter-clockwise into a protective barrier and it subsequently came to rest 330 ft (100 m) down from and 16 ft (5 m) behind the point of impact.

As can be seen in figures 19 through 23, the bridge railing received moderate damage. There was 1.0-in (25-mm) deformation to the upper rail element and 0.75 in (19 mm) to the lower rail element near post 5. The flanges on posts 4 and 5 were twisted just above the angles (L 6 by 4 by 1/4 by 4) (152 by 102 by 6 by 102 mm) and these angles were bent as well as the angle on the downstream side of post 6. The TS 6 by 4 by 1/4 by 4 (152 by 102 by 6 by 102 mm) blocks at posts 3, 4, and 5 had dropped down. The vehicle was in contact with the bridge railing for 14.8 ft (4.5 m).

The vehicle sustained damage to the left side as shown in figure 24. Maximum crush at the left front corner at bumper height was 13.0 in (330 mm) and there was a 0.4 in (10 mm) dent into the occupant compartment at the firewall and center tunnel. The frame was bent and the door on the driver side was deformed outward 3.2 in (81 mm). Also, damage was done to the front bumper, hood, grill, radiator, fan, left front quarter panel, left front tire and rim, left door, left rear quarter panel, rear bumper, and left rear rim. Most of the damage to the right side of the vehicle was sustained when the vehicle impacted the protective barrier.

Test Results

The impact speed was 60.4 mi/h (97.2 km/h) and the angle of impact was 20.4 degrees. The speed of the vehicle at time of parallel was 56.6 mi/h (91.1 km/h) and the

coefficient of friction was 0. The vehicle lost contact with the bridge railing traveling at 55.6 mi/h (89.5 km/h), and the exit angle between the vehicle path and the bridge railing was 9.0 degrees. Data from the accelerometer located at the center-of-gravity were digitized for evaluation and occupant risk factors were computed as follows. In the longitudinal direction, occupant impact velocity was 11.7 ft/s (3.6 m/s) at 0.275 s, the highest 0.010-s average ridedown acceleration was 1.0 g between 0.280 and 0.290 s, and the maximum 0.050-s average acceleration was -4.1 g between 0.060 and 0.110 s. Lateral occupant impact velocity was 24.4 ft/s (7.4 m/s) at 0.132 s, the highest 0.010-s occupant ridedown acceleration was -12.3 g between 0.219 and 0.229 s, and the maximum 0.050-s average acceleration was -12.0 g between 0.062 and 0.112 s. The change in vehicle velocity at loss of contact was 4.8 mi/h (7.7 km/h) and the change in momentum was 1,181 lb-sec (5,253 N-s). These data and other pertinent information from the test are summarized in figure 36 and table 3. Sequential photographs for the test sequence are shown in figures 26 and 27. Vehicular angular displacements are displayed in figure 28. Vehicular accelerations versus time traces filtered at SAE J211 (Class 180) are presented in figures 29 through 33.

Conclusions

The bridge railing contained the test vehicle with minimal lateral movement of the bridge railing. There was no intrusion of railing components into the occupant compartment although there was a 0.4-in (10-mm) dent into the occupant compartment at the firewall. The vehicle remained upright and relatively stable during the collision. The bridge railing redirected the vehicle and the effective coefficient of friction was considered good. Velocity change of the vehicle during the collision was 4.8 mi/h (7.7 km/h).

The 1989 AASHTO guide specifications sets forth desired (but not required) limits for occupant risk factors for tests with the 5,400-lb (2 452-kg) vehicle.⁽¹⁾ The AASHTO specifications recommend a limit of 30 ft/s (9.1 m/s) for longitudinal occupant impact velocity and 25 ft/s (7.6 m/s) for the lateral occupant impact velocity. The occupant impact velocities and the occupant ridedown accelerations were within the limits. The vehicle trajectory at loss of contact indicates minimum intrusion into adjacent traffic lanes. See figure 25 and table 3 for more details.

TEST 7069-37

Test Description

A 1981 Ford single-unit truck (figures 34 and 35) was used for the crash test. Empty weight of the vehicle was 10,810 lb (4 908 kg) and its test inertia and gross static mass was 18,000 lb (8 172 kg). The height to the lower edge of the vehicle bumper was 19.0 in (483 mm) and it was 31.0 in (787 mm) to the top of the bumper. Additional dimensions and information on the test vehicle are given in figure 36. The vehicle was directed into the Illinois side mount bridge railing system (shown in figures 37 and 38) using the cable reverse tow and guidance system and was released to be free-wheeling and unrestrained just prior to impact. The vehicle impacted the bridge railing 2.3 ft (701 mm) downstream from post 4 at a speed of 51.4 mi/h (82.7 km/h) and the angle of impact was 14.7 degrees.

Approximately 0.022 s after impact, the left front tire of the vehicle impacted the bridge railing and then rode up and steered into the rail. The vehicle began to redirect at 0.061 s, and by 0.261 s the vehicle was traveling parallel to the bridge railing at a speed of 46.8 mi/h (75.3 km/h). The rear of the vehicle contacted the bridge railing at approximately 0.283 s and the lower edge of the box-van set down on top of the rail at 0.331 s and rode along in this manner until the vehicle exited the rail. The cab of the vehicle reached a maximum roll angle of about 12 degrees at 0.469 s. At 0.725 s the box-van had rolled to a maximum of about 53 degrees, and at 0.822 s began to right itself. The vehicle rode off the end of the bridge railing and the vehicle subsequently came to rest 165 ft (50 m) down from and 9 ft (3 m) behind the point of impact.

As can be seen in figures 39 through 41, the bridge railing received moderate damage with most being contained within the area between posts 4 through 7. The upper and lower rails sustained gouges between posts 4 and 5 from the lug nuts of the wheel of the vehicle. The head of the lower bolt on the top rail at post 5 was torn off and the bolts on the lower element were loose. The angles at post 4 were slightly bent and those at posts 5 and 6 were deformed. The spacers at posts 4 and 5 were knocked loose and down. There was 2.5-in (64-mm) deformation to the upper rail element at post 5. The vehicle was in contact with the bridge railing for 69 ft (21 m).

The vehicle sustained damage mostly to the left side as shown in figure 42. Maximum crush at the left front corner at bumper height was 8.0 in (203 mm). The front springs, shackles, and U-bolt were damaged and the box-van shifted off the frame approximately 6 in (150 mm). Also, damage was done to the front bumper, left front quarter panel, left front tire and rim, left rear outside tire and rim, and lower edge of the box-van.

Test Results

The impact speed was 51.4 mi/h (82.7 km/h) and the angle of impact was 14.7 degrees. The speed of the vehicle at time of parallel was 46.8 mi/h (75.9 km/h) and the coefficient of friction was 0.22. The vehicle remained in contact with the bridge railing and rode off the end subsequently coming to rest behind the installation. Data from the

accelerometer located at the center-of-gravity were digitized for evaluation and occupant risk factors were computed as follows. In the longitudinal direction, occupant impact velocity was 9.1 ft/s (2.8 m/s) at 0.446 s, the highest 0.010-s average ridedown acceleration was -4.3 g between 0.518 and 0.528 s, and the maximum 0.050-s average acceleration was -1.5 g between 0.410 and 0.460 s. Lateral occupant impact velocity was 9.7 ft/s (3.0 m/s) at 0.259 s, the highest 0.010-s occupant ridedown acceleration was -6.3 g between 0.335 and 0.345 s, and the maximum 0.050-s average acceleration was -3.8 g between 0.296 and 0.346 s. These data and other pertinent information from the test are summarized in figure 43 and table 4. Sequential photographs for the test sequence are shown in figures 44 and 45. Vehicular angular displacements are displayed in figure 46. Vehicular accelerations versus time traces filtered at SAE J211 (Class 180) are presented in figures 47 through 53.

Conclusions

The bridge railing contained the test vehicle with minimal lateral movement of the bridge railing. There was no intrusion of railing components into the occupant compartment. The vehicle remained upright and relatively stable during the collision. The bridge railing redirected the vehicle and the effective coefficient of friction was considered good. The vehicle trajectory at loss of contact indicates no intrusion into adjacent traffic lanes. See figure 43 and table 4 for more details.

CHAPTER 4. STRENGTH CALCULATIONS

Analysis of the strength of the railing is based on a plastic hinge, ultimate strength failure mechanism.⁽²⁾ Force from a colliding vehicle is idealized as being a uniformly distributed line load extending over 3.5 ft (1.07 m). The load may be applied at any location along the railing. Possible failure mechanisms are illustrated in figure 54. Relative strengths of the rail element and the posts will determine the controlling mechanism.

For analysis of strength of the post, a plastic hinge is assumed at the top anchor bolts and applied force is assumed to be located 27.9 in (709 mm) above the top anchor bolt (figure 55). This location allows both rails to develop their plastic moment capacities. The gross plastic section modulus for the W6x25 post is 18.9 in³ (309 716 mm³). The net plastic section modulus, considering the two holes in the lower flange and the hole in the web, is 15.2 in³ (249 000 mm³). The plastic moment capacity, M_p , is 547 in-kips (61.9 m-kN). The resulting lateral load resistance of the post would be 19.7 kips (87.7 kN).

Analysis of strength of the connection of the post to the bridge deck, based on the tensile strength of the top anchor bolts, shows that the connection has adequate strength to develop a plastic hinge in the post.

The gross plastic section modulus for the TS 8 by 4 by 5/16-in (203 by 102 by 8-mm) failure modes are computed using the equations given in figure 54. It is assumed that both rail elements are at their full capacity, giving a total plastic moment capacity of 66.5 in-kips (7.5 m-kN). For a single-span failure mechanism, the strength is 118.2 kips (526 kN); for two spans it is 69.1 kips (307.5 kN); for three spans it is 70.5 kips (313.7 kN); and for four spans it is 81.7 kips (363.6 kN). The mechanism having the lowest value is the controlling mechanism. For this railing it is the two-span mechanism with a strength of 69.1 kips (307.5 kN).

$$w\ell = \frac{16M_p}{2L - L_t}$$

$$w\ell = \frac{16M_p + 4P_p L}{4L - L_t}$$

$$w\ell = \frac{16M_p + 8P_p L}{6L - L_t}$$

$$w\ell = \frac{16M_p + 16P_p L}{8L - L_t}$$

Longer mechanisms may also be possible.
