2004 Urban Mobility Report

Congestion continues to grow in America's urban areas. The 2004 Annual Urban Mobility Report presents details on the trends, findings and what can be done to address the growing transportation problems. Trend data from 1982 to 2002 for 85 urban areas provides both a local view and a national perspective on the growth and extent of traffic congestion.

The 2004 Report provides clear evidence that the time for improvements has arrived. Communicating the congestion levels and the need for improvements is a goal of this report. The decisions about which, and how much, improvement to fund will be made at the local level according to a variety of goals, but there are some broad conclusions that can be drawn from this database.

The complete report, methodology, data, charts and tables can be found at: http://mobility.tamu.edu/ums

Major Findings for 2004 – The Big Numbers

The problem can be stated simply – *congestion has grown everywhere in areas of all sizes.* Congestion occurs during longer portions of the day and delays more travelers and goods than ever before. There are ways to address congestion problems, but there are not enough solutions being implemented to keep pace with the growing travel demands. Some important statistics are shown below.

| Performance Measure | 1982 | 2001 | 2002 |
|--|--------|--------|--------|
| Annual delay per peak traveler (hours) | 16 | 45 | 46 |
| Travel Time Index | 1.12 | 1.36 | 1.37 |
| Number of urban areas with more than 20 hours of delay per peak traveler | 7 | 52 | 52 |
| Number of areas with worse or same congestion as previous year (of the 85 studied) | NA | 69 | 62 |
| Total hours of delay (billion) | 0.7 | 3.4 | 3.5 |
| Total gallons of "wasted" fuel (billion) | 1.2 | 5.4 | 5.7 |
| Cost of congestion (billions of 2002 \$) | \$14.2 | \$61.0 | \$63.2 |
| Congestion occurs on: | | | |
| Percent of peak travel | 32 | 66 | 67 |
| Percent of road system | 34 | 58 | 58 |
| Hours per day | 4.5 | 7.1 | 7.1 |
| Hours of delay saved by | | | |
| Operational treatments (million) | NA | 294 | 335 |
| Public transportation (million) | 271 | 1,084 | 1,120 |
| Congestion costs saved by | | | |
| Operational treatments (billions of 2002 \$) | NA | \$5.4 | \$6.0 |
| Public transportation (billions of 2002 \$) | \$5.3 | \$19.8 | \$20.0 |

NA – No Estimate Available

Pre-2000 data do not include effect of operational strategies and public transportation.

Travel Time Index – The ratio of travel time in the peak period to travel time at free-flow conditions. A TTI of 1.35 indicates a 20-minute free-flow trip takes 27 minutes in the peak.

Delay per Peak Traveler – The extra time spent traveling at congested speeds rather than free-flow speeds divided by the number of persons making a trip during the peak period.

Wasted Fuel – Extra fuel consumed during congested travel.

What's New?

Each year the Urban Mobility Report revises procedures and improves the processes and data used in the estimates. In doing so, the report also revises all previous estimates so that true trends can be developed whenever possible. Some key changes for this year are:

- An increase from 75 to 85 areas studied. The new urban areas mean that all urbanized areas in the U.S. with a population greater than 500,000 and all of the top 70 urbanized population areas are included in the report database.
- Five urbanized areas in the 2003 report were combined into two areas for the 2004 report. The US Census Bureau combined Fort Lauderdale, West Palm Beach and Miami into one urban center of 5.0 million persons and Tacoma was combined with Seattle for a total population of 2.7 million persons.
- The value of truck delay cost is lower than estimated in previous reports, which lowers the total congestion cost. The new values include the efficiencies gained by the trucking industry in the last 20 years, rather than a trend based on the Consumer Price Index.
- Arterial street access management programs were added to the operational treatment list. These elements smooth traffic flow and reduce collisions through a variety of treatments such as deceleration lanes, restricting turns across medians and combining driveways.
- ➤ The operational treatment effects are included for 2000, 2001 and 2002 mobility estimates. The data provide a better picture of the travel conditions in those three years. Unfortunately, the long-term trend analysis does not yet include this information.
- ➤ The delay per traveler measure uses the number of persons beginning their travel using a motorized mode during the peak periods (6 to 9 a.m. and 4 to 7 p.m.). This is a more appropriate mobility measure than the previous delay per capita statistics.
- The Annual Report seeks to provide the best estimate of travel conditions for each year. This year, as in other years, some previous statistics were slightly modified based on better understanding of trends and updated data.

The Problem

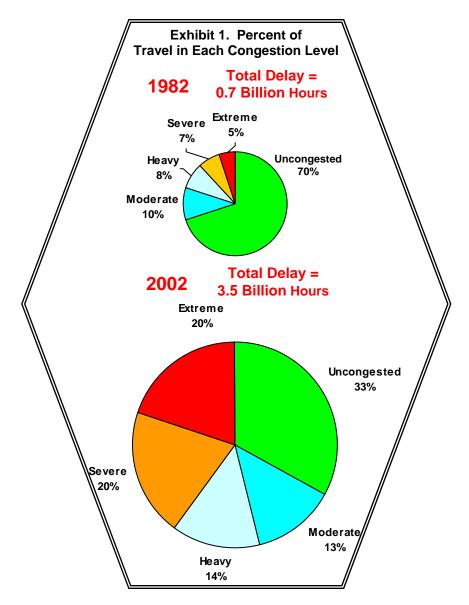

Mobility problems have increased at a relatively consistent rate during the two decades studied. Congestion is present on more of the transportation systems, affecting more of the trips and a greater portion of the average week in urban areas of all sizes.

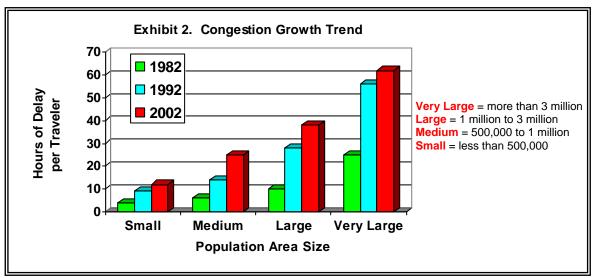

Congestion affects more of the roads, trips and time of day. The worst congestion levels increased from 12% to 40% of peak period travel. And free-flowing travel is less than half of the amount in 1982 (Exhibit 1).

Congestion has grown in areas of every size. Measures in all of the population size categories show more severe congestion that lasts a longer period of time and affects more of the transportation network in 2002 than in 1982. The average annual delay for every person using motorized travel in the peak periods in the 85 urban areas studied climbed from 16 hours in 1982 to 46 hours in 2002 (Exhibit 2).

The delay statistics in Exhibit 2 point to the importance of action. Major projects, programs and funding efforts take 10 to 15 years to develop. In that time, congestion endured by travelers and businesses grow to those of the next largest population group. So in ten years, medium-sized regions will have the traffic problems that large areas have now, if trends do not change.

CAUTION: See http://mobility.tamu.edu/ums for improved performance measures and updated data.

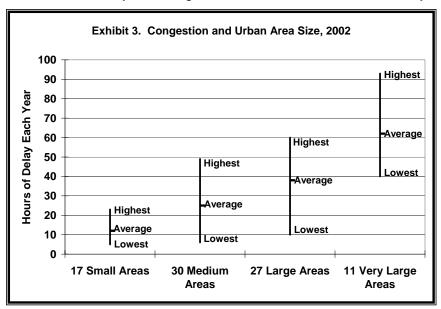

Congestion costs are increasing. The total congestion "invoice" for the 85 areas in 2002 was \$63 billion, an increase from \$61 billion in 2001. The 3.5 billion hours of delay and 5.7 billion gallons of fuel consumed due to congestion are only the elements that are easiest to estimate. The effect of uncertain or longer delivery times, missed meetings, business relocations and other congestion results are not included.

Congestion is more severe in larger areas. Exhibit 3 shows the range of congestion levels for each population size group. It is not surprising that congestion is more severe in larger cities. What might not be expected is the large range of values. Congestion problems occur in many ways. Some congestion is determined by the design of an area, some is determined by

geographic features. weather, collisions and vehicle breakdowns, and some congestion is the result of decisions about investment levels. Likewise, the mobility levels targeted by agencies in each area will vary as well. The answer is not to grade every city. every project and every hour of delay on the same scale, but rather to identify the community goals. benefits, and costs and decide how to reach the mobility targets.

The Solutions

The problem has grown too rapidly and is too complex for only one technology or service to be deployed. A broad range of solutions are recommended to address current problems and meet growing travel demand including:

- more road and public transportation projects
- efficient utilization of current facilities
- managing the demand to avoid peak period travel
- providing land use options that reduce the effect of growth

The increasing trends also indicate the urgency of the improvement need. Major improvements can take 10 to 15 years and smaller efforts may not satisfy all the needs. So we recommend a **balanced approach**—begin to plan and design **major projects, plans or policy changes** while relieving critical **bottlenecks** or chokepoints, and aggressively pursuing **minor capacity** additions, **operations** improvements and **demand** management options that are available.

The solutions will vary not only by the state or city they are implemented in, but also by the type of development, the level of activity and constraints in particular sub-regions, neighborhoods and activity centers. Portions of a city might be more amenable to construction solutions, other areas might use more demand management, efficiency improvements and land use pattern or redevelopment solutions.

The "Solution" is really a diverse set of options that require the commitment of decision-makers, businesses and the public to boost transportation investment levels, as well as a variety of changes in the ways the transportation system is used. The effectiveness of options will vary from area to area, but the growth in congestion over the past 20 years suggests that more needs to be done in the future.

- ➤ More capacity—More road and public transportation improvement projects are part of the equation. Some of the growth in travel demand must be accommodated with new roads and systems and expansions of existing systems. And more capacity is needed to address some of the mobility deficiencies that currently exist (see Exhibit 4).
- ➤ **Greater efficiency**—More efficient operation of roads and public transportation can provide more productivity from the existing system at relatively low cost. Some of these can be accelerated by information technology, some are the result of educating travelers about their options, and some are the result of providing a more diverse set of travel and development options than are currently available.
- Manage the demand—The way that travelers use the transportation network can be modified to accommodate more demand. Using the telephone or internet for certain trips, traveling in off-peak hours and using public transportation and carpools are examples. Projects that use tolls or pricing incentives can be tailored to meet both transportation needs and economic equity concerns. The key will be to provide better conditions and more travel options for shopping, school, health care and a variety of other activities.
- ➤ **Development patterns**—There are a variety of techniques that are being tested in urban areas to change the way that commercial, office and residential developments occur. These also appear to be part, but not all, of the solution. Sustaining the urban "quality of life" and gaining an increment of economic development without the typical increment of mobility decline is one way to state this goal.
- ➤ Realistic expectations are also part of the solution. Large cities will be congested. Some locations near key activity centers in smaller cities will also be congested. But congestion does not have to be an all-day event. Identifying solutions and funding sources that meet a variety of community goals is challenging enough without attempting to eliminate congestion in all locations.

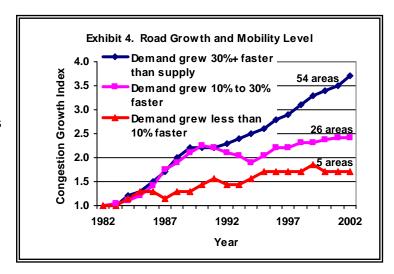

The Benefits of Action

All types of improvement actions are necessary. Without a detailed analysis it is impossible to say which action or set of actions will best meet the corridor or community needs. But, it is important to recognize that actions can make a difference. It is possible to at least slow the growth and in the right circumstances, reduce congestion.

Roadway Capacity Increases

Cities that address the growing travel demand have seen lower delay growth than areas where travel growth greatly exceeds supply growth. Exhibit 4 illustrates that when changes in supply more closely match changes in demand, there is less increase in delay. The three groups were studied using data from 1982 to 2002. The change in miles traveled was compared to the change in lane-miles for each of the 85 urban areas. The change in congestion level was calculated for the following groups:

- Significant mismatch—Traffic growth was more than 30 percent faster than the growth in road capacity for the 54 urban areas in this group.
- Closer match—Traffic growth was between 10 percent and 30 percent more than road capacity growth. There were 26 urban areas in this group.
- Narrow gap—Road growth was within 10 percent of traffic growth for the 5 urban areas in this group.

Additional roadways reduce the rate of increase in the time it takes travelers to make congested period trips. It appears that the growth in facilities has to be at a rate slightly greater than travel growth in order to maintain constant travel times if additional roads are the only solution used to address mobility concerns. It is clear that adding roadway at about the same rate as traffic grows will slow the growth of congestion.

It is equally clear, however, that if only five of the 85 areas studied were able to accomplish that rate, *there must be a broader set of solutions* applied to the problem, as well as more of each solution.

Public Transportation Service

Regular route public transportation service on buses and trains provides a significant amount of peak period travel in the most congested corridors and cities in the U.S. If public transportation service was discontinued and the riders traveled in private vehicles, the 85 urban areas would have suffered an additional 1.1 billion hours of delay in 2002.

Public transportation service provides many additional benefits in the corridors and areas it serves. Access to jobs, shops, medical, school and other destinations for those who do not have access to private transportation may provide more societal benefits than the congestion relief, but this report only examined part of the mobility aspect. Typically, in contrast to roads, the ridership is concentrated in a relatively small portion of the urban area. That is often the most congested area and the locations where additional road capacity is difficult to construct.

In the 85 urban areas studied there were approximately 44 billion passenger-miles of travel on public transportation systems in 2002 (1). The annual travel ranges from an average of 17 million miles per year in Small urban areas to about 3.1 billion miles in Very Large areas. Overall, if these riders did not have access to public transportation systems, the 1.1 billion hours of additional roadway delay would represent a 32 percent increase in delay and an additional congestion cost of \$20 billion. More information on the effects for each urban area is included in Table 3.

- ➤ The Very Large areas would experience an increase in delay of about 915 million hours per year (37 percent of total delay) if there were no public transportation service. Most of the urban areas over 3 million population have significant public transportation ridership, extensive rail systems and very large bus systems.
- ➤ The Large urban areas would experience the second largest increase in delay with about 180 million additional hours of delay per year if public transportation service were not available.

Exhibit 5. Delay Increase if Public Transportation Service Were Eliminated – 85 Areas

| | Average Annual | Delay Reductio | n Due to Public | Transportation |
|---|-------------------------------------|--------------------------|--------------------------|----------------------------|
| Population Group and Number of Areas | Passenger-Miles of Travel (million) | Hours of Delay (million) | Percent of Base Delay | Dollars Saved (million \$) |
| Very Large (11) | 3,143 | 913 | 37 | 16,353 |
| Large (27) | 265 | 179 | 17 | 3,197 |
| Medium (30) | 59 | 26 | 9 | 466 |
| Small (17) | 17 | 2 | 5 | 33 |
| 85 Area Total | 43,791 | 1,120 | 29 | 20,049 |

Source: APTA Operating Statistics and TTI Review

High-Occupancy Vehicle Lanes

High-occupancy vehicle lanes (also known as diamond lanes, bus and carpool lanes, transitways) provide a high-speed travel option to buses and carpools as an incentive to reduce the number of vehicle trips. The lanes are most used during the peak travel periods when congestion is worst and the time savings compared to the general travel lanes are the most significant. In addition to saving time on an average trip, the HOV lanes also provide more reliable service because they are less affected by collisions or vehicle breakdowns.

The Urban Mobility Report includes estimates of the mobility improvements provided by HOV lanes in eight regions where detailed project data are available. Because HOV lane travel is not included in the basic freeway statistics, the person miles traveled and the travel time can be added directly to the mobility measures. The effect of this is to create an estimate of the mobility level provided to the combination of travelers in the slow speed freeway lanes and the higher speed HOV lanes. While only a partial list of HOV projects are included in the current study database (see http://mobility.tamu.edu/ums/hov), it provides a way to understand the measures and the mobility contribution provided by HOV facilities.

Data for the 19 significantly congested corridors studied showed a median decline of 0.20 for the Travel Time Index measure. This involved comparing the mainlane freeway congestion levels and the combined freeway and mainlane value. This is equivalent to 10 to 15 years worth of congestion growth in the average area. These HOV lanes carry one-third of the peak-direction passenger load, providing significant passenger movement at much higher speeds and with more reliable travel times than the congested mainlanes.

Operational Treatments

The 2004 Urban Mobility Report includes the effect of four technologies or treatments designed to gain more benefits from the existing infrastructure (2). These four techniques provide smoother and more regular traffic flow, which also reduces collision rates and the effect of vehicle breakdowns. Freeway entrance ramp metering, freeway incident management, traffic signal coordination and arterial street access management were estimated to provide 335 million hours of delay reduction and \$6 billion in congestion savings for the 85 cities studied with 2002 data. If these treatments were deployed on all the major roads in every area, an estimated 700 million hours of delay and more than \$12 billion would be saved.

Freeway Entrance Ramp Metering

Entrance ramp meters regulate the flow of traffic on freeway entrance ramps using traffic signals similar to those at street intersections. They are designed to create more space between entering vehicles so those vehicles do not disrupt the mainlane traffic flow. The signals allow one vehicle to enter the freeway at some interval (for example, every two to five seconds). They also reduce the number of entering vehicles due to the short distance trips that are encouraged to use the parallel streets to avoid the ramp wait time (3).

Twenty-three of the urban areas reported ramp metering on some portion of their freeway system in 2002 (4,5) for a total of 17 percent of the freeway miles. The effect was to reduce delay by 101 million person hours, approximately 5 percent of the freeway delay in those areas.

Freeway Incident Management Programs

Freeway Service Patrol, Highway Angel, Highway Helper, The Minutemen and Motorists Assistance Patrol are all names that have been applied to the operations that attempt to remove crashed and disabled vehicles from the freeway lanes and shoulders. They work in conjunction with surveillance cameras, cell phone reported incident call-in programs and other elements to remove these disruptions, decrease delay and improve the reliability of the system. The benefits of these programs can be significant. Benefit/cost ratios from the reduction in delay between 3:1 and 10:1 are common for freeway service patrols (6). An incident management program can also reduce "secondary" crashes—collisions within the stop-and-go traffic caused by the initial incident. The range of benefits is related to traffic flow characteristics as well as to the aggressiveness and timeliness of the service.

Seventy areas reported one or both treatments in 2002, with the coverage representing from 31 percent to 63 percent of the freeway miles in the cities (4,5). The effect was to reduce delay by 170 million person hours, approximately 7 percent of the freeway delay in those areas.

Traffic Signal Coordination Programs

Traffic signal timing can be a significant source of delay on the major street system. Much of this delay is the result of managing the flow of intersecting traffic, but some of the delay can be reduced if the traffic arrives at the intersection when the signal is green instead of red. This is difficult in a complex urban environment, and when traffic volumes are very high, coordinating the signals does not work as well due to the long lines of cars already waiting to get through the intersection in both directions.

All 85 areas reported some level of traffic signal coordination in 2002, with the coverage representing slightly over half of the street miles in the cities (4,5). Signal coordination projects have the highest percentage treatment within the cities studied because the technology has been proven, the cost is relatively low and the government institutions are familiar with the implementation methods. The effect of the signal coordination projects was to reduce delay by 18 million person hours, approximately one and one-half percent of the street delay. While the total effect is relatively modest, the cost is relatively low and the benefits decline as the system becomes more congested. The modest effect does not indicate that the treatment should not be implemented—why should a driver encounter a red light if it were not necessary?

Arterial Street Access Management Programs

Providing smooth traffic flow and reducing collisions are the goal of a variety of individual treatments that make up a statewide or municipal access management program. Typical treatments include consolidating driveways to minimize the disruptions to traffic flow, median turn lanes or turn restrictions, acceleration and deceleration lanes and other approaches to reduce the potential collision and conflict points. Such programs are a combination of design standards, public sector regulations and private sector development actions.

Eighty-three areas reported characteristics of an access management treatment in 2002, with the coverage representing just less than 40 percent of the major street miles in the cities $(\underline{4},\underline{5})$. The effect was to reduce delay by 46 million person hours, approximately 3.6 percent of the street delay in those areas.

Operational Treatment Summary

Estimating the effect of a few operational projects on urban area congestion levels with a "national default value" sort of analysis may not be a particularly useful exercise. This type of methodology misses the importance of addressing the operating bottlenecks in the system and do not accommodate the benefits from exceptionally aggressive operating practices or policies aimed at congested locations. Recognizing these shortcomings, the information suggests that 9 percent of the roadway delay is being addressed by these four operational treatments for a total of 335 million hours in 2002 (Exhibit 6). And if the treatments were deployed on all major freeways and streets, the benefit would expand to about 18 percent of delay. These are significant benefits, especially since these techniques can be enacted much quicker than significant roadway or public transportation system expansions can occur. But the operational treatments do not replace the need for those expansions.

Exhibit 6. Operational Improvement Summary

| | _ | ion from Current ojects | Possible Delay Reduction if |
|----------------------|-----------------------|----------------------------|--|
| Operations Treatment | Hours Saved (million) | Dollars Saved (million \$) | Implemented on All Roads (million hours) |
| Ramp Metering | 101 | 1,814 | 322 |
| Incident Management | 170 | 3,031 | 239 |
| Signal Coordination | 18 | 315 | 36 |
| Access Management | 46 | 826 | 103 |
| TOTAL | 335 | 5,986 | 700 |

Note: This analysis uses nationally consistent data and relatively simplistic estimation procedures. Local or more detailed evaluations should be used where available. These estimates should be considered preliminary pending more extensive review and revision of information obtained from source databases.

Other Actions

Most large city transportation agencies are pursuing all of these strategies as well as others. The mix of programs, policies and projects may be different in each city and the pace of implementation varies according to overall funding, commitment, location of problems, public support and other factors. It also seems that big city residents should expect congestion for 1 or 2 hours in the morning and in the evening. The agencies should be able to improve the performance and reliability of the service at other hours and they may be able to slow the growth of congestion, but they cannot expand the system or improve the operation rapidly enough to eliminate congestion.

Methodology

The base data for the 2004 Annual Report come from the states and the US Department of Transportation (4,5). The travel and road inventory statistics are analyzed with a set of procedures developed from computer models and empirical studies. The travel time and speed estimation process is described at: http://mobility.tamu.edu/ums/report/methodology.stm

The methodology creates a set of "base" statistics developed from traffic density values. The density data – daily traffic volume per lane of roadway -- is converted to average peak-period speed using a set of estimation curves based on relatively ideal travel conditions—no crashes, breakdowns or weather problems for the years 1982 to 2002.

The "base" estimates, however, do not include the effect of many transportation improvements. The 2004 Report addresses this estimation deficiency with methodologies designed to identify the effect of operational treatments and public transportation services. The delay, cost and index measures for 2000, 2001 and 2002 include these treatments and identify them as "with strategies." The national datasets do not, however, include deployment information for other years and the trend information will not be compatible with the decade of the 1990s when many areas began investing in operational treatments. While this currently does not provide a long-term trend analysis of the true "on the ground" conditions, the project database will be expanded in coming years. The effects of public transportation are shown for every year since 1982.

The calculation details for estimating the effect of operational treatments and public transportation service are described in a separate report available at http://mobility.tamu.edu/ums/report/volume_2.stm Operational treatment estimates are calculated from national statistics and computer modeling techniques based on the effects of implemented projects (4,5,7). Public transportation service effects are estimated for 1982 to 2002 based on national ridership statistics (1) and assumptions about the effect of eliminating the service and placing travelers in the general purpose lanes.

Combining Performance Measures

The congestion problem has many dimensions and no single performance measure or statistic has been developed to illustrate all of them. Urban regions large and small are also pursuing different combinations of improvement strategies that are evaluated with different measures. Urban area population, as depicted in Figure 3, also has an affect on the amount and intensity of congestion and on the scale of improvements that might be implemented. The Urban Mobility Report, therefore, has several measures to assess mobility solutions or congestion problems.

Table 6 illustrates an approach to understanding several of the key measures. The value for each statistic is rated according to the relationship to the average value for the population group. The terms "higher" and "lower" than average congestion are used to characterize the 2002 values. The change in values since 1982 is described as "faster" or "slower" growth in congestion. These descriptions do not indicate any judgment about the extent of mobility problems. Cities that have better than average rankings may have congestion problems that residents consider significant. What Table 6 does, however, is provide the reader with some context for the mobility discussion.

The intervals used in Table 6 are tied to the authors' estimate of discernible differences in the data. Large urban areas differences of less than five hours of delay per peak traveler, for example, may not have significantly different congestion levels. The national averages and "one-size-fits-all" methodology used in the Annual Report, combined with variations in traffic and data collection practices, make it difficult to say that congestion statistics within these ranges indicate a real difference in mobility.

Very Large Urban Areas—over 3 million population.

Large Urban Areas—over 1 million and less than 3 million population.

Annual Delay per Traveler – Extra travel time for peak period travel during the year divided by the number of travelers who begin a trip during the peak period (6 to 9 a.m. and 4 to 7 p.m.). Free-flow speeds (60 mph on freeways and 35 mph on principal arterials) are used as the comparison threshold.

Travel Time Index – The ratio of travel time in the peak period to the travel time at free-flow conditions. A value of 1.35 indicates a 20-minute free-flow trip takes 27 minutes in the peak

2002 values include the effects of operational treatments.

Table 1. Key Mobility Measures, 2002, Continued

Medium Urban Areas—over 500,000 and less than 1 million population. Small Urban Areas—less than 500,000 population.

Annual Delay per Traveler – Extra travel time for peak period travel during the year divided by the number of travelers who begin a trip during the peak period (6 to 9 a.m. and 4 to 7 p.m.). Free-flow speeds (60 mph on freeways and 35 mph on principal arterials) are used as the comparison threshold.

Travel Time Index – The ratio of travel time in the peak period to the travel time at free-flow conditions. A value of 1.35 indicates a 20-minute free-flow trip takes 27 minutes in the peak.

2002 Values include the effects of operational treatments.

Very Large Urban Areas—over 3 million population.

Large Urban Areas—over 1 million and less than 3 million population.

Travel Delay – Travel time above that needed to complete a trip at free-flow speeds.

Excess Fuel Consumed – Increased fuel consumption due to travel in congested conditions rather than free-flow conditions.

Congestion Cost – Value of travel time delay (estimated at \$13.45 per hour of person travel and \$71.05 per hour of truck time) and excess fuel consumption (estimated using state average cost per gallon).

2002 Values include the effects of operational treatments.

Very Large Urban Areas—over 3 million population.

Large Urban Areas—over 1 million and less than 3 million population.

Operational Treatments – Freeway incident management (i), freeway ramp metering (r) arterial street signal coordination (s) and arterial street access management (a).

Public Transportation – Regular route service from all public transportation providers in an urban area.

Delay savings are affected by the amount of treatment or service in each area, as well as the amount of congestion and the urban area population.

Medium Urban Areas—over 500,000 and less than 1 million population.

Small Urban Areas—less than 500,000 population.

Operational Treatments – Freeway incident management (i), freeway ramp metering (r) arterial street signal coordination (s) and arterial street access management (a).

Public Transportation – Regular route service from all public transportation providers in an urban area.

Delay savings are affected by the amount of treatment or service in each area, as well as the amount of congestion and the urban area population.

Very Large Urban Areas—over 3 million population.

Large Urban Areas—over 1 million and less than 3 million population.

Annual Delay per Traveler – Extra travel time for peak period travel during the year divided by the number of travelers who begin a trip during the peak period (6 to 9 a.m. and 4 to 7 p.m.). Free-flow speeds (60 mph on freeways and 35 mph on principal arterials) are used as the comparison threshold.

2001 and 2002 data include the effects of operational treatments.

Very Large Urban Areas—over 3 million population.

Large Urban Areas—over 1 million and less than 3 million population.

Travel Time Index – The ratio of travel time in the peak period to the travel time at free-flow conditions. A value of 1.35 indicates a 20-minute free-flow trip takes 27 minutes in the peak. Free-flow speeds (60 mph on freeways and 35 mph on principal arterials) are used as the comparison threshold.

2001 and 2002 data include the effects of operational treatments.

Medium Urban Areas—over 500,000 and less than 1 million population.

Small Urban Areas—less than 500,000 population.

Travel Time Index – The ratio of travel time in the peak period to the travel time at free-flow conditions. A value of 1.35 indicates a 20-minute free-flow trip takes 27 minutes in the peak. Free-flow speeds (60 mph on freeways and 35 mph on principal arterials) are used as the comparison threshold.

2001 and 2002 data include the effects of operational treatments.
