Development and Technology  
Washington, DC 20590

## Analysis of Historical Non-Destructive Evaluation Probability of Detection Data for Railroad Tank Cars: Appendices A Through I

# Contents

---

Appendix A. Traditional Statistics POD Summary Graphs – Fillet Welds .....	1
Visual Testing (VT) .....	1
Penetrant Testing (PT) .....	2
Magnetic Particle Testing (MT) With Contrast .....	3
Magnetic Particle Testing Without Contrast.....	4
Ultrasonic Testing (UT).....	5
Appendix B. Traditional Statistics POD Summary Graphs – Butt Welds.....	7
Visual Testing (VT) .....	7
Penetrant Testing (PT) .....	8
Magnetic Particle Testing (MT) Without Contrast.....	10
Ultrasonic Testing (UT).....	11
Phased-Array Ultrasonic Testing (PAUT).....	12
Appendix C. Traditional Statistics POD Graphs for Individual Operator – Fillet Welds .....	14
Appendix D. Traditional Statistics POD Operator Graphs – Butt Welds.....	59
Appendix E. DOEPOD Plots – Fillet Welds .....	111
Appendix F. DOEPOD Plots – Butt Welds .....	201
Appendix G. DOEPOD Plots – DOEPOD Summary Tables for Fillet Welds Panels .....	305
Appendix H. DOEPOD Plots – DOEPOD Summary Tables for Butt Weld Panels.....	315
Appendix I. Breakdown of Individual Participants by Different Methods.....	325
Abbreviations and Acronyms .....	327

## Appendix A. Traditional Statistics POD Summary Graphs – Fillet Welds

This appendix presents the summary of the number of observations, hits, misses and false calls for each crack interval for fillet welds (FW) for all operators and for each nondestructive evaluation (NDE) method applied. The probability of hits (POHs) are also calculated and displayed on top of the median number of hits for each crack distribution. Note that there is a crack size interval of 0-inches that corresponds to the locations in the panels where there were no cracks or flaws. This means that false calls will only appear in the zero-crack size interval for the FW as shown by the yellow bar.

### Visual Testing (VT)

Figure 1 is the distribution of the frequency of number of observations, median number of hits and misses, and median of false calls for the VT method and a crack size interval of 0.5-inches. In addition, researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of false calls is only shown in the 0-inch crack size interval and the 0.5- to 1-inch interval presents the highest number of misses and it is the only case where this number exceeds the number of hits.

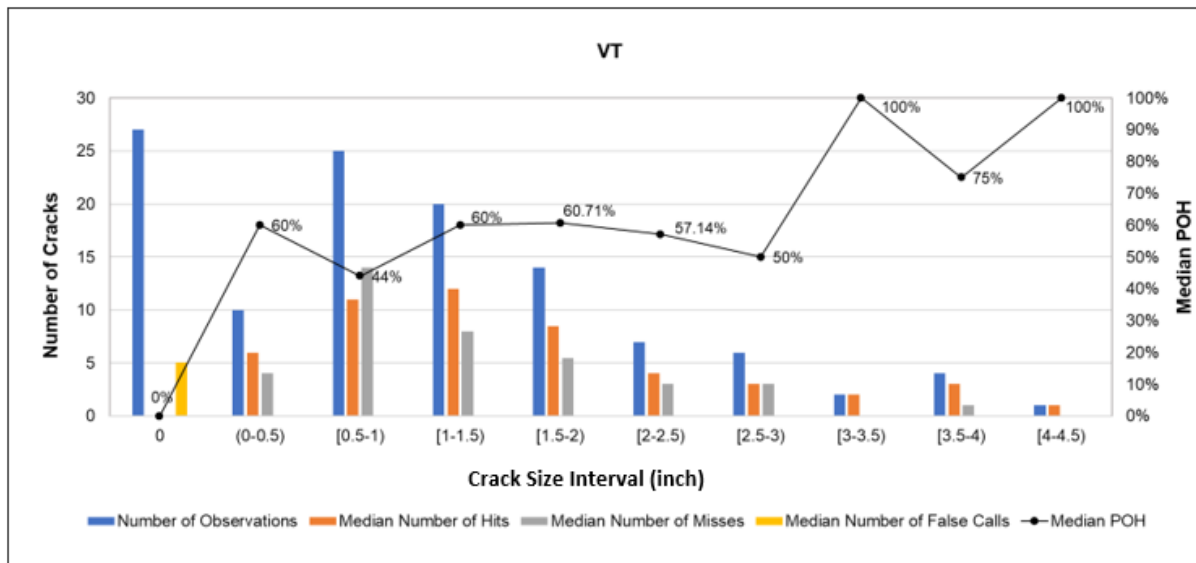

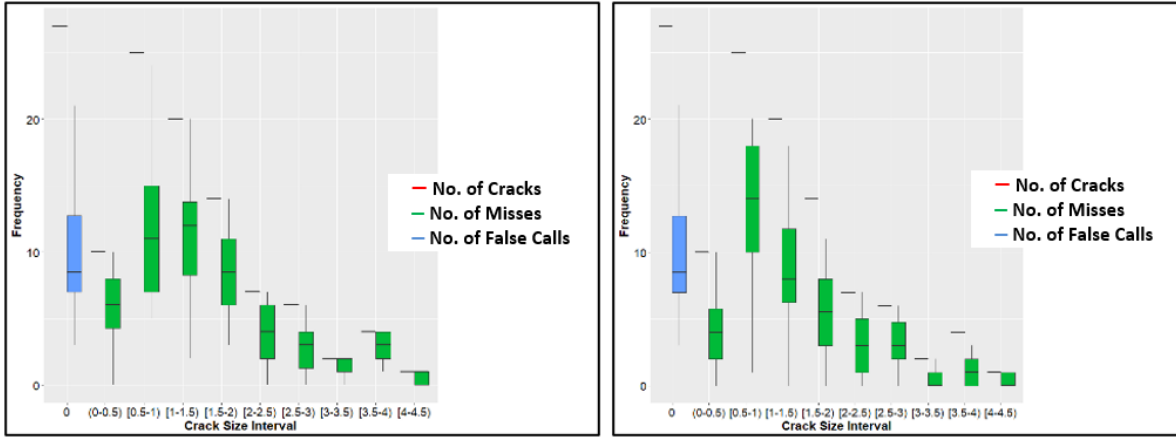

Figure 1. VT Summary for FW Panels

Figure 2 is the box plot for the frequency of the number of cracks, hits, misses and false calls per crack size interval. The figure shows that 0.5- to 1-inch and 1- to 1.5-inch crack size intervals show the highest variability in the data.

**Figure 2. VT Box Plot Summary for FW Panels**

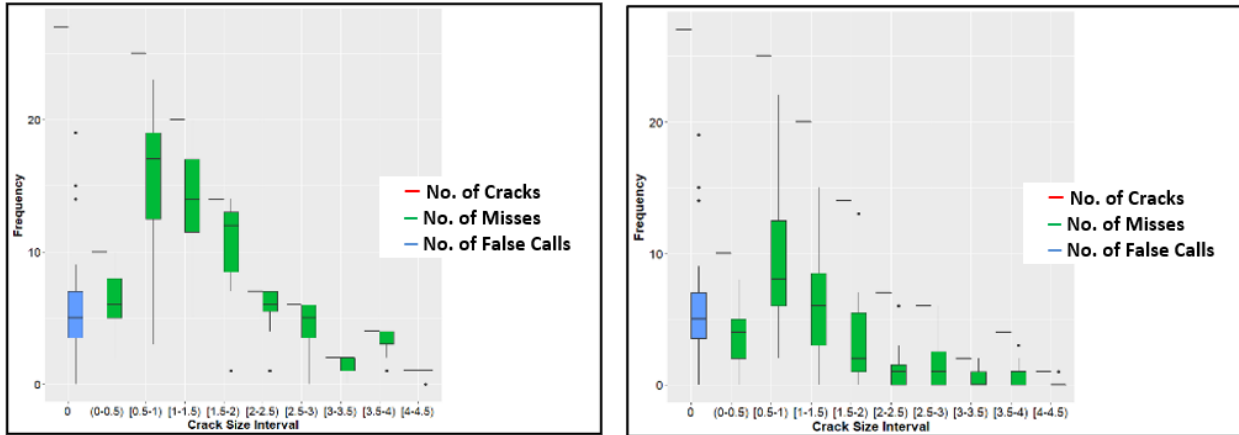

**Penetrant Testing (PT)**

Figure 3 is the distribution of the frequency of number of observations, median number of hits and misses, and median of false calls for PT method and a crack size interval of 0.5 inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of false calls is only shown in the 0-inch crack size interval and the 0.5- to 1-inch interval presents the highest number of hits and misses, and in all intervals the number of hits was greater than the number of misses.

**Figure 3. PT Summary for FW Panels**

Figure 4 is the box plot for the frequency of the number of cracks, hits, misses, and false calls per crack size interval. The figure shows that 0.5- to 1-inch and 1- to 1.5-inch crack size intervals show the highest variability in the data.

**Figure 4. PT Box Plot Summary for FW Panels**

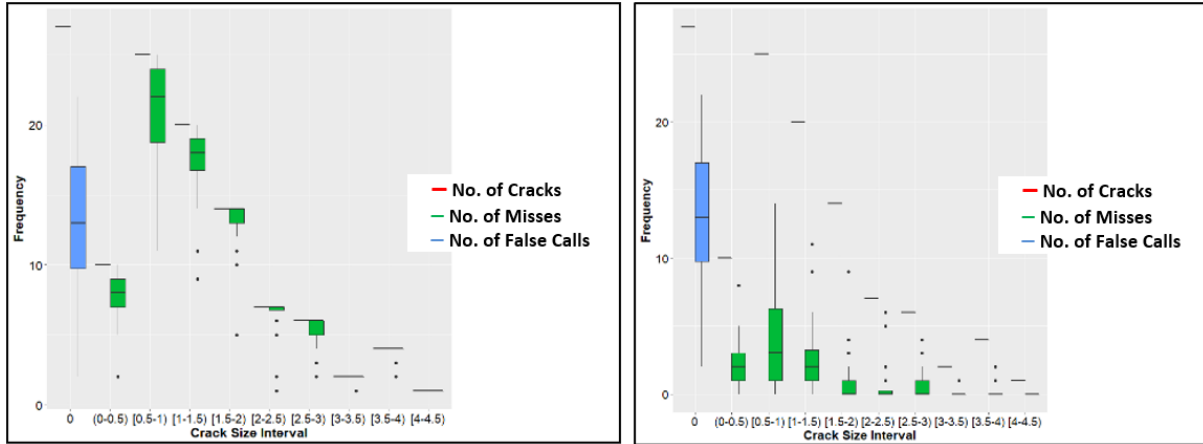

**Magnetic Particle Testing (MT) with Contrast**

Figure 5 is the distribution of the frequency of number of observations, median number of hits and misses, and median of false calls for MT with contrast method and a crack size interval of 0.5-inches. In addition, researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of false calls is only shown in the 0-inch crack size interval and it has a higher number of false calls compared to the previous two inspection methods. Additionally, the 0.5- to 1-inch interval presents the highest number of hits and misses and this method has a lower probability of misses compared to the previous two methods.

**Figure 5. MT with Contrast Summary for FW Panels**

Figure 6 is the box plot for the frequency of the number of cracks, hits, misses and false calls per crack size interval. The figure shows that 0.5- to 1-inch crack size interval show the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses respectively. These outstanding data points might be interpreted as an indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 6. MT with Contrast Box Plot Summary for FW Panels**

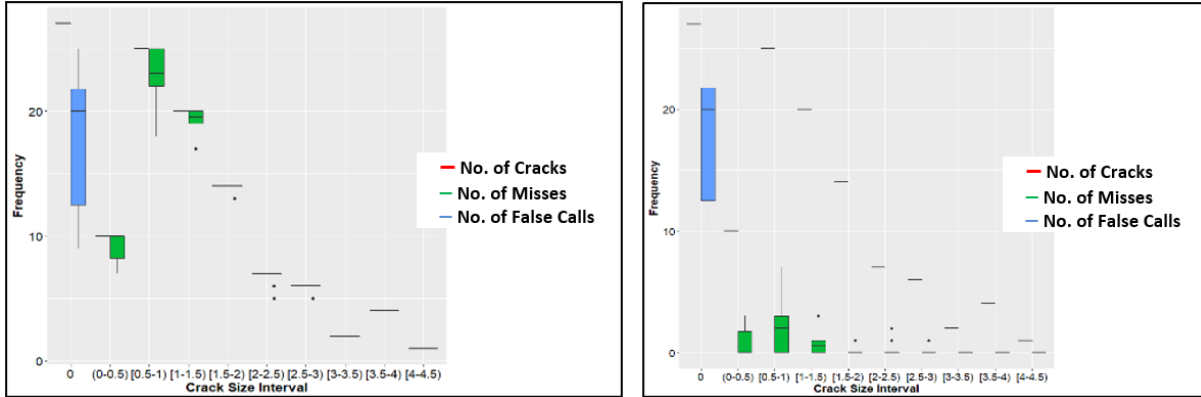

***Magnetic Particle Testing Without Contrast***

Figure 7 is the distribution of the frequency of number of observations, median number of hits and misses, and median of false calls for MT without contrast method and a crack size interval of 0.5-inches. In addition, researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of false calls is only shown in the 0-inch crack size interval and it has a higher number of false calls compared to the previous two inspection methods. Additionally, the 0.5- to 1-inch interval presents the highest number of hits and misses and this method has lower probability of misses compared to the previous two methods. There were no misses reported in crack size intervals greater than or equal to 1.5-inches.

**Figure 7. MT without Contrast Summary for FW Panels**

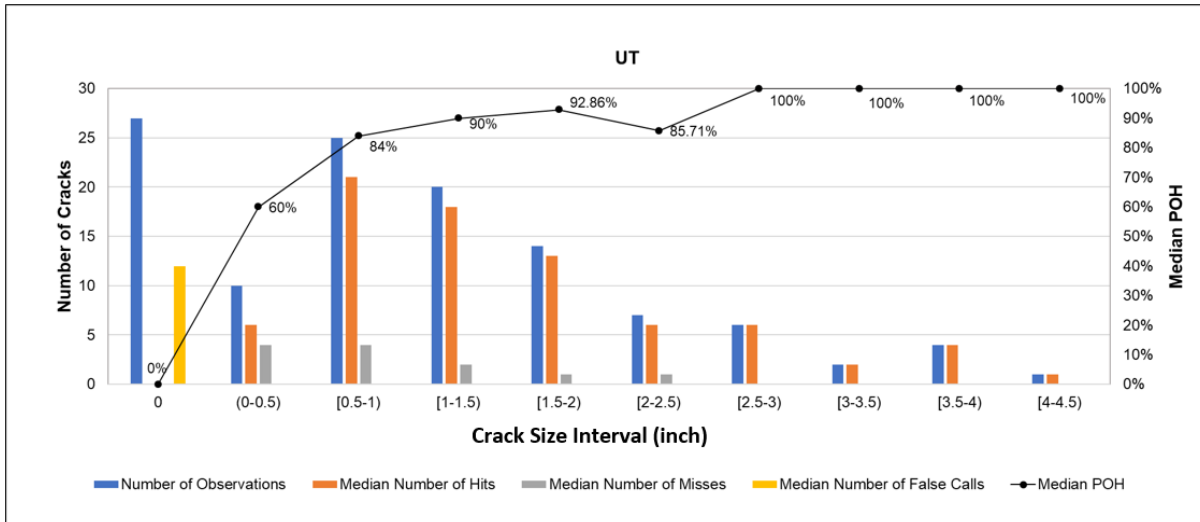

Figure 8 is the box plot for the frequency of the number of cracks, hits, misses and false calls per crack size interval. The figure shows that 0.5- to 1-inch crack size interval shows the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses respectively. These outstanding data points might be interpreted as an indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 8. MT without Contrast Box Plot Summary for FW Panels**

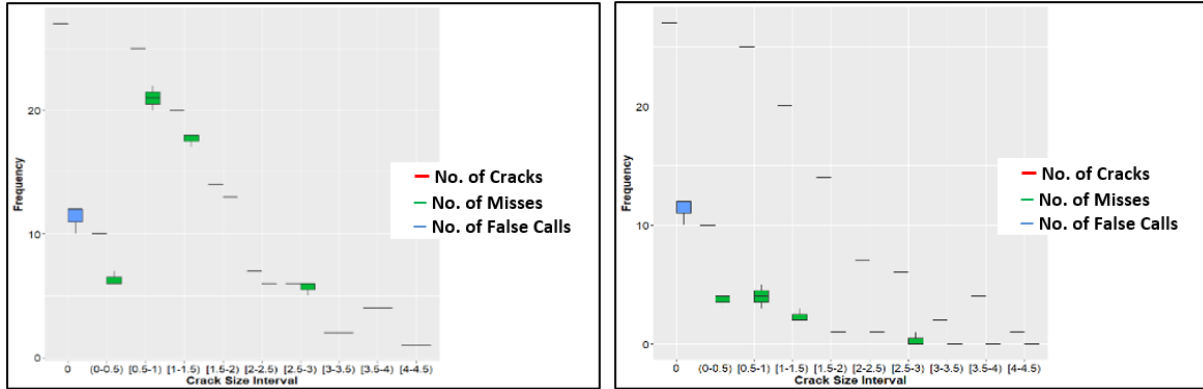

**Ultrasonic Testing (UT)**

Figure 9 is the distribution of the frequency of number of observations, median number of hits and misses, and median of false calls for the UT method and a crack size interval of 0.5-inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of false calls is only shown in the 0-inch crack size interval. Additionally, the 0.5- to 1-inch interval presents the highest number of hits compared to the other crack size intervals.

**Figure 9. UT Summary for FW Panels**

Figure 10 is the box plot for the frequency of the number of cracks, hits, misses and false calls per crack size interval. The figure shows that the 0.5- to 1-inch crack size interval shows the highest variability in the data. However, the variability in the data is smaller compared to the previous inspection methods.

**Figure 10. UT Box Plot Summary for FW Panels**

## Appendix B. Traditional Statistics POD Summary Graphs – Butt Welds

This appendix presents the summary of the median frequency of hits and misses for the distribution of cracks in butt welds (BW) for all operators and for each NDE method applied. An estimation of POH are also calculated and displayed on top of the median number of hits for each crack distribution.

Again, another way to visualize the same traditional statistics data for BW is using box plots. The box plot is a graphical method that allows data visualization by using various summary numbers: first quartile (or 25th percentile), median, third quartile (or 75th percentile), and minimum, maximum (based on the interquartile range). Depending on the data, potential outliers (data points outside the minimum and maximum) can be visualized. In this case, the box plot showed the frequency of hits and misses in separate plots with the total number of cracks and the false calls. From the plots, crack size intervals of 0.5- to 1-inches and 1- to 1.5-inches have the largest frequency of cracks as well as the largest variability in the data as shown in the box plots.

### Visual Testing (VT)

Figure 11 is the distribution of the frequency of number of observations, median number of hits and misses, and the VT method with a crack size interval of 0.5-inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of hits for a crack size interval less than 1-inch was less than the number of misses.

Figure 11. VT Summary for BW Panels

Figure 12 is the box plot for the frequency of the number of cracks, hits and misses per crack size interval, and the median number of false calls. The figure shows that the 0 to 0.5-inch crack size interval shows the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers in the 3- to 3.5-inch interval for hits and misses,

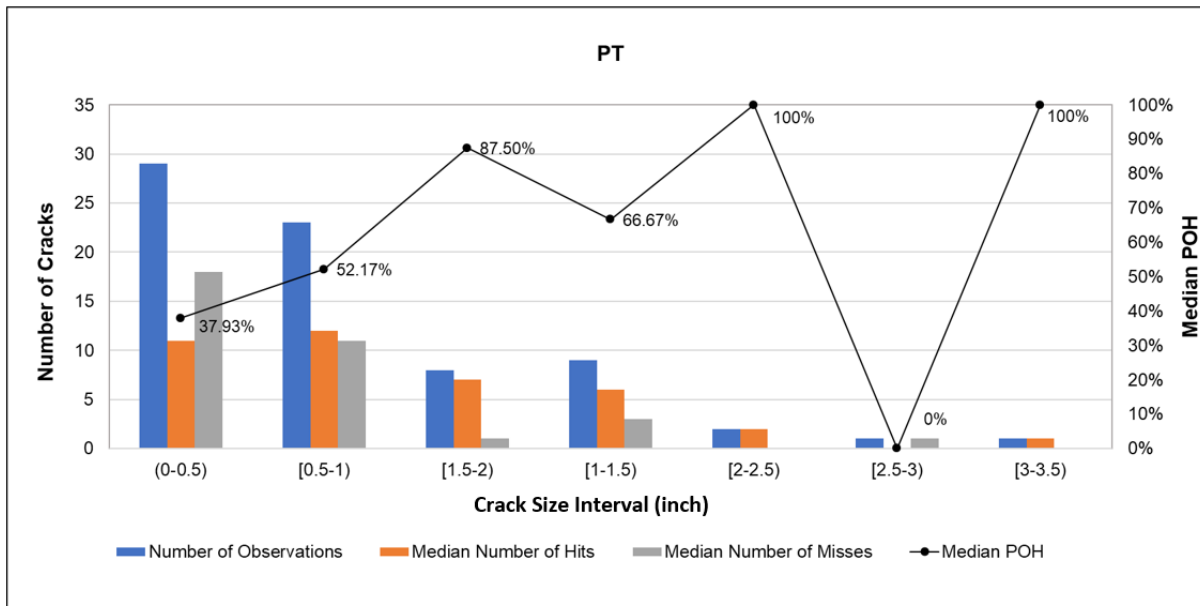

respectively. These outstanding data points might be interpreted as an indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 12. VT Box Plot Summary for BW Panels**

**Penetrant Testing (PT)**

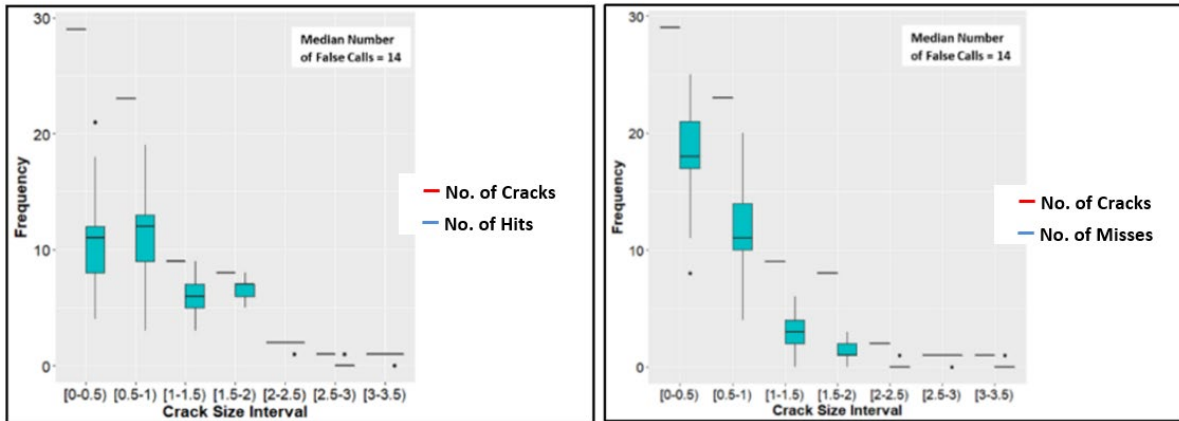

Figure 13 is the distribution of the frequency of number of observations, median number of hits and misses, and the VT method with a crack size interval of 0.5-inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the number of hits for crack size interval less than 0.5-inches was less than the number of misses. There were no misses found for crack size intervals of 2- to 2.5-inches and 3- to 3.5-inches.

**Figure 13. PT Summary for BW Panels**

Figure 14 is the box plot for the frequency of the number of cracks, hits and misses per crack size interval, and the median number of false calls. The figure shows that the 0.5- to 1-inch crack

size interval shows the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses, respectively. These outstanding data points might be interpreted as indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 14. PT Box Plot Summary for BW Panels**

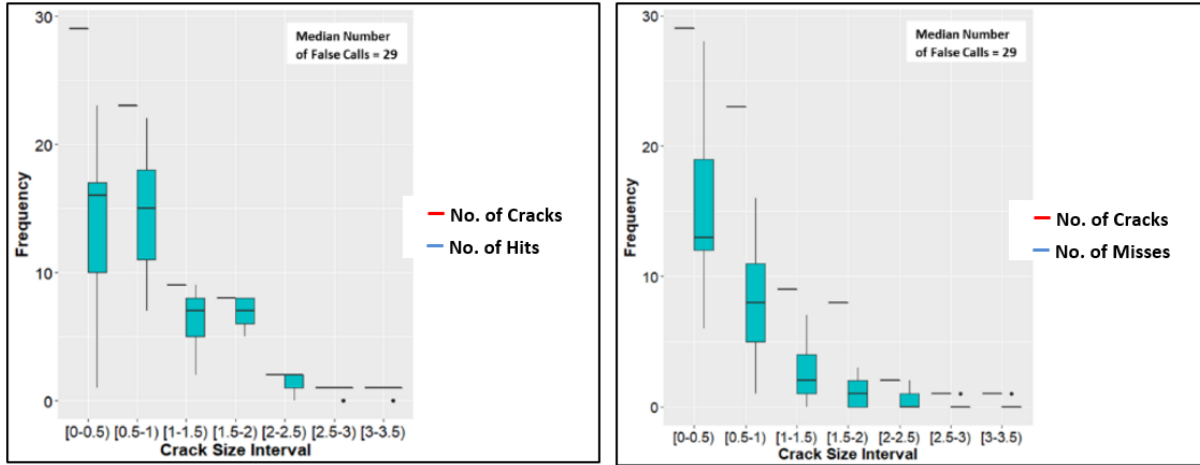

**Magnetic Particle Testing (MT) with Contrast**

Figure 15 is the distribution of the frequency of number of observations, median number of hits and misses, and MT with contrast method with a crack size interval of 0.5-inch. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the crack size interval of 0 to 0.5-inches has the highest number of hits and misses. There were not misses found for crack sizes greater than or equal to 2 inches.

**Figure 15. MT with Contrast Summary for BW Panels**

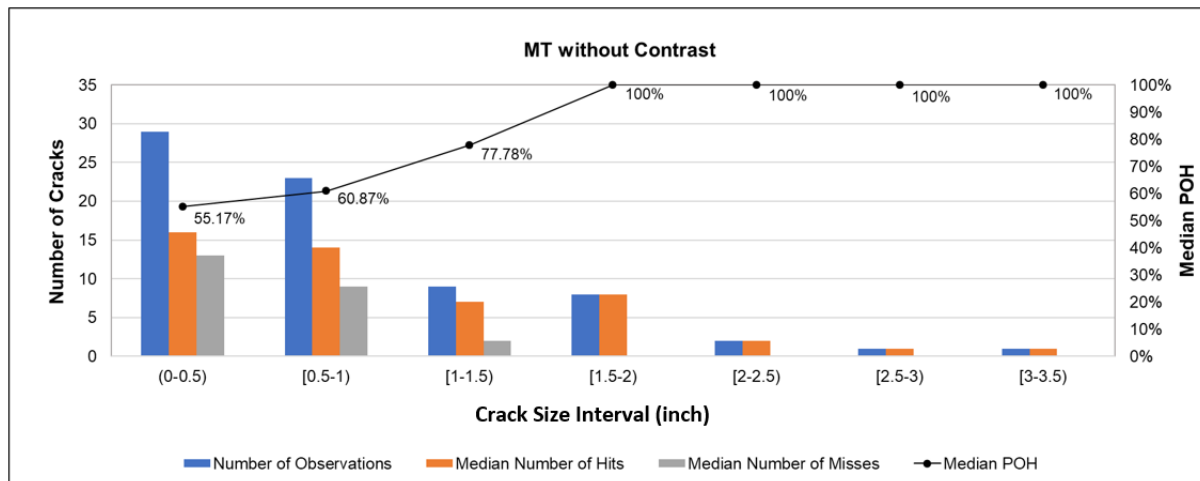

Figure 16 is the box plot for the frequency of the number of cracks, hits and misses per crack size interval, and the median number of false calls. The figure shows that 0 to 0.5-inch crack size interval shows the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses, respectively. These outstanding data points might be interpreted as indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 16. MT with Contrast Box Plot Summary for BW Panels**

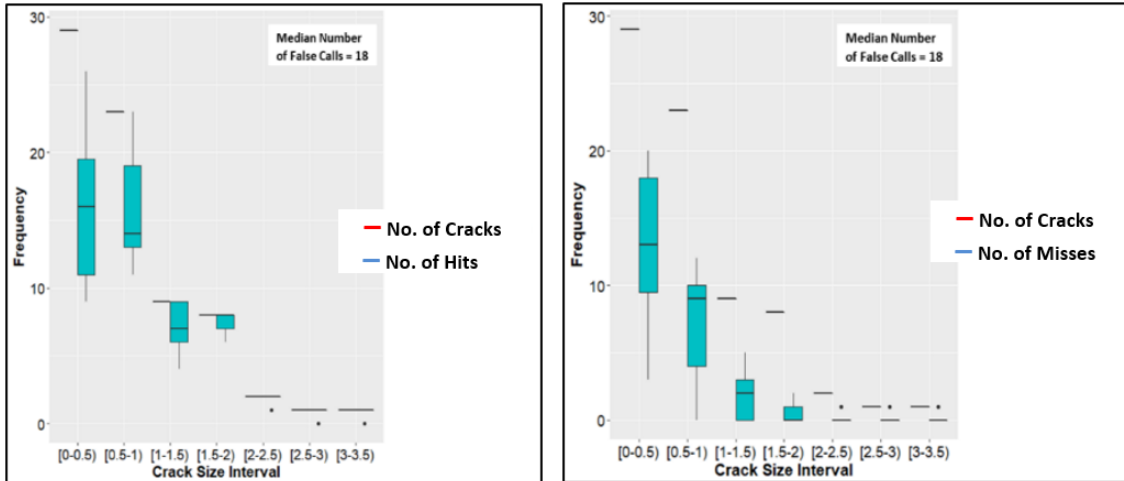

***Magnetic Particle Testing (MT) Without Contrast***

Figure 17 is the distribution of the frequency of number of observations, median number of hits and misses, and the MT without contrast method with a crack size interval of 0.5-inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the crack size interval of 0 to 0.5-inch has the highest number of hits and misses. There were no misses found for crack sizes greater than or equal to 1.5-inches.

**Figure 17. MT Without Contrast Summary for BW Panels**

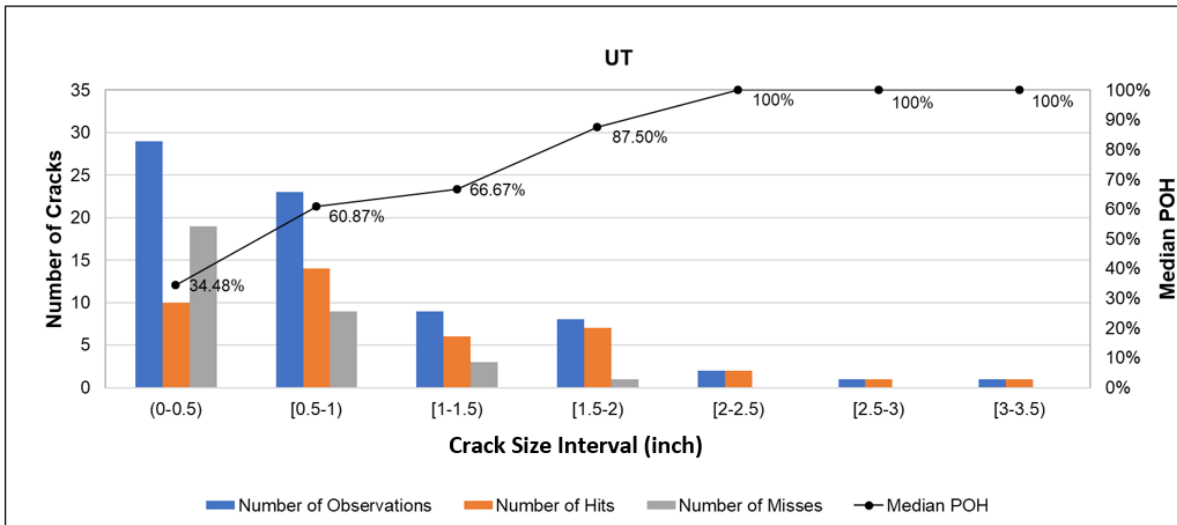

Figure 18 is the box plot for the frequency of the number of cracks, hits and misses per crack size interval, and the median number of false calls. The figure shows that the 0 to 0.5-inch crack size interval shows the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses, respectively. These outstanding data points might be interpreted as indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 18. MT Without Contrast Box Plot Summary for BW Panels**

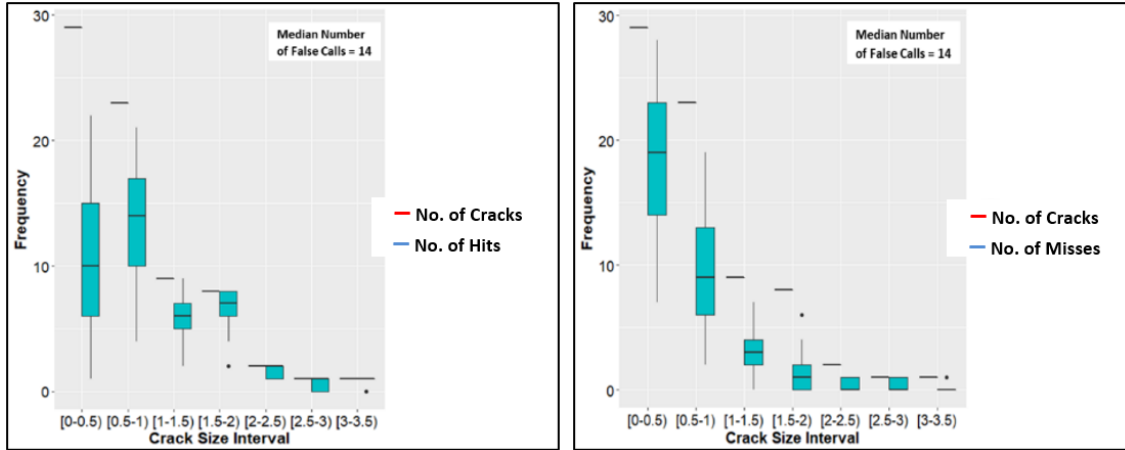

**Ultrasonic Testing (UT)**

Figure 19 is the distribution of the frequency of number of observations, median number of hits and median number of misses for the UT method and a crack size interval of 0.5-inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the crack size interval of 0 to 0.5-inches has the largest number of misses and the interval of 0.5 to 1-inches has the highest number of hits. There were no misses found for crack sizes greater than or equal to 2 inches.

**Figure 19. UT Summary for BW Panels**

Figure 20 is the box plot for the frequency of number of cracks, hits, and misses per crack size interval, and the median number of false calls. The figure shows that a 0 to 0.5-inch crack size interval shows the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses, respectively. These outstanding data points might be interpreted as an indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 20. UT Box Plot Summary for BW Panels**

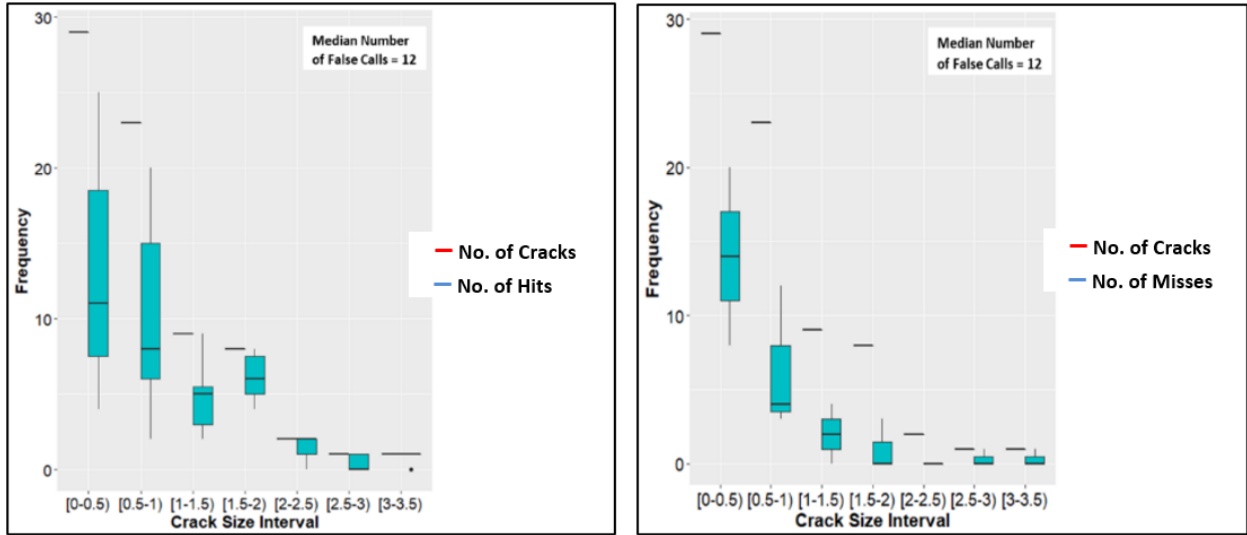

**Phased-Array Ultrasonic Testing (PAUT)**

Figure 21 is the distribution of the frequency of number of observations, median number of hits and misses for the PAUT method and a crack size interval of 0.5-inches. Researchers presented the POH based on the relative frequency of hits per crack size interval. From the figure, note that the crack size interval of 0 to 0.5-inches has the highest number of misses and the interval of 0.5- to 1-inches has the highest number of hits. There were no misses found for crack sizes greater than or equal to 1.5-inch.

**Figure 21. PAUT Summary for BW Panels**

Figure 22 is the box plot for the frequency of the number of cracks, hits, and misses per crack size interval, and the median number of false calls. The figure shows that 0- to 0.5-inch and 0.5- to 1-inch crack size intervals show the highest variability in the data. In addition, there are outstanding data points outside the lower and upper whiskers for hits and misses, respectively. These outstanding data points might be interpreted as an indication of potential outliers in the frequency of hits and misses for this inspection method.

**Figure 22. PAUT Box Plot Summary for BW Panels**

## Appendix C. Traditional Statistics POD Graphs for Individual Operator – Fillet Welds

## Abbreviations and Acronyms

---

ACRONYMS	EXPLANATION
BW	Butt Weld
$X_{\text{BEST LCL}}$	Class length (flaw size) exhibiting the maximum LCL
$X_{\text{POD}}$	Class length at which the lower confidence limit (value) is 0.90 or greater (90/95 POD) @ 95% confidence
$X_{\text{POH}}$	Class length where there are no misses above this class length, and POH = 1 above this class length
DOEPOD	Design of Experiments Probability of Detection
FW	Fillet Welds
$X_L$	Largest Class Length in Entire Dataset
NDE	Nondestructive Evaluation
PT	Penetrant Testing
PAUT	Phased Array Ultrasonic Testing
POD	Probability of Detection
POH	Probability of Hits
UT	Ultrasonic Testing
VT	Visual Testing
