14. ABSTRACT The U.S. Department of Transportation (DOT) John A. Volpe National Transportation Systems Center, under the direction of the DOT's Federal Railroad Administration (FRA), Office of Research, Development and Technology, studied the effects of the implementation of quiet zones on trespass accidents along the national rail network. This study focused on 333 quiet zones established between 6/1/2012 and 5/31/2018. Trespass casualties that occurred within the 333 quiet zones were compared before and after the establishment of the quiet zones. Trespass casualties in quiet zones with 2 and 3 years of observable accident data increased from 28 before to 40 after and from 39 before to 47 after the establishment of the quiet zones, respectively. However, trespass casualties in quiet zones with 1 year of observable accident data decreased from 19 before to 17 after the establishment. There was no statistically significant difference in trespass casualties before and after the establishment of the quiet zones for all three observable periods.

Executive Summary

The John A. Volpe National Transportation Systems Center (Volpe) was tasked by the Federal Railroad Administration (FRA) Office of Research, Development and Technology to analyze rail trespass accident data to determine the effects of implementing quiet zones (QZs) on trespass accidents. A *quiet zone* is an area at least one-half mile in length that contains one or more consecutive public grade crossings at which railroads do not routinely sound locomotive horns when approaching those crossings. Localities seeking to establish a quiet zone are first required to mitigate the increased risk caused by the absence of a horn. This is typically done through supplemental safety measures (SSMs) such as gates with channelization or medians, four-quadrant gates, one-way streets, and crossing closures. SSMs are designed for the motoring public and not necessarily for other crossing users such as pedestrians and cyclists. Additionally, SSMs target grade crossing safety and generally do not address potential nearby trespass issues on the right-of-way (ROW).

Researchers analyzed 333 quiet zones established between June 2012 and May 2018 to determine their effects on trespass accidents. Trespass casualties from June 2011 to May 2019 were spatially analyzed in relation to the 333 quiet zones. Trespass casualties that occurred within the 333 quiet zone were then classified into casualties that occurred before, and those that occurred after the establishment of the quiet zone. A total of 190 trespass casualties were observed within the 333 quiet zones; 86 were observed before and 104 were observed after the establishment of the quiet zones.

Results indicated that trespass casualties in quiet zones with 1 year of observable accident data decreased from 19 before to 17 after the establishment of the quiet zones. However, trespass casualties in quiet zones with 2 and 3 years of observable accident data increased from 28 before to 40 after and from 39 before to 47 after the establishment of the quiet zones, respectively. There was no statistically significant difference in trespass casualties before and after the establishment of the quiet zones for all three observable periods.

Additionally, results showed that trespass casualties along the railroad ROW decreased by 11.1 percent – from 63 before to 56 after the establishment of the quiet zones. However, trespass casualties at grade crossings increased by 108.7 percent from 23 before to 48 after the establishment of the quiet zones. In comparison, overall grade crossing incidents increased by 7.4 percent from 2,064 in 2011 to 2,217 in 2019.

The analysis was also performed based on quiet zone type and on basis section (the regulatory provision that provides the basis for establishing the quiet zone). The analysis by quiet zone type revealed that neither quiet zone types designated as *New* nor *Wayside Horns* showed a significant difference in trespass casualties following the establishment of the quiet zones. The analysis based on basis section also revealed that there was no statistically significant difference in number of trespass casualties following the establishment of the quiet zones for all basis sections included in this study.

Volpe recommends that FRA advise communities establishing a quiet zone to consider the effects of the absence of train horns on railroad trespassing, including at crossings, and encourage those communities to develop appropriate trespass mitigation strategies. Furthermore,

FRA should consider adding similar trespass-specific requirements to the Train Horn Rule (49 CFR Part 222).

Volpe also recommends conducting a more in-depth analysis in 2 to 3 years, when there will be a much bigger dataset of trespass accidents with location information and a trespass risk methodology that FRA is currently working on becomes available so that factors such as population density and train frequency can be incorporated into the analysis.

1. Introduction

The John A. Volpe National Transportation Systems Center (Volpe) provides technical support to the Federal Railroad Administration (FRA) on grade crossing safety and trespass prevention research. This support includes key research associated with highway-rail grade crossing safety and rail right-of-way (ROW) trespass prevention. One major effort is to develop a more precise understanding of the risks presented by trespassing on ROWs and then determine how best to mitigate the risks. This report presents the findings of a study of the effects of the implementation of quiet zones (QZs) on trespass accidents along the national rail network.

1.1 Background

Trespassing along railroad ROWs is the leading cause of rail-related deaths in America. Generally, most trespassers are pedestrians who use railroad tracks as a shortcut. More than 500 trespass fatalities and nearly as many injuries occur in the U.S. every year, with the vast majority of these events being preventable.

Figure 1 shows a heat map of U.S. rail ROW trespass casualties from June 2011, when latitude/longitude information was first required to be submitted to FRA, to September 2019.

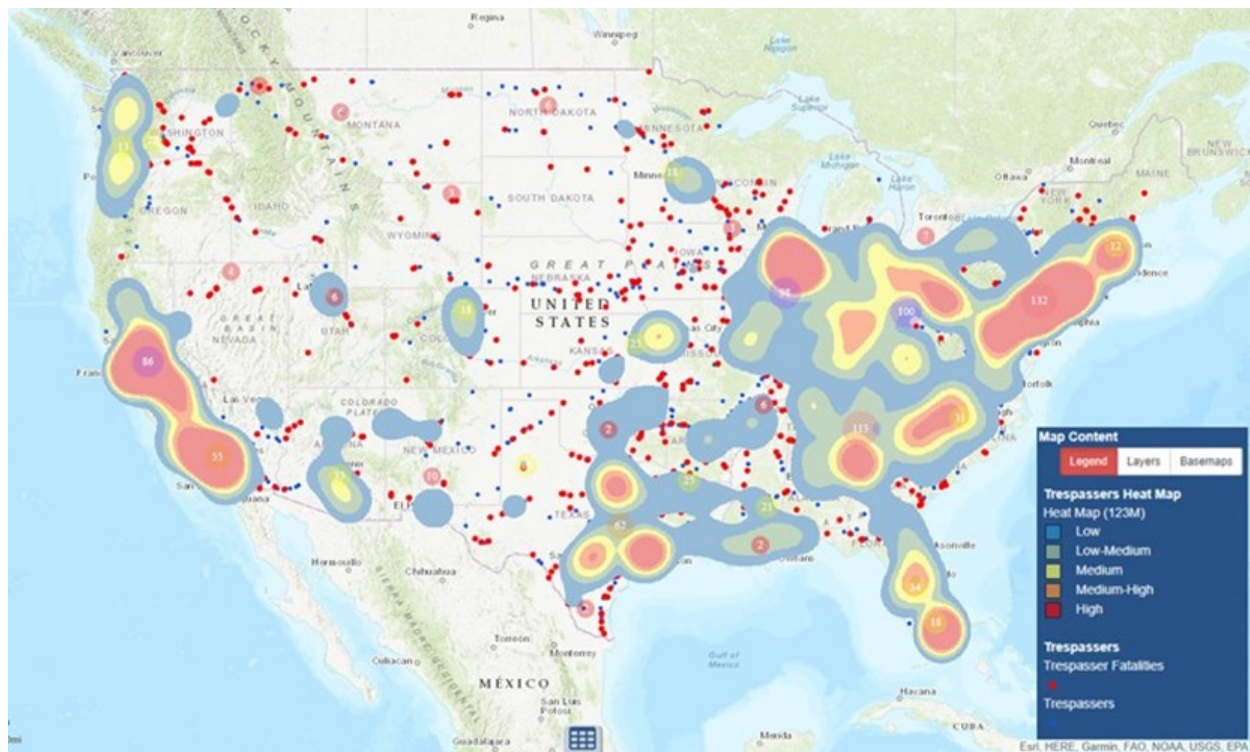

Figure 1. FRA Trespass Casualty Map, 6/2011–9/2019

Analysis of the ROW trespass data revealed that trespass casualties have been increasing. In 2018 alone, there were 1,016 trespassing casualties on the nation's rail network, excluding pedestrian accidents at active crossings and known suicides. A total of 532 of these casualties

were fatalities.¹ In addition, there were 201 grade crossing accidents involving pedestrians classified as trespassing at the time of the accident.

FRA's Train Horn Rule (49 CFR Part 222), enacted in 2005, mandates that locomotive engineers must begin sounding horns 15–20 seconds before entering public grade crossings, no more than one-quarter mile in advance.² The rule also provides an opportunity for localities nationwide to mitigate the effects of train horn noise by establishing “quiet zones.” A quiet zone (QZ) is an area at least one-half mile in length that contains one or more consecutive public grade crossings at which railroads do not routinely sound locomotive horns when approaching those public grade crossings. In a QZ, railroads have been directed to cease the routine sounding their horns when approaching public highway-rail grade crossings. However, locomotive engineers can still sound their horns in an emergency situation, such as the presence of trespassers or vehicles violating the grade crossing warning devices, or to comply with other railroad or FRA rules. There were a total of 906 QZs as of February 14, 2020.³

Localities wanting to establish a QZ are first required to mitigate the increased risk caused by the absence of a horn. This is typically done through additional safety improvements such as gates with channelization or medians, four-quadrant gates, one-way streets, and crossing closures. These supplemental safety measures (SSMs) are designed to compensate for the absence of a locomotive horn. SSMs are designed for the motoring public and not necessarily for other crossings users such as pedestrians and cyclists. Additionally, SSMs target grade crossing safety and generally do not address potential nearby trespass issues on the ROW.

The majority of trespass casualties occur near grade crossings. A recent FRA analysis revealed that, although trespassing casualties can occur anywhere along the ROW, about 74 percent occur within 1,000 feet (less than one-quarter mile) of a grade crossing.⁴ At least half occur within a much closer distance to a crossing – within 400 feet. Table 1 shows the results of the analysis, which excludes suicides.

Not sounding the train horn on approach to grade crossings within QZ may have an effect on trespassing accidents near those crossings, since trespassers may not have the benefit of the sounding of the horn of an oncoming train. Again though, locomotive engineers can still sound their horns in certain situations including observing the presence of trespassers in their path.

Table 1. Locations of Pedestrian Trespasser Casualties* November 2013 to October 2017

Distance from a Highway-Rail Grade Crossing (feet)	Number	Percentage of Total	Cumulative	
			Number	Percentage
At a grade crossing	516	12.2%	516	12.0%
Within 50'	337	7.9%	853	20.0%
50' to 100'	263	6.2%	1,116	26.0%
100' to 200'	492	11.6%	1,608	38.0%
200' to 300'	365	8.6%	1,973	46.0%
300' to 400'	259	6.1%	2,232	53.0%
400' to 500'	230	5.4%	2,462	58.0%
500' to 600'	196	4.6%	2,658	63.0%
600' to 700'	140	3.3%	2,798	66.0%
700' to 800'	147	3.5%	2,945	69.0%
800' to 900'	104	2.5%	3,049	72.0%
900' to 1,000'	93	2.2%	3,142	74.0%
1,000' to 1,250'	186	4.4%	3,328	78.0%
1,250' to 1,500'	149	3.5%	3,477	82.0%
1,500' to 2,000'	234	5.5%	3,711	87.0%
2,000' to 3,000'	239	5.6%	3,950	93.0%
3,000' to 5,000'	157	3.7%	4,107	97.0%
5,000' to 10,000'	79	1.9%	4,186	99.0%
More than 10,000'	56	1.3%	4,242	100.0%
Total Casualties	4,242	100.0%		

* Deaths and injuries, excluding suicides.

1.1.1 Past Research

In 2013, FRA conducted an internal study on the effectiveness of quiet zones. The study included an analysis of 997 crossings in 203 QZs to “determine whether or not silencing train horns has had a negative effect on crossing safety and whether or not the FRA has accurately assessed that the installation of SSMs and Alternative Safety Measures (ASMs) mitigate the negative impact that the lack of a train horn has on safety at highway-rail grade crossings.”⁴ The number of accidents before and after the establishment of a quiet zone was recorded for each crossing in the QZ and then aggregated across crossings within the QZ. The results indicated that there was no statistically significant difference in the number of accidents before and after the establishment of QZs, meaning that the safety risk remained the same. That analysis, however, did not assess safety impacts on the trespass problem.

In a provision of the Fixing America's Surface Transportation (FAST) Act, the U.S. Government Accountability Office (GAO) was directed to examine quiet zone regulations. GAO conducted

an analysis and issued a report to Congress on its findings in 2017.⁵ The agency recommended that FRA should revise the methodology for the analysis to take into account relevant changes over time, including changes in train and automotive traffic (e.g., volume and speed) or in the physical characteristics of the grade crossing. FRA concurred with the recommendations to explore alternative methods, and conduct the analysis using those methods if deemed suitable for the data. This analysis, again, did not look at the potential impact on trespassing.

1.2 Objectives

Volpe sought to study the effects of implementation of quiet zones on trespass accidents along the national rail network.

1.3 Overall Approach

The research team analyzed the rail trespass accident data to determine the effects of implementing QZs on trespass accidents, and pedestrian accidents at crossings as well. Localities wanting to establish a QZ are first required to mitigate the increased risk at grade crossings caused by the absence of a horn. This is typically done through additional safety improvements such as gates with channelization or medians, four-quadrant gates, one-way streets, and crossing closures. However, no trespass mitigation requirements are included in this study. It is uncertain how well these improvements work in place of the train horn for both pedestrian safety at crossings and trespassing on the rail ROW.

1.4 Scope

This study investigated the frequency of trespass accidents on the U.S. rail network, specifically along sections designated as quiet zones. The analysis included pedestrian accidents at active crossings as well, as they are classified by the FRA as trespassers if they violate the activated crossing warning devices. However, the analysis does not include reported suicides.

1.5 Organization of the Report

This report is organized as follows:

- Section [2](#) describes the data collection.
- Section [3](#) describes the analysis method.
- Section [4](#) presents the findings.
- Section [5](#) presents the conclusions of the study.
- Section [6](#) presents the potential limitations of the study.

⁵ “Quiet Zone Analyses and Inspections Could Be Improved,” Government Accountability Office, October 2017, available at <https://www.gao.gov/assets/690/688079.pdf>.

2. Data Collection

The primary source of data for this study is the FRA data file on quiet zones and the FRA Office of Railroad Safety Data Analysis website. The researcher received a list of all quiet zones established as of March 28, 2019 from FRA. Each QZ is identified by a unique train horn number and contains a lists of highway-rail grade crossings at which locomotive horns are not routinely sounded when approaching the crossing. The list also includes information such as QZ type, start date, basis section (the regulatory provision that provides the basis for establishing the QZ), and SSMs (describes pre-approved risk reduction engineering treatments).

FRA developed the Grade Crossing Inventory System (GCIS) database in 1970, managed by its Office of Railroad Safety. It contains all U.S. public and private highway-rail grade crossings, with detailed information on individual crossings. This database was used to identify the locations and characteristics of the individual crossings within a given QZ.

FRA developed the Railroad Accident Incident Reporting System (RAIRS) database in 1975, also managed by the Office of Railroad Safety. It contains all the accidents involving a highway user, railroad equipment, and railroad-related casualties. This database was used to obtain trespass casualties for an 8-year period from June 1, 2011 to May 31, 2019.

2.1 Quiet Zone Data

FRA started requiring railroads to submit trespass casualties location data starting in June 2011; therefore, trespass casualty data from June 1, 2011 to May 31, 2019 was used for this study.

To use a before-and-after study design, the analysis required equal numbers of observable periods before and after the establishment of a QZ, with a minimum of 1 year of observable data. This data selection process resulted in selecting QZs established between June 1, 2012 and May 31, 2018. During this 6-year period, a total of 333 QZs containing 1,318 highway-rail grade crossings were established. Out of the total of 333 QZs, 111 were QZs with only 1 grade crossing and 222 were QZs with 2 or more grade crossings (the number of grade crossing in this group ranged from 2 to 47).

[Table 2](#) lists a breakdown of the 333 QZs by the observable period length. QZs in Group 1 had an observable period of 12 months before and 12 months after their establishment, those in Group 2 had an observable period of 24 months before and 24 months after their establishment, and those in Group 3 had an observable period of 36 months before and 36 months after their establishment.

Table 2. Breakdown of QZs by Number of Observable Months

Group	Observable period before and after QZ Establishment (months)	Established Between		Number of QZs	Number of Crossings
1	12	6/1/2012	5/31/2013	47	254
2	24	6/1/2013	5/31/2014	50	207
3	36	6/1/2014	5/31/2015	51	177
3	36	6/1/2015	5/31/2016	60	194
2	24	6/1/2016	5/31/2017	63	243
1	12	6/1/2017	5/31/2018	62	243
Total				333	1,318

Four QZs types were selected: *New*, *New Partial*, *Pre-Rule*, and *Wayside Horns*. There was one QZ with a missing QZ type. Table 3 shows the breakdown of the QZs and grade crossings by QZ type. Most QZs (92.5 percent) and the grade crossings (93.1 percent) are New Quiet Zone type. The definition of each QZ type is provided below.⁶

- *New Quiet Zone* means a segment of a rail line within which is situated one or a number of consecutive public highway-rail grade crossings at which routine sounding of locomotive horns is restricted pursuant to this part and which does not qualify as either a Pre-Rule Quiet Zone or Intermediate Quiet Zone.
- *New Partial Quiet Zone* means a segment of a rail line within which is situated one or a number of consecutive public highway-rail crossings at which locomotive horns are not routinely sounded between the hours of 10 p.m. and 7 a.m., but are routinely sounded during the remaining portion of the day, and which does not qualify as a Pre-Rule Partial Quiet Zone or an Intermediate Partial Quiet Zone.
- *Pre-Rule Quiet Zone* means a segment of a rail line within which is situated one or a number of consecutive public highway-rail crossings at which State statutes or local ordinances restricted the routine sounding of locomotive horns, or at which locomotive horns did not sound due to formal or informal agreements between the community and the railroad or railroads, and at which such statutes, ordinances, or agreements were in place and enforced or observed as of October 9, 1996 and December 18, 2003.
- *Wayside Horn* means a stationary horn located at a highway rail grade crossing, designed to provide, upon the approach of a locomotive or train, audible warning to oncoming motorists of the approach of a train.

⁶ 49 CFR §222.9 Definitions, available at <https://www.ecfr.gov/cgi-bin/text-idx?SID=5b54e66e049741371a77e43730b92b35&mc=true&node=pt49.4.222&rgn=div5#sp49.4.222.b>

Table 3. Breakdown of QZs by QZ Type

QZ Type	Number of QZs	Number of Crossings within QZ Types
New	308	1,227
New Partial	2	6
Pre-Rule	7	49
Wayside Horns	15	35
(Blank)	1	1
Total	333	1,318

Localities wanting to establish a QZ are required to meet one of the following conditions:

- The Quiet Zone Risk Index (QZRI) is less than or equal to the Nationwide Significant Risk Threshold (NSRT) with or without additional safety improvements.
- The QZRI is less than or equal to the Risk Index With Horns (RIWH).
- SSMs are installed at every public grade crossing.

As noted in the FRA Guide to the Quiet Zone Establishment Process⁷:

The QZRI is the average risk for all public highway-rail crossings in the quiet zone, including the additional risk for absence of train horns and any reduction in risk due to the risk mitigation measures. The NSRT is the level of risk calculated annually by averaging the risk at all of the Nation's public highway-rail grade crossings equipped with flashing lights and gates where train horns are routinely sounded. The RIWH is the average risk for all public highway-rail crossings in the proposed quiet zone when locomotive horns are routinely sounded.

Table 4 shows the breakdown of the QZs and associated grade crossings by basis section. Basis section is a specific reference in the train horn regulation that provides the basis for QZ establishment. Of the total of 333 QZs, 162 (over 48 percent) were established by installing SSMs at every public grade crossing, which falls under Basis Section 222.39(a)(1). However, only 384 of the grade crossings (29.1 percent) in these QZs were upgraded using this method. The QZs established on the basis of this method averaged the least number of grade crossings per QZ at 2.37 (384/162) and ranged from 1 to 12 grade crossing per QZ. The QZs established on the basis of 222.39(a)(3) made up 19.5 percent of the overall QZs but encompassed 38.3 percent of the grade crossings. The number of grade crossings within the QZ established per this basis ranged from 1 to 47 grade crossings and averaged 7.8 grade crossings per QZ.

Table 4. Breakdown of QZs by Basis Section

Basis Section	Description	Number of QZs	Number of Crossings within QZs
222.39(a)(1)	QZ established by implementing SSMS at every public grade crossings.	162	384
222.39(a)(2)(i)	QZ may be established if QZRI is at or below NSRT without SSMS.	19	51
222.39(a)(2)(ii)	QZ established by implementing SSMS which reduce the QZRI to a level at or below NSRT.	15	86
222.39(a)(3)	QZ established by implementing SSMS which reduce the QZRI to a level at or below RIWH.	65	505
222.39(b)(4)(i)(A)	QZ approved by FRA Associate Administrator where QZRI is at or below RIWH.	53	225
222.41(a)(1)(ii)	Pre-Rule QZ established where QZRI is at or below the NSRT.	2	20
222.41(a)(1)(iv)	Pre-Rule QZ established where QZRI is at or below the RIWH.	1	11
222.59	QZ established by installing wayside horns.	16	36
Total		333	1,318

2.2 Trespass Casualty Data

FRA developed the RAIRS Casualty database in 1975. It contains reported cases of railroad related injuries, illnesses, and fatalities. Casualties resulting from trespassing on railroad ROWs can be found by using “TYPPERS” data field for Type of Person=E, trespasser. Railroads are responsible for reporting accidents on their ROWs to the FRA using form 6180.55A.

This database was used to obtain the trespass casualty data on railroad ROWs. This dataset includes trespass accidents at grade crossing but does not include reported cases of suicide. FRA started requiring railroads to submit the geographical location (latitude/longitude coordinates) of trespass casualties starting in June 2011. Therefore, trespass casualty data from June 1, 2011 to May 31, 2019, covering an 8-year period, was used for the analysis. A total of 10,376 trespass casualties resulted in 4,882 fatalities over this period on the entire rail network. [Figure 2](#) shows trespass casualties, injury, and fatality trends from June 1, 2011 to May 31, 2019. As can be seen from the chart, there was almost a linear increase in the number of trespass casualties, injuries, and fatalities over the study period. Trespass casualties, injuries, and fatalities increased by 35.8 percent, 19.2 percent, and 56.5 percent, respectively, over the study period.

Figure 2. Trespass Casualty Statistics, 6/1/2011–5/31/2019

3. Data Analysis Method

To understand the effects of implementing QZs on trespass accidents, trespass casualties that occurred within a QZ were classified into casualties that occurred before and those that occurred after the establishment of the QZ. There is no simple way—such as using a filter for a data field—to query for trespass casualties that occurred within a QZ. Trespass casualties were spatially analyzed using ArcGIS to determine whether they occurred within a QZ.

As discussed in Section 2.1, QZs established between June 1, 2012 and May 31, 2018 were selected for this study. During this 6-year period, a total of 333 QZs covering 1,318 highway-rail grade crossings were established. For the 1,318 grade crossings, location information (latitude/longitude coordinates) was obtained from the FRA GCIS database and plotted in ArcGIS. It is worth noting that railroads and states can change the data in the inventory at any time to keep the information up-to-date. Since location information for some grade crossings can be inaccurate for a variety of reasons including human error during data entry, each grade crossing location was manually verified and corrected as needed. Researchers cross-referenced the street name of the grade crossing and the primary operating railroad from the FRA crossing inventory database with the map to obtain accurate locations for all crossings. An example of a manual validation and correction is the West Hidden Valley Boulevard grade crossing in Boca Raton, Florida (crossing ID 272499F). The latitude and longitude coordinates obtained from the FRA GCIS database for this crossing placed the crossing in the Atlantic Ocean (red pin). Based on crossing street name and primary operating railroad (Florida East Coast Railway), the crossing was correctly placed in its location (green pin).

While the example described above is a unique case, the level of inaccuracy of the grade crossing data in the GCIS is below 6 percent. The inaccuracies are no more than 20 meters (60 feet) between the recorded location and the actual location.

For the 222 QZs with more than one grade crossing, grade crossings within each QZ were joined to form a section of a rail line that represented that QZ. The remaining 111 QZs with one grade crossing were represented by points on a map. As mentioned earlier, Federal regulation requires locomotive engineers begin sounding the horn 15–20 seconds before entering a grade crossing, no more than one-quarter mile in advance. Therefore, a buffer of one-quarter mile was created around each QZ.

The 10,376 trespass casualties that occurred between June 1, 2011 and May 31, 2019 were then plotted on the map along with the QZs layer, and spatial analysis was performed to determine if a trespass casualty had occurred within a QZ buffer. If a trespass casualty fell within multiple QZ buffers or if there were multiple rail lines within a single QZ buffer, a manual validation was conducted to make sure that a trespass casualty was tagged to the correct QZ and was counted only once. Figure 3 shows an example of a review for trespass incident number 000119051. This trespass accident fell within two QZ buffers. Based on the trespass accident narrative, the trespasser on an all-terrain vehicle was struck by a CSX freight train when it became stuck on the tracks. The CSX railroad operates on the northern tracks and Norfolk Southern railroad operates on the southern track. Therefore, the trespass accident was assigned to the QZ located on the CSX tracks (Quiet Zone Case ID Number THR_Request_000000170001).

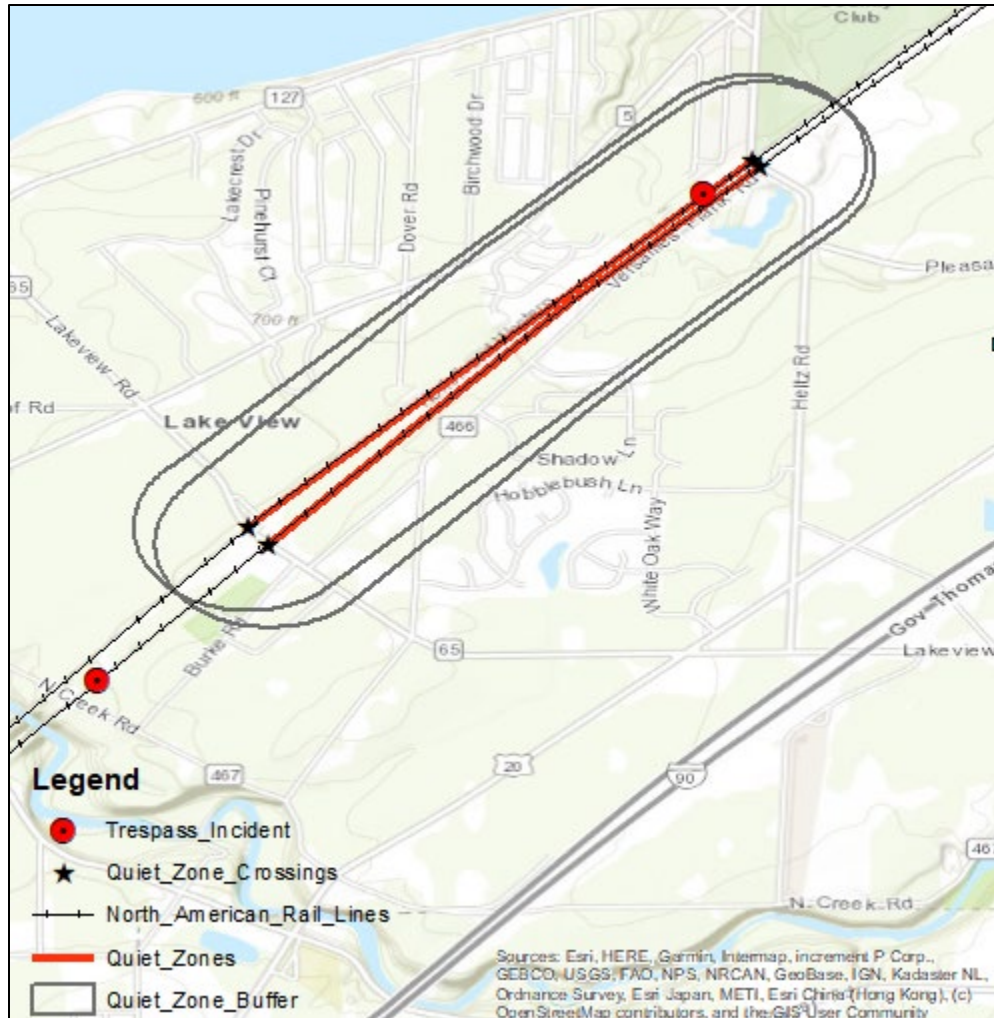

Figure 3. An Example of a Trespass Casualty within Multiple QZ Buffers

Figure 4 shows an example of a review for trespass incident number 0714HO010. This trespass accident falls within the QZ buffer, but it occurred on different tracks that is not part of the QZ. Therefore, this trespass accident was not included in the dataset.

Figure 4. An Example of a Trespass Casualty within a QZ Buffer with Multiple Rail Lines

The trespass accidents that occurred within QZ buffers were then grouped into accidents that occurred before and those that occurred after the establishment of the QZ. To use a before-and-after study design, the experiment required an equal number of observable periods with a minimum of one year of observable data. The notice of establishment (NOE) date and availability of trespass accident data with location information (June 1, 2011 to May 31, 2019) was used to determine how many years of data was available before and after the QZ was established. For example, if a QZ was established on July 19, 2013, 2 years of accident data prior to (July 19, 2011 to July 18, 2013) and following (July 20, 2013 to July 19, 2015) the establishment of the QZ was used.

4. Results

Over the 8-year period from June 1, 2011 to May 31, 2019, a total 337 trespass casualties were observed within the 333 QZs. Based on the requirement of equal observation periods before and after the establishment of the QZs and a 1-year minimum observable period, 190 trespass casualties were selected for this study. A total of 86 trespass casualties (46 fatalities and 40 injuries) were observed prior to the establishment of the QZs, and 104 trespass casualties (47 fatalities and 57 injuries) were observed after the establishment of the QZs.

Out of 190 trespass casualties selected for this study, 71 occurred at grade crossings and 119 occurred along railroad ROWs. Trespasser casualties at grade crossing increased by 108.7 percent (from 23 before to 48) after the establishment of the QZs, and trespasser casualties along the railroad ROW decreased by 11.1 percent (from 63 before to 56) after the establishment of the QZs. In comparison, overall grade crossing incidents increased by 7.4 percent (from 2,064 in 2011 to 2,217 in 2019). This dataset does not include reported cases of suicide. [Appendix A](#) lists the 190 trespass casualties that occurred within the QZs.

4.1 Observable Period

The main indicator for this study was changes in number of trespass casualties before and after the establishment of the QZs. [Table 5](#) shows the distribution of the QZs by number of years of available accident data, along with the number of QZs and trespass casualties before and after the establishment of each group. As shown in [Table 5](#), trespass casualties over all three groups increased from 86 trespass casualties before to 104 trespass casualties after the establishment of the QZs.

Group 1 corresponds to QZs with 1 year of available accident data before and after the establishment of the QZs. The QZs in this group were established between June 1, 2012 and May 31, 2013, and between June 1, 2017 and May 31, 2018. The number of trespass casualties in this group decreased by 10.5 percent, from 19 trespass casualties before to 17 trespass casualties after the establishment of the QZs. A paired t-test revealed that this decrease in trespass casualties was not statistically significant ($t(108)=0.425$, $p=0.672$). [Appendix B](#) provides the results of paired t-test.

Group 2 corresponds to QZs with 2 years of available accident data before and after the establishment of the QZs. The QZs in this group were established between June 1, 2013 and May 31, 2014, and June 1, 2016 and May 31, 2017. The number of trespass casualties in this group increased by 42.9 percent, from 28 trespass casualties before to 40 trespass casualties after the establishment of the QZs. However, a paired t-test revealed that this decrease was not statistically significant ($t(112)=-1.615$, $p=0.109$).

Group 3 corresponds to QZs with 3 years of available accident data before and after the establishment of the QZs. The QZs in this group were established between June 1, 2014 and May 31, 2016. The number of trespass casualties in this group increased by 20.5 percent, from 39 trespass casualties before to 47 trespass casualties after the establishment of the QZs. However, a paired t-test revealed that this decrease was not statistically significant ($t(110)=-0.695$, $p=0.489$).

Table 5. QZ Grouping Based on Years of Available Data

Group	Number of Observable Years before and after NOE	# of QZs in group	Casualties before NOE	Casualties after NOE	Percent Change
1	1	109 (32.7%)	19 (22.1%)	17 (16.3%)	-10.5%
2	2	113 (33.9%)	28 (32.6%)	40 (38.5%)	42.9%
3	3	111 (33.3%)	39 (45.3%)	47 (45.2%)	20.5%
	Total	333	86	104	

4.2 Quiet Zone Type

[Table 6](#) shows the distribution of the QZs by QZ type, along with the number of QZs and trespass casualties before and after the establishment of each QZ type. *New Partial* and *Pre-Rule* QZ types were not included in this QZ type analysis because of their small sample size. (QZ type with at least 15 QZs were included.) Based on a paired t-test, neither *New QZ* nor *Wayside Horns* QZ types showed a significant difference in trespass casualties following the establishment of the QZs [*New*: (t(307)=-0.926, p=0.355) and *Wayside Horns*: (t(14)=-1.0, p=0.334)]. However, note that the number of trespass casualties in QZs designated as *Wayside Horns* doubled from three before to six after the establishment of the QZs. [Appendix C](#) provides the results of the paired t-test for QZ type.

Table 6. QZ Grouping based on QZ Type

QZ Type	Number of QZs	Casualties before NOE	Casualties after NOE	Percent Change
New	308 (92.8%)	82 (95.3%)	95 (91.3%)	15.9%
Wayside Horns	15 (4.5%)	3 (3.5%)	6 (5.8%)	100.0%
Pre-Rule	7 (2.1%)	1 (1.2%)	3 (2.9%)	200.0%
New Partial	2 (0.6%)	0	0	
Blank	1	0	0	
Total	333	86	104	20.9%

4.3 Basis Section

As previously noted, there are different ways localities can mitigate the effects of train horn noise in order to establish a QZ. The basis section codes identify the methods used to establish each QZ. [Table 7](#) shows the distribution of the QZs by QZ basis section, along with the number of QZs and trespass casualties before and after establishment of each QZ. Similar to the analysis performed for QZ type, only basis sections with at least 15 or more QZs were analyzed. Based on a paired t-test, there was no statistically significant difference in trespass casualties before and after the establishment of the QZs for all basis section types. However, note that the number of trespass casualties in the QZs established based on Basis Sections 222.39(a)(2)(ii) and 222.59 increased by 125 percent (from four before to nine after) and by 100 percent (from three before

to six after), respectively. Basis Section 222.59 refers to QZs established by installing wayside horns. One QZ with the blank QZ type was established based on Basis Section 222.59. [Appendix D](#) provides the results of the paired t-test for QZs grouping based on basis section. Basis Section 222.41(a)(1)(ii) and 222.41(a)(1)(iv) are not included in the analysis.

Table 7. QZ Grouping based on Basis Section

Basis Section	# of QZs in Group	Casualties before NOE	Casualties after NOE	Percent Change
222.39(a)(1)	162	24	26	8.3%
222.39(a)(2)(i)	19	0	2	
222.39(a)(2)(ii)	15	4	9	125.0%
222.39(a)(3)	65	36	50	38.9%
222.39(b)(4)(i)(A)	53	19	11	-42.1%
222.41(a)(1)(ii)	2	0	0	
222.41(a)(1)(iv)	1	0	0	
222.59	16	3	6	100.0%
Total	333	86	104	20.9%

5. Conclusion

This study focused on 333 QZs that were established between June 1, 2012 to May 31, 2018. To understand the effects of implementing QZs on trespass accidents, trespass casualties that occurred within the 333 QZs were classified into casualties that occurred before, and those that occurred after the establishment of the QZs. A total of 190 trespass casualties were observed within the 333 QZs, 86 trespass casualties (46 fatalities and 40 injuries) were observed before and 104 trespass casualties (47 fatalities and 57 injuries) were observed after the establishment of the QZs. Trespass casualties along the railroad ROW decreased by 11.1 percent from 63 before to 56 after the establishment of the QZs, but trespass casualties at grade crossing increased by 108.7 percent from 23 before to 48 after the establishment of the QZs. In comparison, overall grade crossing incidents increased by 7.4 percent, from 2,064 in 2011 to 2,217 in 2019.

Trespass casualties in QZs with 1 year of observable accident data decreased from 19 before to 17 after the establishment of the QZs. However, trespass casualties in QZs with 2 and 3 years of observable accident data increased from 28 before to 40 after and from 39 before to 47 after the establishment of the QZs, respectively. There was no statistically significant difference in trespass casualties before and after the establishment of the QZs for all three observable periods. Note that there was a linear increase in the overall number of trespass casualties on the nation's rail network from June 2011 to May 2019. The number of trespass casualties increased by 35.8 percent, from 1,149 to 1,560.

The analysis by QZ type revealed that neither QZ types designated as *New* nor *Wayside Horns* showed a significant difference in trespass casualties following the establishment of the QZs [*New*: ($t(307)=-0.926$, $p=0.355$) and *Wayside Horns*: ($t(14)=-1.0$, $p=0.334$)]. The number of trespass casualties increased from 82 before to 95 after the establishment of QZs designated as *New* and from 3 before to 6 after the establishment of QZs designated as *Wayside Horns*.

The analysis based on basis section also revealed that there was no statistically-significant difference in the number of trespass casualties following the establishment of the QZs for all basis sections included in this study. The number of trespass casualties increased after the establishment of the QZs for all basis sections except for the QZs established based on Basis Section 222.39(b)(4)(i)(A) (QZ approved by FRA Associate Administrator where QZRI is at or below RIWH). The number of trespass casualties in this group decreased by 42.1 percent, from 19 before to 11 after the establishment of the QZs.

Volpe recommends that the FRA advise communities establishing a QZ to consider the effects of the absence of train horn on railroad trespassing, including at grade crossings, and encourage those communities to develop appropriate trespass mitigation strategies. Furthermore, FRA should consider adding similar trespass-specific requirements to the Train Horn Rule.

Finally, Volpe recommends conducting a more in-depth analysis in 2 to 3 years, when there will be a much bigger dataset of trespass accidents with location information, and a trespass risk methodology, currently under development by the FRA, becomes available, so that factors such as population density and train frequency can be incorporated into the analysis.

6. Potential Limitations

The major limiting factor for this study was the availability of trespass casualty records with location information. As discussed earlier, FRA started requiring railroads to submit trespass casualty location information starting on June 1, 2011. Therefore, trespass casualties over an 8-year period from June 1, 2011 to May 31, 2019 were used for this study. A before-and-after study design used in this study required an equal period of observable data before and after the establishment of the QZs. This resulted in an observable period that ranged from 1 to 3 years for each QZ. This observable period length, especially the 1 year before and after period used for almost one-third of the QZs in this analysis, might not be a sufficient amount of time to assess the effect of a QZ on trespass casualties.

This same limiting factor also resulted in selecting QZs that were established between June 1, 2012 and May 31, 2018 for this study. There were 333 QZs established during this 6-year period. This number represented a little over one-third of the overall number of QZs in the national rail network.

Note that the analysis used in this study assumes that changes in trespass accidents is primarily due to the effects of implementation of the QZs. It does not take into account other changes—such as changes in rail traffic, train speed, population density, or changes to the surrounding roads or infrastructure—that might contribute to trespass accidents.

Lastly, the QZ grade crossing and trespass casualty location information was obtained from the FRA GCIS and RAIRS databases. These data are manually entered into the database, and as such contained some errors. The location of the QZ grade crossings were manually verified and corrected as needed by cross-referencing the street name of the grade crossing and the primary operating railroad from the FRA GCIS database with the map. However, there may have been some errors in crossing locations that were not identified.

Similar to grade crossings location, trespass casualty location also included some error. To account for errors in trespass casualty location, researchers created a quarter-mile buffer on both sides of each QZ to capture trespass casualties that occurred within these zones. However, there may be trespass casualties that may have been affected by the absence of the locomotive horn but fell outside of the quarter-mile buffer and were therefore excluded from the analysis.
