1. Report No. FHWA/TX-21/0-6968-R10		2. Government Accession No.		3. Recipient's Catalog No.	
4. Title and Subtitle MASH TEST 4-12 OF SHALLOW ANCHORAGE SINGLE SLOPE TRAFFIC RAIL (SSTR)				5. Report Date Published: December 2020	
				6. Performing Organization Code	
7. Author(s) Sana M. Moran, Roger P. Bligh, Wanda L. Menges, William Schroeder, and Darrell L. Kuhn				8. Performing Organization Report No. Report 0-6968-R10	
9. Performing Organization Name and Address Texas A&M Transportation Institute The Texas A&M University System College Station, Texas 77843-3135				10. Work Unit No. (TRAIS)	
				11. Contract or Grant No. Project 0-6968	
12. Sponsoring Agency Name and Address Texas Department of Transportation Research and Technology Implementation Office 125 E. 11 th Street Austin, Texas 78701-2483				13. Type of Report and Period Covered Technical Report: September 2017–August 2020	
				14. Sponsoring Agency Code	
15. Supplementary Notes Project performed in cooperation with the Texas Department of Transportation and the Federal Highway Administration. Project Title: Roadside Safety Device Analysis, Testing, and Evaluation Program URL: http://tti.tamu.edu/documents/0-6968-R10.pdf					
16. Abstract <p>The purpose of the tests reported herein was to assess the performance of the Texas Department of Transportation's (TxDOT's) shallow anchorage single slope traffic rail (SSTR) according to the safety-performance evaluation guidelines included in the American Association of State Highway and Transportation Officials (AASHTO) <i>Manual for Assessing Safety Hardware (MASH)</i>. MASH Test 4-12 was performed on the TxDOT shallow anchorage SSTR to determine the structural adequacy of the anchorage.</p> <p>Two different barrier configurations were evaluated: with and without dowel bars between barrier segments across expansion joints. This report provides details of the TxDOT shallow anchorage SSTR, the crash tests and results, and the performance assessment of the TxDOT shallow anchorage SSTR as a MASH Test Level 4 (TL-4) longitudinal barrier.</p> <p>Both variations of the TxDOT shallow anchorage SSTR (with and without dowel bars between barrier segments across expansion joints) were determined to be MASH TL-4 compliant. No delamination or damage to the deck was observed in the test installation after impact.</p>

ACKNOWLEDGMENTS

This project was conducted in cooperation with TxDOT and FHWA. The authors thank Wade Odell, TxDOT Research and Technology Implementation Division project manager, and Taya Retterer and Jon Ries with the TxDOT Bridge Division for their design input and guidance during the project. This project was successful due to their contributions and assistance.

CHAPTER 1. INTRODUCTION

The Texas Department of Transportation's (TxDOT's) single slope traffic rail (SSTR) has performed acceptably according to the American Association of State Highway and Transportation Officials (AASHTO) *Manual for Assessing Safety Hardware (MASH)* Test Level 4 (TL-4) longitudinal barriers (1). Different configurations of the SSTR have been tested and shown to satisfy *MASH* TL-4 criteria (2). However, it is further desired to be able to anchor an SSTR into a 4½-inch-thick cast-in-place deck slab that is constructed over a prestressed box beam, slab beam, or prestressed panel. The main concern with this application is the strength of the anchoring system.

The purpose of the tests reported herein was to assess the performance of the TxDOT shallow anchorage SSTR according to the safety-performance evaluation guidelines included in the AASHTO *MASH*. *MASH* Test 4-12 was performed on the TxDOT shallow anchorage SSTR to determine the structural adequacy of the anchorage.

This report provides details of the TxDOT shallow anchorage SSTR, the crash tests and results, and the performance assessment of the TxDOT shallow anchorage SSTR as a *MASH* TL-4 longitudinal barrier.

CHAPTER 2. SYSTEM DETAILS

2.1. TEST ARTICLE AND INSTALLATION DETAILS

The installation consisted of three sections of 36-inch-tall concrete SSTR. Two of the sections were 25 ft. in length, and the third section, placed on the left end when viewing from the traffic side, was 74 ft. 9¾ inches long. There was a 2-inch joint between each barrier section, which resulted in a total length of 125 ft. 1¾ inches. The SSTR was anchored in place using No. 4 rebar anchors embedded in a cast-in-place concrete slab measuring 4½ inches thick. The rebar anchors rested on the top surface of precast concrete panels that were 8 ft. 4 inches long, 10 ft. wide, and 4 inches thick. The upper concrete slab was then cast in place over the precast concrete panels to simulate field construction.

Figure 2.1 presents overall information on the TxDOT shallow anchorage SSTR, and Figure 2.2 provides photographs of the test installation. Appendix A provides further details on the TxDOT shallow anchorage SSTR. Drawings were provided by the Texas A&M Transportation Institute (TTI) Proving Ground, and construction was performed by Tucker Construction and supervised by TTI Proving Ground personnel.

2.2. DESIGN MODIFICATIONS

For Test No. 469680-02-2, the dowel bars between barrier segments across the expansion joints were cut through so the barrier segments were not connected. After only minor barrier movement and damage in Test No. 469680-02-1, this was done to see if acceptable impact performance could be achieved without the need for dowel bars across adjacent joints. Prior to the third test (Test No. 469680-02-3), the concrete apron was extended downstream of the barrier to replace the soil beyond the end of the barrier to provide a more uniform and representative runoff area.

2.3. MATERIAL SPECIFICATIONS

The specified compressive strength of the concrete used in the panels, deck, and parapet was 5000 psi, 4000 psi, and 3600 psi, respectively. On the day of the first test, June 16, 2020, the average compressive strength of the concrete was as follows:

- Average concrete strength for the panels: 5360 psi at 42 days of age.
- Average concrete strength for the deck: 5121 psi at 33 days of age.
- Average concrete strength for the parapet: 4255 psi at 25 days of age.

Appendix B provides material certification documents for the materials used to install/construct the TxDOT shallow anchorage SSTR.

Q:\Accreditation-17025-2017\EIR-000 Project Files\469680 - TxDOT - Bligh-2 Shallow Anchorage SSTR\02-2 (Additional 4-12 Test)\Drafting_02-2\469680-02-2

Figure 2.1. TxDOT Shallow Anchorage SSTR Details.

Figure 2.2. TxDOT Shallow Anchorage SSTR prior to Testing.

CHAPTER 3. TEST REQUIREMENTS AND EVALUATION CRITERIA

3.1. CRASH TEST PERFORMED/MATRIX

Table 3.1 shows the recommended test conditions and evaluation criteria for *MASH* TL-4 longitudinal barriers.

Table 3.1. Test Conditions and Evaluation Criteria Specified for *MASH* TL-4 Longitudinal Barriers.

Test Article	Test Designation	Test Vehicle	Impact Conditions		Evaluation Criteria
			Speed	Angle	
Longitudinal Barrier	4-10	1100C	62 mi/h	25°	A, D, F, H, I
	4-11	2270P	62 mi/h	25°	A, D, F, H, I
	4-12	10000S	56 mi/h	15°	A, D, G

MASH Test 4-12 was performed on the TxDOT shallow anchorage SSTR. Test 4-12 was the critical test for evaluating the strength of the anchorage system. Tests 4-10 and 4-11 were not considered necessary to assess *MASH* compliance of the anchorage system. Previous tests that have been performed on single slope barriers indicate the profile is *MASH* compliant for the 1100C passenger car and 2270P pickup truck (3, 4).

The target critical impact point (CIP) for the test was determined using the information provided in *MASH* Section 2.2.1, Section 2.3.2, and Table 2-8. Figure 3.1 shows the target CIP for *MASH* Test 4-12 on the TxDOT shallow anchorage SSTR, which is 5 ft. upstream of an expansion joint.

Figure 3.1. Target CIP for First and Third *MASH* Test 4-12 on TxDOT Shallow Anchorage SSTR (Test No. 469680-02-1 and 3).

Figure 3.2. Target CIP for Second *MASH* Test 4-12 on TxDOT Shallow Anchorage SSTR (Test No. 469680-02-2)

In Test No. 469680-02-2, the dowels bars across the expansion joints were cut such that the barrier segments were not connected. For this test, the impact point was shifted to an undamaged barrier section with the CIP as shown in Figure 3.1. In this test, the vehicle rolled onto its roof, causing excessive occupant compartment deformation. The rollover was partially attributed to an uneven runout area (part soil and part concrete) beyond the barrier installation. Therefore, *MASH* Test 4-12 was repeated on the system without dowel bars (Test No. 469680-02-3) with a more uniform and representative runout area. Since both barrier segments had been previously impacted, the impact point was shifted back to the first barrier segment as shown in Figure 3.1.

The crash test and data analysis procedures were in accordance with guidelines presented in *MASH*. Chapter 4 presents brief descriptions of these procedures.

3.2. EVALUATION CRITERIA

The appropriate safety evaluation criteria from Tables 2-2 and 5-1 of *MASH* were used to evaluate the crash tests reported herein. Table 3.1 lists the test conditions and evaluation criteria required for *MASH* Test 4-12, and Table 3.2 provides detailed information on the evaluation criteria. An evaluation of the crash test results is presented in Chapter 7.

Table 3.2. Evaluation Criteria Required for MASH Test 4-12.

Evaluation Factors	Evaluation Criteria
Structural Adequacy	<p>A. <i>Test article should contain and redirect the vehicle or bring the vehicle to a controlled stop; the vehicle should not penetrate, underride, or override the installation although controlled lateral deflection of the test article is acceptable.</i></p>
Occupant Risk	<p>D. <i>Detached elements, fragments, or other debris from the test article should not penetrate or show potential for penetrating the occupant compartment, or present undue hazard to other traffic, pedestrians, or personnel in a work zone.</i></p> <p><i>Deformations of, or intrusions into, the occupant compartment should not exceed limits set forth in Section 5.2.2 and Appendix E of MASH.</i></p>
	<p>G. <i>It is preferable, although not essential, that the vehicle remain upright during and after the collision.</i></p>

CHAPTER 4. TEST CONDITIONS

4.1. TEST FACILITY

The full-scale crash tests reported herein were performed at the TTI Proving Ground, an International Standards Organization (ISO)/International Electrotechnical Commission (IEC) 17025-accredited laboratory with American Association for Laboratory Accreditation (A2LA) Mechanical Testing Certificate 2821.01. The full-scale crash tests were performed according to TTI Proving Ground quality procedures, as well as *MASH* guidelines and standards.

The test facilities of the TTI Proving Ground are located on The Texas A&M University System RELIS Campus, which consists of a 2000-acre complex of research and training facilities situated 10 mi northwest of the flagship campus of Texas A&M University. The site, formerly a United States Army Air Corps base, has large expanses of concrete runways and parking aprons well suited for experimental research and testing in the areas of vehicle performance and handling, vehicle-roadway interaction, highway pavement durability and efficacy, and roadside safety hardware and perimeter protective device evaluation. The site selected for construction and testing of the TxDOT shallow anchorage SSTR was along the edge of an out-of-service apron. The apron consists of an unreinforced jointed-concrete pavement in 12.5-ft × 15-ft blocks nominally 6 inches deep. The aprons were built in 1942, and the joints have some displacement but are otherwise flat and level.

4.2. VEHICLE TOW AND GUIDANCE SYSTEM

Each test vehicle was towed into the test installation using a steel cable guidance and reverse tow system. A steel cable for guiding the test vehicle was tensioned along the path, anchored at each end, and threaded through an attachment to the front wheel of the test vehicle. An additional steel cable was connected to the test vehicle, passed around a pulley near the impact point and through a pulley on the tow vehicle, and then anchored to the ground such that the tow vehicle moved away from the test site. A 2:1 speed ratio between the test and tow vehicle existed with this system. Just prior to impact with the installation, the test vehicle was released and ran unrestrained. The vehicle remained freewheeling (i.e., no steering or braking inputs) until it cleared the immediate area of the test site.

4.3. DATA ACQUISITION SYSTEMS

4.3.1. Vehicle Instrumentation and Data Processing

Each test vehicle was instrumented with a self-contained onboard data acquisition system. The signal conditioning and acquisition system is a 16-channel Tiny Data Acquisition System (TDAS) Pro produced by Diversified Technical Systems Inc. The accelerometers, which measure the x, y, and z axes of vehicle acceleration, are strain gauge type with linear millivolt output proportional to acceleration. Angular rate sensors, measuring vehicle roll, pitch, and yaw rates, are ultra-small, solid-state units designed for crash test service. The TDAS Pro hardware and software conform to the latest SAE J211, Instrumentation for Impact Test. Each of the 16 channels is capable of providing precision amplification, scaling, and filtering based on transducer specifications and calibrations. During the test, data are recorded from each channel at

a rate of 10,000 samples per second with a resolution of one part in 65,536. Once data are recorded, internal batteries back these up inside the unit in case the primary battery cable is severed. Initial contact of the pressure switch on the vehicle bumper provides a time zero mark and initiates the recording process. After each test, the data are downloaded from the TDAS Pro unit into a laptop computer at the test site. The Test Risk Assessment Program (TRAP) software then processes the raw data to produce detailed reports of the test results.

Each of the TDAS Pro units is returned to the factory annually for complete recalibration and to ensure that all instrumentation used in the vehicle conforms to the specifications outlined by SAE J211. All accelerometers are calibrated annually by means of an ENDEVCO® 2901 precision primary vibration standard. This standard and its support instruments are checked annually and receive a National Institute of Standards Technology (NIST) traceable calibration. The rate transducers used in the data acquisition system receive calibration via a Genisco Rate-of-Turn table. The subsystems of each data channel are also evaluated annually, using instruments with current NIST traceability, and the results are factored into the accuracy of the total data channel per SAE J211. Calibrations and evaluations are also made anytime data are suspect. Acceleration data are measured with an expanded uncertainty of ± 1.7 percent at a confidence factor of 95 percent ($k = 2$).

TRAP uses the data from the TDAS Pro to compute the occupant/compartment impact velocities, time of occupant/compartment impact after vehicle impact, and highest 10-millisecond (ms) average ridedown acceleration. TRAP calculates change in vehicle velocity at the end of a given impulse period. In addition, maximum average accelerations over 50-ms intervals in each of the three directions are computed. For reporting purposes, the data from the vehicle-mounted accelerometers are filtered with an SAE Class 180-Hz low-pass digital filter, and acceleration versus time curves for the longitudinal, lateral, and vertical directions are plotted using TRAP.

TRAP uses the data from the yaw, pitch, and roll rate transducers to compute angular displacement in degrees at 0.0001-s intervals, and then plots yaw, pitch, and roll versus time. These displacements are in reference to the vehicle-fixed coordinate system with the initial position and orientation being initial impact. Rate of rotation data is measured with an expanded uncertainty of ± 0.7 percent at a confidence factor of 95 percent ($k = 2$).

4.3.2. Anthropomorphic Dummy Instrumentation

MASH does not recommend or require use of a dummy in the 10000S vehicle, and no dummy was placed in the vehicle.

4.3.3. Photographic Instrumentation Data Processing

Photographic coverage of the test included three digital high-speed cameras:

- One overhead with a field of view perpendicular to the ground and directly over the impact point.
- One placed upstream from the installation at an angle to have a field of view of the interaction of the rear of the vehicle with the installation.
- A third placed with a field of view parallel to and aligned with the installation at the downstream end.

A flashbulb on the impacting vehicle was activated by a pressure-sensitive tape switch to indicate the instant of contact with the TxDOT shallow anchorage SSTR. The flashbulb was visible from each camera. The video files from these digital high-speed cameras were analyzed to observe phenomena occurring during the collision and to obtain time-event, displacement, and angular data. A digital camera recorded and documented conditions of each test vehicle and the installation before and after the test.

CHAPTER 5. MASH TEST 4-12 (CRASH TEST NO. 469680-02-1)

5.1. TEST DESIGNATION AND ACTUAL IMPACT CONDITIONS

MASH Test 4-12 involves a 10000S vehicle weighing 22,000 lb \pm 660 lb impacting the CIP of the longitudinal barrier at an impact speed of 56 mi/h \pm 2.5 mi/h and an angle of 15 degrees \pm 1.5 degrees. The CIP for *MASH* Test 4-12 on the TxDOT shallow anchorage SSTR was 5 ft \pm 1 ft upstream of the centerline of the joint between Segments 1 and 2. Figure 3.1 and Figure 5.1 depict the target impact setup.

Figure 5.1. TxDOT Shallow Anchorage SSTR/Test Vehicle Geometrics for Test No. 469680-02-1.

The 10000S vehicle weighed 22,340 lb, and the actual impact speed and angle were 56.9 mi/h and 14.6 degrees. Minimum target impact severity (IS) was 142 kip-ft, and actual IS was 153 kip-ft. The actual impact point was 3.4 ft upstream of the centerline of the joint between Segments 1 and 2, which is 1.6 ft downstream of the target impact point and 0.6 ft outside the recommended *MASH* tolerance for impact point, and thus is out of specifications for *MASH*. When speaking about the impact point for large trucks, *MASH* Section 2.3.2.2 states that “the critical impact point for these vehicles should be chosen to maximize loading on critical barrier elements such as joints and splices.” Section A2.3.2.2 further elaborates that “impact point selection guidelines presented in Section 2.3.2.2 are based on the distance from initial contact to the location of maximum lateral force.” The objective of *MASH* Test 4-12 on the TxDOT shallow anchorage SSTR was to evaluate the effectiveness of the shallow anchorage system at a critical area near a barrier end/joint. Film analysis of this test showed that both the initial frontal impact and the subsequent rear impact of the truck occurred on the downstream end of the impacted barrier segment in advance of the joint. In fact, the lateral impact forces were applied to the barrier at a point closer to the segment end than initially planned, making it even more critical for evaluation of both the barrier and anchorage system. Thus, the outcome of the test was considered valid despite the actual impact point falling 0.6 ft downstream of the recommended *MASH* tolerance for CIP.

5.2. WEATHER CONDITIONS

The test was performed on the afternoon of June 16, 2020. Weather conditions at the time of testing were as follows: wind speed: 10 mi/h; wind direction: 203 degrees (vehicle was traveling at a heading of 185 degrees); temperature: 89°F; relative humidity: 48 percent.

5.3. TEST VEHICLE

Figure 5.2 shows the 2011 International 4300 single-unit truck (SUT) used for the crash test. The vehicle's test inertia weight was 22,340 lb, and its gross static weight was 22,340 lb. The height to the lower edge of the vehicle bumper was 18.5 inches, and height to the upper edge of the bumper was 33.5 inches. The height to the center of gravity of the vehicle's ballast was 61.75 inches. Table C.1 in Appendix C.1 gives additional dimensions and information on the vehicle. The vehicle was directed into the installation using a cable reverse tow and guidance system and was released to be freewheeling and unrestrained just prior to impact.

Figure 5.2. Test Vehicle before Test No. 469680-02-1.

5.4. TEST DESCRIPTION

Table 5.1 lists events that occurred during Test No. 469680-02-1. Figures C.1 and C.2 in Appendix C.2 present sequential photographs during the test.

Table 5.1. Events during Test No. 469680-02-1.

Time (s)	Events
0.000	Vehicle bumper impacts barrier
0.006	Right front tire leaves pavement
0.035	Vehicle begins to redirect
0.143	Left front tire leaves pavement
0.207	Left rear tires leave pavement
0.244	Vehicle travels parallel with barrier
0.251	Right lower rear corner of box contacts top of barrier
1.105	Left front tire contacts pavement

For longitudinal barriers, it is desirable for the vehicle to redirect and exit the barrier within the exit box criteria (not less than 65.6 ft for heavy vehicles). The test vehicle exited within the exit box criteria defined in *MASH*. Brakes on the vehicle were applied at 2.5 s after impact. After loss of contact with the barrier, the vehicle came to rest 279 ft downstream of the point of impact and 70 ft toward the field side of the barrier.

5.5. DAMAGE TO TEST INSTALLATION

Figure 5.3 shows the damage to the TxDOT shallow anchorage SSTR. Before the test, any cracks in the deck and barrier were noted with a black paint marker. No additional cracks or enlarging of existing cracks were evident after the test. The deck was tested for delamination at the interface between the two concrete slabs, and none were detected. There was gouging and scuffing present on the traffic face of the barrier at the impacted joint. Rebar was exposed on the downstream end of Segment 1 at the joint between Segments 1 and 2. There was also gouging at the top of the field side corner of Segments 1 and 2 from contact with the bottom frame of the box of the truck. Working width* was 78.4 inches, and height of working width was 152.2 inches. No dynamic deflection during the test or permanent deformation after the test was observed.

5.6. DAMAGE TO TEST VEHICLE

Figure 5.4 shows the damage sustained by the vehicle. The front bumper, hood, right front tire and rim, right front spring assembly and U-bolts, right fuel tank and side steps, right door, right floor pan, right lower edge of box, right rear outer tire and rim, and right rear U-bolts were damaged. Maximum exterior crush to the vehicle was 18.0 inches in the front plane at the right front corner at bumper height. Maximum occupant compartment deformation was 2.5 inches in the right front floor pan/firewall. Figure 5.5 shows the interior of the vehicle.

5.7. VEHICLE INSTRUMENTATION

Data from the accelerometers were digitized for informational purposes only and are reported in Figure 5.6. Figure C.3 in Appendix C.3 shows the vehicle angular displacements, and Figures C.4 through C.9 in Appendix C.4 show acceleration versus time traces. Figure 5.6 summarizes pertinent information from the test.

* Per *MASH*, "The working width is the maximum dynamic lateral position of any major part of the system or vehicle. These measurements are all relative to the pre-impact traffic face of the test article." In other words, working width is the total barrier width plus the maximum dynamic intrusion of any portion of the barrier or test vehicle past the field side edge of the barrier.

Figure 5.6. Summary of Results for MASH Test 4-12 on TxDOT Shallow Anchorage SSTR.

CHAPTER 6. MASH TEST 4-12 WITHOUT DOWEL BARS (CRASH TEST NO. 469680-02-2)

6.1. TEST DESIGNATION AND ACTUAL IMPACT CONDITIONS

In the original test installation, dowel bars were included between barrier segments across the expansion joints to provide load transfer and continuity between barrier segments and limit barrier movement and possible deck damage. Based on the results of the first test (i.e., no barrier movement and no deck damage or delamination), TxDOT requested an additional *MASH* Test 4-12 without the dowel bars. If successful, this configuration would reduce construction complexity of the barrier in the field.

For Test No. 469680-02-2, the dowel bars between barrier segments across the expansion joints were cut through such that the barrier segments were not connected. The CIP for *MASH* Test 4-12 on the TxDOT shallow anchorage SSTR without dowel bars was 5 ft ± 1 ft upstream of the centerline of the joint between Segments 2 and 3. This downstream joint was selected to avoid the need for barrier repair at the previously impacted joint.

Figure 3.2 and Figure 6.1 depict the target impact setup. The remaining target impact conditions for *MASH* Test 4-12 are stated in Section 5.1.

Figure 6.1. TxDOT Shallow Anchorage SSTR without Dowel Bars/Test Vehicle Geometrics for Test No. 469680-02-2.

The 10000S vehicle weighed 22,190 lb, and the actual impact speed and angle were 56.7 mi/h and 14.2 degrees. The actual impact point was 4.5 ft upstream of the centerline of the joint between Segments 2 and 3. Minimum target IS was 142 kip-ft, and actual IS was 144 kip-ft.

6.2. WEATHER CONDITIONS

The test was performed on the morning of August 10, 2020. Weather conditions at the time of testing were as follows: wind speed: 9 mi/h; wind direction: 190 degrees (vehicle was traveling at a heading of 185 degrees); temperature: 89°F; relative humidity: 58 percent.

6.3. TEST VEHICLE

Figure 6.2 shows the 2011 International 4300 SUT used for the crash test. The vehicle's test inertia weight was 22,190 lb, and its gross static weight was 22,190 lb. The height to the lower edge of the vehicle bumper was 18.25 inches, and height to the upper edge of the bumper was 33.25 inches. The height to the center of gravity of the vehicle's ballast was 63.4 inches. Table D.1 in Appendix D.1 gives additional dimensions and information on the vehicle. The vehicle was directed into the installation using a cable reverse tow and guidance system, and was released to be freewheeling and unrestrained just prior to impact.

Figure 6.2. Test Vehicle before Test No. 469680-02-2.

6.4. TEST DESCRIPTION

Table 6.1 lists events that occurred during Test No. 469680-02-2. Figure D.1 in Appendix D.2 presents sequential photographs during the test.

Table 6.1. Events during Test No. 469680-02-2.

Time (s)	Events
0.0000	Vehicle bumper impacts barrier
0.0150	Right front tire leaves pavement
0.0360	Vehicle begins to redirect
0.1050	Left front tire leaves pavement
0.2450	Left rear tires leave pavement
0.2890	Vehicle travels parallel with barrier
0.8370	Left front tire returns to pavement

For longitudinal barriers, it is desirable for the vehicle to redirect and exit the barrier within the exit box criteria (not less than 65.6 ft for heavy vehicles). The test vehicle exited within the exit box criteria defined in *MASH*. Brakes on the vehicle were not applied. After loss of contact with the barrier, the vehicle rolled 192 degrees and came to rest on its roof 229 ft downstream of the point of impact and 43 ft toward the field side of the barrier.

6.5. DAMAGE TO TEST INSTALLATION

Figure 6.3 and Figure 6.4 show the damage to the TxDOT shallow anchorage SSTR without dowel bars. No cracks were observed in the barrier or deck slab. No delaminations were detected at the interface between the two concrete slabs. Some gouging occurred on the traffic face of the barrier in the impact region, and contact and scuff marks were evident from the point of impact to the end of the barrier. Working width* was 60.6 inches, and height of working width was 150.9 inches. No dynamic deflection during the test nor permanent deformation after the test was observed.

6.6. DAMAGE TO TEST VEHICLE

Figure 6.5 and Figure 6.6 show the damage sustained by the vehicle. After loss of contact with the barrier, the vehicle rolled 192 degrees and came to rest on its roof. Before the vehicle rolled over, the front bumper, hood, front axle, right and left front spring assembly and U-bolts, right front tire and rim, right front door, right fuel tank and side steps, rear of cab, lower edge of the box, and right rear outer rim were damaged. Maximum exterior crush to the vehicle before rollover was 16.0 inches in the side plane at the right front corner at bumper height. Due to rollover, the occupant compartment deformation was unable to be measured.

6.7. VEHICLE INSTRUMENTATION

Data from the accelerometers were digitized for informational purposes only and are reported in Figure 6.2. Figure D.2 in Appendix D.3 shows the vehicle angular displacements, and Figures D.3 through D.8 in Appendix D.4 show acceleration versus time traces. Figure 6.7 summarizes pertinent information from the test.

* Per *MASH*, "The working width is the maximum dynamic lateral position of any major part of the system or vehicle. These measurements are all relative to the pre-impact traffic face of the test article." In other words, working width is the total barrier width plus the maximum dynamic intrusion of any portion of the barrier or test vehicle past the field side edge of the barrier.

Figure 6.7. Summary of Results for MASH Test 4-12 on TxDOT Shallow Anchorage SSTR without Dowel Bars.

CHAPTER 7. MASH TEST 4-12 WITHOUT DOWEL BARS AND WITH CONCRETE APRON EXTENDED DOWNSTREAM OF THE BARRIER (CRASH TEST NO. 469680-02-3)

7.1. TEST DESIGNATION AND ACTUAL IMPACT CONDITIONS

In the previous *MASH* Test 4-12 (469680-02-2), the vehicle rolled onto its roof, causing excessive occupant compartment deformation. Analysis indicated that soil in the runout area immediately downstream of the test installation contributed to the roll of the SUT after it exited the barrier system. The impact side tires and wheels furrowed into the soil, while the tires on the opposite side of the truck were on concrete pavement. *MASH* Section 3.2 states that “a flat surface, preferably paved, should be used when accelerating the test vehicle to the desired speed and to provide for unrestricted trajectory of the vehicle following impact. The surface should be free of curbs, swales, ditches, or other irregularities that could influence impact or post-impact behavior of the vehicle except when test conditions require such features.”

Consequently, *MASH* Test 4-12 was repeated with a modification to the runout area. Figure 7.1 shows how the concrete apron was extended downstream of the test installation to replace the existing soil immediately beyond the end of the barrier. The extension of the concrete downstream of the barrier is considered more representative of the field applications for this system on high-speed bridge structures. The CIP for *MASH* Test 4-12 on the TxDOT shallow anchorage SSTR without dowel bars was 5 ft ± 1 ft upstream of the centerline of the joint between Segments 1 and 2. Damage to the barrier at this location from Test No. 469680-02-1 was repaired using a non-shrink grout. Figure 3.1 and Figure 7.2 depict the target impact setup. The remaining target impact conditions for *MASH* Test 4-12 are described in Section 5.1.

The 10000S vehicle weighed 22,500 lb, and the actual impact speed and angle were 57.4 mi/h and 14.7 degrees. The actual impact point was 5.0 ft upstream of the centerline of the joint between Segments 1 and 2. Minimum target IS was 142 kip-ft, and actual IS was 160 kip-ft.

Figure 7.1. Runout Area Extended for Test No. 469680-02-3.

Figure 7.2. TxDOT Shallow Anchorage SSSTR without Dowel Bars and with Concrete Apron Extended Downstream of Barrier/Test Vehicle Geometrics for Test No. 469680-02-3.

7.2. WEATHER CONDITIONS

The test was performed on the afternoon of August 19, 2020. Weather conditions at the time of testing were as follows: wind speed: 8 mi/h; wind direction: 72 degrees (vehicle was traveling at a heading of 185 degrees); temperature: 96°F; relative humidity: 23 percent.

7.3. TEST VEHICLE

Figure 7.3 shows the 2009 International 4300 SUT used for the crash test. The vehicle's test inertia weight was 22,500 lb, and its gross static weight was 22,500 lb. The height to the lower edge of the vehicle bumper was 18.25 inches, and height to the upper edge of the bumper was 33.25 inches. The height to the center of gravity of the vehicle's ballast was 61.25 inches. Table E.1 in Appendix E.1 gives additional dimensions and information on the vehicle. The vehicle was directed into the installation using a cable reverse tow and guidance system, and was released to be freewheeling and unrestrained just prior to impact.

Figure 7.3. Test Vehicle before Test No. 469680-02-3.

7.4. TEST DESCRIPTION

Table 7.1 lists events that occurred during Test No. 469680-02-3. Figures E.1 and E.2 in Appendix E.2 present sequential photographs during the test.

Table 7.1. Events during Test No. 469680-02-3.

Time (s)	Events
0.000	Vehicle bumper impacts barrier
0.012	Right front tire leaves pavement
0.037	Vehicle begins to redirect
0.185	Left front tire leaves pavement
0.226	Left rear tires leave pavement
0.234	Lower right rear corner of box frame contacts barrier
0.294	Vehicle travels parallel with barrier
0.650	Left front tire returns to pavement

For longitudinal barriers, it is desirable for the vehicle to redirect and exit the barrier within the exit box criteria (not less than 65.6 ft for heavy vehicles). The test vehicle exited within the exit box criteria defined in *MASH*. Brakes on the vehicle were applied at 2.75 s after impact. After loss of contact with the barrier, the vehicle came to rest 263 ft downstream of the point of impact and 99 ft toward the field side of the barrier.

7.5. DAMAGE TO TEST INSTALLATION

Figure 7.4 and Figure 7.5 show the damage to the TxDOT shallow anchorage SSTR without dowel bars. No cracks were observed in the barrier or deck slab. No delamination was detected at the interface between the two concrete slabs. There was some gouging on the face of the concrete barrier in the impact region and on Segment 2, with scuffing running along the length of the barrier. A section of rebar was exposed on the traffic side of Segment 1 at the joint between Segments 1 and 2. Working width* was 81.5 inches, and height of working width was 142.5 inches. No dynamic deflection during the test nor permanent deformation after the test was observed.

7.6. DAMAGE TO TEST VEHICLE

Figure 7.6 and Figure 7.7 show the damage sustained by the vehicle. The front bumper, hood, right floor pan, front axle, U-bolts, spring assembly, right front tire and rim, right fuel tank and side steps, right front corner of the box, and right rear outer tire and rim were damaged due to contact with the barrier. After loss of contact with the barrier, the vehicle rolled onto its left side, which caused damage to the left front door, windshield, left side steps and battery box, and left air tanks. Maximum exterior crush to the vehicle was 16.0 inches in the side plane at the

* Per *MASH*, "The working width is the maximum dynamic lateral position of any major part of the system or vehicle. These measurements are all relative to the pre-impact traffic face of the test article." In other words, working width is the total barrier width plus the maximum dynamic intrusion of any portion of the barrier or test vehicle past the field side edge of the barrier.

right front corner at bumper height. Maximum occupant compartment deformation was 9.75 inches in the right floor pan area at the seam with the right door. Figure 7.8 shows the interior of the vehicle after the test.

Figure 7.9. Summary of Results for MASH Test 4-12 on TxDOT Shallow Anchorage SSTR without Dowel Bars and with Concrete Apron Extended Downstream of the Barrier.

CHAPTER 8. SUMMARY AND CONCLUSIONS

8.1. ASSESSMENT OF TEST RESULTS

The crash tests reported herein were performed in accordance with *MASH* Test 4-12 on the TxDOT shallow anchorage SSTR. During the first test (469680-02-1), the impact point was out of the ± 1 ft specification per *MASH*, but the outcome of the test was considered valid since the vehicle impacted the barrier at a location more critical for evaluation of both the barrier and anchorage system. Table 8.1 provides an assessment of this test based on the applicable safety evaluation criteria for *MASH* Test 4-12 for longitudinal barriers.

For both the second and third tests (469680-02-2 and 3), the dowel bars between barrier segments across the expansion joints were cut through such that the barrier segments were not connected. In the second test (469680-02-2), the vehicle rolled over onto its roof. Table 8.2 provides an assessment of the test based on the applicable safety evaluation criteria for *MASH* Test 4-12 for longitudinal barriers. The third test was a repeat of the second test. It was determined that soil in the runout area at the end of the test installation contributed to the rollover of the truck in the second test. Therefore, prior to the third test (469680-02-3), the concrete apron was extended downstream of the barrier to replace the soil immediately beyond the end of the barrier to provide a runout area that was more uniform and consistent with anticipated field implementation. Table 8.3 provides an assessment of the test based on the applicable safety evaluation criteria for *MASH* Test 4-12 for longitudinal barriers.

8.2. CONCLUSIONS

Table 8.1 and Table 8.3 show that the TxDOT shallow anchorage SSTR (with and without dowel bars between barrier segments across expansion joints) meets the performance criteria for *MASH* Test 4-12 for longitudinal barriers.

Table 8.1. Performance Evaluation Summary for MASH Test 4-12 on TxDOT Shallow Anchorage SSTR.

<p><i>Deformations of, or intrusions into, the occupant compartment should not exceed limits set forth in Section 5.2.2 and Appendix E of MASH.</i></p>	<p>Maximum occupant compartment deformation was 9.75 inches in the right floor pan at a seam location with the door.</p>	
<p>G. <i>It is preferable, although not essential, that the vehicle remain upright during and after collision.</i></p>	<p>The 10000S vehicle rolled counterclockwise and came to rest on its left side.</p>	<p>Pass</p>

CHAPTER 9. IMPLEMENTATION*

The TxDOT shallow anchorage SSTR attached to a 4.5-inch-thick cast-in-place deck performed acceptably for *MASH* Test 4-12 both with and without No. 8 rebar dowels between adjacent barrier segments across expansion joints. There was no structural damage to the deck, and only minor damage to the SSTR.

MASH Test 4-10 with the 1100C passenger car and Test 4-11 with the 2270P pickup truck were considered unnecessary. When impacted by the SUT, the shallow anchorage SSTR had no dynamic or permanent movement and behaved as a rigid barrier. The SSTR has previously been successfully crash tested with the passenger vehicles, demonstrating the impact performance of the single slope profile (3, 4). Thus, the TxDOT shallow anchorage SSTR attached to a 4.5-inch-thick cast-in-place deck is considered *MASH* compliant.

The shallow anchorage applications of interest to TxDOT include anchorage over a prestressed concrete panel inset from the deck edge, and on the edge of a deck over a prestressed box or slab beam. The application over a panel would have a minimum cast-in-place deck thickness of 4.5 inches, and the deck over a box or slab beam would have a thickness of at least 5 inches. The shallow anchorage over a panel was considered to be the critical case for evaluation due to the shallower anchor embedment and opportunity for concrete fracture or delamination around or beneath the anchor bars. Based on the successful *MASH* testing of this application, the less critical application of a shallow anchorage SSTR attached to the edge of a 5-inch-thick deck cast in place over a prestressed box beam or slab beam is also considered *MASH* compliant and suitable for implementation.

The 25-ft barrier segments evaluated in the tests represent a minimum segment length for field implementation. Implementation can be accomplished through revision of bridge rail standard detail sheets.

* The opinions/interpretations identified/expressed in this chapter are outside the scope of TTI Proving Ground's A2LA Accreditation.
