### DEVELOPMENT OF A MODEL PERFORMANCE-BASED SIGN SHEETING SPECIFICATION BASED ON THE EVALUATION OF NIGHTTIME TRAFFIC SIGNS USING LEGIBILITY AND EYE-TRACKER DATA: DATA AND ANALYSES

by

Paul J. Carlson Research Engineer Texas Transportation Institute

Eun Sug Park Associate Research Engineer Texas Transportation Institute

and

Jeff D. Miles Assistant Research Engineer Texas Transportation Institute

Report 0-5235-1-VOL2 Project 0-5235 Project Title: Determining Nighttime Driver Signing Needs

> Performed in cooperation with the Texas Department of Transportation and the Federal Highway Administration

> > September 2009 Published: September 2010

TEXAS TRANSPORTATION INSTITUTE The Texas A&M University System College Station, Texas 77843-3135

### DISCLAIMER

The contents of this report reflect the views of the authors, who are responsible for the facts and the accuracy of the data presented herein. The contents do not necessarily reflect the official view or policies of the Federal Highway Administration (FHWA) or the Texas Department of Transportation (TxDOT). This report does not constitute a standard, specification, or regulation. The engineer in charge of the project was Paul J. Carlson, P.E., (Texas, # 85402).

### ACKNOWLEDGMENTS

This project was conducted in cooperation with TxDOT and FHWA. Besides the authors, several key people were involved with the research, including:

- Gary Tarter, TxDOT, Project Director,
- Charlie Wicker, TxDOT, Project Monitoring Committee;
- John Bassett, TxDOT, Project Monitoring Committee, retired,
- Jerry Howell, TxDOT, Project Monitoring Committee, retired,
- Greg Brinkmeyer, TxDOT, Project Monitoring Committee, retired;
- Johnnie Miller, TxDOT, Project Monitoring Committee,
- Doug Skowronek, TxDOT, Project Monitoring Committee,
- Teresa Van Hoozer, TxDOT, Bryan District Sign Shop Supervisor,
- Michael Jedlicka, TxDOT, Bryan District Traffic Engineer,
- Troy Rother, City of College Station, Traffic Engineer,
- Ivan Lorenz, Dick Zimmer, Dillon Funkhouser, Laura Higgins, Jon Re, and Jesse Stanley of TTI, and
- Marc Sandhu, Texas A&M University, 2007 Undergraduate Transportation Scholars Program.

### **CHAPTER 1: PHASE I**

This chapter includes details from the Phase I effort, which was designed to validate the test equipment and experimental study. Figures 1 through 3 show the course at the Texas A&M University Riverside campus and along a nearby local road maintained by the Brazos County. Figures 4 and 5 show the luminance measurements of the signs used in Phase I.

### **CHAPTER 2: STATISTICAL RESULTS FROM PHASE II**

### **INTRODUCTION**

In this chapter, detailed statistical testing results are presented. These results are from an exploratory effort to examine the legibility data from Phase II and test various techniques to quantify the distance-luminance profiles from the internally illuminated signs. The aim was to better understand how different levels of luminance and different shapes of distance-luminance profiles effect nighttime legibility distance.

In this chapter, Sign 1 is the warning sign, Sign 2 is the guide sign, Sign 3 is the regulatory sign with the 14-inch legend, and Sign 4 is the regulatory sign with the 7-inch legend.

### SEPARATE ANALYSIS BY SIGN

In the analyses, the model with Age Group, Acuity Group, Legend, and Aspect of Profile as main effects and Age Group\*Legend, Legend\*Aspect of Profile, Age Group\*Aspect of Profile, and Acuity Group\*Aspect of Profile as two-way interactions are used for all of four signs as an initial model. Although the larger models with additional two-way interaction terms were also explored, those additional interaction terms turned out to be insignificant and they are not considered here.

### **ANALYSIS FOR SIGN 1**

### Analysis with CLum\_CTime 40LI

Table 1 presents the results under the initial model with CLum\_CTime 40LI in place of Aspect of Profile for Sign 1. The profiles were defined as follows:

Variables	Description
CLum_CTime 40LI	Total amount of light available to the study subject as
	they approach the sign from the 40 to the 20LI region
Log 40LI	Log transform of CLum_CTime 40LI
CLum_CTime 50LI	Total amount of light available to the study subject as
	they approach the sign from the 50 to the 20LI region
Log 50LI	Log transform of CLum_CTime 50LI
CLum_CTime 80LI	Total amount of light available to the study subject as they approach the sign from the 80 to the 20LI region
Log 80LI	Log transform of CLum_CTime 80LI

### Table 1. Output for the Initial Model with CLum\_CTime 40LI for Sign 1. Response leg\_dist sign=1

The effect of CLum\_CTime 40LI on the legibility distance is positive, i.e., as CLum\_CTime 40LI increases, the legibility distance increases, although the coefficient is not shown in the table. Also, there is a significant interaction effect Age Grp\*CLum\_CTime 40LI on the legibility distance, suggesting that the rate of increase (slope for CLum\_CTime 40LI) of legibility distance as CLum\_CTime 40LI increases is different for Old and Young Drivers. The residual plot was examined to ensure that underlying model assumptions are satisfied. Figure 6 contains the residual plot, showing seven outliers (represented by squares).

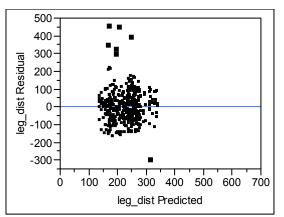

Figure 6. Residual by Predicted Plot for the Initial Model with CLum\_CTime 40LI for Sign 1.

The model was refitted after removing those outliers. Table 2 contains the results.

- 1----

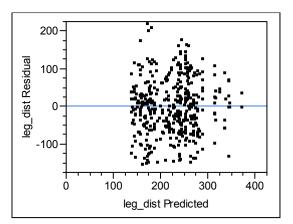

Figure 7. Residual by Predicted Plot for the Initial Model with CLum\_CTime 40LI for Sign 1 after Removing Outliers.

An effort has been made to select a more parsimonious model while maintaining good overall model fit. Table 3 contains the model with statistically significant (at  $\alpha$ =0.05) effects as well as the main effect variables that are part of significant two-way interaction effects. Table 3 suggests that the overall model fit stays almost the same (especially in terms of the adjusted

R-square) as the initial model(s). The model in Table 3 can be selected as a final model for Sign 1 with CLum\_CTime 40LI.

# Table 3. Output for the Final Model with CLum\_CTime 40LI for Sign 1 without Outliers. Response leg\_dist sign=1 Summary of Fit

RSquare RSquare Adj Root Mean Square Error Mean of Response Observations (or Sum Wgts)	0.71567 0.71293 49.8785 222.098 42	2 8 6

CLum_CTime 40LI	0.251	0549	0.031077	381.8	8.08	<.0001
Age Grp[0]*(CLum_CTime 40LI-82.1944)	0.094	2351	0.031077	381.8	3.03	0.0026
Fixed Effect Tests						
Source	Nparm	DF	DFDen	F Ratio	Prob > F	
Age Grp	1	1	32.77	1.1332	0.2949	
Acuity Grp	1	1	32.73	5.2587	0.0284	
CLum_CTime 40LI	1	1	381.8	65.2623	<.0001	
Age Grp*CLum_CTime 40LI	1	1	381.8	9.1950	0.0026	

Table 3 also shows the estimated model coefficients in the Parameter Estimates table. A prediction equation for Legibility distance (Y) for Sign 1 can be written using those coefficients (if desired) as follows:

```
Y=193.98417+15.277267 Age Grp[0] + 31.209211 Acuity Grp[0] +0.2510549 CLum_CTime 40LI
```

```
+0.0942351 Age Grp[0]*(CLum_CTime 40LI-82.1944)
```

(1)

where Age Grp[0] and Acuity Grp[0] are indicator functions, i.e.,

Age Grp[0] = 1 when Age Group = 0

= 0 otherwise.

Acuity Grp[0] = 1 when Acuity Group = 0

= 0 otherwise.

For example, when Age Group = 0 and Acuity Group = 0, Equation (1) can be rewritten

as:

```
Y=193.98417+15.277267 + 31.209211 +0.2510549 CLum_CTime 40LI
```

+0.0942351 (CLum_CTime 40LI-82.1944)	
= 232.7251+ 0.3453 CLum_CTime 40LI	(2)

and when Age Group = 1 and Acuity Group = 1, Equation (1) can be rewritten as:

From Equations (2) and (3), it can be seen that the rate of increase (slope for

CLum\_CTime 40LI) of legibility distance (as CLum\_CTime 40LI increases) is larger for young drivers than for old drivers.

### Analysis with Log 40LI

Table 4 presents the results under the initial model with Log 40LI in place of Aspect of Profile for Sign 1. Because the same outliers as in the case of CLum\_CTime 40LI were observed again, they were removed and the model was fitted to the remaining data.

### Table 4. Output for the Initial Model with Log 40LI for Sign 1 without Seven Outliers.Response leg\_dist sign=1

### Table 10. Output for the Initial Model with CLum\_CTime 80LI for Sign 1 without Seven Outliers.

Table 11 contains the model with statistically significant (at  $\alpha$ =0.05) effects as well as the main effect variables that are part of two-way interaction effects. Table 11 suggests that the overall model fit stays almost the same (especially in terms of the adjusted R-square) as the initial model(s). The model in Table 11 can be selected as a final model for Sign 1 with CLum CTime 80LI.

legend*CLum_CTime 40LI	11	11	360.8	0.9905	0.4545	

The effect of CLum\_CTime 40LI on the legibility distance is positive, i.e., as CLum\_CTime 40LI increases, the legibility distance increases, although the coefficient is not shown in the table. The residual plot is given in Figure 8, which indicates that the underlying model assumptions are generally satisfied.

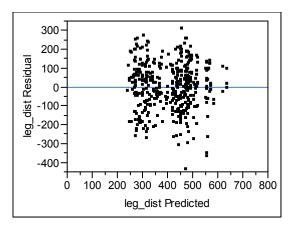

Figure 8. Residual by Predicted Plot for the Initial Model with CLum\_CTime 40LI for Sign 2.

An effort has been made to select a more parsimonious model while maintaining good overall model fit. Because the interaction effect Age Grp\*CLum CTime 40LI became significant at  $\alpha$ =0.05 as soon as one of the least significant terms, AcuityGrp\*CLum CTime 40LI, was removed from the model, the term Age Grp\*CLum CTime 40LI was decided to be kept in the final model. Table 15 contains the model with statistically significant (at  $\alpha$ =0.05) effects as well as the main effect variables that are part of two-way interaction effects. It can be seen that the overall model fit stays almost the same (especially in terms of the adjusted R-square) as the initial model(s).

## Table 15. Output for the Final Model with CLum CTime 40LI for Sign 2.

Table 15 also shows the estimated model coefficients in the Parameter Estimates table. A prediction equation for Legibility distance (Y) for Sign 2 can be written using those coefficients (if desired) as follows:

Y=360.78866+34.074443 Age Grp[0] + 59.975283 Acuity Grp[0] +0.2153271 CLum\_CTime 40LI +0.0758134 Age Grp[0]\*(CLum\_CTime 40LI-82.1944)
 (4) where Age Grp[0] and Acuity Grp[0] are indicator functions as defined previously.

Equation (4) can be simplified by replacing the indicator function by either 0 or 1 depending on whether the condition is satisfied. For example, when Age Group = 0 and Acuity Group = 0, Equation (4) can be rewritten as:

Y=360.78866+34.074443 + 59.975283 +0.2153271 CLum\_CTime 40LI

+0.0758134 \*(CLum\_CTime 40LI-82.1944)

= 448.6069+ 0.2911 CLum\_CTime 40LI

and when Age Group = 1 and Acuity Group = 1, Equation (1) can be rewritten as:

Y=360.78866+0.2153271 CLum\_CTime 40LI (6)

(5)

From Equations (5) and (6), it can be seen that the rate of increase (slope for CLum\_CTime 40LI) of legibility distance (as CLum\_CTime 40LI increases) is larger for young drivers than for old drivers as the significant interaction effect Age Grp\*CLum\_CTime 40LI suggests.

### Analysis with Log 40LI

Table 16 presents the results under the initial model with Log 40LI in place of Aspect of Profile for Sign 2.

### Table 24. Output for the Initial Model with Log 80LI for Sign 2. log\_dist\_sign=2

Table 25 contains the model with statistically significant (at  $\alpha$ =0.05) effects as well as the main effect variables that are part of two-way interaction effects. Table 25 suggests that the overall model fit stays almost the same (especially in terms of the adjusted R-square) as the initial model(s). The model in Table 25 can be selected as a final model for Sign 2 with Log 80LI.

#### Table 25. Output for the Final Model with Log 80LI for Sign 2.

#### Table 26. Output for the Initial Model with CLum\_CTime 40LI for Sign 3.

Response leg\_dist sign=3

The effect of CLum\_CTime 40LI on the legibility distance is positive, i.e., as CLum\_CTime 40LI increases, the legibility distance increases, although the coefficient is not shown in the table. The residual plot is given in Figure 9, which indicates that the underlying model assumptions are generally satisfied.

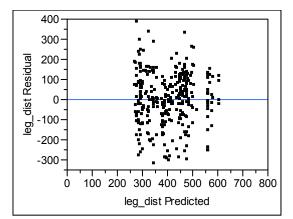

Figure 9. Residual by Predicted Plot for the Initial Model with CLum\_CTime 40LI for Sign 3.

An effort has been made to select a more parsimonious model while maintaining good overall model fit. Because the interaction effect Age Grp\*CLum\_CTime 40LI became significant at  $\alpha$ =0.05 as soon as one of the least significant terms, AcuityGrp\*CLum\_CTime 40LI, was removed from the model, the term Age Grp\*CLum\_CTime 40LI was decided to be kept in the final model. Table 27 contains the model with statistically significant (at  $\alpha$ =0.05) effects as well as the main effect variables that are part of two-way interaction effects. It can be

seen that the overall model fit stays almost the same (especially in terms of the adjusted R-square) as the initial model(s).

Age Grp*CLum CTime 40LI	1	1	276.5	11.1168	0.0010	

Table 27. Output for the Final Model with CLum CTime 40LI for Sign 3.

Table 27 also shows the estimated model coefficients in the Parameter Estimates table. A prediction equation for Legibility distance (Y) for Sign 3 can be written using those coefficients (if desired) as in Equations (1)–(6). Note that a significant interaction effect Age Grp\*CLum\_CTime 40LI suggests that the rate of increase (slope for CLum\_CTime 40LI) of legibility distance (as CLum\_CTime 40LI increases) is different for young drivers and old drivers. From the positive coefficient for the interaction term Age Grp\*CLum\_CTime 40LI shown in the Parameter Estimates table, it can be concluded that the rate of increase (slope for CLum\_CTime 40LI) is larger for young drivers than for old drivers.

#### Analysis with Log 40LI

Table 28 presents the results under the initial model with Log 40LI in place of Aspect of Profile for Sign 3.

#### Table 28. Output for the Initial Model with Log 40LI for Sign 3.

#### Response leg\_dist sign=3 Summary of Fit

RSquare RSquare Adj Root Mean Square Error Mean of Response Observations (or Sum Wgts)		0.834047 0.817101 71.75196 401.8678 314				
Fixed Effect Tests

Log 40LI		62.89774	5	6.402691	276.5	9.82	<.0001
Acuity Grp[0]*(Log 40LI-1.59292)		27.15395	8	6.402691	276.5	4.24	<.0001
Fixed Effect Tests							
Source	Nparm	DF	DFDen	F Ratio	Pro	ob > F	
Acuity Grp	1	1	34.03			.0007	
Log 40LI	1	1	276.5			.0001	
Acuity Grp*Log 40LI	1	1	276.5	17.9863	<	.0001	

Table 29 also shows the estimated model coefficients in the Parameter Estimates table. A prediction equation for Legibility distance (Y) for Sign 3 by Log 40LI can be written using those coefficients (if desired) as follows:

Y=293.10985+ 72.749527 Acuity Grp[0] +62.897745 Log 40LI

+27.153958 Acuity Grp[0]\*(Log 40LI-1.59292) (7)

where Acuity Grp[0] is an indicator function as defined previously.

Equation (7) can be simplified by replacing Acuity Grp[0] by 0 when Acuity Group = 1

or 1 when Acuity Group = 0. When Acuity Group = 0, Equation (7) can be rewritten as:

Y=293.10985+ 72.749527 +62.897745 Log 40LI+27.153958 \*(Log 40LI-1.59292)

= 322.6053+ 90.0517 Log 40LI (8)

and when Acuity Group = 1, Equation (7) becomes:

```
Y=293.10985+ 62.897745 Log 40LI
                                                                      (9)
```

From Equations (8) and (9), it can be seen that the rate of increase (slope for Log 40LI) of legibility distance (as Log 40LI increases) is larger for the drivers with good vision than for the drivers with poor vision as the significant interaction effect Acuity Grp\* Log 40LI suggests.

#### Analysis with CLum\_CTime 50LI

#### Table 38. Output for the Initial Model with CLum\_CTime 40LI for Sign 4.

Response leg\_dist sign=4

The effect of CLum\_CTime 40LI on the legibility distance is positive, i.e., as CLum\_CTime 40LI increases, the legibility distance increases, although the coefficient is not shown in the table. The residual plot was examined to ensure that underlying model assumptions are satisfied. Figure 10 contains the residual plot, which shows an extreme outlier (row # 439 represented by a square).

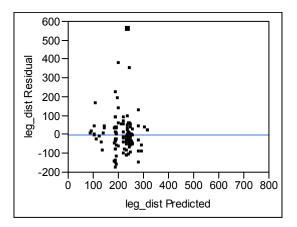

Figure 10. Residual by Predicted Plot for the Initial Model with CLum\_CTime 40LI for Sign 4.

The model was refitted after removing that outlier. Table 39 contains the results.

	an Ex	treme	Outlier.

### Table 39. Output for the Initial Model with CLum\_CTime 40LI for Sign 4 after Removing an Extreme Outlier.

The residual plot contained in Figure 11 shows that the model assumptions are not seriously violated.

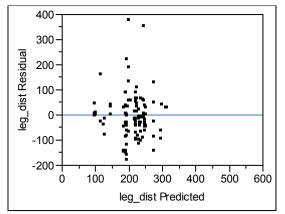

Figure 11. Residual by Predicted Plot for the Initial Model with CLum\_CTime 40LI for Sign 4 after Removing an Extreme Outlier.

Figure 11 indicates that there might be two other potential outliers (observations #448 and #726 corresponding to the top two points of Figure 11), but they are not further removed from the data because they are not as extreme as the one previously removed (#439) and the removal of them changes the conclusions in an unexpected way (e.g., the effect of Legend suddenly becomes significant).

An effort has been made to select a more parsimonious model while maintaining good overall model fit. Table 40 contains the model with statistically significant (at  $\alpha$ =0.05) effects as

well as the main effect variables that are part of two-way interaction effects. Table 40 suggests that the overall model fit stays almost the same (especially in terms of the adjusted R-square) as the initial model(s). The model in Table 40 can be selected as a final model for Sign 4 with CLum CTime 40LI.

## Table 41. Output for the Initial Model with Log 40LI for Sign 4 without an ExtremeOutlier.

Table 42 contains the model with statistically significant (at  $\alpha$ =0.05) effects. Because the main effect Log 40LI became significant at  $\alpha$ =0.05 when one of the least significant terms Age Grp\*legend was removed from the model, the term Log 40LI was decided to be kept in the final model. It can be seen from the table that the overall model fit stays almost the same (especially in terms of the adjusted R-square) as the initial model(s).

Table 50.	Output for the Second Model with Log 80LI for Sign 4 without an Extreme
	Outlier.

Table 50 shows that the interaction effect Age Grp\*Log 80LI becomes insignificant at  $\alpha$ =0.05 when other insignificant terms of Table 49 are removed from the model. The reduced model without insignificant terms Age Grp\*Log 80LI and Age Grp is fitted again to the Sign 4 data.

Table 51 contains a final model for Sign 4 with Log 80LI. It can be seen from the table that the overall model fit for the model in Table 51 stays almost the same (especially in terms of the adjusted R-square) as the models in Table 49 and Table 50.

## Table 51. Output for the Final Model with Log 80LI for Sign 4 without an Extreme Outlier.

Note that Table 51 also shows the estimated model coefficients in the Parameter Estimates table. A prediction equation for Legibility distance (Y) for Sign 4 by Log 80LI can be written using those coefficients as in Equations (1)–(3).

#### ANALYSIS OF LEGIBILITY DATA WITHOUT ACUITY

In the current analyses, the model with Legibility Distance as a response variable, Age Group, Legend, and Aspect of Profile (each of six variables, CLum\_Ctime 40LI, CLum\_CTime50LI, Log 40LI, LOG(CLum)\_Ctime 40LI, Log 50LI, and LOG(CLum)\_Ctime 50LI) as main effects and Age Group\* Legend, Legend\* Aspect of Profile, and Age Group\* Aspect of Profile, as two-way interactions were used as an initial model for all of the four signs. Then the insignificant effects (at  $\alpha$ =0.05) as well as the main effect variables that are part of significant two-way interaction effects were retained in the final model. The overall model fit (R<sup>2</sup> and adjusted R<sup>2</sup>) did not change significantly between the initial model and the final model.

Also, the same set of outliers were identified as in the previous analysis (although the current analysis does not contain Acuity, and the variables LOG(CLum)\_Ctime 40LI and LOG(CLum)\_Ctime 50LI are newly added): for Sign 1, 6 outliers (observation # 709, 712, 727, 730, 736, 739) from Subject 21 and 1 outlier (observation # 1116) from Subject 32 were observed, and for Sign 4, an extreme outlier (observation # 439) from Subject 13 was observed

again. Those outliers had been removed from the data before more parsimonious models were explored. In this report, only the results from the final models are presented.

#### **Analysis for Sign 1**

Table 52 shows that there is a statistically significant interaction effect between Age Group ( $0: \le 55$  years, 1: > 55 years) and CLum\_CTime 40LI. The estimated model coefficients in the Parameter Estimates table suggest that the rate of increase (slope for CLum\_CTime 40LI) of legibility distance (as CLum\_CTime 40LI increases) is larger for young drivers than for old drivers. Tables 53 through 75 show additional analysis results by aspect of profile.

## CHAPTER 3: STATISTICAL RESULTS OF LEGIBILITY DATA FROM PHASE III

#### INTRODUCTION

In this chapter, detailed statistical testing results are presented for the legibility data obtained from Phase III of the study. These analyses were aimed at determining the effect of sign reflective levels on legibility distance. The dependent variable of the analysis is Legibility Distance (measured in feet) and the main factor of interest is Reflective Level (Low, Medium, High). Other variables considered in the analysis are driver's Age (Old:  $\geq$  55 years, Young: < 55 years), Reflectivity Type (II: Internally Illuminated, RS: Reflective Sheeting), Course Type (Closed, Open), Course Setting (Rural, Urban), Letter Height (6, 7, 8, 10), and Headlight Beam Type (Low, High). Although there were some additional variables such as Gender, Ethnicity, Employment, and Education in the original data, those variables turned out to be insignificant when included in the models explored and are not considered here.

There are four different sign types: Warning, Regulatory, Guide, and Street Name. Analyses are conducted separately by sign type. For each sign type, the data are analyzed utilizing the split-plot design with Subject (driver) as a whole-plot and each treatment combination as a split-plot. The variable Age is treated as a whole plot factor while some of the remaining variables mentioned above serve as split-plot factors. It needs to be noted that for these data, not all conditions were replicated throughout the study, and except for Age and Reflective Level, the levels of other factors/variables are different for different sign types (i.e., factor levels are nested within each sign type). Table 76 shows the levels of factors/variables for each sign type.

	Table 70. Levels of Factors/ variables for Each Sign Type.							
Sign Type	Warning	Regulatory	Guide	Street Name

		Low or Medium)						

Table 76. Levels of Factors/Variables for Each Sign Type.

Note: A(B) represents that level A exists only for level B (of another factor).

### **ANALYSIS FOR WARNING SIGNS**

#### Analysis by Reflectivity Type

For warning signs, Reflectivity Type II (Internally Illuminated) is present only for Course Type=Closed and Course Setting=Rural, and for Reflective Level = Low or High. To prevent potential confounding between Reflectivity Type and other factors, data are analyzed separately for each level of Reflectivity Type, rather than just ignoring Reflectivity Type in the analysis.

#### Analysis for Internally Illuminated Warning Signs

A split-plot model with Age and Reflective Level as main effects, Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a random effect is used as an initial model for internally illuminated warning signs. Table 77 contains the results obtained by the initial model. It can be observed from the Fixed Effect Tests table that the effect of Reflective Level is significant at  $\alpha$ =0.05. Effect Details table for Reflective Level shows the least squares means for legibility distance for each level of Reflective Level, suggesting that a High reflective level leads to longer legibility distance.

## Table 77. Output for the Initial Model for Internally Illuminated Warning Signs.

### Analysis for Reflective Sheeting Warning Signs

For Reflectivity Type RS (Reflective Sheeting), there are two levels for each of Course Type and Course Setting. To get a better understanding of the effects of Course Type and Course Setting as well as their joint effect on legibility distance, factors 'Course Type' and 'Course Setting' are combined into a new factor 'Course' with three levels (Closed-Rural, Open-Rural, Open-Urban) for Reflective Sheeting Warning signs. A split-plot model with Age, Reflective Level, and Course as main effects, Age\*Reflective Level and Course \*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is used as an initial model. Table 79 contains the results under the initial model, which shows that Reflective Level, Course, and Age were significant at  $\alpha$ =0.05 (see Fixed Effect Tests table). It can be observed from the Effect Details table that a higher reflective level, Closed course, and/or Young age group corresponds to longer legibility distance. Figure 12 contains the plots of least squares means, which illustrates the effects of each factor. Note that the interaction plots (Figures 12d and 12e) are information purposes only (interactions were not statistically significant).

Young,High	243.74871	22.403431							

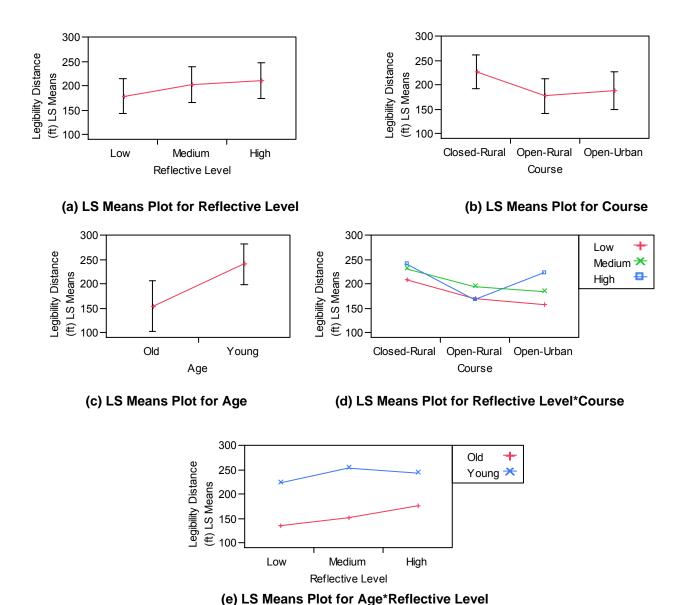

Figure 12. Least Squares Means Plots of Factor Effects for Reflective Sheeting Warning Signs.

Table 80 contains the reduced model with Reflective Level, Course, and Age (which were statistically significant at  $\alpha$ =0.05 in the initial model) as main effects and Drivers (nested within Age) as random effects, which leads to basically the same conclusions on the effects of Reflective Level, Course, and Age as above. Multiple comparison tests (Fisher's Protected LSD) indicate that for Reflective Level, High and Medium are significantly different from Low although High and Medium are not significantly different. For Course, Closed-Rural is

significantly different from Open-Rural and Open-Urban although Open-Rural and Open-Urban are not significantly different.

### Analysis by Reflective Level

Researchers were also interested in determining if there was a statistically significant difference between the internally illuminated and the reflective sheeting when a reflective level is fixed. Only the data collected on the closed course were used for this test.

#### Analysis for Low Reflective Level Warning Signs

Table 81 contains the results obtained under the model with Age and Reflectivity Type as main factors, Age\*Reflectivity Type as a two-way interaction, and Drivers (nested within Age) as a random effects when Reflective Level is fixed at Low. As can be observed from the table,

there was a significant interaction effect between Age and Reflectivity Type, which suggests that the effect of Reflectivity Type is different for Young and Old drivers.

Levels not connected by same letter are significantly different.

## Analysis for High Reflective Level Warning Signs

Table 83 and Figure 14 contain the results obtained under the model with Age and Reflectivity Type as main factors, Age\*Reflectivity Type as a two-way interaction, and Drivers (nested within Age) as a random effects when Reflective Level is fixed at High. As can be observed from the table and the figure, none of the effects in the model were statistically significant in this case.

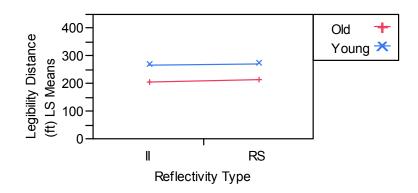

Figure 14. Interaction Plot of Age\*Reflectivity Type for High Reflective Warning Signs.

#### ANALYSIS FOR REGULATORY SIGN

For regulatory signs, half of the signs (#4–#11) were tested with high headlight beams, and the other half were tested with low headlight beams. The data from the regulatory signs tested with low headlight beams and those with high headlight beams are analyzed separately.

### ANALYSIS FOR REGULATORY SIGNS TESTED WITH LOW HEADLIGHT BEAMS

#### Analysis by Reflectivity Type

For regulatory signs, Reflectivity Type II (Internally Illuminated) is present only for Course Type=Closed and for Reflective Level=Low or High. To prevent potential confounding between Reflectivity Type and other factors, data are analyzed separately for each level of Reflectivity Type as in warning signs, rather than just ignoring Reflectivity Type in the analysis.

### Analysis for Internally Illuminated Regulatory Signs

A split-plot model with Age and Reflective Level as main effects, Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a random effect is used as an initial model for internally illuminated regulatory signs with low headlight beams. Table 84 contains the results obtained by the initial model. It can be observed from the Fixed Effect Tests table that the effect of Reflective Level is significant at  $\alpha$ =0.05 and the effect of Age is significant at  $\alpha$ =0.1 while the interaction effect is not significant. The Effect Details table for Reflective Level shows the least squares means for legibility distance for each level of Reflective Level and Age, suggesting that a High reflective level leads to longer legibility distance and young drivers tend to see farther.

## Table 84. Output for the Initial Model for Internally Illuminated Regulatory Signs.

### Analysis for Reflective Sheeting Regulatory Signs

210.86972

Young

For Reflectivity Type RS, there are two levels for Course Type and three levels for Reflective Level. A split-plot model with Age, Reflective Level, and Course Type as main effects, Age\*Reflective Level and Course Type\*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is used as an initial model. Table 86 contains the results under the initial model, which shows that Reflective Level, Course Type, and Age are statistically significant (see Fixed Effect Tests table). It can be observed from the Effect Details table that High reflective level, Closed course type, and/or Young age corresponds to longer legibility distance.

Low		В	161.04702					
Medium		В	156.72537					

Levels not connected by same letter are significantly different.

### **Analysis by Reflective Level**

Researchers were also interested in determining if there was a statistically significant difference between the internally illuminated and the reflective sheeting when a reflective level is fixed for regulatory signs. Only the data collected on the closed course were used for this test.

#### Analysis for Low Reflective Level Regulatory Signs

Table 89 contains the results obtained under the model with Age and Reflectivity Type as main factors, Age\*Reflectivity Type as a two-way interaction, and Drivers (nested within Age) as a random effects when Reflective Level is fixed at Low. Only the effect of Age is statistically significant in this case although the interaction plot presented in Figure 15 indicates that young drivers might see reflective sheeting signs better than internally illuminated signs as in the case of warning signs. However, this interaction effect is not statistically significant (partly due to a small sample size).

#### Table 89. Effect of Reflectivity Type for Low Reflective Regulatory Signs.

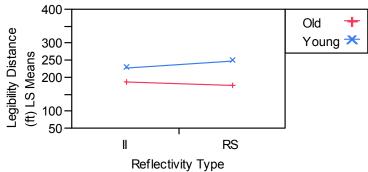

Figure 16. Interaction Plot of Age\*Reflectivity Type for High Reflective Regulatory Signs.

#### Analysis for Regulatory Signs Tested with High Headlight Beams

Signs numbered 4–11 are analyzed here. These regulatory signs were tested with Course Type=Closed, Course Setting = Rural, Reflectivity Type = Reflective Sheeting, and Letter Height = 10. Reflective Level has two levels: Low (corresponding to Signs 4, 6, 7, 11) and Medium (corresponding to Signs 5, 8, 9, 10) in this experiment. Researchers were interested in testing whether there is a significant difference between Low and Medium reflective levels under high beam headlight illumination. A split-plot model with Age and Reflective Level as main effects, and Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a random effect is used as an initial model for reflective sheeting regulatory signs with high headlight beams. It was assumed that sign ordering does not significantly affect the effect of Reflective Level on legibility distance. Table 91 contains the results obtained by the initial model. It can be observed from the Fixed Effect Tests table that the effect of Reflective Level is significant at  $\alpha$ =0.05, and the effect of Age is significant at  $\alpha$ =0.1 while the interaction effect is not significant. The Effect Details table for Reflective Level shows the least squares means for legibility distance for each level of Reflective Level and Age, suggesting that Medium reflective level leads to longer legibility distance than Low reflective level and young drivers tend to see farther.

## Analysis for Guide Sign

Guide signs were tested only on the open course with two course setting levels (Rural and Urban). A split-plot model with Age, Reflective Level, and Course Setting as main effects, Age\*Reflective Level and Course Setting\*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is employed for guide signs. Table 93 contains the results. It can be observed from the Fixed Effect Tests table that the effect of Course Setting \*Reflective Level is significant at  $\alpha$ =0.05, and the effect of Age\*Reflective Level is significant at  $\alpha$ =0.1.

Old,Medium			С	D	204.99990
Old,High			С	D	193.29269
Old,Low				D	167.47999

Levels not connected by same letter are significantly different.

Figure 18 contains the Course Setting\*Reflective Level interaction plot, which shows that the effect of Reflective Level on legibility distance is different for Rural and Urban. Table 95 presents the Fisher's protected LSD multiple comparison test results. It can be concluded that for Rural Course Setting, Medium and High Reflective Levels lead to longer legibility distances than Low Reflective Level while there is no significant difference between Medium and High. Also, Low Reflective Level seems to work better under the urban course setting than under the rural course setting.

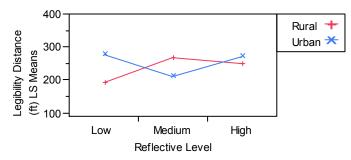

Figure 18. Interaction Plot of Course Setting\*Reflective Level for Guide Signs.

Rural,Low			С	193.38629

Levels not connected by same letter are significantly different.

### Analysis for Street Name Sign

Street name signs were tested only on the open course with two course setting levels (Rural and Urban). A split-plot model with Age, Reflective Level, and Course Setting as main effects, Age\*Reflective Level and Course Setting \*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is employed for street name signs. Table 96 contains the results of running the initial model for Street Name signs . It can be observed from the Fixed Effect Tests table that the effects of Age and Course Setting are significant at  $\alpha$ =0.05 while the effect of Reflective Level as well as interaction effects are all insignificant.

Table 97 contains the reduced model with main effects only and Drivers (nested within Age) as random effect, which leads to the same conclusions on the effects of Age, Reflective Level, and Course Setting as above. For street name signs, it appears that signs can be seen better (i.e., have longer legibility distance) under Urban setting than under Rural setting. Also, Reflective Level does not seem to matter.

## CHAPTER 4: STATISTICAL RESULTS FROM EYE-TRACKER DATA FROM PHASE III

### **INTRODUCTION**

In this chapter, detailed statistical testing results are presented for the eye-tracker data obtained from Phase III of the study. The objective of this analysis was to assess the effect of sign reflective levels on the number of Glances (within 40LI), legibility glance duration, average glance duration without the legibility glance (measured in sec), total glance duration (within 40LI), and legibility glance start distance (measured in feet). The dependent variable of the analysis is each of these five variables, Number of Glances within 40LI, Leg. Glance Duration, Avg. Glance Duration W/O Leg, Total Glance Duration within 40LI, and Legibility Glance Start Distance. The main factor of interest is Reflective Level (Low, Medium, High). Other variables considered in the analysis are driver's Age (Old:  $\geq$  55 years, Young: < 55 years), Reflectivity Type (II: Internally Illuminated, RS: Reflective Sheeting), Course Type (Closed, Open), Course Setting (Rural, Urban), Letter Height (6, 7, 8, 10), and Headlight Beam Type (Low, High). Although there were some additional variables such as Gender, Ethnicity, Employment, and Education in the original data, those variables turned out to be insignificant when included in the models explored and are not considered here.

There are four different sign types: Warning, Regulatory, Guide, and Street Name. Analyses are conducted separately by sign type. For each sign type, the data are analyzed utilizing the split-plot design with Subject (driver) as a whole-plot and each treatment combination as a split-plot in the cases where there are repeated measures for each driver (to account for correlation among the measurements from the same driver). The variable Age is treated as a whole plot factor while some of the remaining variables mentioned above serve as split-plot factors. In the cases where there was mostly one measurement for each driver, the ordinary Analysis of Variance (ANOVA) was employed. For a discrete response variable Number of Glances, both the original Number of Glances and the transformed Number of Glances (z=(y+3/8)1/2 where y is the number of glances) were analyzed in case that the underlying analysis assumptions such as normality and a constant variance assumption for errors are violated for the original variable. There were no noticeable differences between two analyses, and only the results based on the original variable are reported here (the results of these analyses are available by contacting the authors).

85

It needs to be noted that for these data, not all conditions were replicated throughout the study, and except for Age and Reflective Level, the levels of other factors/variables are different for different sign types (i.e., factor levels are nested within each sign type). Refer to Report 0-5235-1 Volume 1 to find the levels of factors/variables existing for each sign type.

#### ANALYSIS FOR WARNING SIGNS

#### Analysis by Reflectivity Type (Main Study Factor: Reflective Level)

For warning signs, Reflectivity Type II (Internally Illuminated) is present only for Course Type=Closed and Course Setting=Rural, and for Reflective Level = Low or High. To prevent potential confounding between Reflectivity Type and other factors, data are analyzed separately for each level of Reflectivity Type, rather than just ignoring Reflectivity Type in the analysis.

#### Analysis for Internally Illuminated Warning Signs

A split-plot model with Age and Reflective Level as main effects, Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a random effect is used for internally illuminated warning signs. Tables 98–102 contain the results obtained for each of the five dependent variables (1)–(5). It can be seen from the tables that none of Age, Reflective Level, or Age\*Reflective effects were significant at  $\alpha$ =0.05 for any of the five dependent variables in this case. Note that in Table 100 the number of observations for Avg. Glance Duration W/O Leg. (sec) was much smaller than the other cases due to many missing values. Table 101 contains the Least Squares (LS) means plot for Age\*Reflective effect (interaction plot) for information purposes although the effect was not significant at at  $\alpha$ =0.05.

## Deenenee Lexibility Clance Start Distance (ff) Deflectivity Tyre

### Analysis for Reflective Sheeting Warning Signs

For Reflectivity Type RS, there are two levels for each of Course Type and Course Setting. To get a better understanding of the effects of Course Type and Course Setting as well as their joint effect on legibility distance, factors 'Course Type' and 'Course Setting' are combined into a new factor 'Course' with three levels (Closed-Rural, Open-Rural, Open-Urban) for Reflective Sheeting Warning signs. A split-plot model with Age, Reflective Level, and Course as main effects, Age\*Reflective Level and Course\*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is employed.

Tables 103–107 contain the results obtained for each of the five dependent variables (1)– (5) for reflective sheeting warning signs. It can be seen from Tables 6 and 7 that none of Age, Reflective Level, Course, Age\*Reflective, or Course\*Reflective effects were significant at  $\alpha$ =0.05 for Number of Glances as well as for Leg. Glance Duration.

Reflective Level*Course	4	4	74.33	1.1858	0.3241	
Age*Reflective Level	2	2	69.36	2.1618	0.1228	

Due to a very low sample size (n = 28), the above model could not be fitted to Avg. Glance Duration W/O Leg. Instead, the model with Age, Reflective Level, and Course as main effects, Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a random effect was fitted to Avg. Glance Duration W/O Leg (see Table 105). Again, none of Age, Reflective Level, Course, or Age\*Reflective effects were significant at  $\alpha$ =0.05 although Age\*Reflective was significant at  $\alpha$ =0.1. The LS means plot for Age\*Reflective effect (interaction plot) is also provided in Table 105 for information purposes.

## Table 107. Output for the Analysis on Legibility Glance Start Distance for Reflective Sheeting Warning Signs.

### Analysis by Reflective Level (Main Study Factor: Reflectivity Type)

Researchers were also interested in determining if there was a statistically significant difference between the internally illuminated and the reflective sheeting when a reflective level is fixed. Only the data collected on the closed course were used for this test.

#### Analysis for Low Reflective Level Warning Signs

Tables 108–112 contain the results obtained under the model with Age and Reflectivity Type as main factors, Age\*Reflectivity Type as a two-way interaction, and Drivers (nested within Age) as a random effects when Reflective Level is fixed at Low for each of the response variables (1)–(5).

Table 108 shows that there is a significant interaction effect between Age and Reflectivity Type at  $\alpha$ =0.1 (although not at  $\alpha$ =0.05), which suggests that the effect of Reflectivity Type on Number of Glances may be different for Young and Old drivers.

#### Analysis for High Reflective Level Warning Signs

Tables 16–20 contain the results obtained under the model with Age and Reflectivity Type as main factors, Age\*Reflectivity Type as a two-way interaction, and Drivers (nested within Age) as a random effects when Reflective Level is fixed at High.

Table 113 shows that there is a significant interaction effect between Age and Reflectivity Type at  $\alpha$ =0.05, which suggests that the effect of Reflectivity Type of high reflective level warning sign on Number of Glances is different for Young and Old drivers. The Age\*Reflectivity Type interaction plot is also contained in Table 113, which shows that RS leads to a smaller number of glances (compared to II) for old drivers but not for young drivers. The multiple comparison test results are also provided in Table 113.

It was not possible to fit the above model to Avg. Glance Duration without Leg. (sec) due to a very small sample size (n=13). Due to many missing values, there was mostly one measurement for each driver. The ordinary ANOVA with Age and Reflectivity Type as main effects, and Age\*Reflectivity Type as a two-way interaction was employed instead (see Table 115). Again, the factors of Age, Reflectivity Type or Age\*Reflectivity Type were insignificant at  $\alpha$ =0.05.

#### ANALYSIS FOR REGULATORY SIGNS

For regulatory signs, speed limit signs (signs #5, 6, 7, and 9) were tested with high headlight beams, and non-speed limit signs were tested with low headlight beams. The data from the regulatory signs tested with low headlight beams and those with high headlight beams (speed limit signs) are analyzed separately.

#### ANALYSIS FOR REGULATORY SIGNS TESTED WITH LOW HEADLIGHT BEAMS

#### Analysis by Reflectivity Type (Main Study Factor: Reflective Level)

For regulatory signs, Reflectivity Type II (Internally Illuminated) is present only for Course Type=Closed and for Reflective Level=Low or High. To prevent potential confounding between Reflectivity Type and other factors, data are analyzed separately for each level of Reflectivity Type as in warning signs, rather than just ignoring Reflectivity Type in the analysis.

#### Analysis for Internally Illuminated Regulatory Signs

A split-plot model with Age and Reflective Level as main effects, Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a random effect is used for internally illuminated regulatory signs with low headlight beams. Tables 118–122 contain the results obtained by this model. It can be observed from Table 118 that none of the effects, Age, Reflective Level, or Age\*Reflective Level, on Number of Glances were significant at  $\alpha$ =0.05.

#### Analysis for Reflective Sheeting Regulatory Signs

For Reflectivity Type RS (Reflective Sheeting), there are two levels for Course Type and three levels for Reflective Level. A split-plot model with Age, Reflective Level, and Course Type as main effects, Age\*Reflective Level and Course Type\*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is used as an initial model. Tables 124–128 contain the results obtained by this model. It can be observed from Table 124 that only the effect of Course Type on Number of Glances is significant at  $\alpha$ =0.05.

#### Analysis for Regulatory Signs Tested with High Headlight Beams (Speed Limit Signs)

Signs numbered 5, 6, 7, and 9 are analyzed here. These regulatory signs were tested with Course Type=Closed, Course Setting = Rural, Reflectivity Type = Reflective Sheeting, and Letter Height = 10. Reflective Level has two levels: High (corresponding to Signs 5 and 9) and Medium (corresponding to Signs 6 and 7) in this experiment. Researchers were interested in testing whether there is a significant difference between High and Medium reflective levels under high beam headlight illumination. A split-plot model with Age and Reflective Level as main effects, Age\*Reflective Level as a two-way interaction, and Driver nested within Age as a

random effect is fitted to each of five response variables for reflective sheeting regulatory signs tested with high headlight beams. Table 137 shows that none of the effects on Number of Glances were significant at  $\alpha$ =0.05.

#### Analysis for Guide Sign

Guide signs were tested only on the open course with two course setting levels (Rural and Urban). A split-plot model with Age, Reflective Level, and Course Setting as main effects, Age\*Reflective Level and Course Setting \*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is employed for guide signs. Tables 142–145 contain the results of running the Guide Sign model .

Table 142 shows that there is a significant interaction effect between Reflective Level and Age on Number of Glances at  $\alpha$ =0.05, which suggests that the effect of Reflective Level of Guide signs on Number of Glances is somewhat different for different age groups. It seems that Reflective Level does not make a significant difference in Number of Glances for young drivers, but for old drivers high reflective level leads to a smaller number of glances compared to low and medium reflective levels.

There were only seven observations for Avg. Glance Duration W/O Leg. (sec). Due to the extremely small sample size, a reasonable model could not be fitted. Table 144 shows that none of Age, Reflective Level, Course Setting, Age\*Reflective Level, and Course Setting \*Reflective Level effects were significant at  $\alpha$ =0.05 for Total Glance Duration within 40LI for Guide signs.

#### Analysis for Street Name Sign

**Reflective Level** 

Street name signs were all reflective sheeting signs and tested only on the open course with two course setting levels (Rural and Urban). A split-plot model with Age, Reflective Level, and Course Setting as main effects, and Age\*Reflective Level and Course Setting\*Reflective Level as two-way interactions, and Driver nested within Age as a random effect is employed for street name signs. Tables 146–149 contain the results.

Table 146 shows that none of Age, Reflective Level, Course Setting, Age\*Reflective Level, and Course Setting \*Reflective Level effects were significant at  $\alpha$ =0.05 for Number of Glances for Street name signs although the effect of Reflective Level was significant at  $\alpha$ =0.1. The Least Squares Means table and LS means plot were provided for information purposes.

Table 147 shows that there is a significant interaction effect between Reflective Level and Course Setting at  $\alpha$ =0.05, which suggests that the effect of Reflective Level of street name signs on Leg. Glance Duration is different for Rural and Urban course settings. The Reflective Level\*Course Setting interaction plot is also contained in Table 147, which indicates that Leg. Glance Duration for high reflective level leads to significantly longer Leg Glance Duration for rural course setting than for urban course setting while the other reflective levels do not make any significance difference in Leg. Glance Duration between rural and urban course setting. The multiple comparison test results are also provided in Table 147.

Levels not connected by same letter are significantly different.

No reasonable model could be fitted to Avg. Glance Duration W/O Leg. (sec) due to an extremely small sample size (n= 8). Table 148 shows that there is a significant interaction effect

between Reflective Level and Course Setting at  $\alpha$ =0.05, which suggests that the effect of Reflective Level of street name signs on Total Glance Duration is different for Rural and Urban course settings. The Reflective Level\*Course Setting interaction plot is also contained in Table 148, which indicates that Total Glance Duration for high reflective level leads to significantly longer Total Glance Duration for rural course setting than for urban course setting while the other reflective levels do not make any significance difference in Leg. Glance Duration between rural and urban course setting. The multiple comparison test results are also provided in Table 148.
