INTRODUCTION

The Nebraska Department of Roads, in cooperation with the Federal Highway Administration, collected and analyzed data at 61 continuous traffic count locations in 2006. Of these 61 locations, 38 are on rural state and federal highways, 8 on low volume rural roads, 2 on city streets in Grand Island, 3 on city streets in Lincoln, 7 on city streets in Omaha, 1 on the Interstate in South Sioux City, 1 on a city street in Scottsbluff, and 1 on a city street in Holdrege. Most of our machines have been converted to collect data on vehicle type, not just volume. As a result, continuous classification data is available at the majority of our stations. Short-term manual vehicle classification data was collected during 2006 at many of the remaining permanent continuous traffic counters.

A traffic counter detects each passing vehicle and records hourly totals electronically. This information is retrieved periodically over the telephone lines by the Planning and Project Development Division of the Nebraska Department of Roads. Here the information is processed into Average Daily Traffic (ADT) figures. Some of the uses of these ADT values are determination of design standards, classification of highways, development of improvement programs and safety programs. Another important use of the information provided by these permanent traffic counters is to adjust many statewide 24 and 48 hour machine counts and 8-hour manual counts to annual average daily traffic volumes.

The tables and graphs on the following pages are a summarization of the more detailed data presented in this report.

ANNUAL AVERAGE DAILY TRAFFIC BY STATIONS FOR THE YEARS 1996 TO 2006

USE OF ATR DATA TO DETERMINE DESIGN HOUR VOLUMES

Although the number of continuous count stations is limited, these locations offer the best source of data available for use in studying the peaking characteristics of traffic.

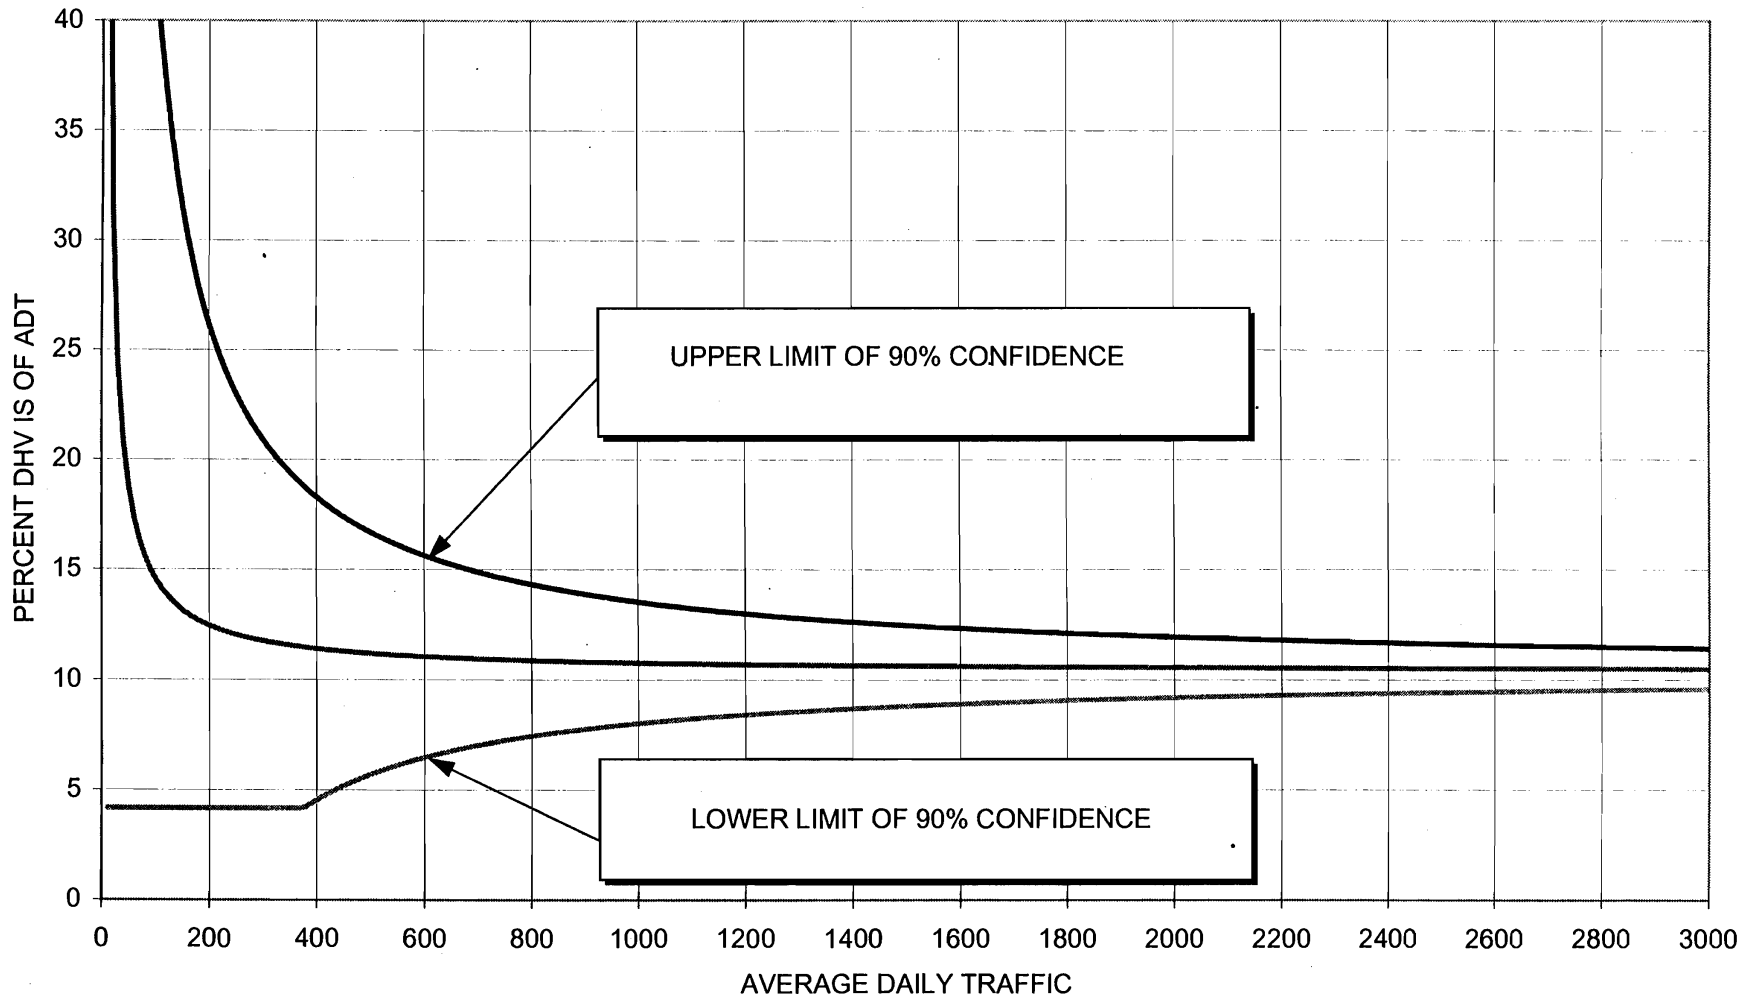

A knowledge of peak volumes is essential when selecting a specific hourly volume, which should be used for design purposes. While designing a road based on the average hourly volume would fall far short of providing an acceptable level of service, it would be economically unreasonable to design a road, which would provide a high level of service for the highest anticipated hourly volume of traffic, which is expected to occur during the design year. The 30th highest hour has customarily been adopted as a compromise between the cost of design and the level of service provided.

We have grouped our continuous count stations into five roadway system categories and then summarized data for the past ten years. Stations where peak hours are known to be heavily influenced by peculiar local events were selectively excluded from the analysis. The least squares method was used to determine a line of regression, which would statistically express the relationship between DHV (30th highest hour) and ADT (average daily traffic) for each category. (The standard error of estimate may be used to measure the variation about the line of regression and to determine confidence levels.) The intended use of these formulas is to provide the traffic analyst or roadway designer with a base volume from which to determine an appropriate design hour volume. This base volume may be modified by the anticipated effects of unusual local events or conditions.

The formulas for five major roadway groups are given below. The relationship for Other Rural Highways is expressed graphically as a percent of ADT on the following page.

RURAL INTERSTATE	DHV= 265.32 + (.0968)(ADT)	STD ERROR OF EST = 132.44
OTHER RURAL HIGHWAYS	DHV= 4.21 + (.1035)(ADT)	STD ERROR OF EST = 16.72
LOW VOLUME RURAL ROADS	DHV= 5.60 + (.1159)(ADT)	STD ERROR OF EST = 4.79
URBAN INTERSTATE	DHV= 267.63 + (.0950)(ADT)	STD ERROR OF EST = 331.41
OTHER URBAN HWYS & STS	DHV= 105.46 + (.0922)(ADT)	STD ERROR OF EST = 77.04

PERCENT DHV IS OF ADT ON OTHER RURAL HIGHWAYS COMPUTED FROM ATR DATA FROM 1997-2006
