<b>16. Abstract</b> This study evaluates the effectiveness of utilizing remotely sensed three-dimensional (3D) spatial data, including Light Detection and Ranging (lidar) and Interferometric Synthetic Aperture Radar (InSAR) for interpreting change detections of eastern Ohio (Districts 5, 10, and 11) landslides. The performance of lidar methods used by specialty firm Teren were evaluated for their ability to detect 99 inventoryed landslides, relative to field inspection surveys. The performance of InSAR methods used by specialty firm EO59 were evaluated for their ability to detect a subset of 15 inventoryed landslides, relative to field inspection surveys. Four selected case studies are detailed to showcase the performance of these methods. Ultimately this work is anticipated to support the potential adoption of remote sensing technologies to supplement or substitute current ODOT landslide inventory field surveys. Our research team believes that in the near-term, the integration of lidar-based approaches with the landslide inventory can potentially increase landslide detection reliability and reduce overall costs. InSAR may additionally be considered for either indicating subtle movements for lower risk landslides, or frequently monitoring movements of higher risk landslides.

# **CHAPTER 1: INTRODUCTION**

## **1.1 Scope of Work**

The Ohio Department of Transportation (ODOT) is interested in evaluating the effectiveness of utilizing remotely sensed three-dimensional (3D) spatial data, including Light Detection and Ranging (lidar) and Interferometric Synthetic Aperture Radar (InSAR) for interpreting change detections of eastern Ohio (Districts 5, 10, and 11) landslides. Approximately 80% of the over 8,300 landslides due for re-inspection during Fiscal Year 2023 were characterized as being lower risk (i.e., Tier 1; out of 4) during their last inspection. However, approximately 10% of landslides that were inspected in Fiscal Year 2022 were found to have progressed to a higher risk tier since their preceding inspection. These observations highlight the increasing risks of landslides in eastern Ohio and the need for more efficient and objective techniques to supplement field inspection efforts by ODOT for their evaluation.

The objective of this project is to evaluate the capabilities of lidar and InSAR change detection methods for interpreting a subset of inventoried landslides relative to ODOT risk categories, Tiers 1-4, which are currently determined from on-site field inspections.

The project goals are:

1. Perform a field visit to understand typical field inspection approaches used by ODOT for characterizing landslides.
2. Evaluate the capabilities and the performance of the lidar methods used by specialty firm Teren to detect a subset of 99 inventoried landslides, relative to field inspection surveys.
3. Evaluate the capabilities and the performance of the InSAR methods used by specialty firm EO59 to detect a subset of 15 inventoried landslides, relative to field inspection surveys.
4. Interpret and describe key case studies that showcase the comparative performance of the lidar and InSAR methods.
5. Discuss the relative advantages and limitations of the proposed remote sensing methods for interpreting landslide occurrence and their impact to ODOT structural assets.
6. Provide recommendations for the potential adoption of these technologies to supplement or substitute current ODOT landslides inventory approaches for risk Tier determination.

## **1.2 Outline of the Report**

Chapter 2 provides a brief background of landslide hazards in eastern Ohio, a summary of current ODOT landslide inventory approaches, and a literature review regarding the current state of practice and research for the adoption of lidar and InSAR methods for landslide inventory updating.

Chapter 3 describes the data availability, processing, and results obtained by Teren and EO59. Teren's dataset was obtained near 99 selected inventoried landslides. Teren's results are separated into two components: (1) the “geohazard polygon” detection and ranking system as

obtained from lidar scans at a single epoch (i.e., one instance of time), and (2) the “change detection polygons” obtained from the comparison of two epochs. EO59’s dataset is provided as series of Persistent Scatterer (PS) time series points obtained from Advanced Differential InSAR (A-DInSAR) near 15 of the 99 selected inventoried landslides.

Chapter 4 presents general comparisons of the results from the lidar geohazard detections, lidar change detections, and A-DInSAR derived PSs. Four selected case studies are detailed to showcase the performance of these methods.

Chapter 5 presents a bulleted list describing some of the key relative advantages and limitations of the proposed remote sensing methods for interpreting landslide occurrence and their impact to ODOT structural assets.

Chapter 6 presents the conclusions and recommendations from this work.

Appendix A includes the most relevant details used in this study for the 99 selected inventoried landslides. Appendix B includes a field summary report for a site visit conducted on May 10, 2023 that included 13 inventoried landslide sites of varying risk Tiers. Appendices C and D include resources and presentations provided by Teren and EO59, respectively, which were considered for interpreting their provided datasets.

## **CHAPTER 2: BACKGROUND**

### **2.1 Landslides in Eastern Ohio**

Although the occurrence of landslides is generally rare in much of Ohio, the eastern portion of the state is characterized by hilly terrain that poses a landslide risk along Ohio roadways. The most prevalent outcropping geologic units in eastern Ohio are the Pennsylvanian-age Conemaugh and Monongahela groups, and the Permian-age Dunkard group (e.g., Fisher et al. 1968, Hansen 1995). Weak shales and mudstones known as “red beds” are abundant within these geologic units. The red beds are highly susceptible to weathering and strength loss when saturated with water (Schumacher et al. 2013). Slip failures along these red beds account for about 85% of landslides in eastern Ohio (Hansen 1995).

The most common types of landslides in eastern Ohio are rotational slides and flows (Fisher et al. 1968). Rotational slides are characterized as a large moving mass of sediment along a curved failure surface, exhibiting zones of rupture (scarp) and depressions along the crest of the slide and bulging at the toe of the slide. The rate of movement of a rotational slide can vary significantly. Flows are relatively smaller and often slower downslope movements consisting of mixed sediments displacing in a viscous manner with inconsistent shear surfaces. Other landslides in Ohio may occur as translational slides, lateral spreads, or complex slides (e.g., a combination of the mechanisms mentioned). Only debris (coarse-grained soils) and earth (fine-grained soils) landslides are considered here-in; not rock slides. Landslides in Ohio are often caused by over-steepened slopes due to erosion or construction activities, increased weight due to rain and meltwater or construction activities, increased soil pore pressures due to rain infiltration, and removal of vegetation.

### **2.2 Current ODOT Landslide Inventory**

The ODOT landslide inventory (ODOT 2023a) was first developed by the Office of Geotechnical Engineering (OGE) in 2007 to identify and characterize potential landslide hazards along state roadways, assess their relative risks, and establish monitoring and mitigation protocols. The ODOT Landslide Dashboard database (ODOT 2023b) lists 10,263 active landslides at the time of this report, with 139 new landslides added to the database over the past year. The level of data collection and the re-inspection frequency for each landslide site depends on their assigned risk Tier.

The risk Tier is determined according to observed landslide characteristics and professional judgement from field inspections per the landslide inventory manual. Each soil slope is particularly evaluated based on two criteria: (1) the probability of additional movement of the slope (i.e., an occurrence score of 1 to 4), and (2) the probability of significant impact to an ODOT asset or adjacent property or feature (i.e., an impact score of 1 to 4). The product of the occurrence and impact scores provides a Tier Determination Score of 1 to 16, that is then translated to an overall risk Tier of 1 to 4 according to Table 1.

The level of data collection during the field inspection then proceeds according to the assigned Tier. Tier 1 data collection includes photographic documentation, estimation of the slide

geometry (e.g., depth, height, slope angle, length), progression since last inspection, as well as past remediation, maintenance, and accidents. Tier 2 sites additionally require details regarding the geometric and traffic data, type of landslide movement, rate of movements, possible cause of landslide, impact to assets, soil origin and type, and measurements of roadway cracks and dips. Tier 3 and 4 sites additionally require the collection of hydrological data, including the presence of groundwater or surface water, or other potential hydraulic maintenance issues.

**Table 1.1.** Tier based on Tier Determination Score (ODOT 2023a)

Tier Determination Score	Tier Action
1 or 2	<b>Tier 1 Site</b> No Detailed Rating Needed
3 or 4	<b>Tier 2 Site</b> Detailed Rating Needed
6, 8, or 9	<b>Tier 3 Site</b> Detailed Rating Needed
12 or 16	<b>Tier 4 Site</b> Detailed Rating Needed

The Landslide Dashboard (ODOT 2023b) currently indicates that of the total active landslide sites, 80.1% are Tier 1, 12.5% are Tier 2, 6.8% are Tier 3, and 0.4% (or 39 landslides) are Tier 4. Tier 1 sites are re-inspected every 5 years, Tier 2 sites are re-inspected every 3 years, Tier 3 sites are re-inspected every 2 years, and Tier 4 sites are re-inspected annually. However, field inspections require significant resources to keep up with this pace. Over 75% of the sites are due for re-inspection according to current estimates in the dashboard.

## 2.3 Landslide Inventories from Lidar

Airborne laser scanning with lidar has been widely used for the characterization, detection, hazard assessment, modeling, and monitoring of landslides (e.g., Jaboyedoff et al. 2012). In recent years, several US state agencies have considered the use of static (i.e., at a single epoch) lidar digital elevation models (DEMs) as well as change detections from repeat lidar scans for landslide inventory mapping.

One of the early lidar-based protocols for landslide inventory mapping was developed by the Oregon Department of Geology and Mineral Industries (DOGAMI) in cooperation with United States Geological Survey (USGS) (e.g., Burns and Madin 2009). Their methodology involved obtaining spatial and tabular data from a lidar-derived DEM at a single epoch, in combination with other data (e.g., previously mapped landslides, air photos), to identify and characterize landslides throughout Oregon. This protocol has also been adopted by the Washington Geological Survey (WGS 2023). Another study by DOGAMI (Burns et al. 2010) found that change detections from two lidar-derived DEMs (with 0.5 m pixel resolution, taken 3 months apart) during leaf-off (i.e., winter) and leaf-on (i.e., spring) conditions, was less useful for mapping landslides. The accuracy of change detections depended on the use of a detection threshold of 1 to 1.5 times the pixel resolution to remove noise, a spatial pattern recognition algorithm relating grouped detections to expected slope movement, and supplemental satellite imagery. The change detections were also affected by heavy vegetation in the leaf-on DEMs.

As indicated by the Burns et al. (2010) study, change detections using lidar can be interpreted using various approaches and algorithms, and can be prone to several uncertainties. A study by Mora et al. (2018) correctly identified 53 out of 80 inventory mapped landslides near Zanesville, Ohio using probabilistic vertical change detections and support vector machine (SVM) classifications of surface features based on airborne lidar-derived DEMs between 2008 and 2012. This study highlighted the need to consider uncertainty due to both the data source (e.g., lidar data acquisition) and the data preparation (e.g., interpolation of the DEMs). The different parametric choices made in the development of such an algorithm can also pose a bias relative to the type of landslide movement (e.g., rotational slides, translational slides, debris flows). More recently, a USGS study considered lidar change detections for mapping landslides before and after a major 2012 storm in northeast Minnesota (Delong 2022; full study is currently under review). This study used an object-based image analysis (OBIA) approach that combined the elevation changes with optical imagery and DEM-derived attributes (e.g., slope aspect, spatial extent) to delineate landslides. The North Dakota Geological Survey has also recently begun using lidar change detections coupled with geological interpretations for inventory updating (Maike 2023).

These studies indicate the general acceptance of lidar DEMs, and the growing use of lidar change detections, for improving landslide inventory mapping efforts. However, this past work also suggests that lidar change detections are influenced by errors and uncertainties, and need to be supplemented with additional data or interpretations. Finally, it should be noted that with improving spatial resolution, lidar offers better capabilities to detect smaller surface changes as well as better shape recognition.

## 2.4 Landslide Inventories from InSAR

InSAR has been widely used for the evaluation of landslides over the past two decades. InSAR encompasses a large variety of satellite image sources, and can be used for various landslide applications, including back-analysis of failures, characterization, input for modeling, inventory updating, mapping, and monitoring (Solari et al. 2020). Multiple satellite constellations from various space agencies are available, the most common of which use C-band (5.5 cm wavelength) or X-band (3.1 cm wavelength) data. The Sentinel-1 C-band satellite, with a ground sampling distance (GSD) resolution of about 5 to 20 m and 12-day data collection intervals, has become widely used due to its open-access availability. The Italian-based COSMO-SkyMed X-band satellite with a resolution of about 3 m has shown great improvements for landslide detection. Additionally, the NASA-ISRO Synthetic Aperture Radar (NISAR) L-band and S-band satellite, expected to launch in 2024, will provide open-access 3 to 10 m resolution data (e.g., Hlepas et al. 2023).

Multiple InSAR techniques have been deployed for various landslide activities, from event-driven landslides, such as those following the 2016 Kaikoura, New Zealand earthquakes (e.g., Jelenek and Kopackova 2021), to slow moving landslides and coastal subsidence processes, such as in the Calabria region of Italy (e.g., Cigna and Tapete 2021). Over 250 research papers regarding various InSAR techniques for landslide evaluations in Italy alone have been recently published, 15% of which are concerned with landslide inventory updating (Solari et al. 2020). Italy has become a testing ground for such work due to its high propensity for landslides, large

number of Italian-based InSAR providers and research centers, and other factors. One such work by Antonielli et al. (2019), the methodology of which is of greatest relevance to this current study, used A-DInSAR with both C-band (i.e., Envisat) and X-band (i.e., COSMO-SkyMed) data to suggest updates to the activity of 18 out of 26 inventoried landslides within the heavily forested Lombardy region. Their work also pointed to the ability of X-band data to retrieve over 10 times as many coherent persistent scatterer (PS) points relative to C-band data, and the importance of the satellite line of sight (LOS) relative to the slope orientation.

To the awareness of the authors, InSAR methods have not been adopted by US state agencies for landslide inventory purposes. Recent work by the Southern Methodist University and the USGS evaluated change detections between pairs of L-band InSAR images, coupled with optical imagery and high-resolution DEMs, to delineate 588 non-inventoried landslides along the US west coast (Xu et al. 2021). The datasets and processing techniques used by that study are greatly different than those used for this current study but serve a similar purpose. There is still no state-of-practice for the use of the InSAR for landslide inventory updating. As higher-resolution data becomes more widely accessible, the use of InSAR datasets for landslide inventories is expected to improve and become more well-accepted.

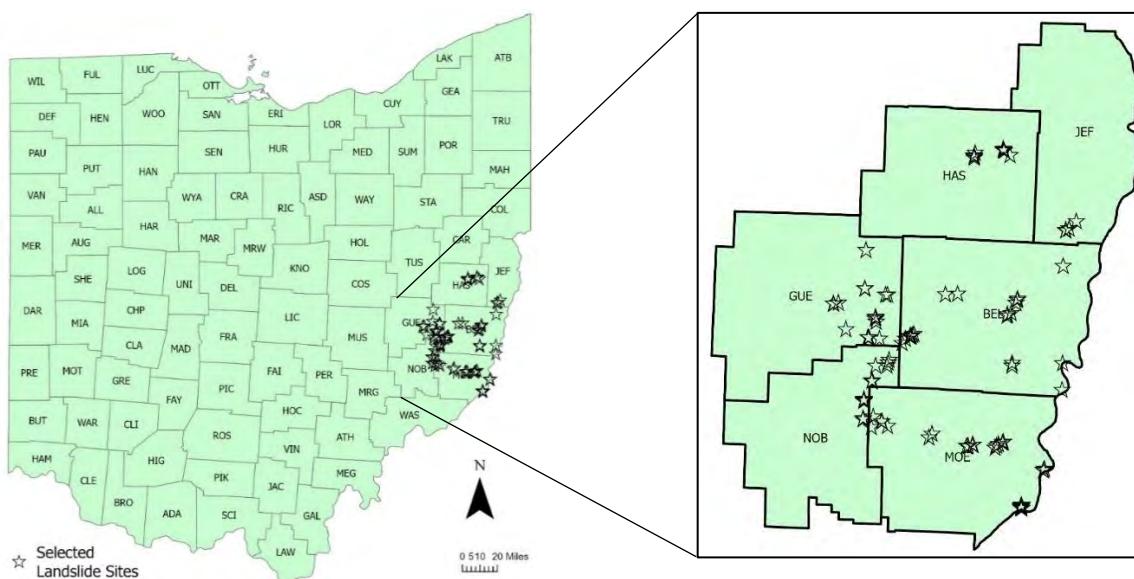

## CHAPTER 3: DATA PROCESSING AND FINDINGS FROM LIDAR AND INSAR

### 3.1 General

A total of 99 landslide sites from the ODOT inventory were selected by ODOT for this work. These sites were geospatially processed using two remote sensing sources: (1) Light Detection and Ranging (lidar) and (2) Interferometric Synthetic Aperture Radar (InSAR). All 99 sites were evaluated by lidar, and a subset of 15 sites were evaluated with InSAR. Details about the distribution of selected landslide sites and data collected and processed from these two sources are discussed in this chapter.

### 3.2 Selected Landslide Sites for this Study

The landslide inventory data selected for this study comprises 99 sites in eastern Ohio from 6 different counties (i.e., Guernsey, Monroe, Jefferson, Noble, Belmont, and Harrison). Data pertaining to these sites has been documented following multiple field surveys over the past several years and added to ODOT landslide inventory (ODOT 2023a; more details in section 2.2). Figure 3.1 shows the selected 99 sites in eastern Ohio. These sites display a range of landslide types, Tier scores, remediation status, landslide extent (area, height, slope angle) and movements. A succinct description of the most pertinent landslide features is presented in this section to clarify the provided ODOT inventory data.

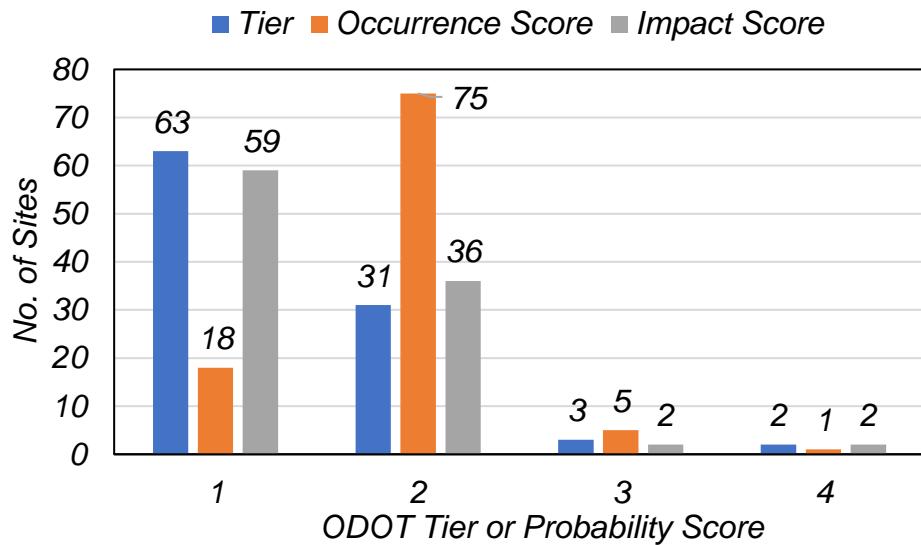

**Figure 3.1.** Selected landslide sites in eastern Ohio.

#### 3.2.1 Tier Scores

The risk Tier classification in the ODOT inventory is determined from two probability scores accounting for: (1) the probability of additional movement of the slope (i.e., an occurrence score of 1 to 4), and (2) the probability of significant impact to an ODOT asset or adjacent property or

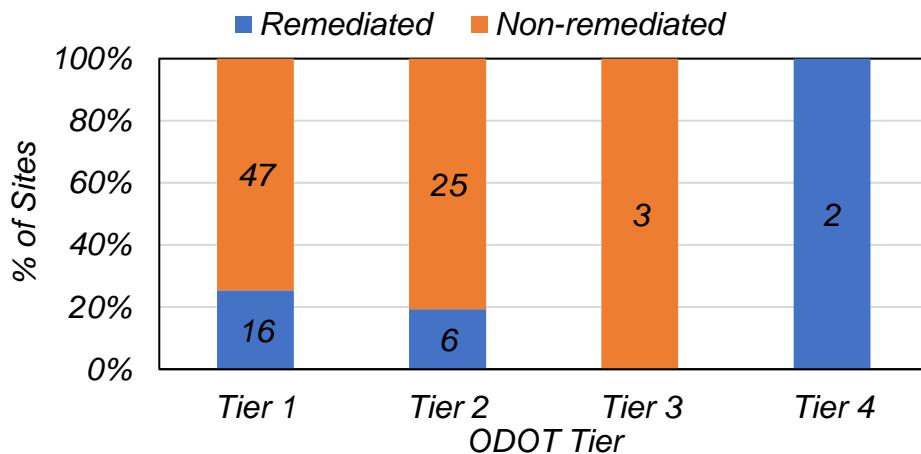

feature (i.e., an impact score of 1 to 4). These probability scores are index values based on observed landslide characteristics and professional judgement from field inspections. Higher probability scores denote a higher probability or susceptibility for that factor. These are combined into the overall Tier as described in Section 2.2. Figure 3.2 shows a bar chart depicting the overall Tier classification and probability scores for the 99 selected sites.

**Figure 3.2.** Distribution of Tiers and probability scores for the 99 selected sites.

### 3.2.2 Remediation

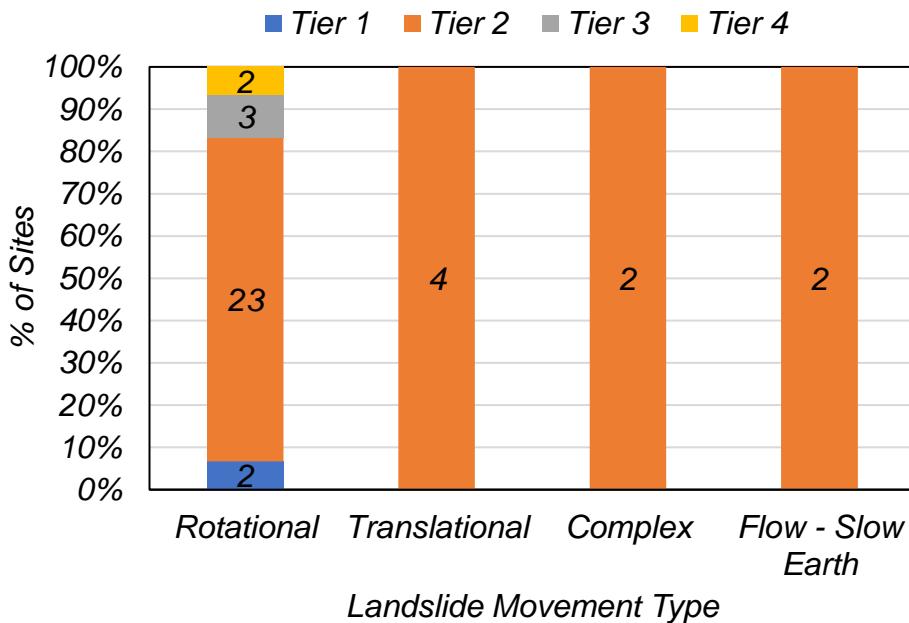

The distribution of remediated and non-remediated sites relative to the ODOT Tier is shown in Figure 3.3. Twenty-four of the study sites were remediated. Remediation measures (e.g., retaining walls, H-pile walls, rock blankets) were performed prior to the study period (Fall 2020) in most cases.

**Figure 3.3.** Distribution of Tiers and remediation status (Note: the numbers on bars represent the total landslide count).

### **3.2.3 Landslide Type**

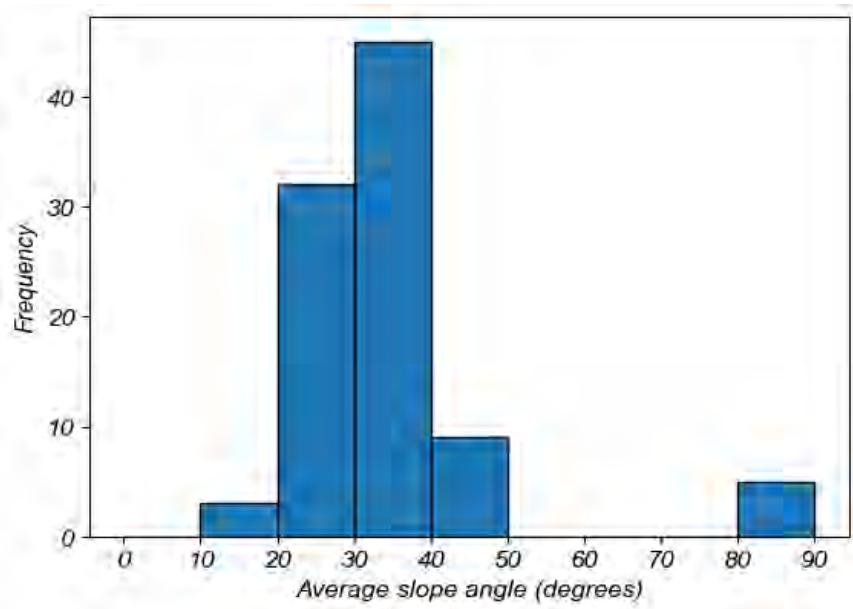

Out of 99 sites only 38 sites have details about the type of landslide movement (i.e., this was typically not recorded for Tier 1 sites). Figure 3.4 shows the distribution of landslide type compared to the ODOT Tier. Only sites above Tier 1 include landslide movement information with few exceptions. The majority of landslides in the dataset are caused by rotational movements.

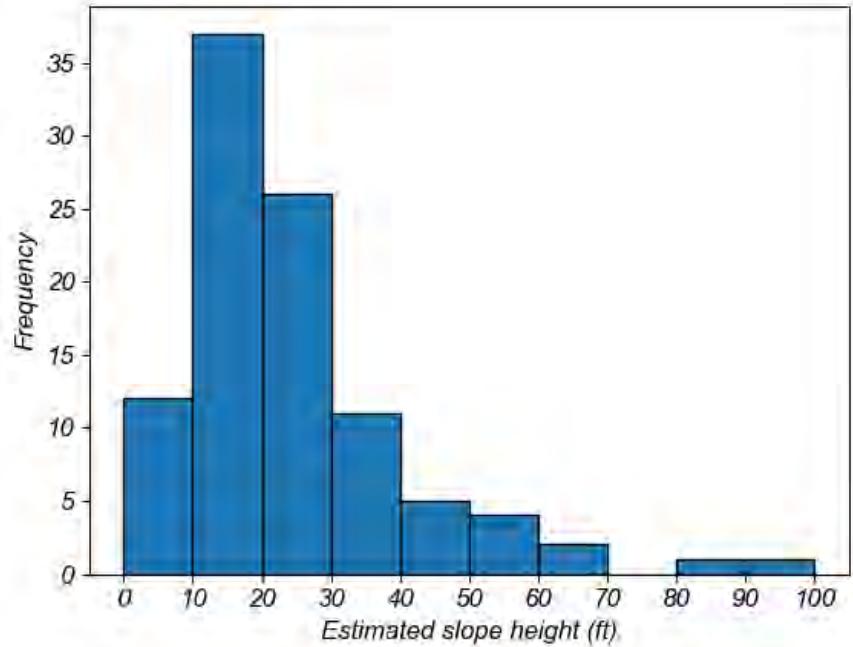

**Figure 3.4.** Distribution of landslide movement type for the 99 selected sites (Note: the numbers on bars represent the total landslide count).

### **3.2.4 Landslide Extent**

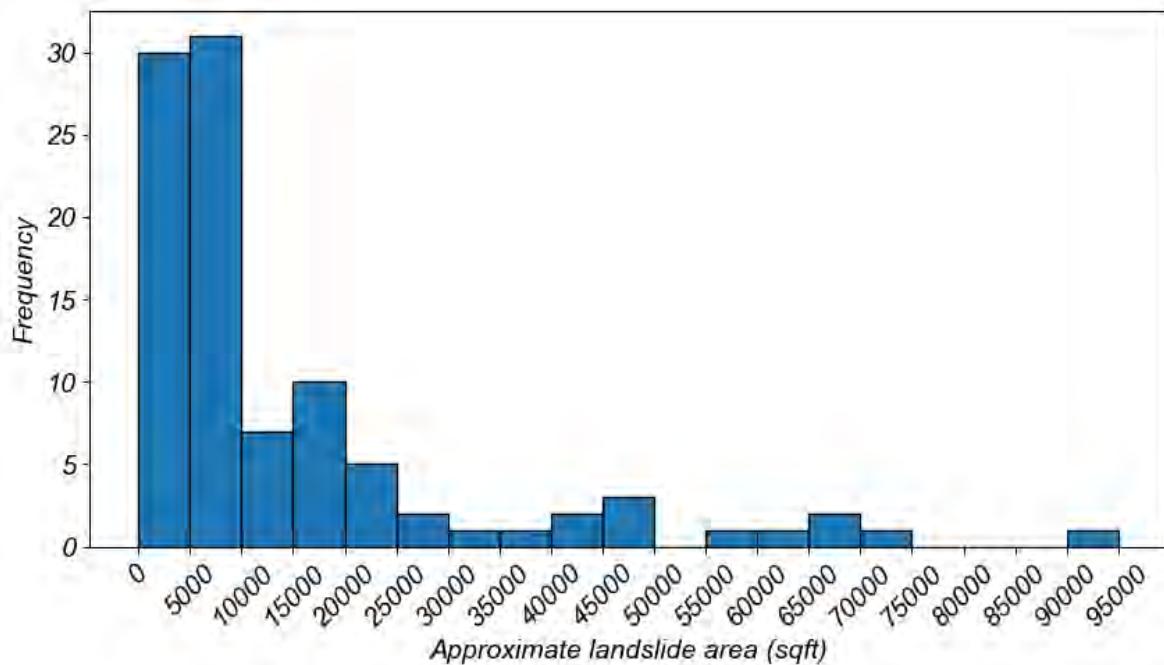

The landslide extent is presented in terms of slope height, slope angle, area, and depth of landslide. Area of the landslide is not explicitly available in the inventory data. It is herein estimated as the product of the available hazard area length and width and is hence termed as an “approximate” landslide area. Figures 3.5, 3.6, 3.7, and 3.8 show the frequency distributions of average slope angle, estimated slope height, approximate landslide area, and depth of sliding surface.

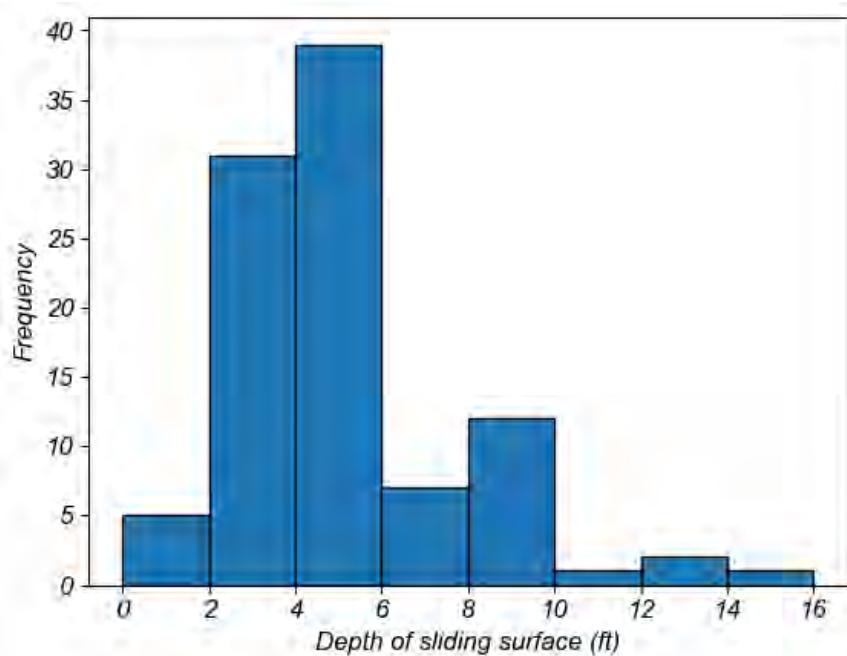

**Figure 3.5.** Frequency distribution for average slope angle for the 99 selected sites.

**Figure 3.6.** Frequency distribution for estimated slope height for the 99 selected sites.

**Figure 3.7.** Frequency distribution for approximate landslide area for the 99 selected sites.

**Figure 3.8.** Frequency distribution for depth of sliding surface for the 99 selected sites.

### **3.3 Lidar Evaluation**

#### ***3.3.1 Data availability and processing***

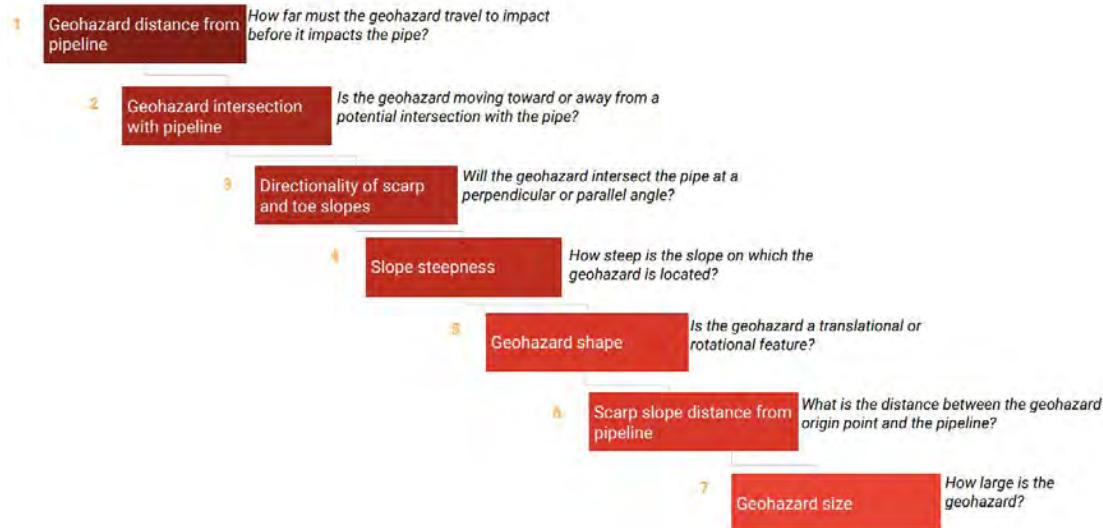

Geospatial data and analytics provider Teren Inc. was retained to complete a lidar evaluation of the study area, encompassing all 99 landslide sites. Teren provides airborne lidar data for four regions in the U.S. Their Appalachia coverage area includes (in entirety or in part) the six Ohio counties containing the 99 landslide sites of this study. The data is collected at a ground sampling distance (GSD) resolution of 40 cm with a potential for a lidar point density of 20 points per meter (PPM) in some areas. Teren collected LiDAR data during two seasons: (1) Fall of 2020 and (2) Spring of 2023 for change detection analysis. Initially change detection was to be carried out between Spring 2020 and Spring 2023, however data collected during Spring 2020 was less than ideal due to heavy vegetation that affected the spatial resolution and data accuracy. Fall 2020 data is considered as “Time 1,” and Spring 2023 is considered as “Time 2” herein.

Data provided by Teren includes two main outputs: (i) the “geohazard polygon” detection and ranking system as obtained from lidar scans at a single epoch (i.e., one instance of time), and (ii) the “change detection polygons” obtained from the comparison of two epochs. A detailed account of these outputs is discussed in the following sections.

##### **3.3.1.1 Geohazard polygons**

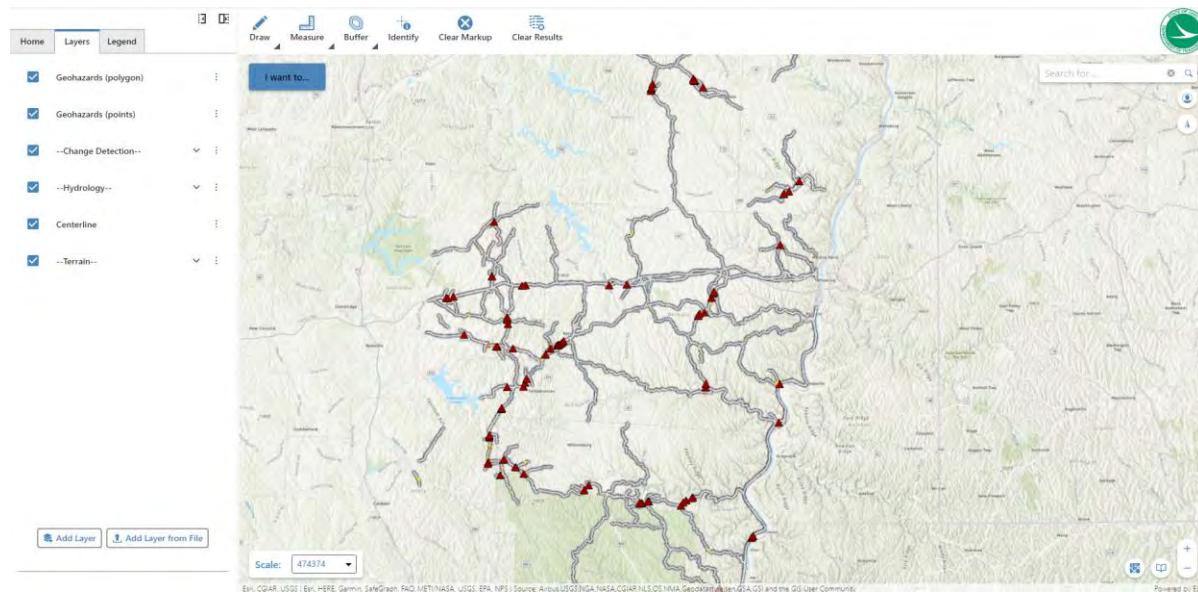

These polygon features represent detected landslide sites from Teren’s lidar evaluations. A computer vision algorithm is used for detecting and delineating each landslide’s structural features, such as scarp and toe slope. Once the polygons were detected by lidar evaluations, a geohazard assessment was used to identify the associated geohazard risk. The area of interest for geohazard identification was set by Teren at 984 ft (300 m) around each ODOT landslide site. For this geohazard assessment, each geohazard polygon is assigned a relative ranking score to indicate the threat to nearby structures. The geohazard assessment was originally devised for pipeline applications but is applied to the roadside landslides for this project. The product overview provided by Teren further describes this process (see Appendix C).

The geohazard ranking system used by Teren is based on a predefined decision tree which considers different variables considering the geohazard and its influence to a nearby structure. Figure 3.9 shows the sequential order of these variables for pipeline applications. In this decision tree, each variable has a threshold for moving from one node of the tree to the other. The process continues until a risk-based ranking can be assigned for the geohazard. For the decision tree in Figure 3.9, Teren switched the pipeline centerline to the road centerline for the landslide applications of this study; however, the centerline may not be the best representation of the roadway.

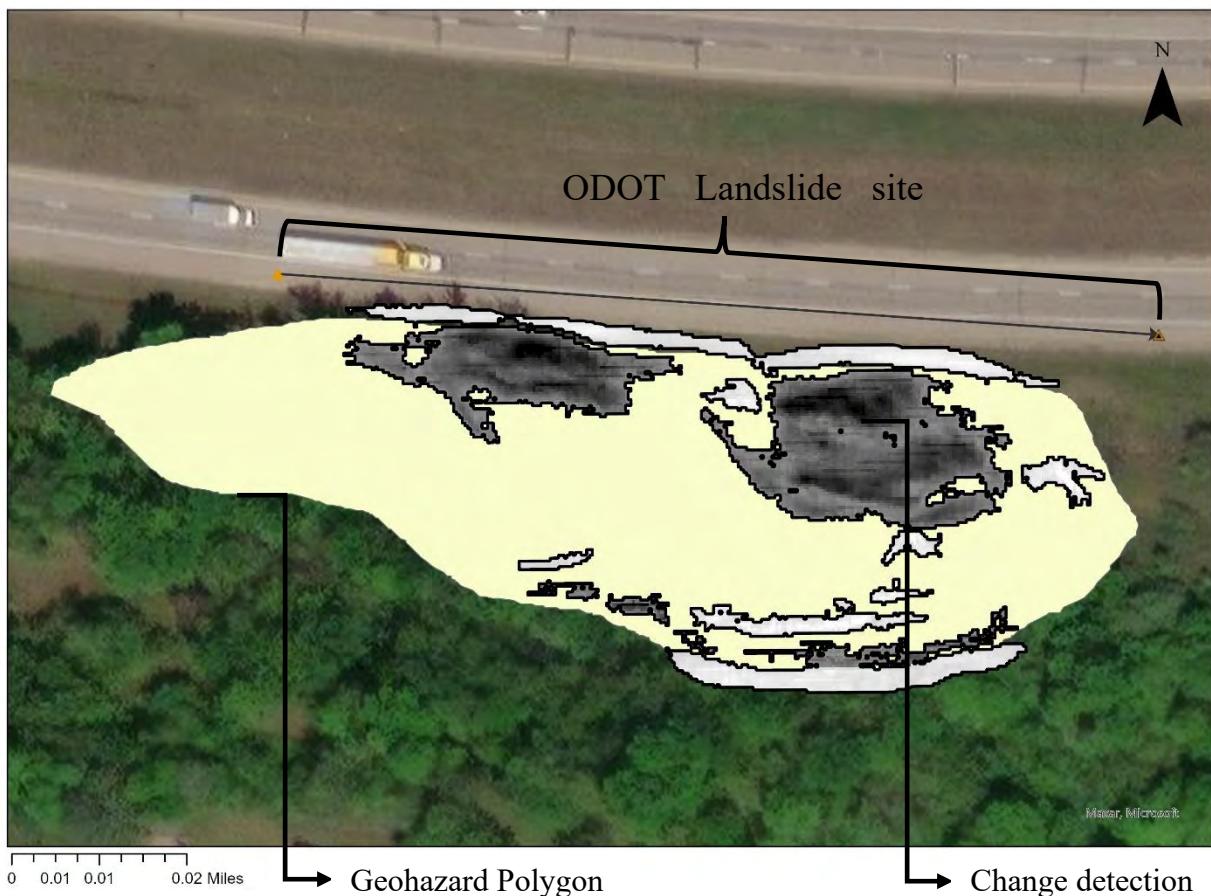

**Figure 3.9.** Decision tree for Teren’s geohazard assessment ranking system, as developed for pipeline applications.

Data provided for the geohazard polygons includes shapefiles containing polygon features for detected landslides by lidar evaluations of the Fall 2020 and the Spring 2023 data. The geohazard ranking is included within the attribute table of the geohazard polygons. Teren also provides an interactive online viewer to visualize and analyze the data. Figure 3.10 is a screenshot of the online viewer, depicting the extent of the dataset and a list of the provided layers. Note that the viewer comes with limited functionality in terms of data analysis and manipulation capabilities. Figure 3.11 shows an example of a detected geohazard polygon near an ODOT landslide site.

**Figure 3.10.** Example screenshot of Teren online viewer.

**Figure 3.11.** Example geohazard polygon with multiple change detection polygons (LS00006904).

### 3.3.1.2 Change detection polygons

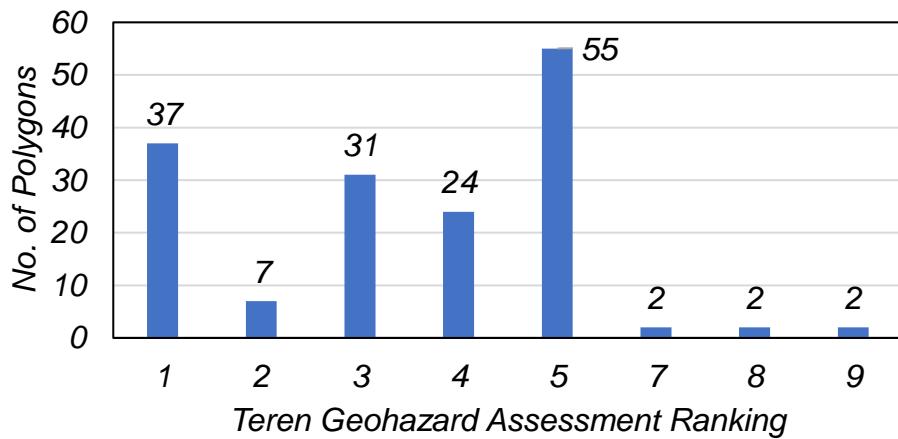

The change detection polygons are geospatial features that indicate the vertical surface changes in the terrain that occur over a time interval. Teren compares the landscape topography from digital terrain models (DTMs) obtained at two different times to detect subtle structural changes. An algorithm is first used to remove vegetation artifacts and perform a range-based elevation correction. Vertical change differences greater than a 1 ft threshold are then obtained within 60 ft from the structural asset centerline. The 1 ft threshold was set by Teren to minimize potential errors; this can be lowered to allow the detection of more polygons with smaller movements. The resulting change detections are presented as polygons with a raster heatmap representing the magnitude of vertical changes over two time periods (i.e., Fall 2020 and Spring 2023 herein). Figure 3.11 shows an example of changes detected within the geohazard polygon. There are a total of 14 change detection polygons in Figure 3.11 (filled with darker grays to indicate larger positive movements and lighter grays to indicate larger negative movements). Vector-format polygon features are also provided for the perimeter of the change detections.

Teren provides edited and unedited change detection data for the specified time period. About 98% of the original changes detected by Teren's analysis were filtered out as false positives. The filtering process first removes systematic or linear trends, then uses an algorithm to detect interpolated artifacts due to vegetation, standing water, and other features (A. Savage, personal communications).

### **3.3.2 Results: geohazard polygons**

The lidar-based evaluation by Teren detected 160 geohazard polygons (i.e., representing landslides) near the ODOT landslide sites. The provided polygon shapefiles include an attribute table with parameters for various characteristics of the detected polygons. The most pertinent parameters of the attribute table can be broadly categorized into three groups: (1) acquisition details, including date, location coordinates, and other identification parameters, such as slip ID, (2) geohazard details which include information about the scarp and toe slope height, direction, and distance from centerline, average slope angle, volume of the slide, impact angle, and (3) geohazard assessment ranking of the polygons. Estimated hydrological details are also available, but not considered herein. A more detailed account of all these parameters can be found in the Data Handoff document and Data Dictionary provided by Teren, and included in Appendix C. Appendix C also includes the full attribute table for geohazard polygons.

Teren's geohazard assessment ranking ranges from 1-10, where 1 represents the least risk and 10 the highest. The ranking for the 160 detected geohazard polygons ranges from 1-9. The distribution of these rankings is plotted in figure 3.12. It is observed that most of the polygons are ranked as 5 or less, and only 6 (~4%) of the polygons are ranked greater than 5.

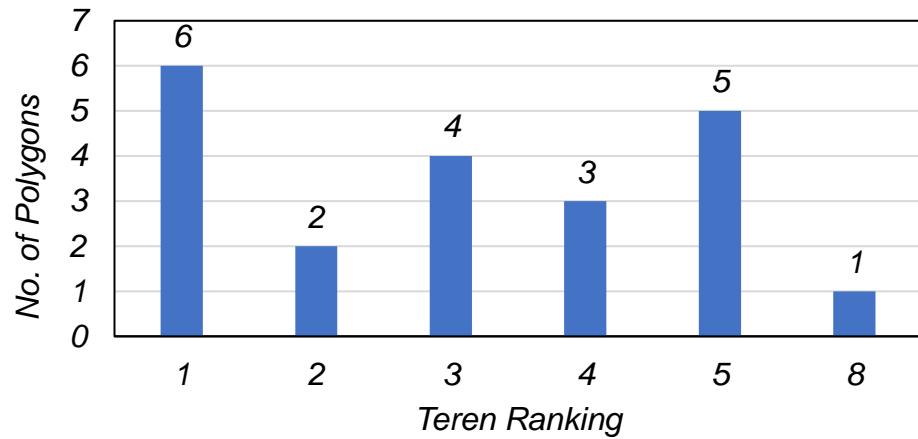

**Figure 3.12.** Distribution of Teren geohazard assessment ranking for 160 landslides detected from the geohazard polygons.

### **3.3.3 Results: change detection polygons**

The lidar-based evaluation and filtering by Teren produced 64 change detection polygons and their respective raster movements. These change detections are concentrated within 21 out of the 160 geohazard polygons. Vertical movements greater than 1 ft are reported with the largest

movement reaching ~9 ft. The attribute table provided by Teren also reports the change detection area, the minimum and maximum movements, and the estimated volume of the moving soil mass, among other details. Appendix C presents the full attribute table for change detection polygons. Figure 3.13 shows the distribution of the Teren geohazard assessment ranking for the 21 geohazard polygons with change detection polygons. It is observed that only one such polygon has a ranking of greater than 5. Appendix C includes the attribute table for change detection polygons.

**Figure 3.13** Distribution of Teren geohazard assessment ranking for the 21 geohazard polygons with change detection polygons.

## 3.4 InSAR Evaluation

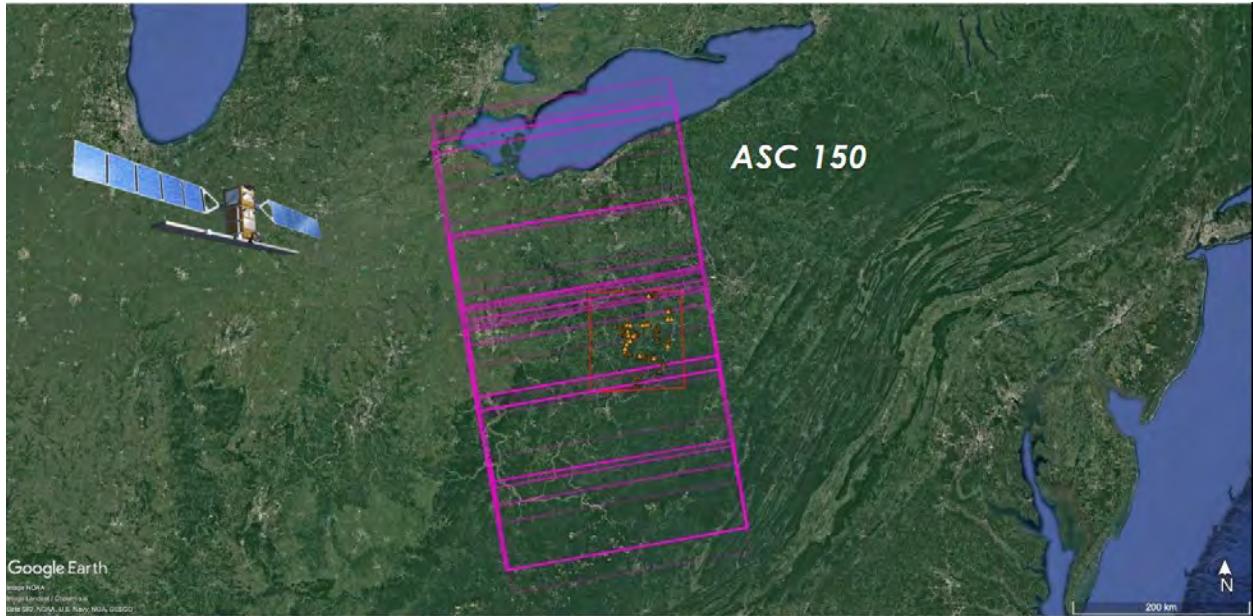

### 3.4.1 Data availability and processing

Radar-based satellite data analytics and software provider EO59 was retained to complete an InSAR data evaluation for selected regions of the study area. EO59 processed InSAR data collected by the Sentinel-1 satellite for time series change detections. Sentinel-1 is the satellite mission of the European Space Agency (ESA), and its data products are publicly available free of cost. The Sentinel-1 captures radar data over the globe once every 12 days for each orbital direction. Only the ascending orbit is available for the eastern Ohio study area. Data at four regions in Jefferson and Monroe County was collected and processed for the time interval between May 2016 to April 2023. Figure 3.14 shows the footprint of data collection covering the area of interest.

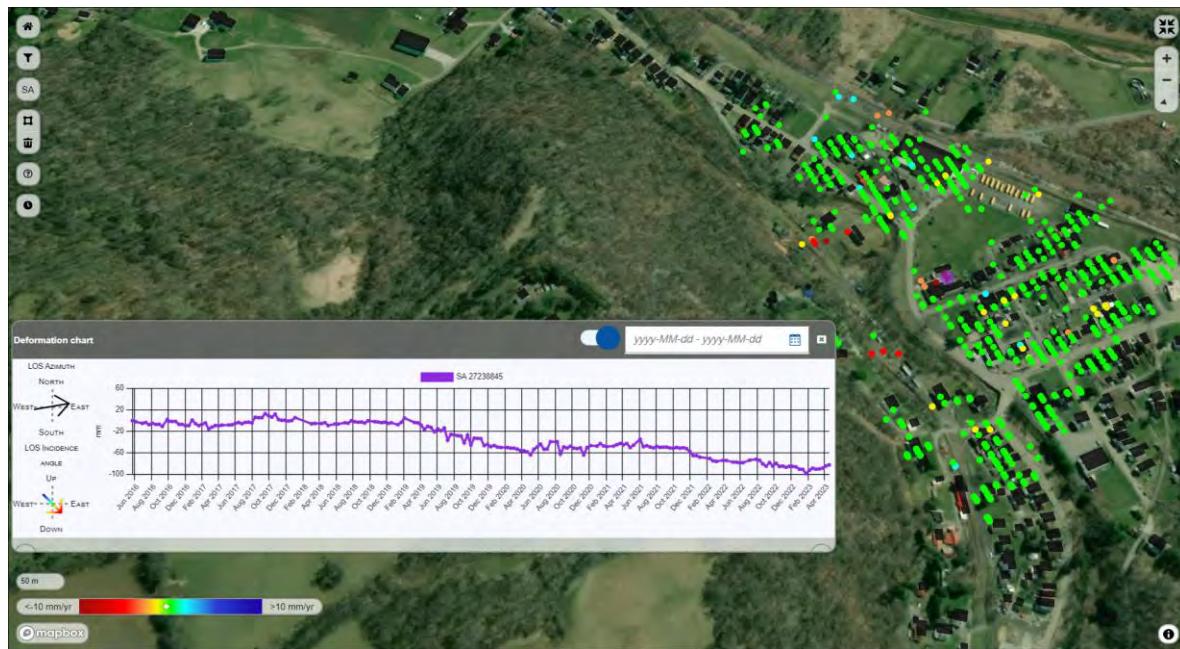

EO59 uses an Advanced Differential InSAR (A-DInSAR) methodology for processing radar data to obtain ground surface change detections. A-DInSAR is a radar-based method in which radar reflections from the Earth's surface are recorded and processed to estimate ground deformation time series. One popular A-DInSAR based technique is Persistent Scatterer Interferometry (PSI) which has wide applications in landslide monitoring. PSI uses a large sequence of synthetic aperture radar (SAR) images to measure subtle ground deformation at a millimeter level of accuracy along the satellite Line of Sight (LOS). PSI along with conventional topographic data can be used for updating landslide inventories. However, PSI relies on the monitoring of Persistent Scatterers (PS) point targets that remain coherent over a long period of time (e.g., buildings, bridges, railways, outcropping rocks). Over a highly vegetated area, the availability of PSs is reduced, which can affect interpretations of the extent and certainty of movement.

EO59 typically performs linear regressions on the PSI times series data to provide cumulative displacements and average velocities over the time interval of interest at each PS point. Following communications with EO59, our research team accordingly reduced the overall time series interval of May 2016 to April 2023 to match the lidar acquisition period of Fall 2020 to Spring 2023. This required re-calibrating the linear regressions and updating the cumulative displacements and average velocities.

The data provided by EO59 includes GEOJSON files for the InSAR captured data points and CSV files for time series data. They also provided an interactive online viewer to visually analyze the data (see example screenshot in Figure 3.15). The online viewer provides PS point locations color-coded for the extent of deformation. Selecting the PS points provides PS displacement time histories for time intervals of interest.

**Figure 3.14.** Footprint of ascending Sentinel-1 data collection for area of interest.

**Figure 3.15.** Example screenshot of EO59 online viewer.

#### 3.4.2 Results: Persistent Scatterers

The methodology discussed in section 3.4.1 was used to process A-DInSAR data for four specified regions: (1) along SR150 in Jefferson County, (2) along SR7 in Monroe County, (3) along SR78 East in Monroe County, and (4) along SR78 West in Monroe County. The number of PS points detected for each study region is shown in Table 3.1. Figures 3.16-3.19 show InSAR

detected PS data points for each of four study regions. Note that the indicated colors represent movements during the full May 2016 to April 2023 monitored period. Appendix D includes supplementary data regarding EO59 data processing.

**Table 3.1.** Number of PS points in each study region.

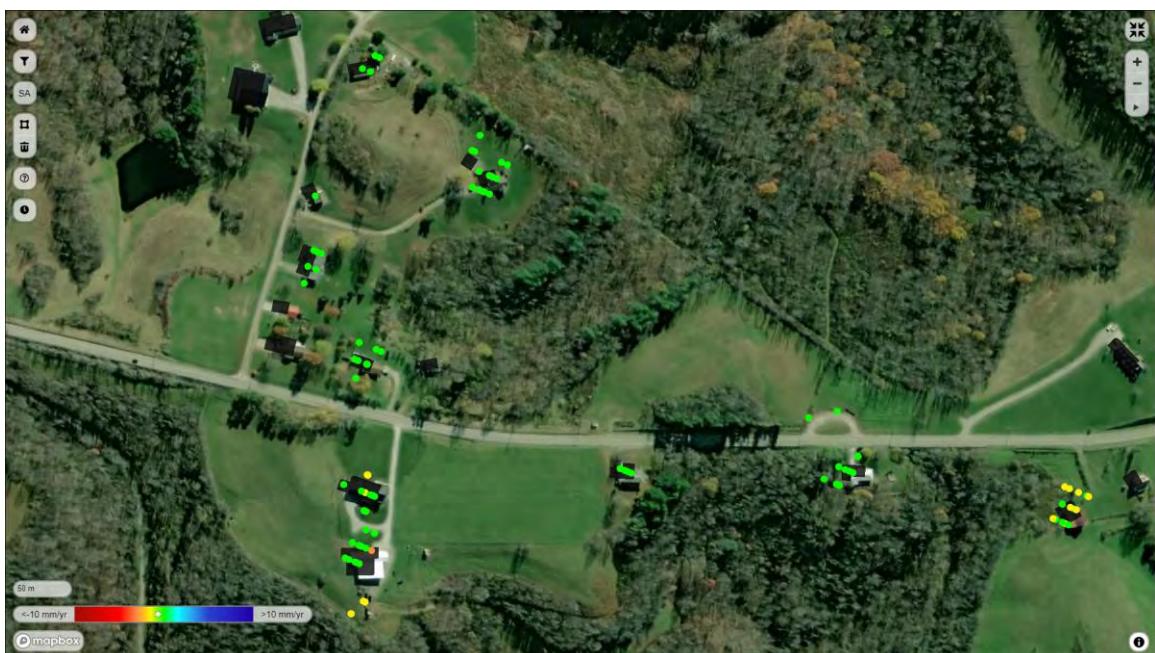

Study region	PS points
Jefferson SR150	891
Monroe East SR78	76
Monroe West SR78	92
Monroe SR7	914

**Figure 3.16.** PSs detected in the Jefferson SR150 study area.

**Figure 3.17.** PSs detected in the Monroe SR 78 East study area.

**Figure 3.18.** PSs detected in the Monroe SR 78 West study area.

**Figure 3.19.** PSs detected in the Monroe SR 7 study area.

## CHAPTER 4: COMPARISON OF REMOTE SENSING DETECTIONS WITH LANDSLIDE INVENTORY

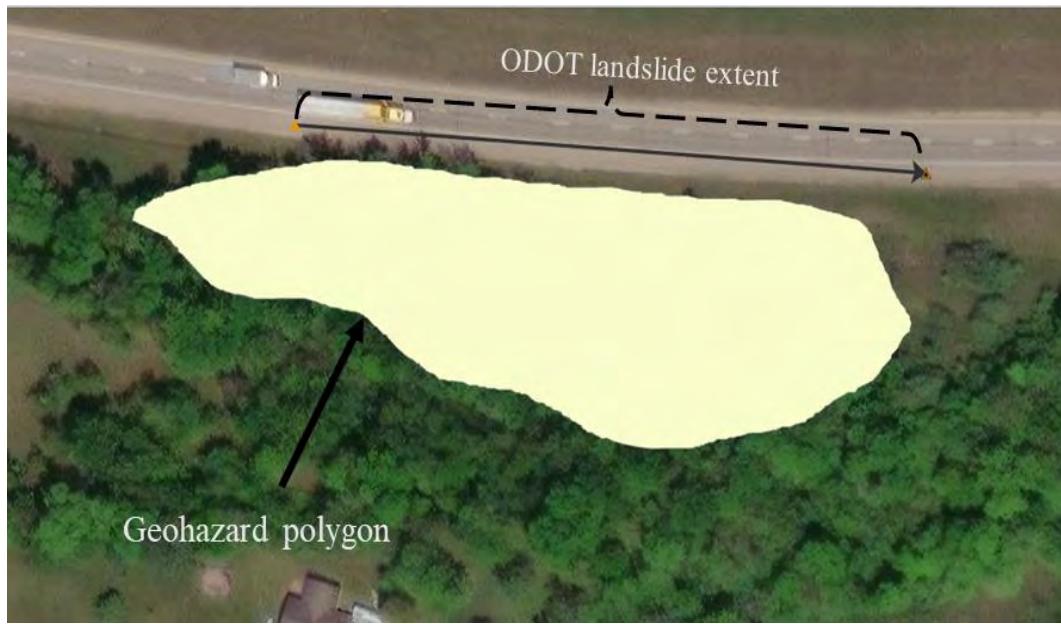

### 4.1 General Comparisons

Our research team conducted comparisons for assessing the effectiveness of lidar and InSAR in detecting the selected sites from the ODOT landslide inventory. In these comparisons, ODOT data serves as a baseline, and any deviations are reported here. These comparisons primarily address two key questions: (1) Does remote sensing adequately detect the presence of landslides?; and (2) How do the predicted metrics from remote sensing compare to the data recorded in the ODOT inventory? The “metrics” suggested by question 2 include qualitative categories (e.g., extent of coverage, rankings) and quantitative variables (e.g., amount of movement).

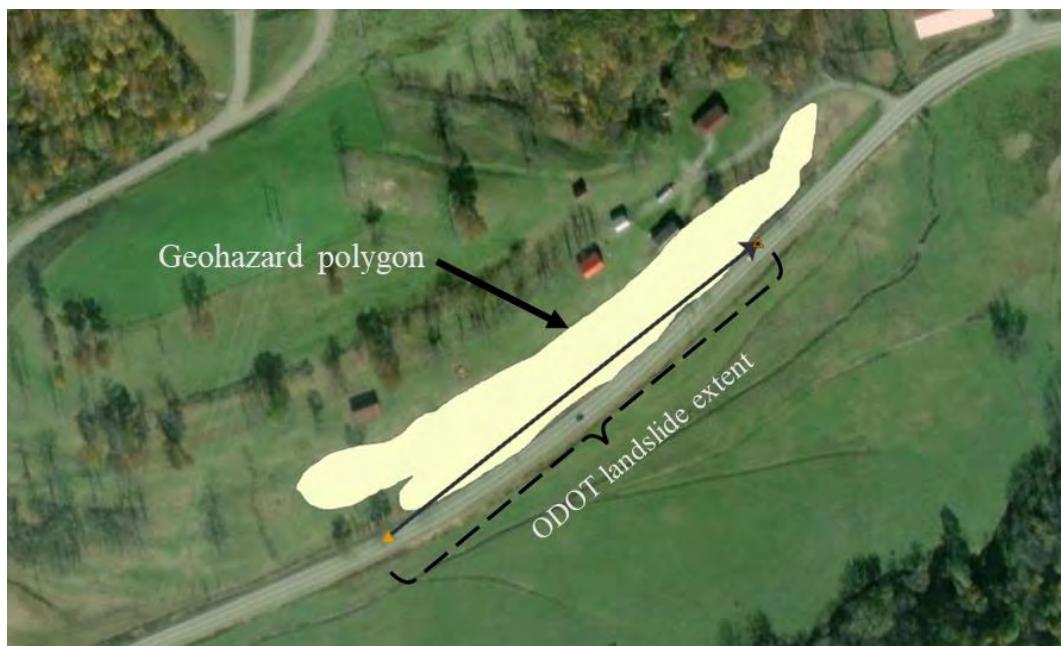

#### 4.1.1 Lidar geohazard polygons

The lidar-derived geohazard polygons represent the area or extent of detected landslides. To compare these polygons with the 99 selected ODOT landslide sites, a coverage category framework was established. These categories indicate how closely the geohazard polygons align with the provided beginning and ending mileposts (e.g., BMP and EMP) of the ODOT landslides.

Five coverage categories are defined based on how well these polygons match the ODOT inventoried extent: (1) Full coverage (FC): the geohazard polygon(s) encompasses the full inventoried extent and may extend beyond it. Figure 4.1 presents examples of FC sites. (2) More than half coverage (MH): the geohazard polygon(s) covers more than half of the inventoried extent. Figure 4.2 presents examples of MH sites. In Figure 4.2(a), two geohazard polygons together cover more than half of the inventoried extent. (3) Less than half coverage (LH): the geohazard polygon covers less than half of the inventoried extent. Figure 4.3 presents examples of different LH coverage scenarios. (4) Not in extent (NE): the geohazard polygon is detected near but is not within the inventoried extent. Any polygon detected on the opposite side of the road also falls into this category. Determining the cardinal direction and relative location of the ODOT landslides in relation to the roadway per the ODOT (2023) was crucial for this comparison. Figure 4.4 presents examples of NE sites. (5) Not detected (ND): no geohazard polygon is detected near the inventoried extent (i.e., lidar did not capture this site). Figure 4.5 presents examples of ND sites.

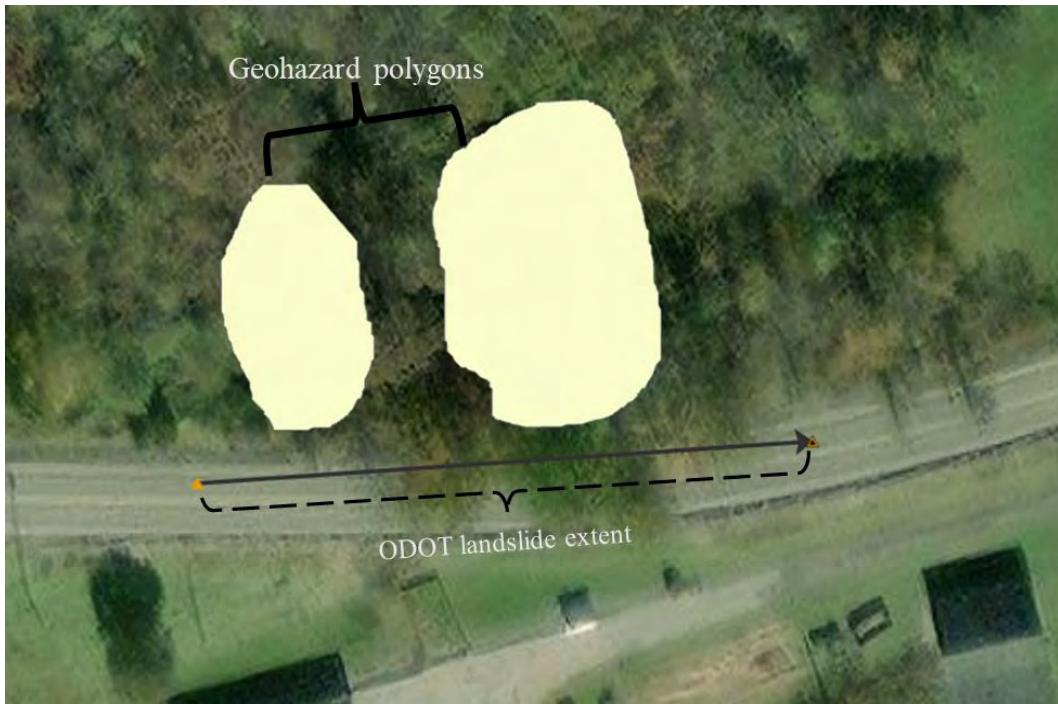

(a)

(b)

**Figure 4.1.** Examples of “full coverage” (FC) sites: (a) LS00006904 and (b) LS00002254.

(a)

(b)

**Figure 4.4.** Examples of “not in extent” (NE) sites.

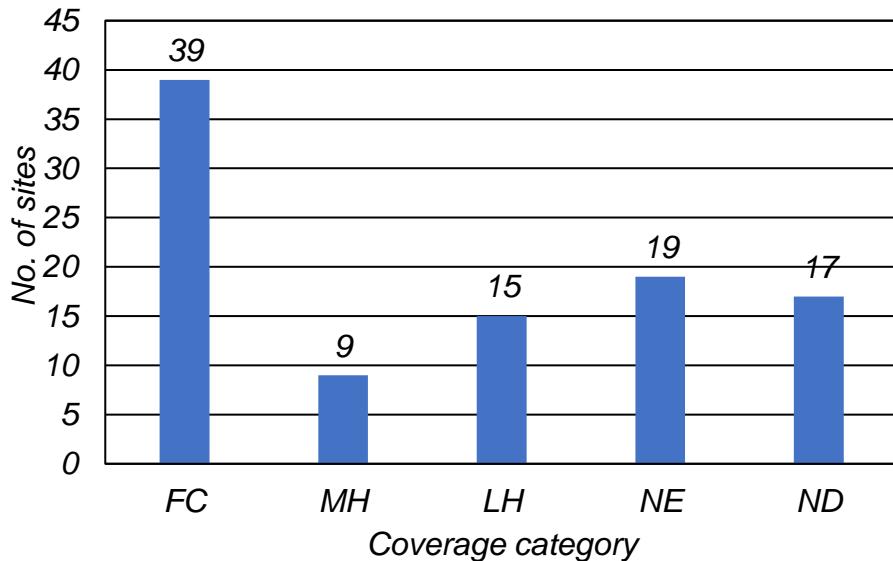

(a)

(b)

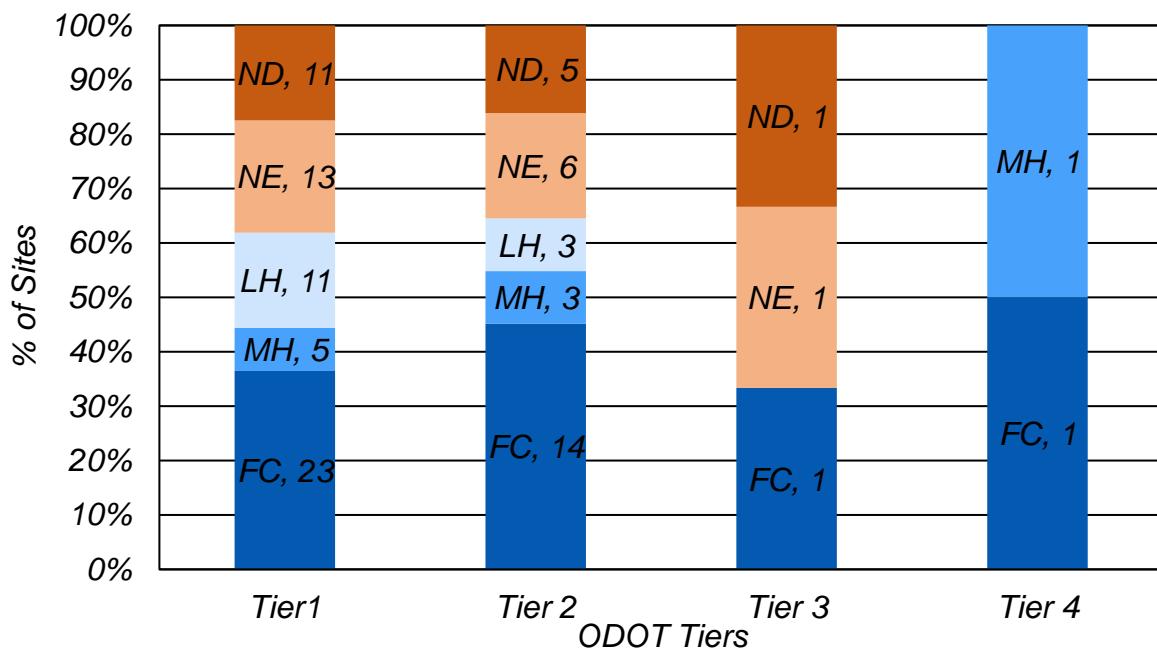

**Figure 4.5.** Examples of sites not detected (ND) by lidar.

All 99 selected ODOT sites were categorized using the coverage framework. The distribution of coverage categories among ODOT sites is shown in Figure 4.6. The lidar evaluation is able to cover or detect approximately 60% of ODOT sites within the extent, with 39 of these sites being fully covered (i.e., FC). About 23% of the sites show nearby polygons outside the inventoried extents, and 17% of the sites are not detected by lidar (i.e., ND).

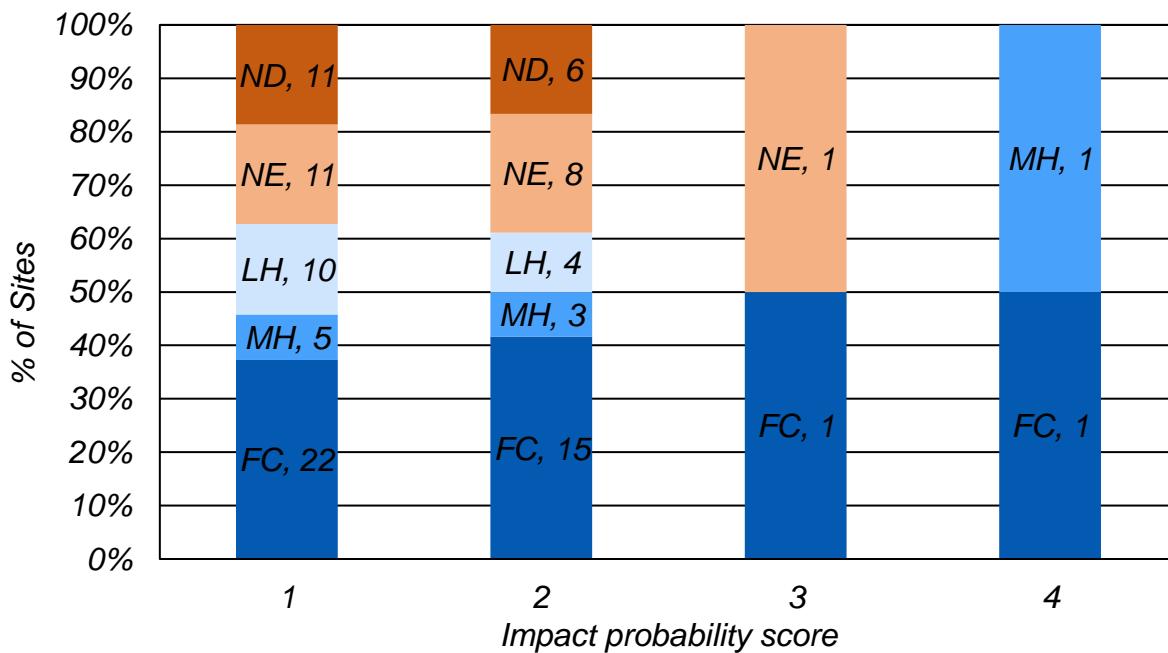

**Figure 4.6.** Distribution of coverage categories among the 99 selected ODOT sites.

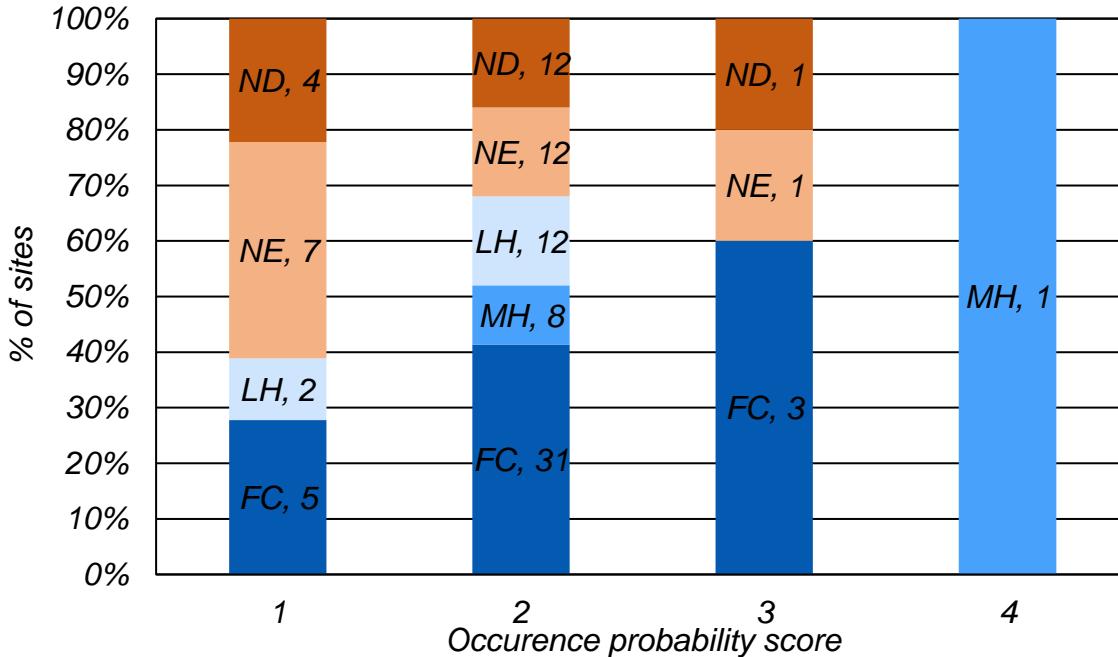

The distribution frequency of coverage categories is considered for each ODOT Tier in Figure 4.7. Tier 1 and 2 sites captured all five coverage categories with somewhat consistent percentages of sites in each category between both Tiers. Between 35-40% of both Tier 1 and Tier 2 were either NE or ND. One out of the five Tier 3-4 sites was NE, and one was ND. Figure 4.8 presents the distribution frequency of coverage categories relative to landslide impact probability scores determined by ODOT. The trends closely mirror those observed in the Tier comparison. Figure 4.9 shows the distribution frequency of coverage categories relative to landslide occurrence probability scores determined by ODOT. It is interesting to note that 61% of occurrence score 1 sites, and 32% of occurrence score 2-4 sites are either NE or ND. This difference in percentages suggests that lidar is more likely to detect sites that show greater evidence of occurrence in the field surveys.

**Figure 4.7.** Distribution frequency of coverage categories with ODOT Tiers for the 99 selected sites.

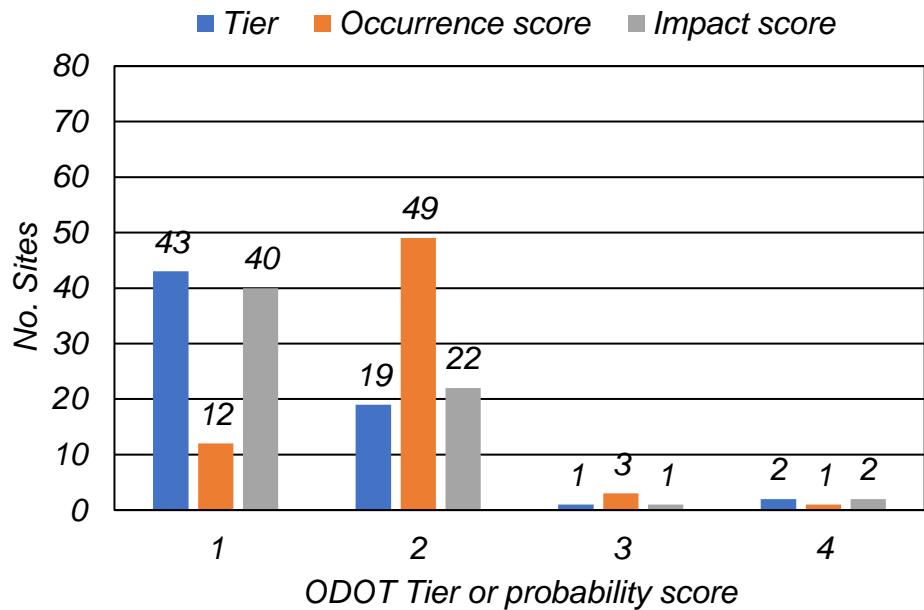

**Figure 4.8.** Distribution frequency of coverage categories with ODOT impact score for the 99 selected sites.

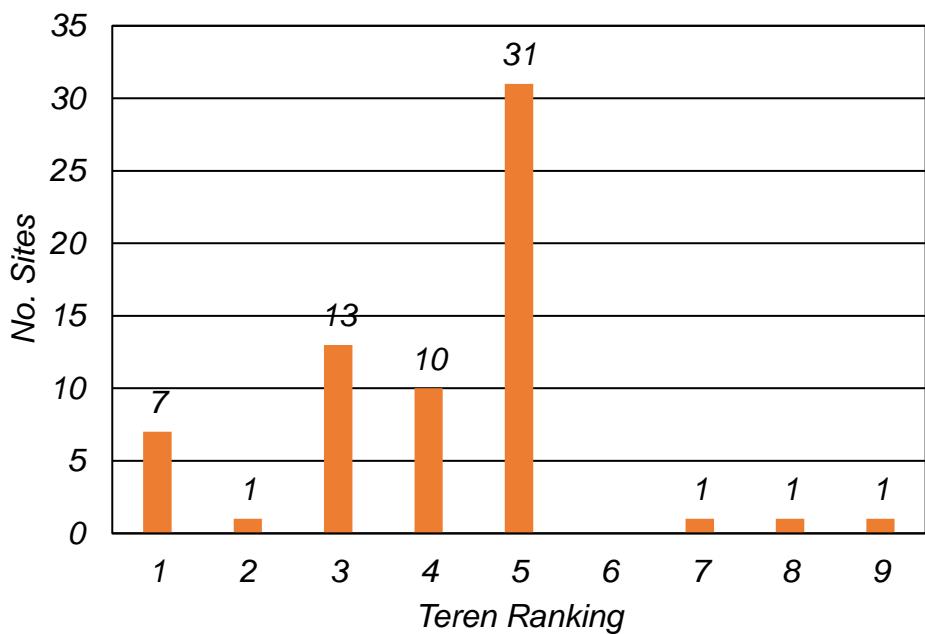

**Figure 4.9.** Distribution frequency of coverage categories with ODOT occurrence score for the 99 selected sites.

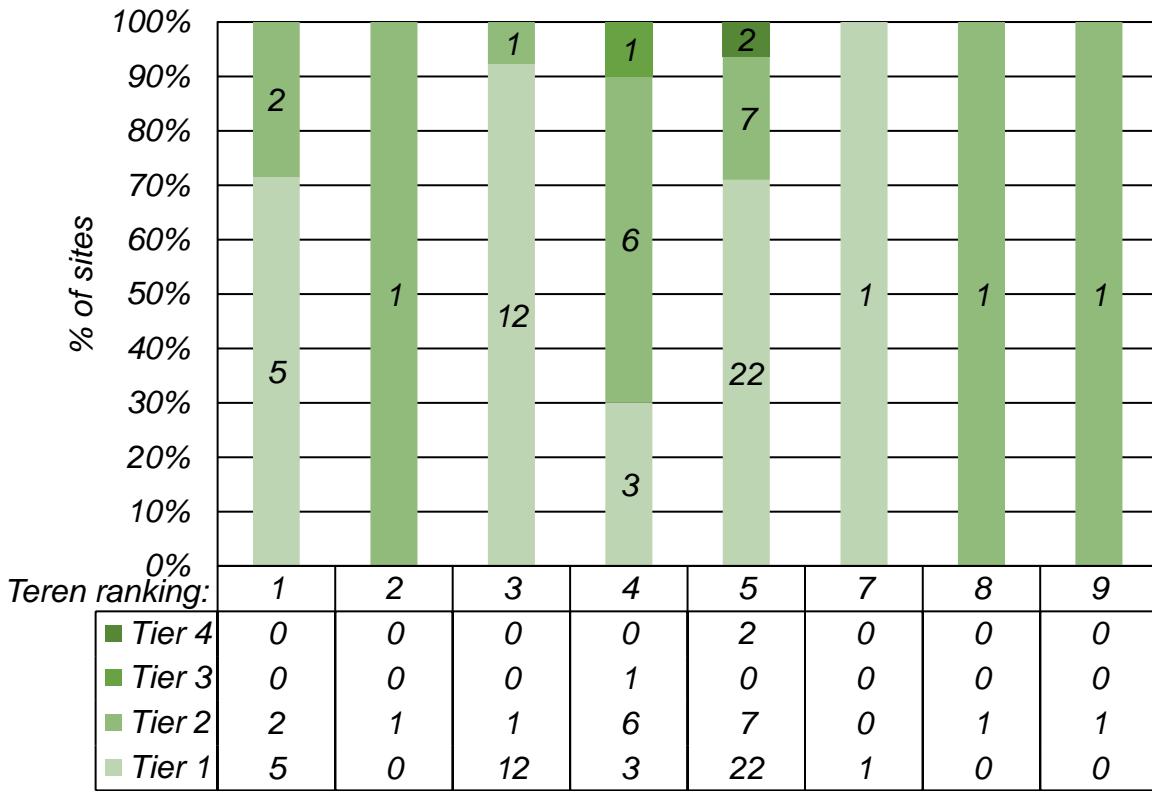

Out of the 160 lidar-derived geohazard polygons, 65 were found within the ODOT inventoried landslide extents. Three ODOT sites encompassed multiple polygons, as exemplified in Figure 4.2a, such that these 65 polygons are captured by the 62 ODOT sites categorized as either FC, MH, or LH. Figure 4.10 presents the distribution of ODOT occurrence score, impact score, and Tiers for these 65 geohazard polygons. Figure 4.11 presents the distribution of Teren's geohazard assessment ranking for these 65 polygons. Notably, this distribution closely mirrors the trends observed in Figure 3.11, with 98% of the polygons falling within rankings 1-5. Figure 4.12 and Table 4.1 provides the frequency distributions of between ODOT Tiers and the Teren ranking. Interestingly, two polygons associated with ODOT Tier 4 correspond to a Teren ranking of 5, while the three polygons with higher Teren rankings of 7-9 align with ODOT Tiers 1 and 2. This suggests a discrepancy between the ODOT Tiers and the Teren ranking, as expected due to the different methodologies and attributes considered. Also, the lidar data may be affected by several uncertainties in the determination of geohazard polygons, and the ODOT Tiers may be affected by subjectivity due to engineering judgement used for Tier determination.

**Figure 4.10.** Distribution of ODOT tier scores for 65 polygons.

**Figure 4.11** Teren ranking distribution for 65 polygons.

**Figure 4.12** ODOT Tier and Teren Ranking comparison.

#### 4.1.2 Lidar change detection polygons

Among the 64 change detection polygons, 39 are identified within the 99 selected ODOT landslide sites. However, several inventoried landslides span multiple change detection polygons within their boundaries as depicted in Figure 3.11, such that the 39 change detection polygons are distributed across only 12 ODOT sites.

Table 4.1 depicts change detection metrics for 12 ODOT sites, along with the ODOT Tier, Teren ranking, and horizontal crack and vertical dip measurements of the road. Of the 12 sites captured 7 (58%) had an ODOT risk Tier of greater than 1. However, only 35 of the 99 considered sites (35%) had an ODOT risk Tier of greater than 1. As expected, the lidar change detections were more likely to capture sites with a higher risk Tier.

The change detection metrics in Table 4.2 include the total area of the change detection polygons, the approximate ODOT landslide area, and the absolute minimum and maximum movements among all change detection polygons. Change detections were typically indicated over a small area (usually <20%) of the approximate landslide area. Oddly, the seven sites with a maximum movement of over 6 ft do not report any crack or dip related movements. It is likely that these movements have not affected the road to any significant degree. There are no other

measurements available within the ODOT inventory to make a more direct comparison to the large rate of landslide movement indicated by lidar change detections.

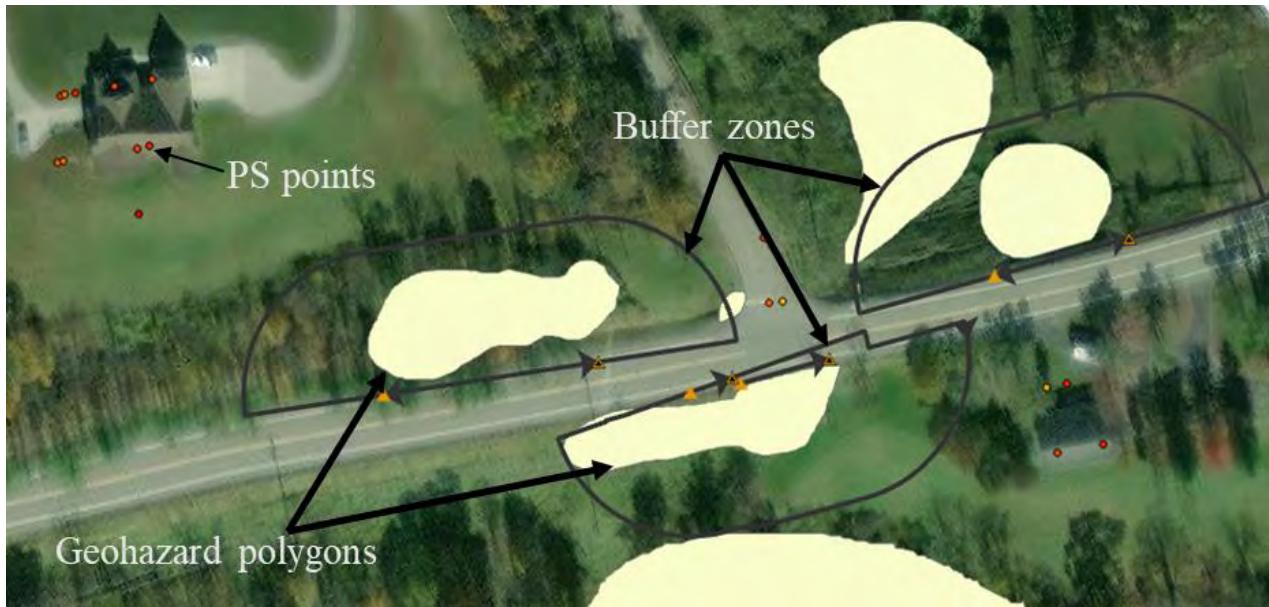

**Table 4.1.** Lidar-based change detection metrics and comparisons at 12 ODOT sites.

Landslide ID	Approx. area of ODOT LS (sqft)	Total area of change detection polygons (sqft)	Min. change movt. over LS (ft)	Max. change movt. over LS (ft)	ODOT Tier	Teren Ranking	ODOT crack hor. disp. (in)	ODOT dip vert. disp. (in)
LS00001485	4641	228	1	1.9	2	1	0	0.2
LS00002151	7938	488	1	6.4	1	3	0	0
LS00002354	18522	5697	1	6.8	1	5	0	0
LS00003377	14000	1665	1	8.5	4	5	0	0
LS00006384	8732	1060	1	7.0	1	1	0	0
LS00006795	4240	512	1	3.3	2	5	0.25	0
LS00006904	47672	17045	1	7.4	2	3	0	0
LS00007622	3612	968	1	5.4	2	8	0.5	1
LS00007816	66864	41	1	3.2	2	4	0	1
LS00007830	9150	1376	1.9	9.3	1	5	0	0
LS00008599	9282	458	1	2.2	2	4	0.75	0
LS00008816	11340	997	1	6.9	1	5	0	0

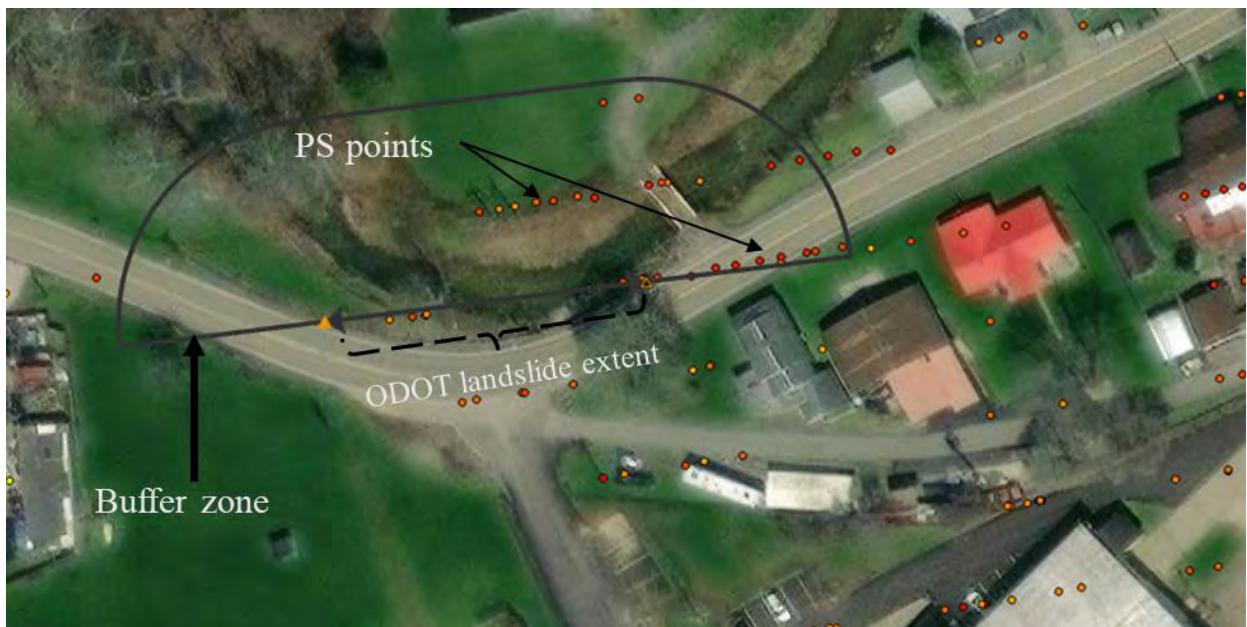

Note that the movement direction of the change detection polygons as uplifting or subsiding is not directly provided by Teren. It is possible to approximate the maximum subsidence and uplift based on the colored raster-format “continuous change layers,” but this has proven to be crude at best. Our team suggests that Teren update this feature and provide the true maximum subsidence and maximum uplift values, rather than absolute values, for more meaningful evaluations.

#### 4.1.3 InSAR Persistent Scatterers

A total of 15 of the selected ODOT landslide sites lie within the InSAR study regions selected by EO59. For each of these ODOT sites a buffer zone is considered around the extent of the landslide area. Figure 4.13 shows examples of the created buffer zones around ODOT sites. ODOT sites shown in Figure 4.13(a) don’t have any PS points within the created buffer zone whereas Figure 4.13(b) shows PS points inside and around the ODOT site. The PS points inside the buffer zone, as well as those near and along the adjacent roadway, were considered relevant to the inventoried landslide extent. However, the PS points away from the landslide extents over nearby buildings were not considered relevant to potential landslide movement.

(a)

(b)

**Figure 4.13.** Examples of buffer zone created around landslide site: (a) example with no PS points within buffer zone; (b) example where important PS points lie outside of buffer zone (the points along the roadway opposite the stream were additionally considered).

Table 4.2 depicts PSI metrics for 12 ODOT sites, along with the ODOT Tier, Teren ranking (where available), and horizontal crack and vertical dip measurements of the road. The number of relevant PS points, and the absolute cumulative displacement (*abs. cum. disp.*) between Fall 2020 and Spring 2023 determined from those points is indicated for each site. Altogether, only eight sites were indicated to have relevant PS points, with a range of maximum displacement from ~2-36 mm. Horizontal crack and vertical dip displacements (*ODOT crack hor. disp.* and *ODOT dip vert. disp.*) were available at two of those eight sites and are included for comparison. Of the eight detected sites, two were ODOT Tier 2, and six were ODOT Tier 1 sites. The three sites with the largest movements detected by A-DInSAR (i.e., greater than 10 mm over the 2.5-year study period) were all risk Tier 1 sites. Furthermore, these sites were not captured by the lidar datasets. The ranging accuracy of lidar is typically around 50 mm, and it is unlikely that change detections of small movements at this scale could be detected. Within the entire database considered, only two sites (LS00002354 and LS00007772) were captured by both the lidar geohazards and the PS points. Of these, only LS0002354 was captured with lidar change detections.

**Table 4.2** InSAR data comparisons for 15 ODOT sites.

Landslide ID	County/state route	No. of PS (within & near buffer)	Abs. cum. disp. (mm)	Teren Ranking (N/A – no geohazard polygon)	ODOT Tier	ODOT crack hor. disp. (in)	ODOT dip vert. disp. (in)

## 4.2 Performance of Example Landslide Sites

Selected case studies are presented herein to showcase the favorable and contrasting performance of the lidar and/or InSAR datasets with the ODOT landslide inventory. Potential reasons for these discrepancies are also discussed herein.

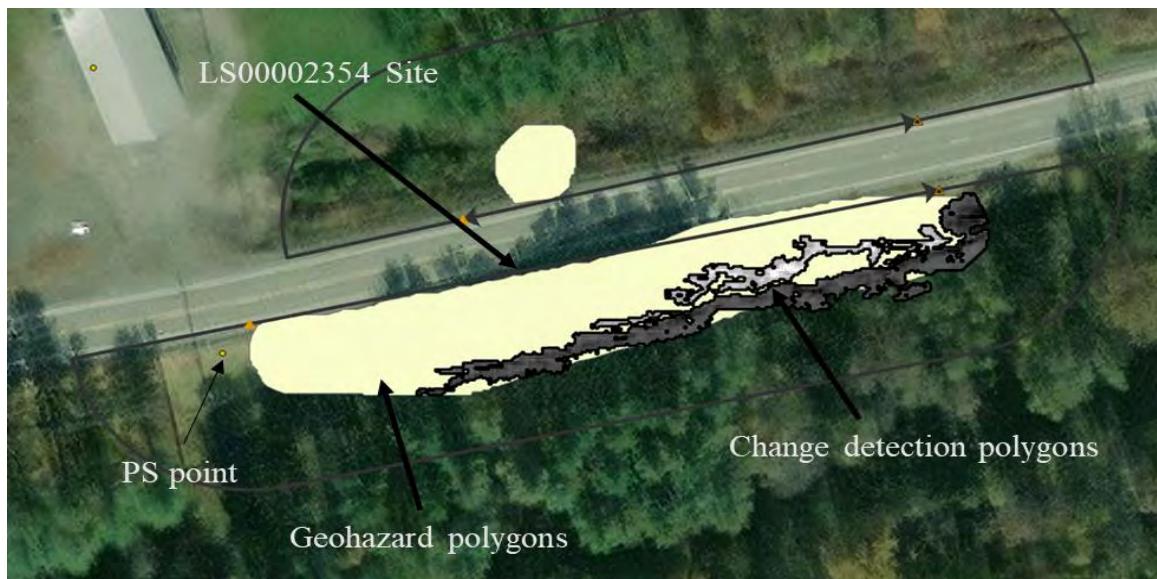

### 4.2.1 Example Site 1: LS00002354

This Tier 1 site is located in Monroe County on State Route 78 East. For this site, all remote sensing datasets indicate movements: lidar geohazard polygons, lidar change detections, and PS points from InSAR.

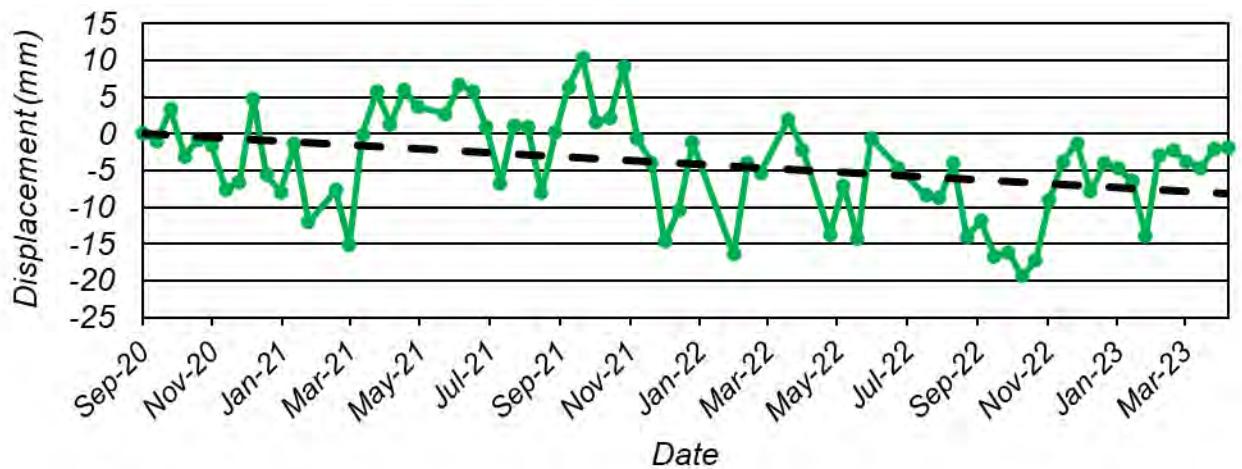

Details from the ODOT inventory for this site are as follows: remediated with H-piles (remediation occurred at some point since the first inspection in 2011; however, this site was rated as Tier 1 during that 2011 inspection as well); soil origin is fill; soil type is A-3; it is reported that the slide affects the guardrail; no crack or dip movements were reported; and no cause of landslide is reported. The occurrence score is 2, and the impact score is 1. It is possible that the remediation measures influenced the remote sensing detections described herein, especially if the remediation was initiated during the Fall 2020 to Spring 2023 study period.

Lidar detects the geohazard polygon at the site with full coverage (FC). The Teren ranking of 5 is assigned to the geohazard polygon at this site. Figure 4.14 shows lidar detected geohazard and change detection polygons for the site. Maximum change movement detected by lidar is about 7 ft (subsidence). Lidar performed well in detecting the overall landslide extent, however the lidar-derived ranking and change detection do not seem to agree with the Tier 1 determination for this site. The change detection polygons were located near the toe of the slope. Because the slope has been remediated with H-piles, movement below the remediation is not of significant concern to ODOT and would result in the Tier 1 rating.

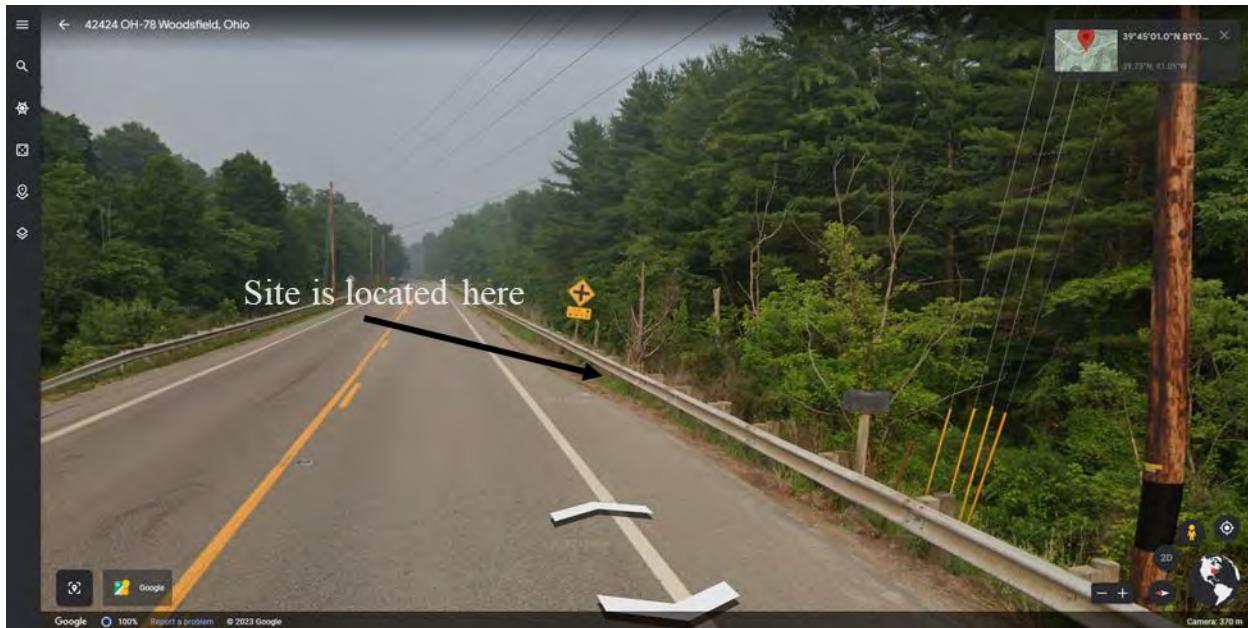

The A-DInSAR analysis detected one PS point near the site, as indicated in Figure 4.19, with a cumulative displacement of ~8 mm (0.3 in). The accuracy of detecting long term landslide movements with only one PS point is questionable and can in no way delineate the extent and orientation of a slide such as this without additional data. Figure 4.15 shows the full PSI displacement time series between Fall 2020 to Spring 2023 for this PS point. The time series depicts oscillating movements for this time interval, as typical for PSI results. However, a long-term trend can also be seen as depicted by the regression line, supporting the obtained displacement. It is likely that the inability to obtain additional PS points can be attributed to the high vegetation cover over the site as shown in the Google earth image in Figure 4.16.

**Figure 4.14.** Lidar and InSAR detections of site LS00002354.

**Figure 4.15.** PS point displacement time series (solid green) and regression line (dashed black) near site LS00002354.

**Figure 4.16.** Google street view image of vegetation cover around site LS00002354 (Google 2023).

#### 4.2.2 Example Site 2: LS00006904

This Tier 2 site is located in Guernsey County along the heavily trafficked Interstate Route 70 East. This site was visited by members of OSU, E.L. Robinson, Terracon, and ODOT on May 10, 2023. The site indicated soil displacements visible in Figure 4.17. The toe of the landslide is about 25 ft away from the nearest interstate lane boundary (i.e., solid white line in Fig. 4.17b). This site was detected by both lidar-based geohazard and change detection polygons. The site is outside of the area covered by InSAR data.

Details from ODOT inventory for this site are as follows: non-remediated; soil origin is weathered claystone rock; soil type is A-7; landslide movement type is rotational; cause of landslide is attributed to presence of soft red clay which does not hold its form properly upon erosion and precipitation; the site is unlikely to affect the roadway but may clog the drain; no crack movements are reported. It is believed that slope instabilities at this site occurred within the red beds discussed in section 2.1.

Lidar detects a geohazard polygon at the site with full coverage (FC) and a Teren risk ranking of 3, as shown in Figure 4.18. Maximum movements detected by the lidar change detection is ~7.5 ft (subsidence). The lidar change detection extents appear to closely match the extents of the ground observations. Even with widespread landslide movement (occurrence score of 3), the site is Tier 2 due to its distance from the road (impact score of 1). Overall, lidar proved to be an effective method of remote sensing for this site. It is possible that the exposure of this landslide (without a thick tree canopy) helped to improve these results.

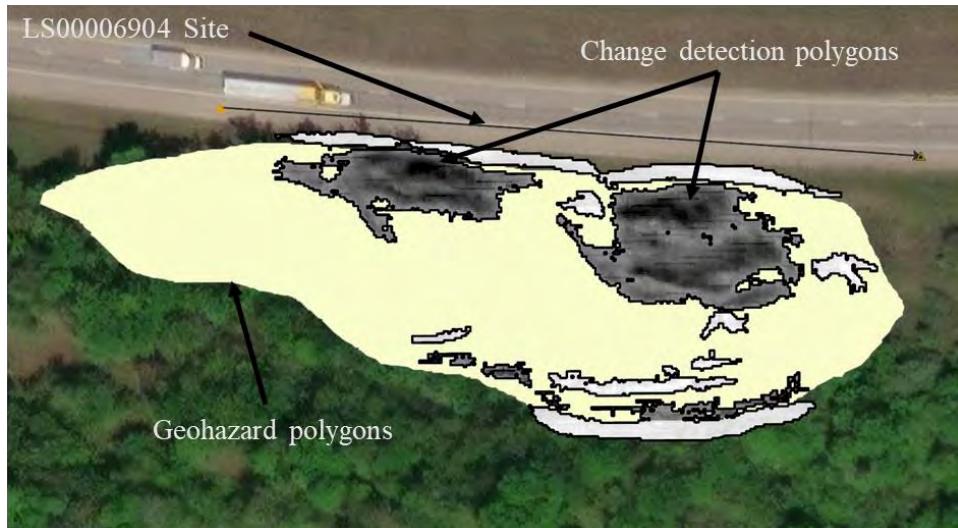

(a)

(b)

**Figure 4.17.** Photos from May 10, 2023 field visit of site LS00006904.

**Figure 4.18.** LiDAR detected geohazard polygon and change detection for site LS00006904.

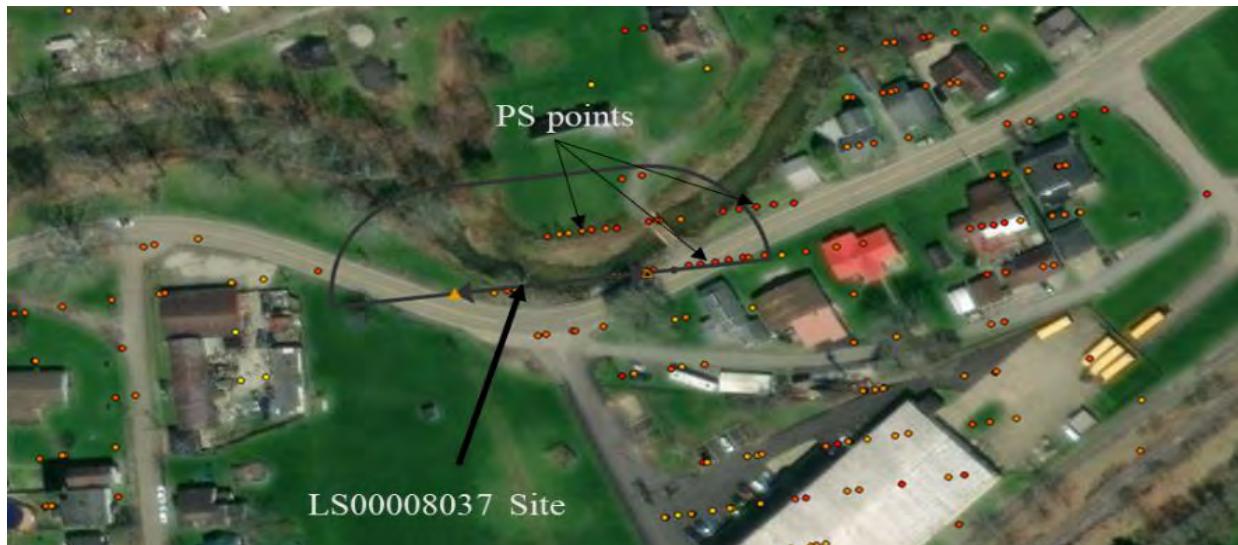

#### 4.2.3 Example Site 3: LS00008037

This Tier 1 site is located in Jefferson County along SR 150. This is a case where InSAR performed well relative to lidar.

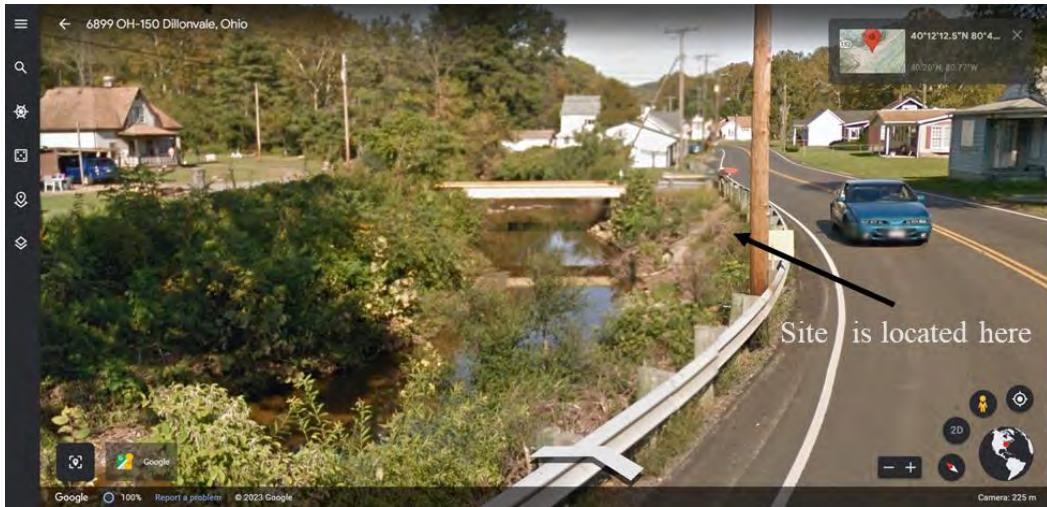

Details from the ODOT inventory data for this site are as follows: non-remediated site with clayey silt soil type; some riprap is present at the site; type of landslide movement is not reported; no crack movements reported; and cause of landslide is not reported. The site is mapped in Figure 4.19 and is depicted in Figure 4.20.

Lidar could not detect any geohazard polygons for this site as shown in Figure 4.19. This is likely due to the coarser precision of the lidar geohazard polygon and change detections (i.e., typically ~14 cm) relative to the slow movements at this site picked up by InSAR.

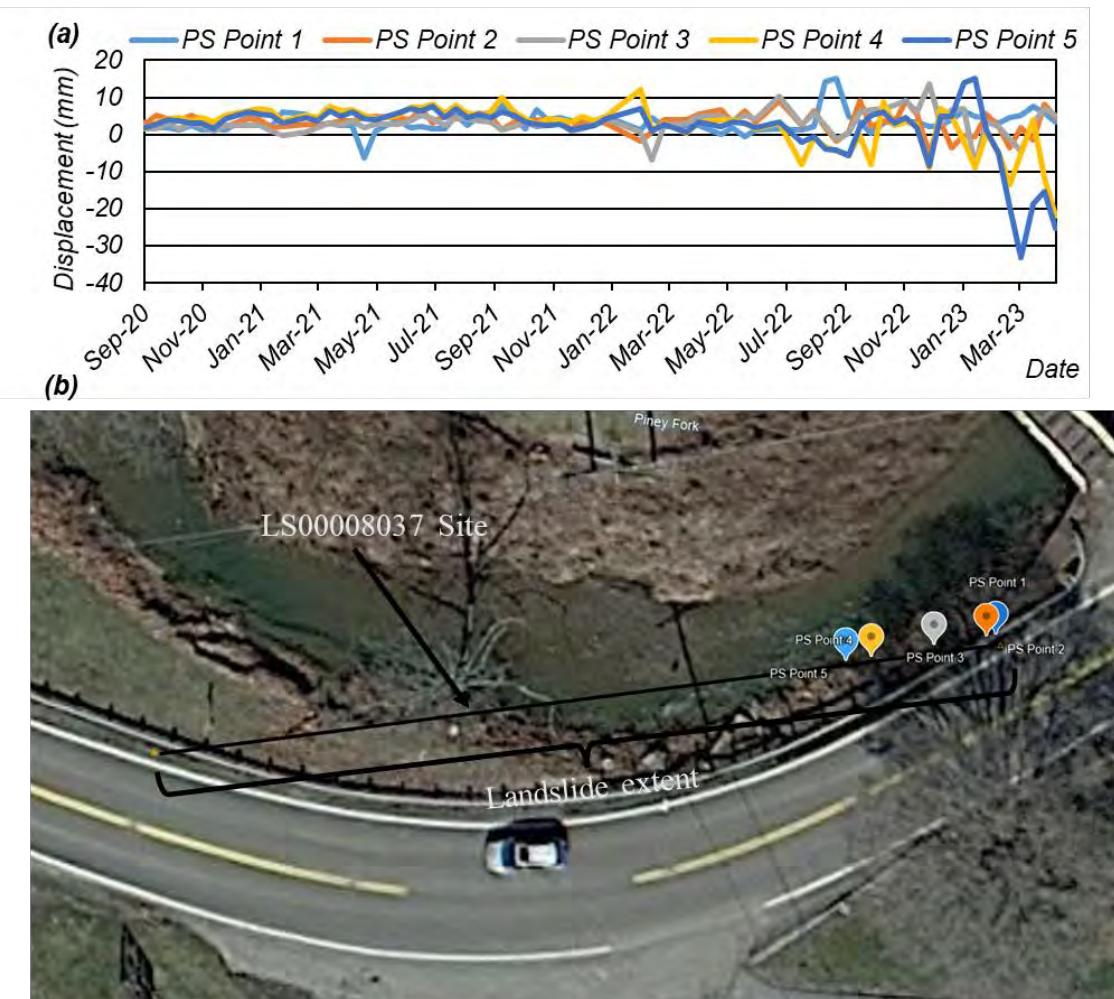

InSAR detected many PS points within and around the buffer zone shown in Figure 4.19. The PS points around the site indicate cumulative displacement of ~12 mm (0.5 in). The displacement time series plot for 5 PS points near the site is shown in Figure 4.21a. These points are mapped in Fig 4.21b. The displacement time series plot shows recent significant movements between January and March 2023. ODOT's latest inspection was completed in January 2023, but there were no reported movements at the time. This is expected because the movements started to occur following the inspection. Regardless, it is possible for a field inspector to miss movements of less than 2 cm if cracks or other observable features are not visible. InSAR may be invaluable for assisting with long-term monitoring at a site like this.

**Figure 4.19** Site map for LS00008037 showing nearby PS points.

**Figure 4.20.** Google street view image for site LS00008037 (Google 2013).

**Figure 4.21.** (a) Displacement time series near site LS00008037 for different PS points (b) location of PS points around the site LS00008037 (Google 2021a).

#### 4.3.3 Example Site 4: LS00008440

This is a Tier 3 site located in Guernsey County along State Route 513. This site was visited by members of OSU, E.L. Robinson, Terracon and ODOT on May 10, 2023. The site was recently remediated after developing large cracks in the pavement. The site is located at the corner of a high slope, making it more vulnerable. Drilled shafts of 2 ft diameter have been placed for remediation by ODOT as seen in Figure 4.23a. During the site visit, an obvious bend was observed along the roadside guard rail due to past landslide movements as shown in Figure 4.23b. The site lies outside the InSAR coverage area.

Lidar was not able to detect any geohazard polygons around this site as shown in Figure 4.24. This may have been due to several factors, including the high density of vegetation around this site (Figure 4.25), the small scale of the landslide, and an influence from the recent remediation.

(a) Recent remediation

(b) Bending in guardrail.

**Figure 4.23** Photos from May 10, 2023 field visit showing remediation and bending in guardrail of site LS00008440.

**Figure 4.24** No detection of geohazard polygon for site LS00008440.

**Figure 4.25** High vegetation cover over site LS00008440 (Google 2021b).

### **4.3 General Observations**

Some of the most salient observations from these comparisons are:

- 61% of the inventoried landslides with an occurrence score 1 (11 of 18), and 32% of the inventoried landslides with an occurrence score 2-4 (26 of 81) were not indicated by the geohazard polygons (i.e., NE or ND). This difference in percentages suggests that lidar is more likely to detect sites that show greater evidence of occurrence in the field surveys.
- 95 lidar-detected landslides (from the geohazard polygons) were not associated with the 99 ODOT landslides, which would suggest they are either (1) false positives by the lidar approach, (2) they were missed by the field surveys, or (3) they were part of the greater ODOT database not assessed in this study. The third situation has not been spot checked for every case by our research team. For example, LS00004980 and LS00009560 are Tier 1 sites picked up by lidar (slip IDs #1843 and #7064), but they are not part of the 99 selected sites. It is likely there are several similar cases, especially as the landslide dashboard (ODOT 2023b) currently indicates 2585 active landslides within the six counties considered in this study.
- The Teren geohazard assessment ranking system is currently incompatible with the ODOT risk Tier. However, such a ranking system can be re-configured as needed.
- As expected, the lidar change detection polygons were more likely to capture sites with a higher risk Tier. A lowering of the 1 ft threshold value is anticipated to detect more sites, however, this may come at the expense of greater noise and uncertainty. Lidar technology is improving, so this accuracy will become better over time.
- The 3 landslides with the largest movements detected by A-DInSAR (i.e., greater than 10 mm over the 2.5-year study period) were all risk Tier 1 sites. Furthermore, these sites were not captured by the lidar datasets. This suggests a unique ability of InSAR methods to detect and monitor subtle movements that may not be readily apparent from field surveys and lidar data, under optimal conditions.
- The inability of A-DInSAR to capture at least 10 mm of movement at 12 of the 15 considered sites is primarily due to the heavy vegetation and associated lack of coherency for obtaining relevant PS points. This suggests a need for higher resolution data to produce more meaningful results.

## CHAPTER 5: ADVANTAGES AND LIMITATIONS OF ALTERNATIVE METHODOLOGIES FOR LANDSLIDE INVENTORY UPDATING

This section highlights some of the relative advantages and limitations of the specific lidar and InSAR methodologies used in this study for their specific potential use in updating the ODOT landslide inventory. These advantages and limitations are based on (1) insights from the resulting comparisons to the 99 ODOT inventoried landslides, (2) the research team's discussions with the data providers (Teren and EO59), and (3) available relevant research concerning these technologies.

### 5.1 Lidar Change Detections

Two lidar-based approaches developed by Teren are used in this study for landslide inventory updating: (1) the geohazard detection and ranking system as obtained from a single lidar-derived DEM, and (2) the change detections obtained as the difference of two DEMs. The advantages and limitations of both approaches are considered together herein.

#### 5.1.1 Advantages

- **Ease of integration** – The lidar data is closely compatible for near-future integration with the current ODOT landslide inventory. The geohazard detection allows for a clear delineation of landslide boundaries. The ranking system developed by Teren can be modified for greater compatibility with the ODOT Tier rating system. The change detection approach can provide additional details regarding the activity of inventoried landslides, for inclusion with a lidar-based ranking system.
- **Landslide occurrence detection** – As observed from the results of this study, 62 of the 99 ODOT landslides were at least partially captured by the lidar-based geohazard delineations (~63% success rate). Also, 55 out of the 81 ODOT landslides with an occurrence probability score of 2 or higher were captured (~68% success rate). The slightly higher capture rate for sites with higher occurrence is as expected. Slides that are more visible from field surveys will likely be more visible from lidar. The sites not captured may be due to inaccuracies and other uncertainties (see limitations).
- **Impact to assets detection** – The digital elevation and terrain models (DEMs and DTMs) produced by lidar data, and the ability to use this data to delineate landslide boundaries, can allow for simple, automated tools for defining impacts to ODOT assets (e.g., distance to roadway relative to scale and orientation of landslide). While the Teren ranking system currently considers impacts to pipelines, it can be adjusted to consider features relevant to roads and other ODOT assets.
- **Geologic considerations** – Lidar assessments associated with DEMs can be configured to detect such items as topographic textures along slope surfaces, erosional features near rivers, and hydraulic influences (e.g., water collection within gullies or other topographic reliefs), among other features.
- **Becoming state-of-practice** – As discussed in Chapter 2, lidar DEMs have been applied for landslide inventories by US state agencies for over a decade. Change detections from multi-temporal lidar DEMs appear to be gaining more attention as well.

### ***5.1.2 Limitations***

- **Data collection frequency** – The frequency of lidar data depends on the availability of airborne data collection. Data collection can be costly, especially if the data and thus cost are not shared with other regional projects.
- **Accuracy** – The vertical and horizontal accuracy for the datasets provided by Teren were stated as within 14 cm and 40 cm, respectively. This is much greater than the relative millimeter scale accuracy from InSAR time series analyses. However, future developments are expected to continually improve the accuracy of lidar.
- **Uncertainties** – Past studies of change detection methods (e.g., Mora et al. 2018, Burns et al. 2010) suggest that uncertainties in lidar data acquisition and data processing can be significant. Heavy vegetation during the spring season in Ohio can also reduce the data resolution.

## 5.2 InSAR Change Detections

The advantages and limitations of the A-DInSAR methodology developed by EO59 is considered herein.

### 5.2.1 Advantages

- **Data collection frequency** – The high frequency of InSAR data collection (e.g., every 12 days with Sentinel-1 for a single orbit direction) provides the unique ability of closely monitoring movements. The case history at ODOT landslide LS00008037 showcases the ability of InSAR to detect recent movements (over the last one year) of a roadside riverbank, that was not detected by lidar (see details in section 4.2.3).
- **High reliability** – The high frequency of data collection improves the temporal reliability of slow movements over a long time period. This can potentially be more reliable than change detections from lidar that are typically based on two (or a small handful of) scans spaced over months or years.
- **Compatibility with other approaches** – The InSAR approach considered herein can be combined with other datasets (e.g., DEMs from lidar, lidar derivative attributes, aerial images) to better delineate and evaluate the activity of potential landslides.
- **Future potential** – As discussed in Chapter 2, satellite coverage is continuing to improve and become more accessible, as well as cost effective. InSAR methodologies relevant to landslide inventory updating are also continuing to improve through additional research.

### 5.2.2 Limitations

- **Data sparsity** – The ability to collect a significant number of meaningful persistent scatterer (PS) points significantly depends on the actual object space conditions. Areas that are heavily vegetated will provide fewer points for analysis relative to surfaces with higher reflectivity (e.g., buildings, infrastructure, or surface features that remain stable over time). In some cases, no relevant PS data will be obtained, as observed for 7 out of the 15 evaluated ODOT landslide sites. This can be improved with higher resolution (e.g., X-band) satellite data (e.g., Antonielli et al. 2019). Furthermore, despite a high temporal resolution, the spatial resolution of lidar is typically much greater than InSAR (especially when considering processing costs).
- **Landslide delineation** – The spatial extents of a landslide cannot be delineated from PS points without additional data. This information is crucial for evaluating the impact of a landslide to nearby assets.
- **Landslide orientation bias** – The orientation of the satellite line of sight (LOS) relative to the landslide slope aspect can influence the results. Currently, only the ascending orbit direction of Sentinel-1 is available in Ohio. This LOS provided by this ascending orbit is more likely to provide more PS points for east-oriented landslides (i.e., because the slope is roughly parallel to the satellite LOS), rather than west-oriented landslides. Geometric distortions such as foreshortening, layover, and shadow effects can also adversely affect the results as dependent on the slope aspect and topographic details (e.g., Antonielli et al. 2019).
- **Event bias** – The A-DInSAR methodology used herein is best-suited for slow moving landslides. Landslides that may occur immediately (e.g., during or following a major storm or other extreme event), may greatly reduce the coherency of the SAR data.

## CHAPTER 6: FINDINGS AND RECOMMENDATIONS

The study herein focused on the evaluation of remotely sensed lidar and InSAR datasets for interpreting change detections of inventoried eastern Ohio landslides. Lidar-derived landslide delineations and change detections were provided by specialty firm Teren near a subset of 99 ODOT inventoried landslides. The A-DInSAR methodology was used by specialty firm EO59 near a subset of 15 ODOT inventoried landslides. The results showed that 62 of the 99 ODOT landslides were at least partially captured by the lidar-based geohazard polygons, 12 of the 99 ODOT landslides were detected by lidar-based change detections for over 1 m of movement, and 3 of 15 ODOT landslides considered with A-DInSAR detected at least 10 mm of filtered movement.

Following are the overarching findings of this study:

- The lidar and InSAR methods used herein each possess their own advantages and limitations.
- The lidar methods used herein can be most readily incorporated within the ODOT landslide inventory because they can delineate landslide extents, provide a ranking system, and have shown reasonable success for detecting landslides for this and similar studies.
- The lidar methods used herein tended to better capture sites with ODOT risk Tiers greater than 1 (particularly those with occurrence scores greater than 1).
- The InSAR methods used herein can be advantageous when applied in combination with other datasets (e.g., DEMs from lidar, lidar derivative attributes, aerial images), especially for their ability to monitor slow-moving landslides. The utility of InSAR for such work is expected to improve over time.
- Both technologies are rapidly continuing to develop and find greater practical use for landslide detections and inventory updates. In particular, the use of InSAR is increasing at a fast pace.
- Ultimately this work is anticipated to support the potential adoption of remote sensing technologies to supplement or substitute current ODOT landslide inventory field surveys. Our research team believes that in the near-term, the integration of lidar-based approaches with the landslide inventory can potentially increase landslide detection reliability and reduce overall costs. InSAR may additionally be considered for either indicating subtle movements for lower risk Tier landslides, or frequently monitoring movements of higher risk Tier landslides.

Some limitations and recommendations for future studies include:

- This study was limited to a subset of 99 inventoried ODOT landslides. Only 15 of these sites were considered with the InSAR methodology. This sample size may not completely represent the entire ODOT landslide inventory, especially considering the various factors that could affect remote sensing interpretations.
- Future work should consider adjusting the lidar-derived change detection threshold which was set at 1 foot for the study herein to obtain a more optimal balance of detected landslides and minimized uncertainties.
- Future work should also consider adjusting the geohazard ranking system provided by Teren to better match the considerations used to determine the ODOT risk Tiers.

- Future work could consider the benefits of higher resolution (e.g., X-band) InSAR data for better capturing heavily vegetated sites.
- Future effort will be needed to integrate the remote sensing approaches evaluated herein for compatibility with the current ODOT inventory.

## **APPENDIX B:**

### **FIELD REPORT FOR VISITED LANDSLIDE SITES**

- Field report for site visit on 10<sup>th</sup> of May 2023.
- Observations and importance information's from each 13 visited site is briefly described.

## **FIELD REPORT FOR VISITED LANDSLIDE SITES**

Date: May 10, 2023

### **Introduction:**

On Wednesday May 10, 2023, the members from OSU, Terracon, ELR, and ODOT visited 13 landslide sites (12 out of 17 originally planned sites; and 1 unplanned site). The goal of this site visit was to better understand ODOT's landslide inventory tier classification and note general observations that may influence aerial measurements. The sites we visited were in three different counties: Guernsey, Belmont, and Noble. This report has been drafted to summarize the observations for each visited site to better understand them. Sites visited were primarily Tier 1 or 2. There were only 2 sites with Tier 3 designation. The subsequent sections will discuss the preliminary observations at each site and the reasoning for their tier classification.

Site abbreviations represent county names: GUE represents Guernsey, BEL represents Belmont, and NOB represents Noble.

## Sites Visited

### 1. LS00006904 (GUE-70-18.747)

Present Tier Classification: 2

Comments: It was T1 in 2017 and changed to T2 in 2023

The site is situated on Interstate 70, which has a heavy traffic load. The site shows large landslide movements and displacement of soil mass which can be seen in Figure 1. The toe of the landslide is about 25 ft away from the nearest interstate lane boundary (i.e., solid white line). This landslide appears active and would likely have a higher Tier than 2 if it was closer to the roadway. ODOT members told us that if this site were 30 ft further from road, it would be even less of a concern. Proximity to the major road and its effect on moving traffic greatly affects the ODOT landslide tier classification.

A wet decomposed claystone was visible along the base of the slide. Water appeared to be seeping from about four feet above the base, and ponded water was visible along the slope base. Overturned trees were abundant along the head scarp.

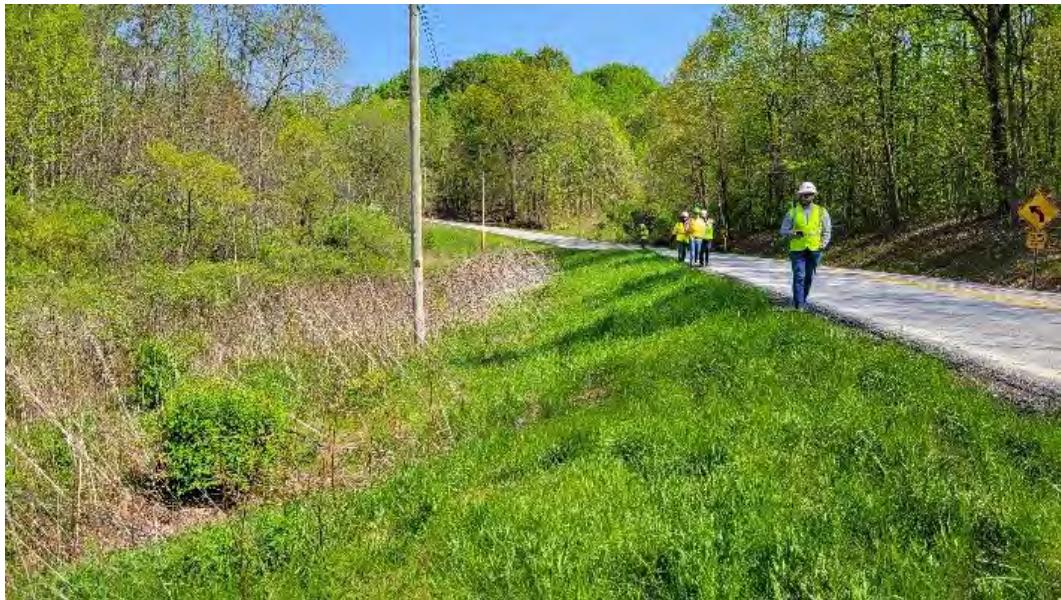

**Figure 1** Photos from site visit for site LS00006904 (GUE-70-18.747).

## **2. LS00006384 (GUE-513-4.311)**

Present Tier Classification: 1

Comments: Tier 1 since 2008

The site is situated along the state route 513. The site is heavily vegetated and located downslope of a rural road. There is no apparent sign of a landslide. For the last 15 years, the site has consistently been Tier 1. It's possible that one reason ODOT still has this site in its inventory is its proximity to the road and the possible threat it might develop if any movements occur.

**Figure 2** Photos of site visit for site LS00006384 GUE-513-4.311

### 3. LS00008440 (GUE-513-4.791)

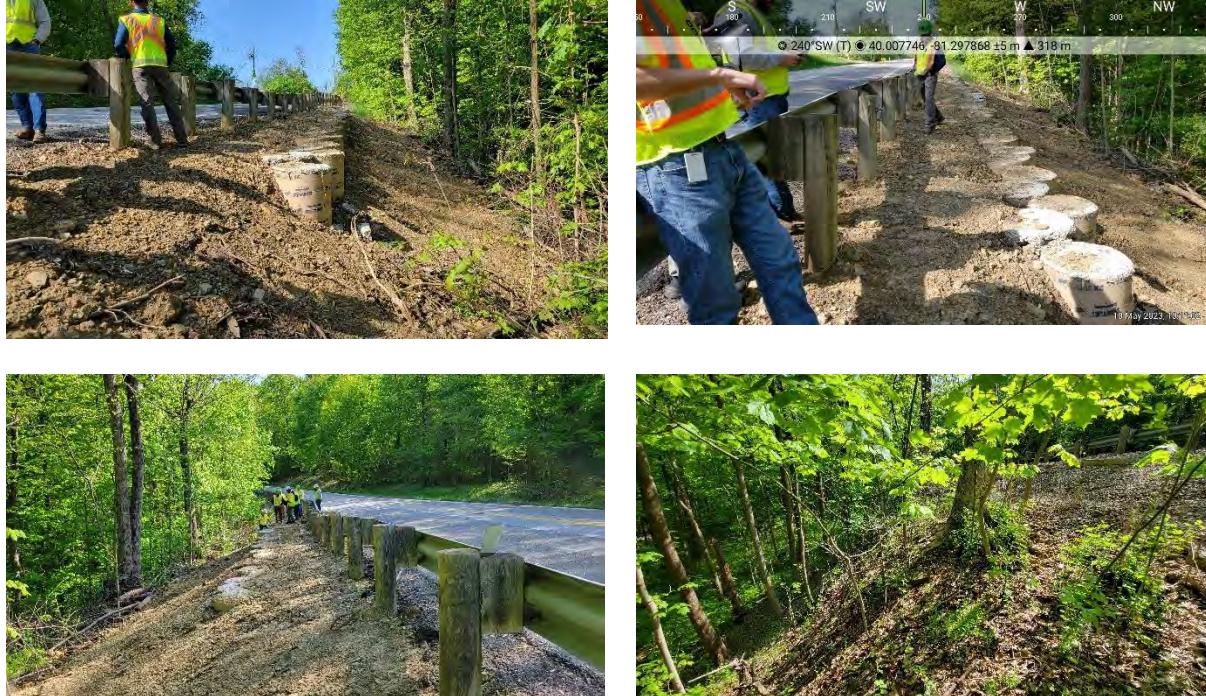

Present Tier Classification: 3

Comments: Since 2009 site was T2 and in 2019 it moved to T3.

The site is situated very close to the previous site (LS00006384) along the same state route 513. The site was recently remediated after developing large cracks in the pavement. The site is located at the corner of a high slope which makes it more vulnerable. The decision to move it to T3 was made based on developing cracks and the threat it poses to vehicular traffic. Drilled shafts (2 ft diameter and assumed max depth of 20-25 ft) have been placed for remediation by ODOT as seen in Figure 3. The roadside guard rail shows clear bending due to landslide movements. Figure 4 shows guard rails and cracks in the pavements.

The location of the site, i.e., at the corner of the high slope is a major reason for its T3 classification as even a small landslide movement will pose a greater risk to the traffic. If we compare this site with the first one (GUE-70-18.747) the landslide movement is not that large but due to its proximity to the road it has a higher tier classification.

ODOT suggested that bedrock was likely within 15 ft below the head scarp. Borings are available on the TIMS website. It is possible there was a water stream present near the base of the slope (difficult to see due to dense vegetation, but Google Earth confirms that a stream is typically there).

**Figure 3** Photos of site visit for site LS00008440 (GUE-513-4.791) showing recent Remediation

**Figure 4** Photos of site visit for site LS00008440 showing bending in guard rails and crack in the pavement.

#### 4. LS00006794 (GUE-265-12.788)

Present Tier Classification: 1

Comments: Tier 1 since 2008

The site is situated adjacent to rural arterial route 265 as shown in Figure 5. There was no sign of active movements at the site. However, there is a 1-in thick crack present near the crest of the slope which suggests possible landslide movement. It is possible that the site is in the inventory because of this crack, however, no further movement was reported in the last 15 years.

The east side of the slope showed evidence of a vehicle impact (e.g., scoured base slope material) from a recent accident that appears to have damaged the guardrail at south of road. The south of road had also been remediated with 30 in diameter shafts (likely within 15 years old; remediation was not performed by ODOT).

UPDATES: Lidar – Not in extent (Landslide detected aligned perpendicular to ODOT's)

**Figure 5** Photos of site visit for site LS00006794 (GUE-265-12.788).

## 5. LS00008439 (GUE-265-12.935)

Present Tier Classification: 2

Comments: Classified as T2 since 2013.

The site is situated close to GUE-265-12.788 along route 265, the guard rail shows clear bending. Also, there is some slight transverse cracking across the road pavement. Figure 6 shows the site location and bent guard rail. There was a small valley in the hill formation at the other side of the road. It is likely that this section of the roadway embankment is founded atop a greater thickness of fill which may have settled. Another possible cause of movement may be freeze-thaw action. The OSU team does not believe this was caused by a natural landslide.

**Figure 6** Photos of site visit for site LS00008439 (GUE-265-14.935)

## 6. LS00007054 (GUE-265-14.686)

Present Tier Classification: 1

Comments: The site is labeled as “T1 progressing,” which means it shows some developments from the last inspection but may not suggest a complete shift to T2 (i.e., it can be considered a T1.5 site, although ODOT does not have a 1.5 tier class)

The site is located along route 265 and is shown in figure 7. We can observe slight cracking at the base of the slope and a series of thin (< 0.25 in) transverse cracks across the road. Water ponding was also present.

**Figure 7** Photos of site visit for site LS00007054 (GUE-265-14.686).

## 7. LS00006361 (BEL-147-3.434)

Present Tier Classification: 1

Comments: T1 (Low/low) since 2012 and changed to T1 (Mod/low) in 2023 (possibly due to potential movement, without affecting the road)

This site is located along route 147. Trees and a power transmission pole have a slight lean. Slight soil slumping is present around a small culvert at side of road. Otherwise, landslide activity is not apparent.

**Figure 8** Photos of site visit for LS00006361 (BEL-147-3.434).

## 8. LS00006360 (BEL-147-2.770)

Present Tier Classification: 2

Comments: T1 since 2012, moved to T2 in 2023.

This site is at the east end of a series of 4 slides along route 147. The site was recently moved from T1 class to T2 by Terracon, however, there was no sign of movement on the day we visited, so it is questionable why they moved it to T2. There are some longitudinal cracks present that may not be attributed to landslide movement, however, these cracks were quite wide at the time of the last inspection done by Terracon. There was also some evidence of seepage near the slope base.

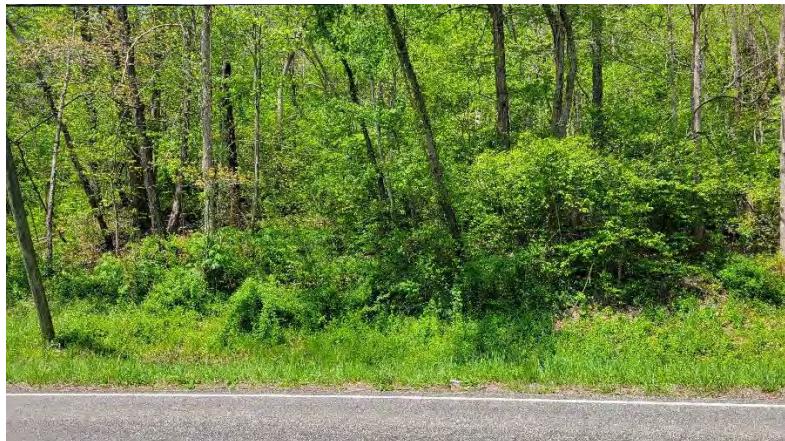

**Figure 9** Photos of site for site LS00006360 (BEL-147-2.770).

## **9. LS00005045 (BEL-147-2.845)**

Present Tier Classification: 1

Comments: T1 since 2012; note of possible remediation

This was the second from the east in a series of 4 slides along route 147. There was no indication of landslide activity, aside from some slightly tilted trees. ODOT commented on the possibility that the road may have been previously damaged by oil and gas trucks that frequent the route but may have been recently fixed by the oil and gas companies.

**Figure 9** Photos of site visit for site LS00005045 (BEL-147-2.770).

## **10. LS00010617 (BEL-147-2.903)**

Present Tier Classification: 2

Comments: The site was lowered from T3 to T2 by Terracon.

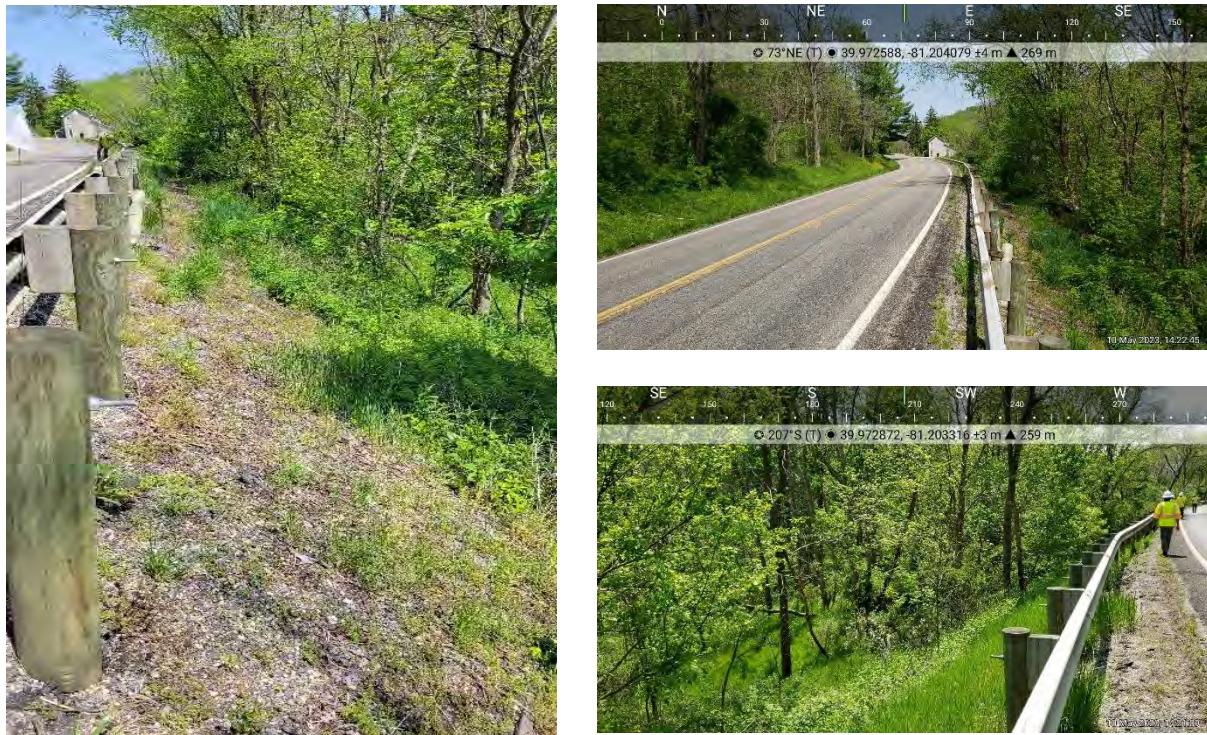

This was the third from the east in a series of 4 slides along route 147. Our team walked by this site but did not notice any obvious landslide movement. No photos were taken.

## 11. LS00009556 (BEL-147-2.957)

Present Tier Classification: 2

Comments: The site has been T2 since 2012, and recently assigned “progressing” status.

This was the westernmost in a series of 4 slides along route 147 that were observed. The bending of the guard rail can be observed at the site as shown in Figure 11. Five borings were taken by ODOT along the roadway, and an inclinometer began taking readings about 1.5 years before this site visit.

**Figure 11** Photos of site visit for site LS00009556 (BEL-147-2.957).

## **12. LS00008935 (BEL-147-1.994)**

Present Tier Classification: 2

Comments: Assign progressing status in 2023.

Figure 12 shows the site location near BEL-147.1.994, there was no sign of active landslide movement. Photos from 2013 available in the Falcon app suggest a significant network of pavement cracking that may have been recently covered up. Other 2013 data suggests a bulge is visible in an area that is now covered with tall grass

**Figure 12** Photos of site visit for site LS00008935 (BEL-147.1.994).

### 13. LS00009082 (GUE-513-3.265)

Present Tier classification: 3

Comments: Site was designated as T1 during past inspections in 2008 and 2018. Recently moved to T3 after this site visit with increased in landslide length.

The site shows widespread cracking in the pavement due to landslide movement, there is clear subsidence of the road observed. The head scarp along the road extends roughly 100 ft, and most damaged section exhibits a 2.5" vertical drop and 2" wide crack. Figure 13 shows the site location and developed cracks in the pavements.

The outer bank of a stream meander at the base of the slope appears to align with the landslide extent, indicating the possibility of stream-driven erosion contributing to the slide. Trees are also tilting in the direction of slide movement.

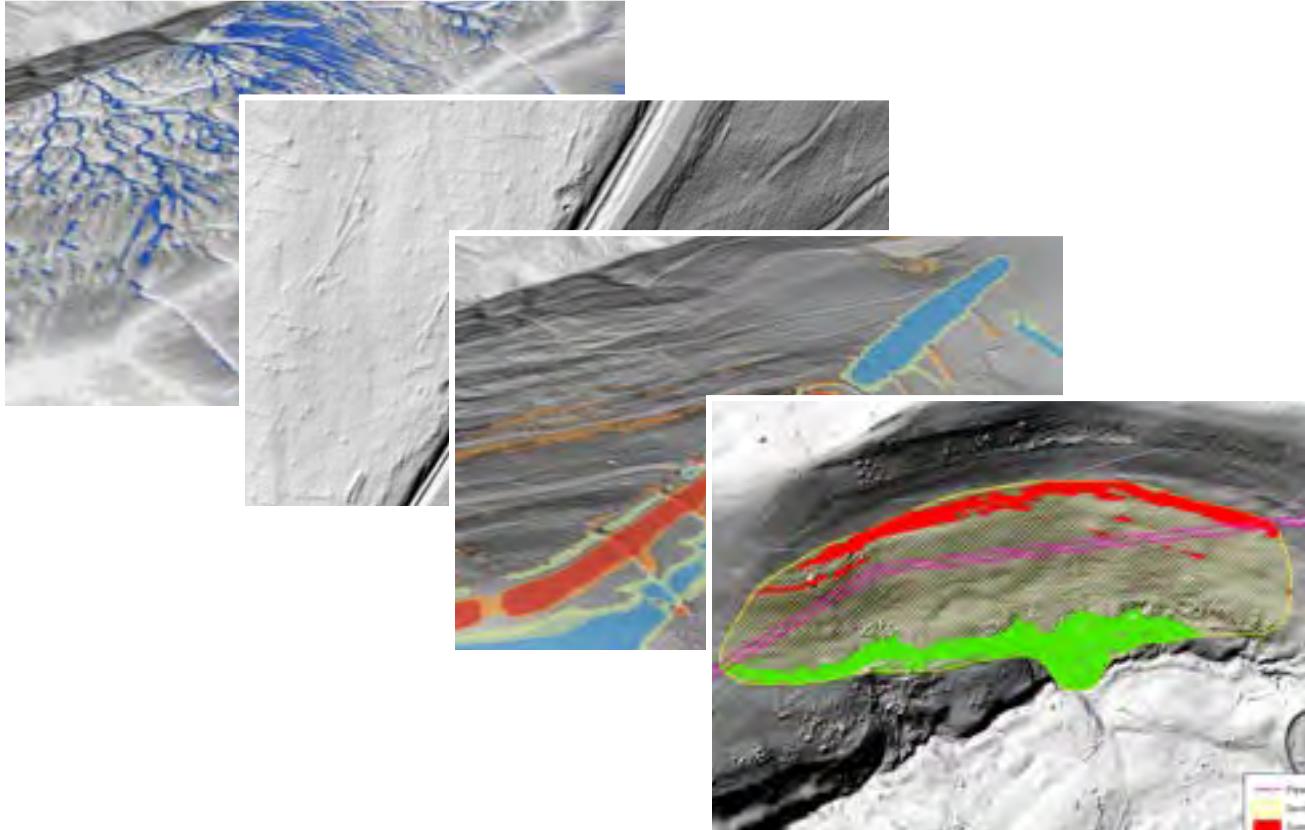

**Figure 13** Photos of site visit for site LS00009082 (GUE-513-3.265).

# **APPENDIX C:**

## **RESOURCES FROM TEREN (LIDAR)**

- Hand-off document

- Presentation: Geohazard change detection utilizing lidar and advanced analytics
- Viewer quick start guide
- Attribute table for geohazard polygons
- Attribute table for change detection polygons

## <Customer> PROJECT

### WELCOME

We at Teren are pleased to present <Customer> with a compilation of support documentation to help users understand and derive maximum value from their <Project Name>.

We suggest beginning with this document, which describes each analytic product. Then, for a deeper dive into the data, please reference accompanying documents including the Data Tour, and Data Dictionary. We welcome any questions or suggestions that may arise along the way.

This document is organized into the following sections:

1. Executive Summary
2. Analytics Definition

## EXECUTIVE SUMMARY

### Project History

TBD if we need this...

### Project Scope

The scope of this project included aerial LiDAR data collection, processing, and analytics of the <project name>.

The deliverables in the first data delivery include:

- Analytics 1
- Analytics 2

Other relevant project milestones here.

## ANALYTICS DEFINITIONS

### PRODUCT OVERVIEW

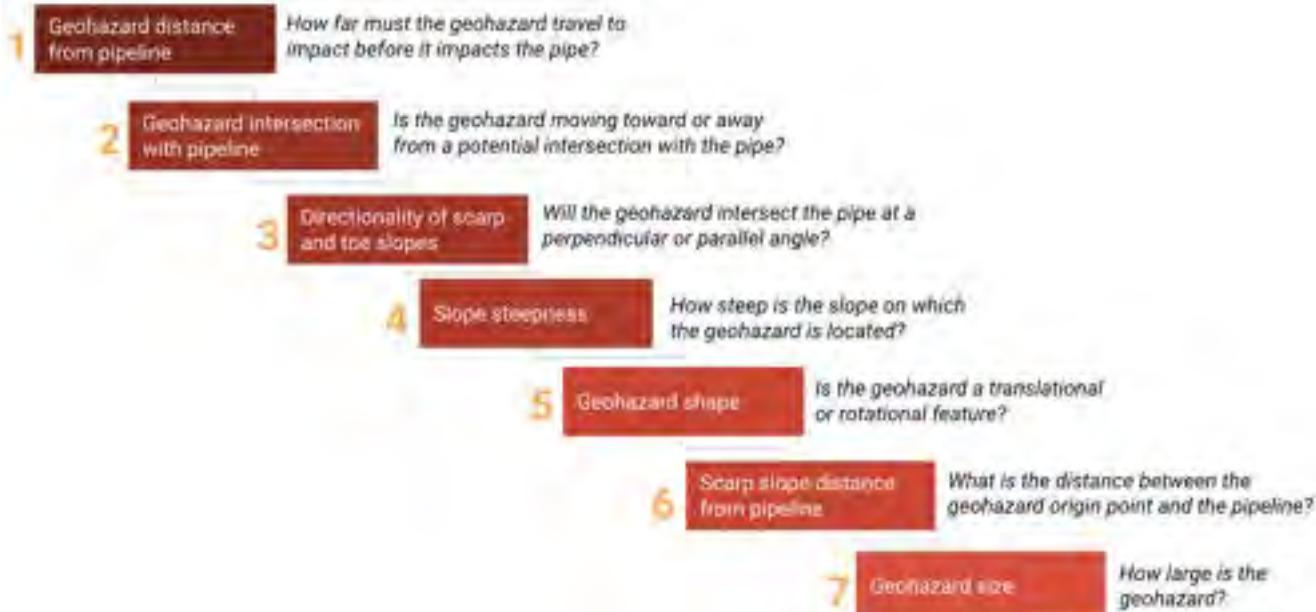

#### Geohazard Analytics

The Geohazard Analytics package consists of several deliverables to aid operators in identifying, predicting, and prioritizing geohazard threats.

**Existing Geohazards.** The Geohazards analytic draws upon computer vision algorithms to detect existing landslides within and near the right of way with the potential to threaten asset integrity. Teren's algorithms then delineate each landslide's structural components, including the toe and scarp slopes. Taking into account landslide structure, situation within the terrain, connectivity to the asset, and other risk factors, Teren performs an Absolute Geohazard Assessment, whereby each geohazard's risk factors and absolute score are measured over time to understand changing risk conditions. Each geohazard is also assigned a relative ranking based on the threat it poses to the pipeline relative to all other identified geohazards.

Teren's Absolute Geohazard Assessment scores individual geohazards according to factors defined in the below model decision tree. An absolute score of 6 and above indicates that the geohazard intersects with the pipe centerline. An absolute score of 5 or below indicates that the geohazard is adjacent to but not intersecting the centerline.

In addition to evaluating changes in existing geohazards, Teren also reports the successful mitigation and emergence of geohazards. Fixed geohazards include landslides that were present in Spring 2021 and absent in Fall 2021 data. New geohazards include landslides that were absent in Spring 2021 and present in Fall 2021 data.

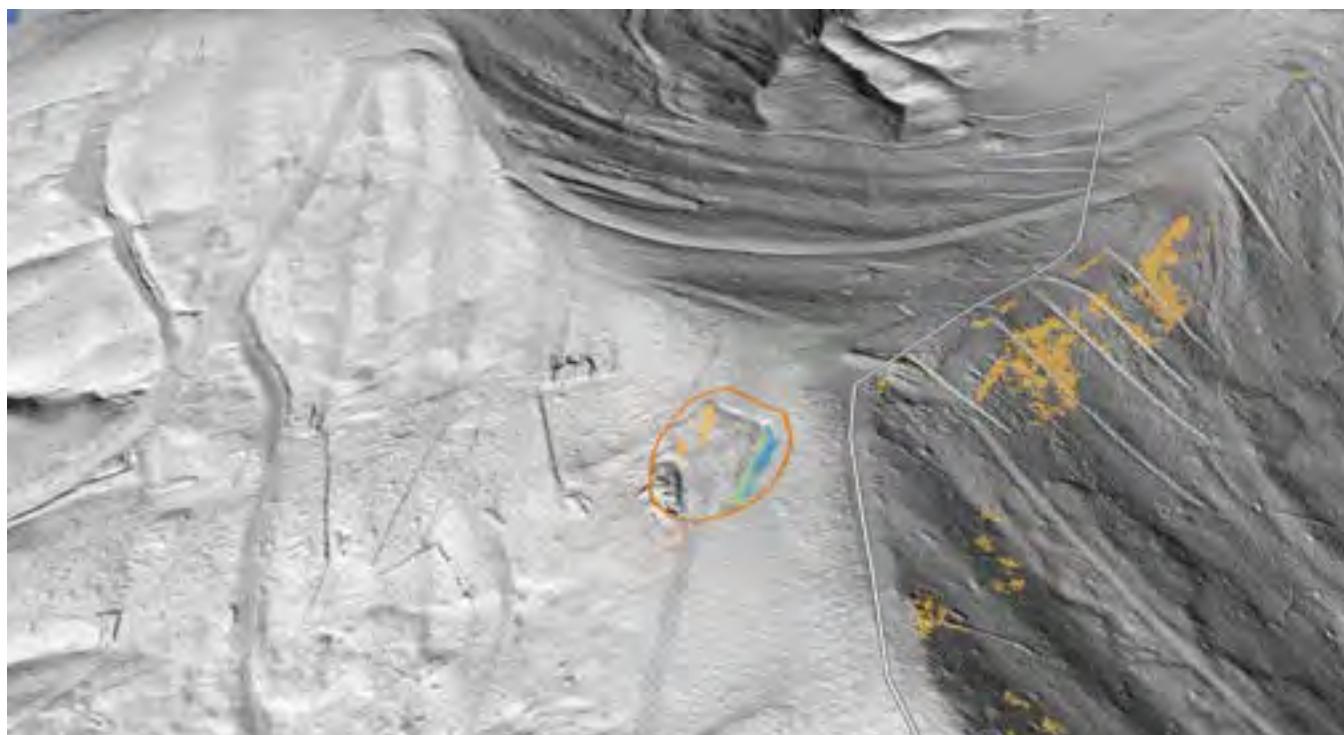

**Problematic Hillslopes.** In addition to delineating and ranking existing geohazards, Teren's Problematic Hillslopes analytic predicts the hillslopes throughout the pipeline system that are most likely to fail and compromise asset integrity. Considering factors such as slope, orientation, soil type, and hydrology, each hillslope connected to the pipeline is delineated and ranked according to its level of threat. Raster-based results empower efficient prioritization of proactive monitoring efforts and minimize surprise incidents.

**Centerline Risk.** The relative level of threat posed by existing geohazards and problematic hillslopes is summarized to the pipeline in three-meter segments and averaged based on a sliding mile to create the Centerline Risk analytic.

## Change Detection Analytic

The Change Detection Analytic enables operators to understand terrain changes on their right of way through time.

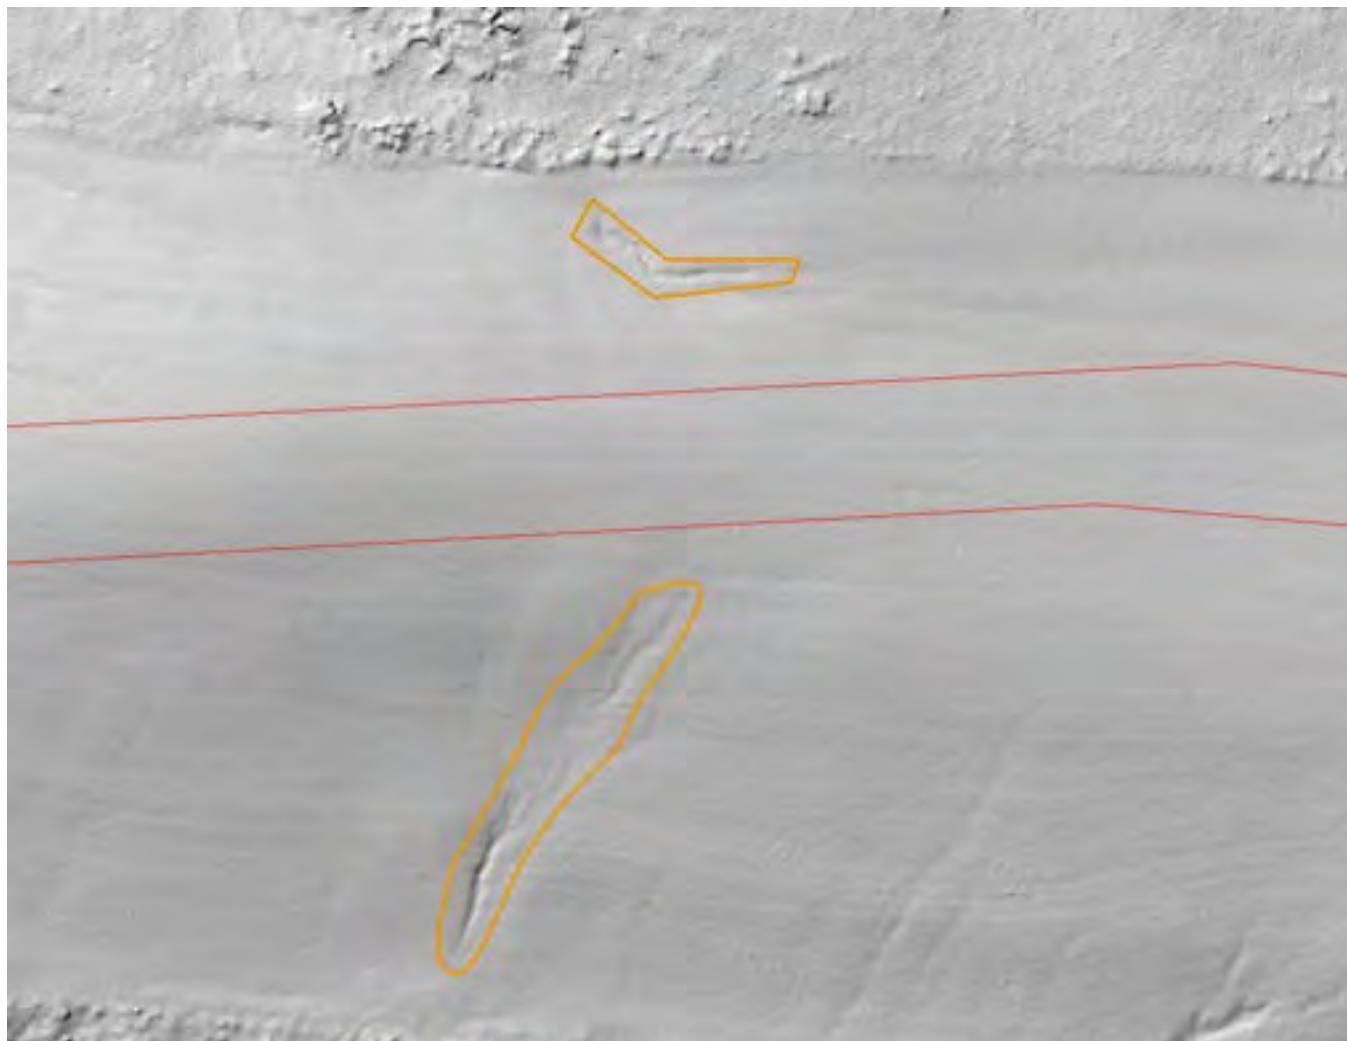

**Continuous Change Detection.** Teren's Continuous Change Detection analytic compares landscape features and terrain between two temporal datasets to detect subtle landform or surface structural changes. The algorithm first removes vegetation and elevation biases from the two temporal datasets under comparison. Then, the analytic measures vertical shifts greater than 1 foot within 60 feet of the centerline. The resulting deliverable is a raster heatmap of natural- and human-triggered material loss, subsidence, accumulation, and other movements that have occurred between Spring 2021 and Fall 2021 flight instances.

## Geohazard Analytics

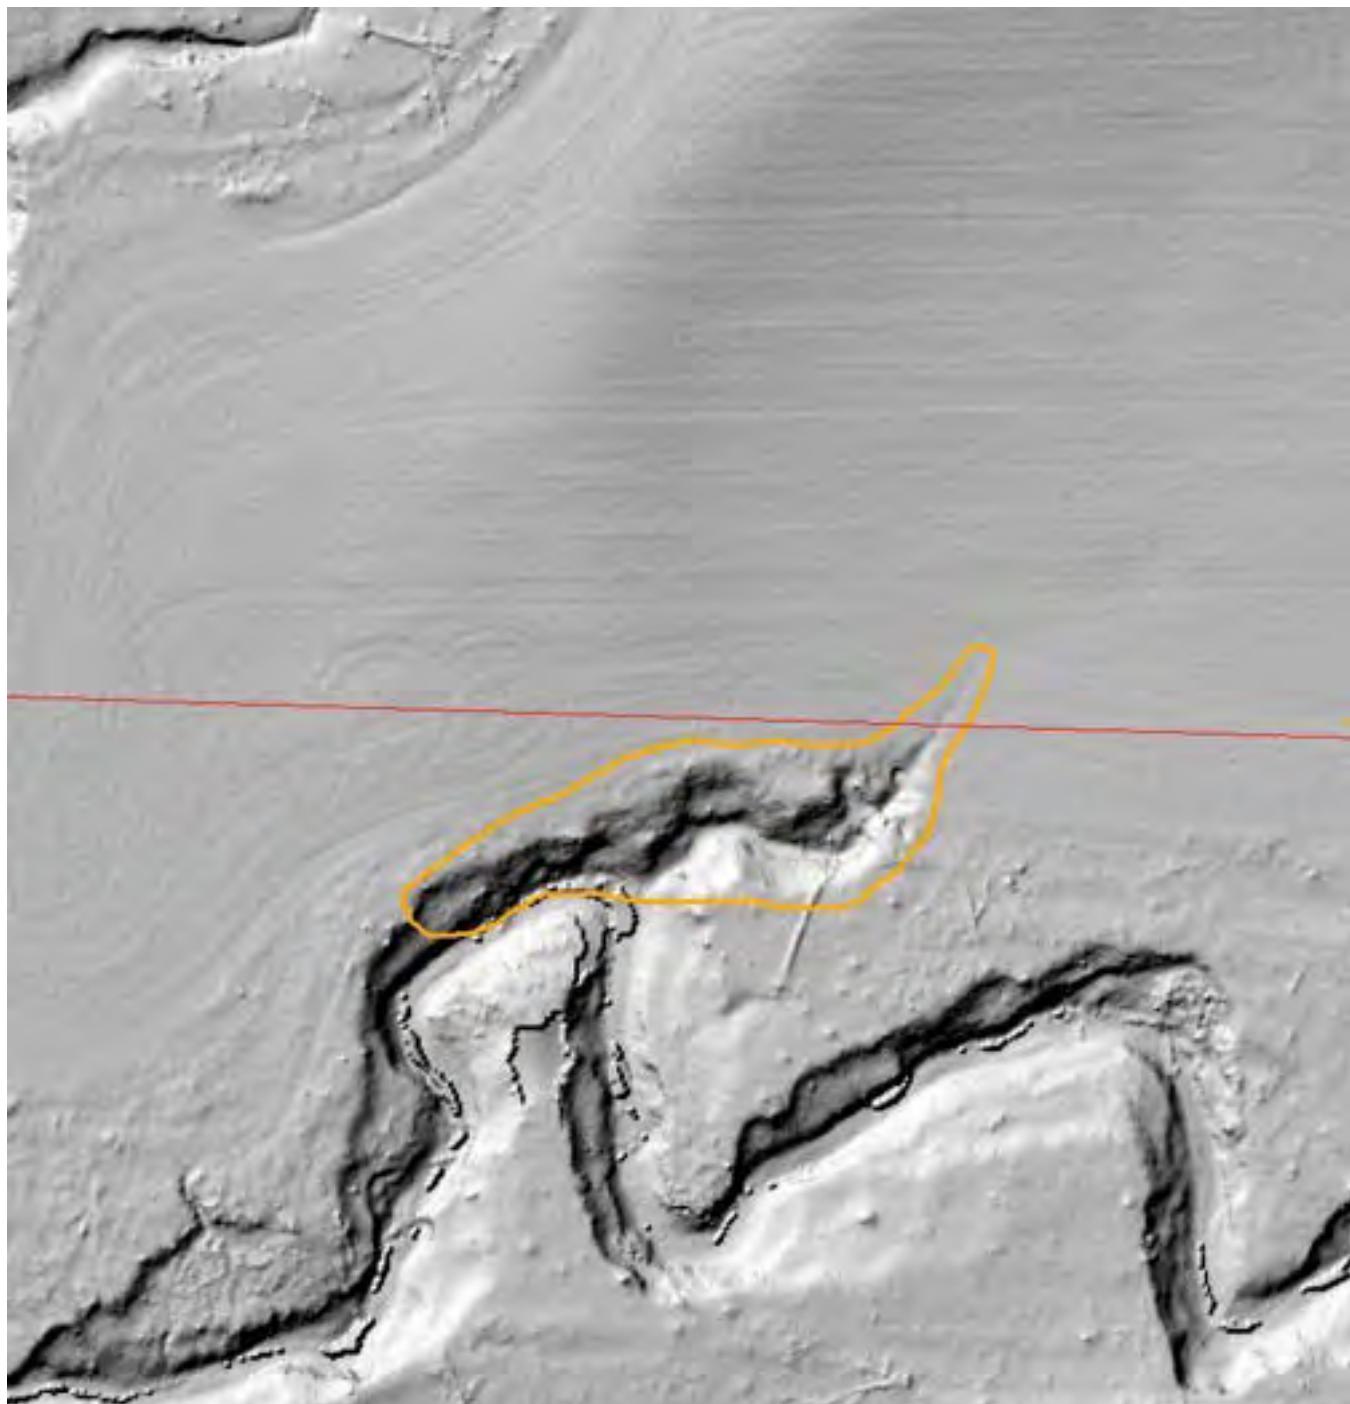

In topographically flat regions, geohazards manifest where hydrologic forces alter the landscape in ways that threaten asset integrity. Teren identifies and delineates the following geohazards to enable targeted monitoring and mitigation where needed most.

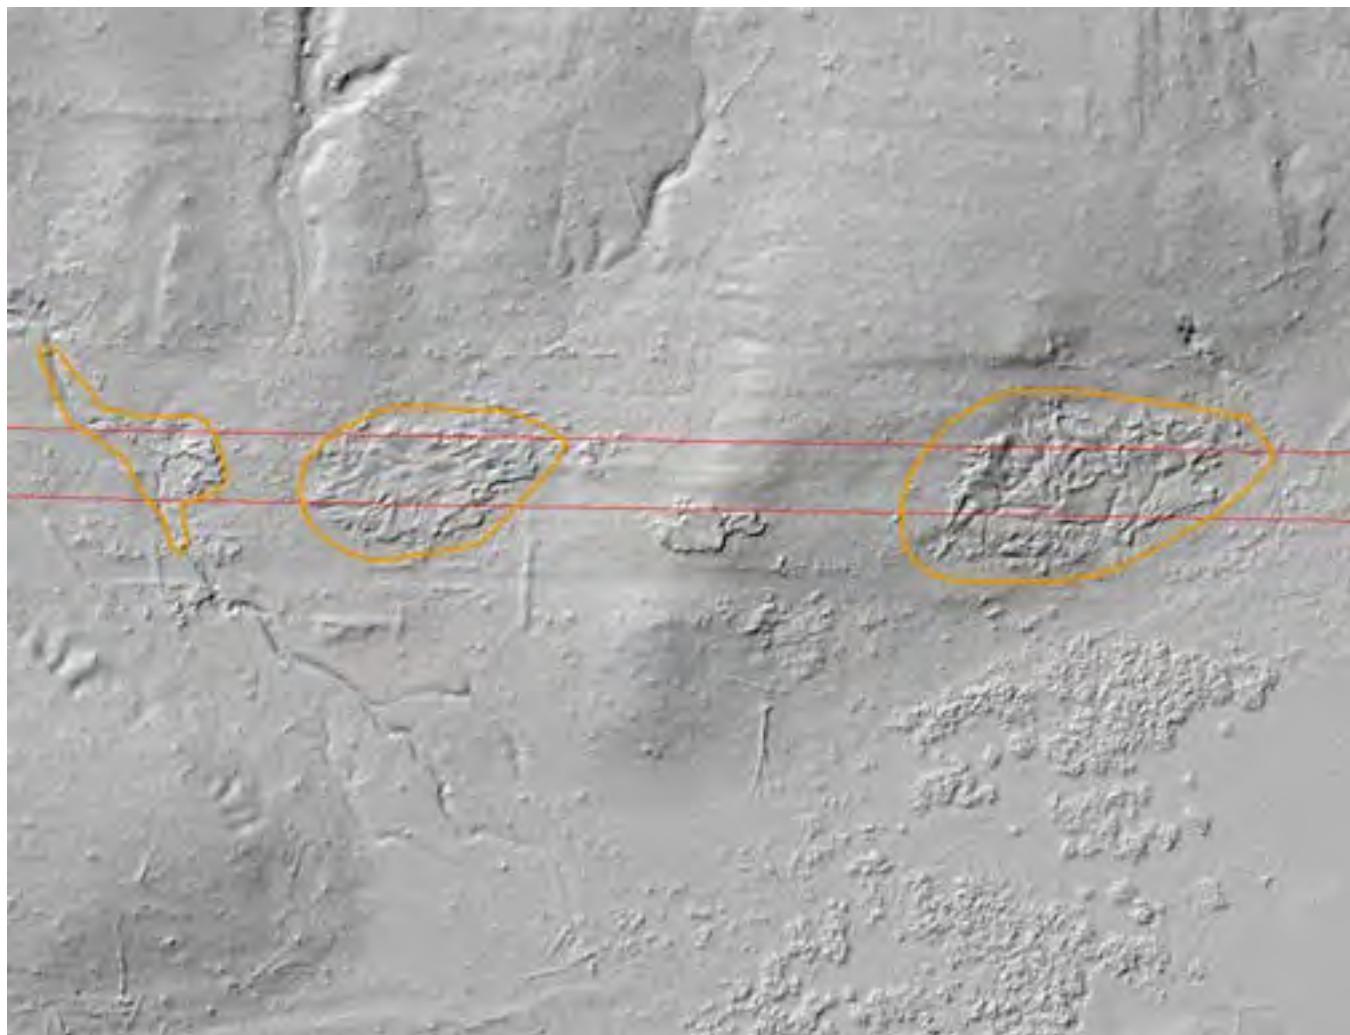

**Cutbank.** Teren's geohazard analytics identifies cutbank hazards which occur where a stream or river is eroding away on the outside bank of a curve in the water channel and the erosion is progressing toward the pipeline.

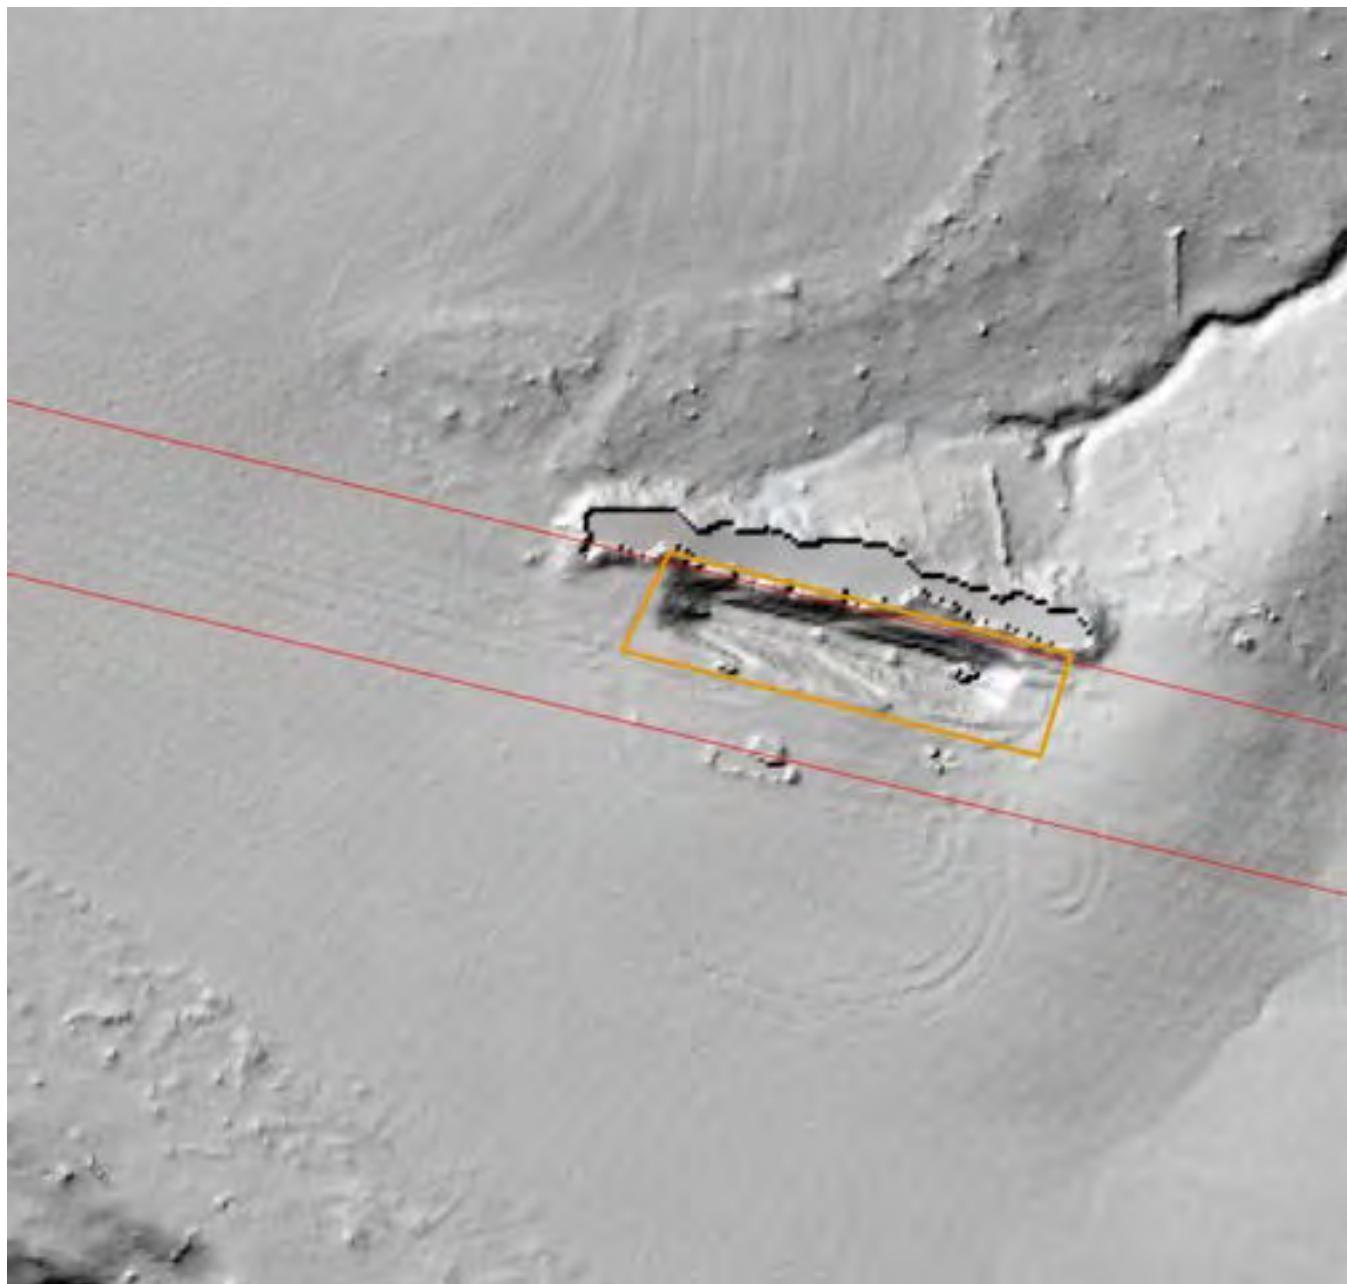

**Rilling and gullying.** Teren's geohazard analytic identifies rill hazards which form as small hydrologic channels that, if left unmanaged, can erode into a larger gully hazard with increasingly greater erosive potential.

**Headcut.** Teren's geohazard analytic identifies headcut hazards which are the most headward or upstream feature of a gully where active erosion and entrenchment occurs.

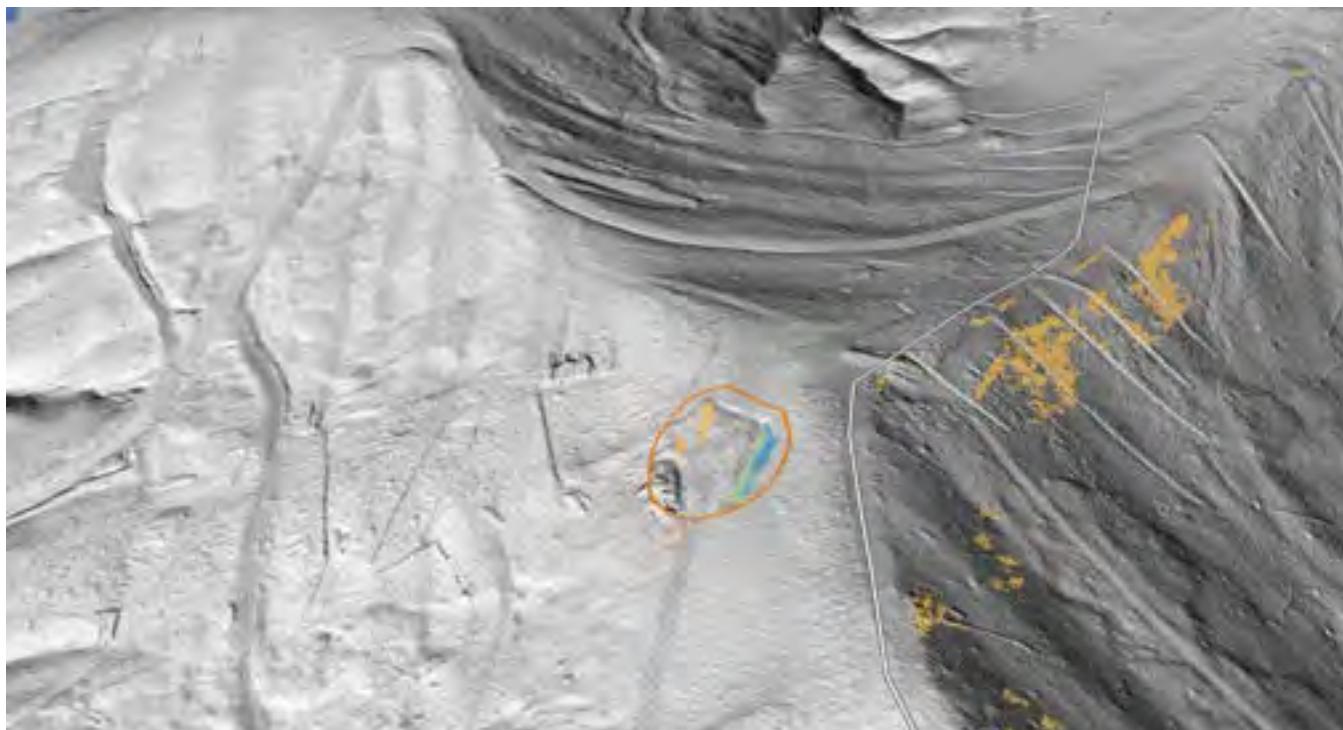

**Saturated zone.** Teren's geohazard analytic identifies saturated zones which occur where the terrain appears to be affected or altered by hydrologic inundation.

**Exposed pipe.** Teren's geohazard analytic identifies exposed pipe hazards which occur where the pipeline is visible above ground.

## Change Detection Analytic

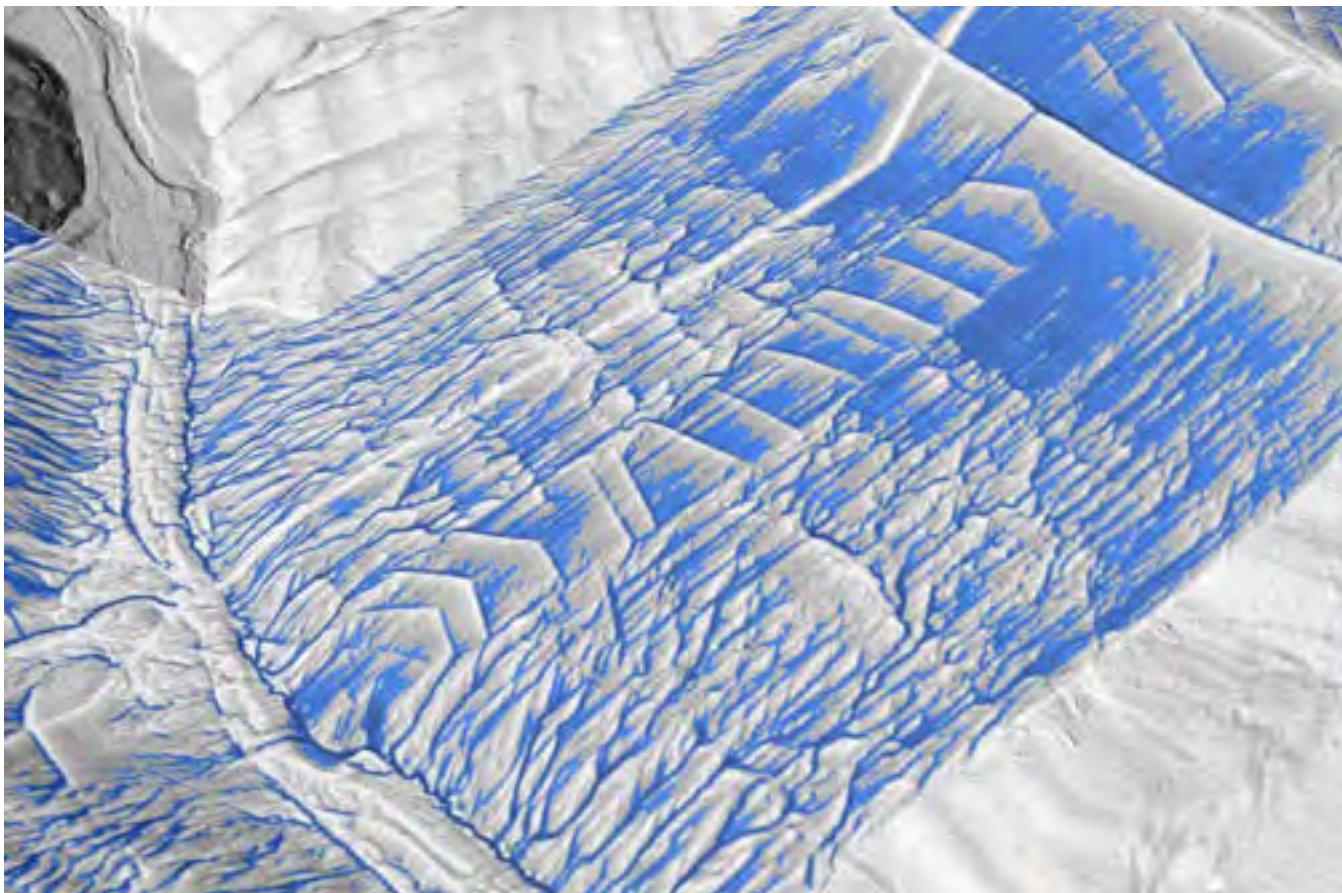

The Change Detection Analytic enables operators to understand terrain changes on their right of way through time.

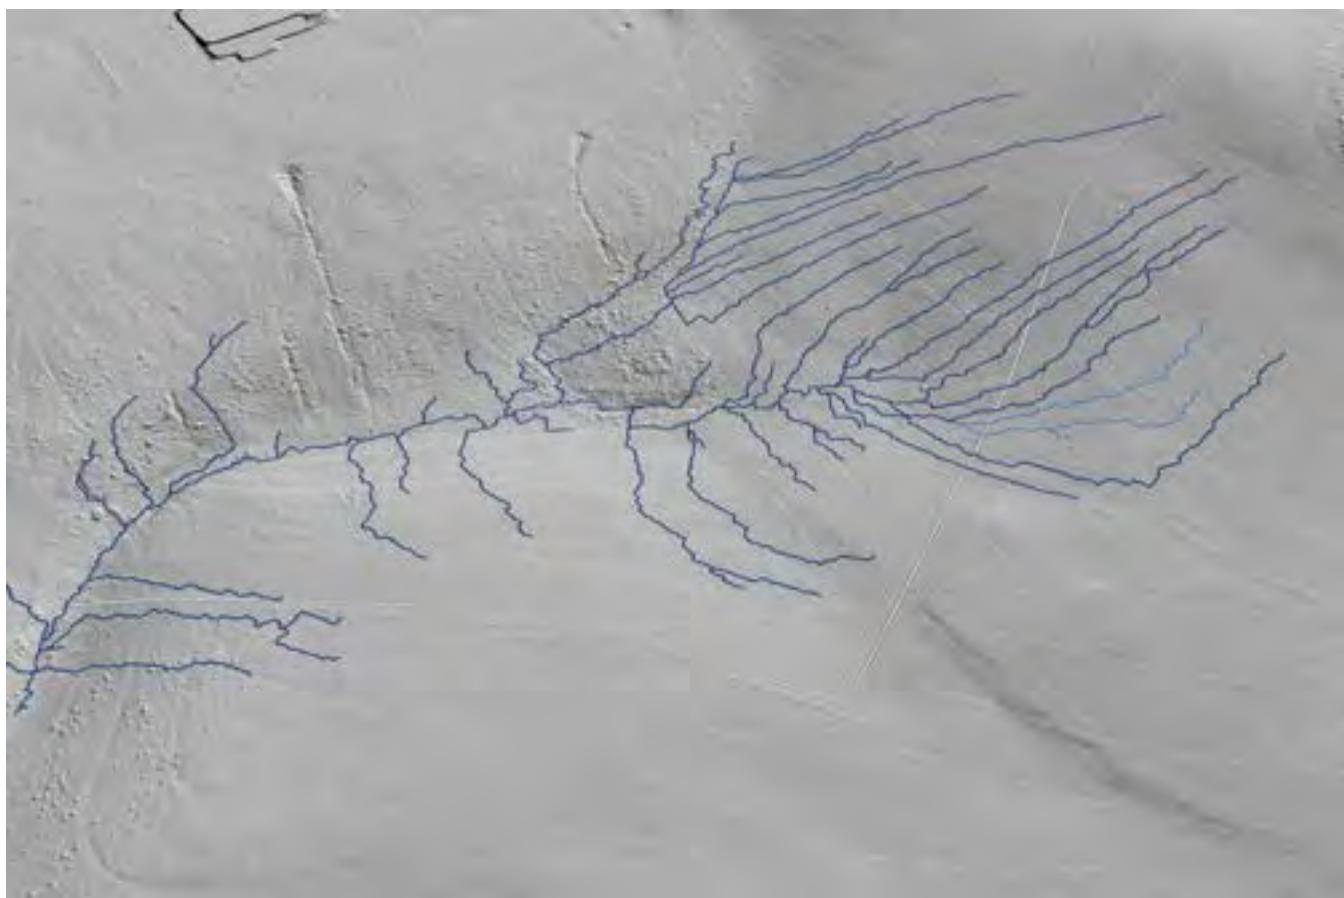

**Continuous Change Detection.** Teren's Continuous Change Detection analytic compares landscape features and terrain between two temporal datasets to detect subtle landform or surface structural changes. The algorithm first removes vegetation and elevation biases from the two temporal datasets under comparison. Then, the analytic measures vertical shifts greater than 1 foot within 60 feet of the centerline. The resulting deliverable is a raster heatmap of natural- and human-triggered material loss, subsidence, accumulation, and other movements that have occurred between Spring 2021 and Fall 2021 flight instances.

## Hydrology Analytics

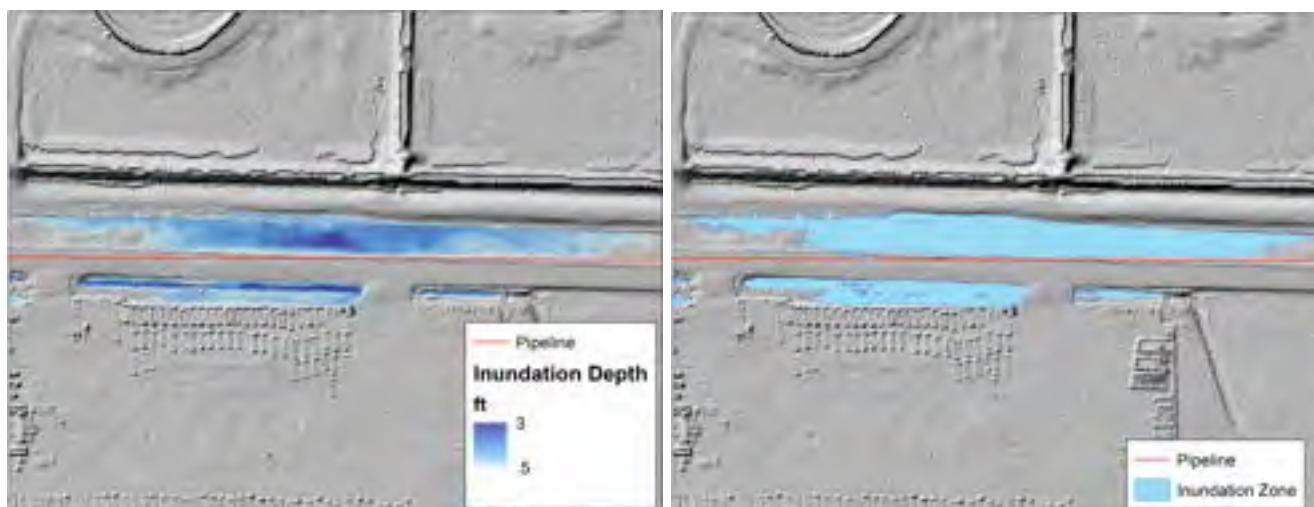

Assessing geohazards provides valuable insight into asset integrity threats; however, geohazards often occur as a result of environmental influences such as hydrology. The Hydrology Analytics package consists of two analytics to aid operators in identifying the root cause of land movement threats, enabling efficient and proactive mitigation activities prior to geohazard formation.

**Problematic Hydrology.** Teren's proprietary Problematic Hydrology analytic accurately models overland flow paths and quantifies the hydrologic energy moving across a right of way. The analytic reveals functioning or failing waterbars along with saturation and erosion zones.

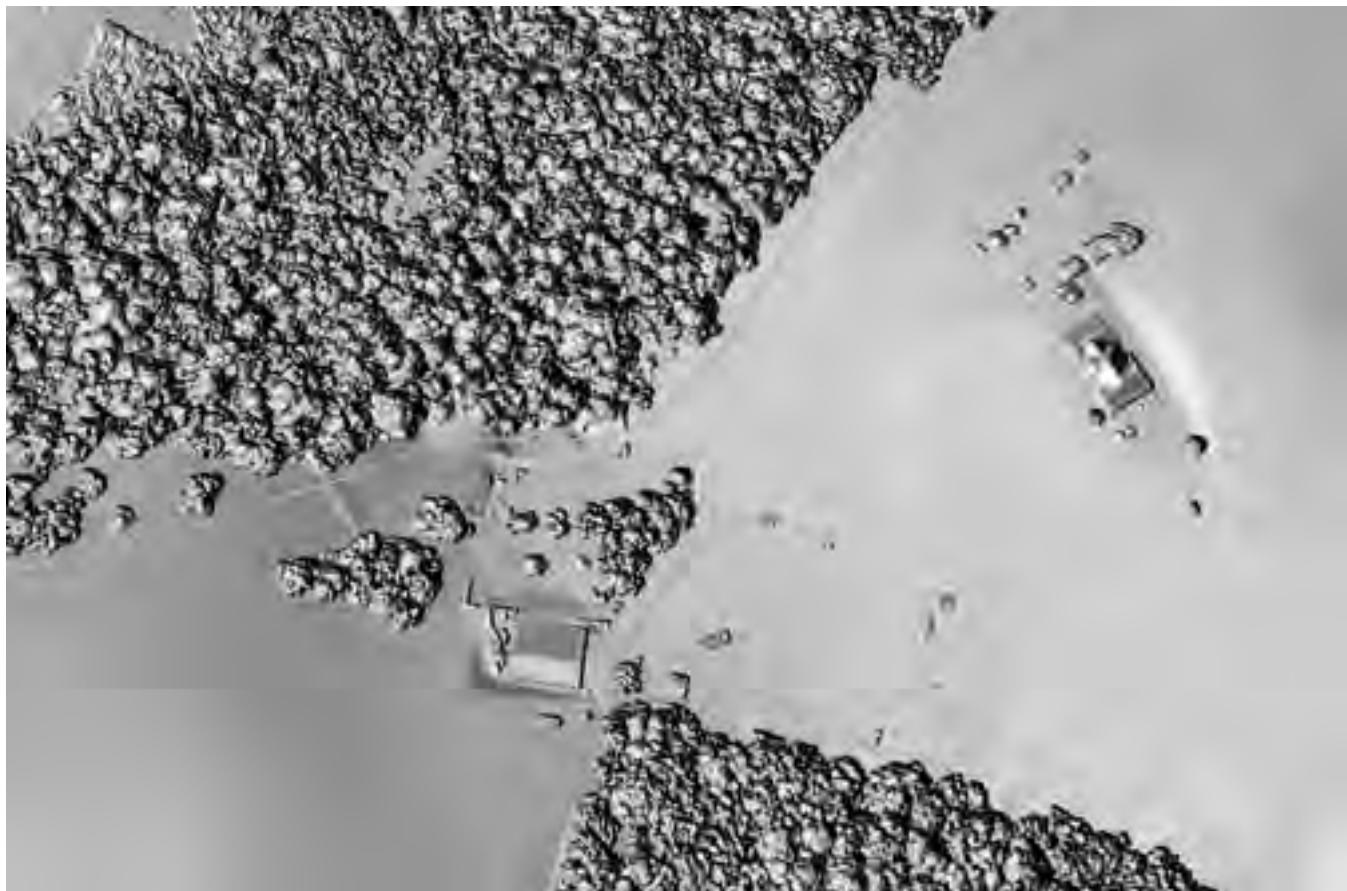

**Flow Paths.** After modeling continuous overland flow, Teren identifies where surface hydrology is most likely to erode or overwater the right of way, endangering slope stability and asset integrity. The Flow Paths analytic models each flow path's hydrologic energy, distance from the pipeline, and direction to assess potential impact to slope stability and asset integrity. The visualized results are limited to only those flowpaths deemed potentially threatening to asset integrity and enable precision placement of stormwater and erosion control devices.

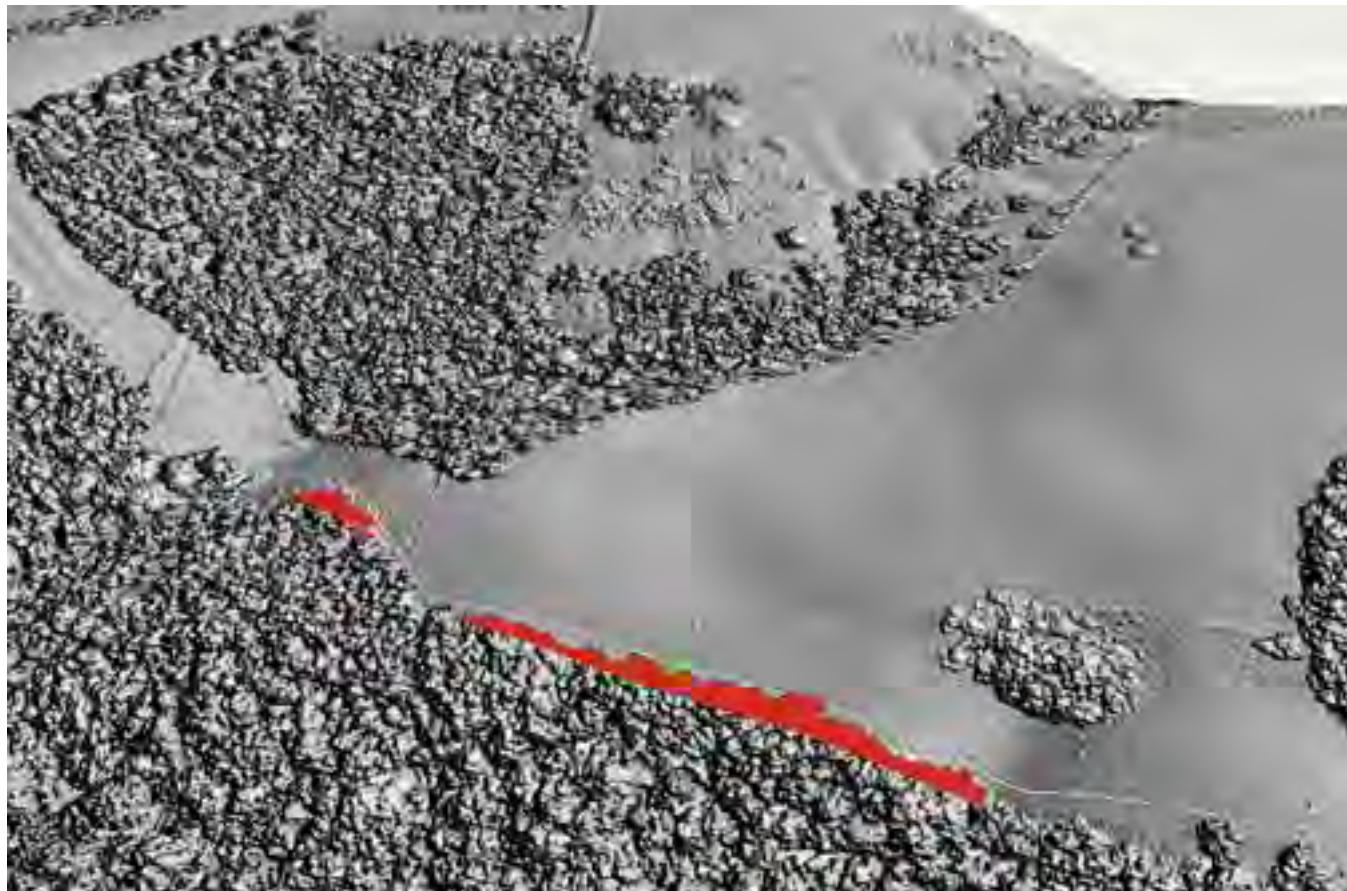

**Inundation.** Teren analyzes terrain data to identify closed basins, playas, flats, or low-lying areas where water accumulates and drains vertically through the soil profile, thus saturating the soil and increasing the likelihood of soil movement or subsidence. The inundation analytic identifies inundation zones within 60 feet of the pipe centerline where accumulation of greater than 10 cubic feet of water occurs.

## Encroachment Analytics

The Encroachment Analytics package consists of two analytics to aid operators in identifying building and vegetation encroachment threats along the right of way with potential implications for asset integrity and regulatory compliance.

**Buildings.** Teren's Building analytic executes machine learning algorithms to detect surface variability in the terrain data and identify vertical and horizontal hard edges within the landscape that form the polygon of a building footprint within 1,000 feet on either side of the centerline. The model detects building footprints at or greater than 200 square feet.

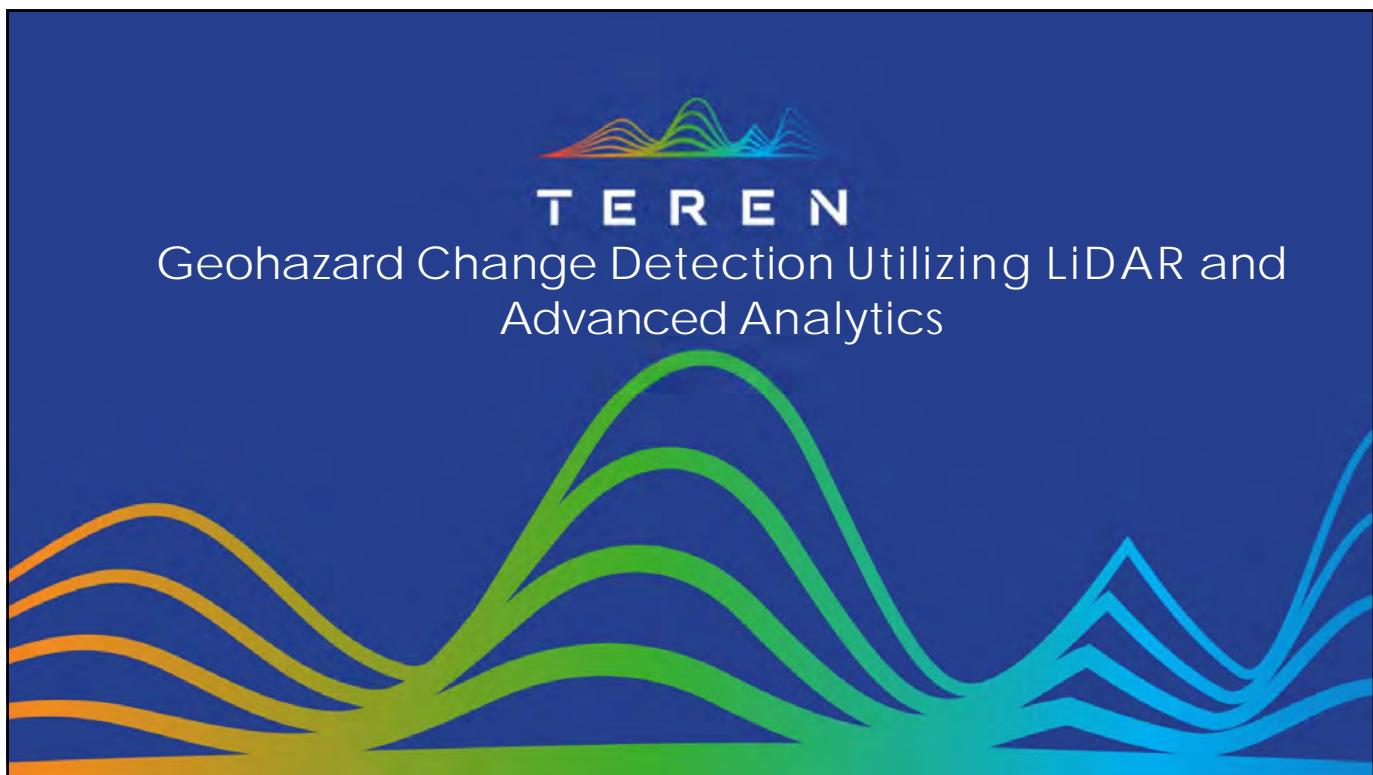

**Vegetation.** The Vegetation analytic depicts where woody vegetation intersects the pipe centerline, thus inhibiting regulatory compliance and effective aerial patrol.

This document supports users in understanding the geospatial data layers and attributes associated with Fall 2022 RoW Integrity Management.

Layer Group	Layer	Layer Description	Attribute	Attribute Description
Encroachment	Veg_mgt_zone	Layer depicts woody vegetation encroachment zones with corresponding average distance-to-pipeline, volume, height, and encroachment threat, in addition to structure variability.	N/A	N/A
Hydrology	Flow_paths	Layer depicts the potential stream flow channels along the surface, incorporating slope and length to identify potential problem areas.	fp_risk	Hydrologic risk score assigned to each flow path based on slope and length.
			net_risk	Risk score assigned to the network of flow paths based on slope steepness, slope length, and distal and proximal connectivity to the pipeline.
			fp_pct	Percentile ranking of flow path network risk to the pipeline.
Hydrology	problematic_hydrology	Raster layer depicts continuous hydrologic surface flow over the RoW.	N/A	N/A
Hazards	Problem_hillslope	Summarized vector layer delineates and ranks hillslope stability threat zones to the pipeline based on landslide potential and hydrology.	CDF_MEAN	Percentile ranking of problematic hillslopes zones.

Average slope (degrees) of the hazard. Major aspect of the hazard. Area/perimeter ratio of the hazard compared to a circle with the same area. A value closer to zero indicates a more irregular oval shape, while a value closer to one is more like a circle. This metric loosely classifies a landslide as a translational slide < ~.55 or a rotational slide > ~.55. Average distance (feet) of the scarp slope from the pipeline. Average height (feet) of the scarp slope. Uphill intersect ratio of the scarp slope with the pipeline. A value of 0 indicates that the scarp slope is 100% below the pipeline, and a value of 100 indicates that the scarp slope is 100% above the pipeline. Direction of the scarp slope from the pipeline based on the slope aspect. A value of 0 indicates that it is above and perpendicular to the pipeline; a value of 90 indicates that the scarp slope is parallel to the pipeline; a value of 180 indicates that it is perpendicular but below the pipeline. Average distance (feet) of the toe slope from the pipeline. Uphill intersect ratio of the toe slope with the pipeline. A value of 0 indicates that it is 100% below the pipeline and a value of 100 indicates that the toe slope is 100% above the pipeline.
Hazards continued				

	Geohazards Fixed New continued		toeslpdir	Direction of the toe slope from the pipeline based on the slope aspect. A value of 0 indicates that it is above and perpendicular to the pipeline; a value of 90 indicates that the toe slope is parallel to the pipeline; a value of 180 indicates that it is perpendicular but below the pipeline.
		hydrology		Ratio between the area of the slide and the local watershed area connected to the slide. This value indicates how much hillslope area is above the slide.
		flow_dst		Hydrological distance (feet) of the slide from the pipeline. This metric indicates how far the slide would have to travel via hydrological processes before impacting the pipeline.
		euclidist		Straight-line distance (feet) of the hazard from the pipeline.
		impactang		Direction that the slide is most likely going to interact with the pipeline. A value of 0 indicates that the uphill portion of the slide will impact the pipeline at a perpendicular angle; a value 90 indicates that the slide is running more parallel to the pipeline; and a value of 180 indicates that the slide is moving downslope and away from the pipeline.
		impactang continued		
Hazards continued		pipelInter		Amount that the uphill portion of the slide is intersecting the pipeline. A value of 0 indicates that the slide is 100% below the pipeline, and a value of 100 indicates that the slide is 100% above the pipeline.
		absrank		Absolute score (1-10) of geohazard threat based on unique combination of risk factors.
		ABS_con		Combination of risk factors contributing to the absolute risk score.
		relthreat		Threat the hazard poses to the pipeline relative to all other identified geohazards. This is a function of distance from the pipeline, impact angle, size, and hillslope steepness.
		relrank		Percentile ranking of the relative threat that the hazard poses to the pipeline compared to all other identified geohazards.
	Persistent	Layer depicts geohazards that were present in Spring 2021 (time 1) and Fall 2021 (time 2) data. Attributes highlight changes that have occurred between the two datasets.	t1_cnt	Number of time 1 geohazards that interact with the geohazard identified at time 2.
			t1_pa_ch	Percent change in area covered by geohazards between time 1 and time 2.
			t1_area_ch	Absolute change in area covered by geohazards between time 1 and time 2.
			t1_dist_ch	Change between time 1 and time 2 in the average distance of the geohazard from the pipeline.
			t1_int_ch	Change between time 1 and time 2 in the amount of intersection of the uphill portion of the geohazard with the pipeline.
			t1_ABS_ch	Change in absolute geohazard score between time 1 and time 2.
			t1_area	Area of a geohazard at time 1.
			t1_dist	Average distance of geohazard from pipeline at time 1.
			t1_inter	Amount that the uphill portion of the geohazard intersected the pipeline at time 1.
			t1_ABS_con	Combination of risk factors contributing to the absolute risk score.
Hazards continued	Continuous Change	Continuous_Change	Raster layer depicts continuous change in surface elevation of the RoW greater than 1 foot between time 1 and time 2.	N/A
				N/A

<b>Continuous Change</b>	Change_detection	Polygon layer that depicts and calculates the absolute change within a continuous change area	Sum	Abolsute value of change within the polygon.
<b>Structures</b>	Buildings	Vector layer depicting identified structures within 1000 feet on either side of the centerline.	N/A	N/A

## Agenda

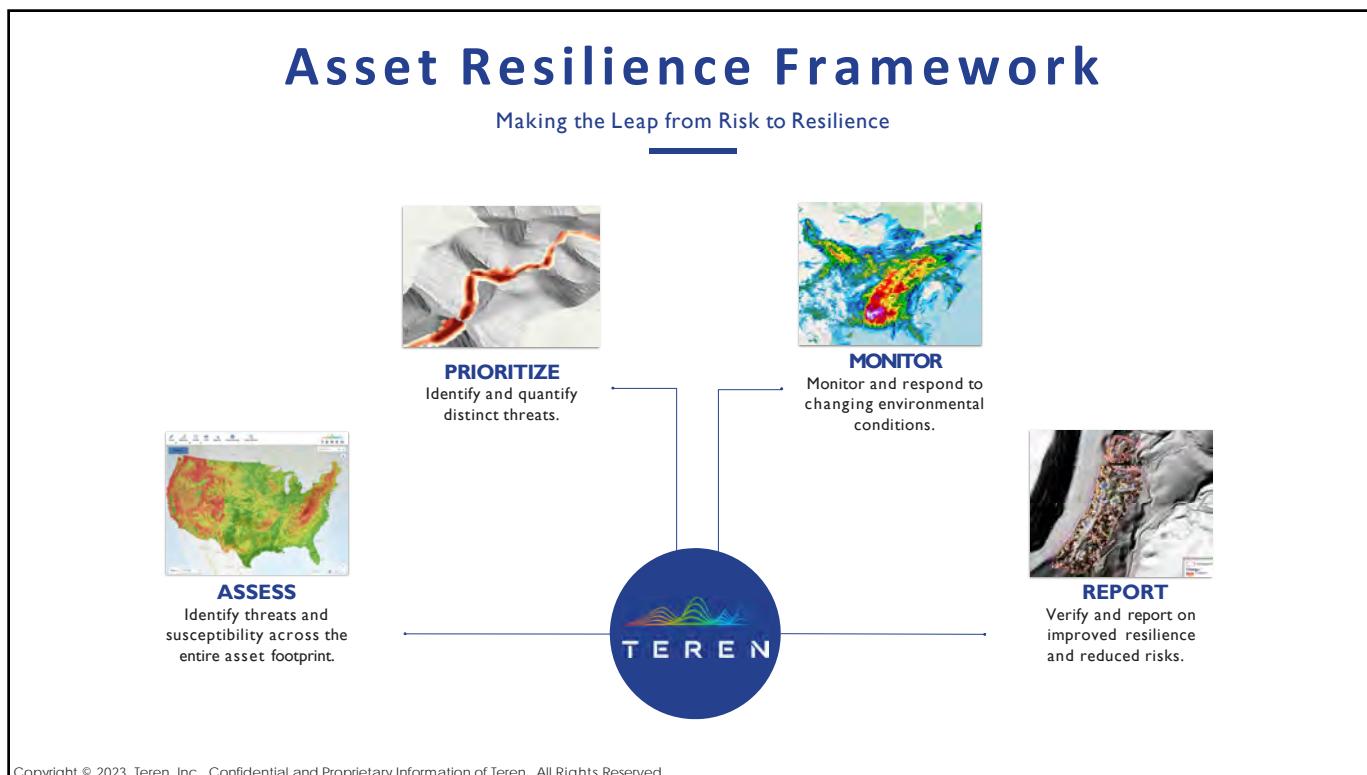

A Closer Look at Geohazards

- Introduction/Overview
- Nationwide Threat & Susceptibility
- Geohazard Identification & Assessment & Prioritization
  - Methodology
  - Landslides & Erosion
  - Hillslope Threats
  - Hydrologic Modeling
  - Debris Flow Analysis
- Key Considerations
- Closing

2

1

3

4

2

# Essentials - Threat and Susceptability

Weather & Climate-Enhanced Geospatial Data

## Climate-Enhanced Data + Powerful Processing

- Curated Analytic Layers
  - Considers temperature, precipitation, etc.
  - Proprietary soils and hydrology data
  - Built by industry experts
- High-Performance Computing for Speed & Scale
  - Analytics for the entire system & nationwide

## Threat & Susceptibility Layers

- Subsidence
- Landslide
- Road Erosion
- Agriculture Erosion
- Seismic
- River Scour
- Coastal & Inland Flooding
- Wildfire Potential
- Weather Summary

5

# Landslide Threat

Climate-Enhanced Data Layer

## Forward-Looking Model

- USGS Landslide
- Teren-Identified Landslides
- Environmental Triggers
- Landslide Potential Algorithm
- 10-meter Resolution
- Powered by HPC

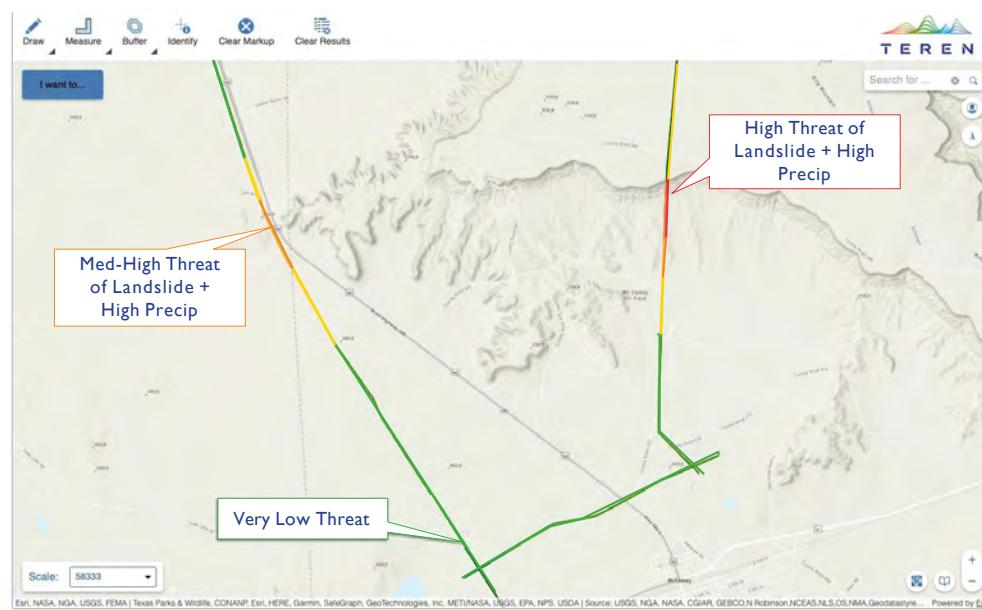

Copyright © 2023 Teren, Inc. Confidential and Proprietary Information of Teren, Inc. All Rights Reserved.

6

3

## Essentials Output

Linear-Referenced Risk Summary

Copyright © 2023 Teren, Inc. Confidential and Proprietary Information of Teren, Inc. All Rights Reserved.

7

## Hillslope Stability Model

Mechanics of Earth Movement

$$HS = \frac{\text{Resisting Forces (strength)}}{\text{Driving Forces (stress)}} \longrightarrow HS = \frac{c + (\sigma) \tan \Phi}{\tau} \longrightarrow HS = \frac{c + \gamma H \cos^2 \Theta \tan \Phi}{\gamma H \cos \Theta \sin \Theta}$$

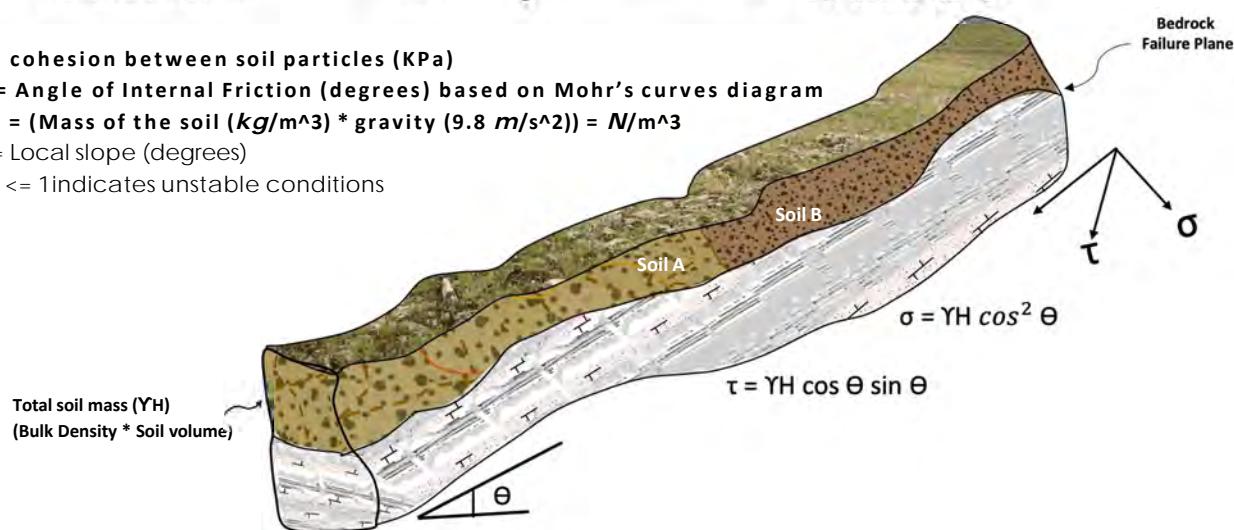

**C** = cohesion between soil particles (KPa)

**Φ** = Angle of Internal Friction (degrees) based on Mohr's curves diagram

**γH** = (Mass of the soil (kg/m<sup>3</sup>) \* gravity (9.8 m/s<sup>2</sup>)) = N/m<sup>3</sup>

**θ** = Local slope (degrees)

HS <= 1 indicates unstable conditions

8

4

# Landslide Potential

## Mechanics of Earth Movement

Development of explanatory variables  
(Terrain and soils information)

- Slope (Degrees)
- Hillslope Curvature
- Hillslope Surface Hydrology
- Hillslope position
- Hillslope Length
- Generalized soil properties
  - Liquid limit
  - Permeability
  - Bulk Density

Development training dataset

- USGS documented landslide (13,800)
- SolSpec documented landslide (900)
- 75 percent observations as training
- 25 percent observation as validation

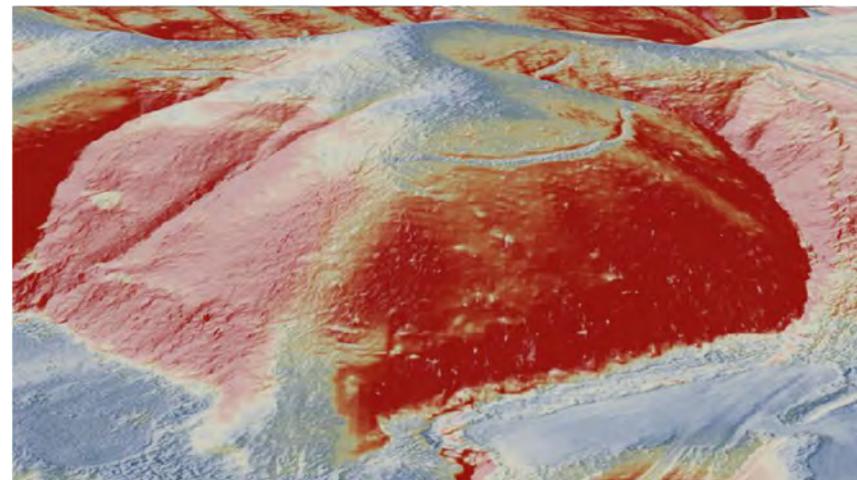

Development landslide probability  
statistical model

- Random Forest approach

Validate model using validation dataset

- 80 percent accuracy rate

Convert statistical model into landslide  
probability raster

9

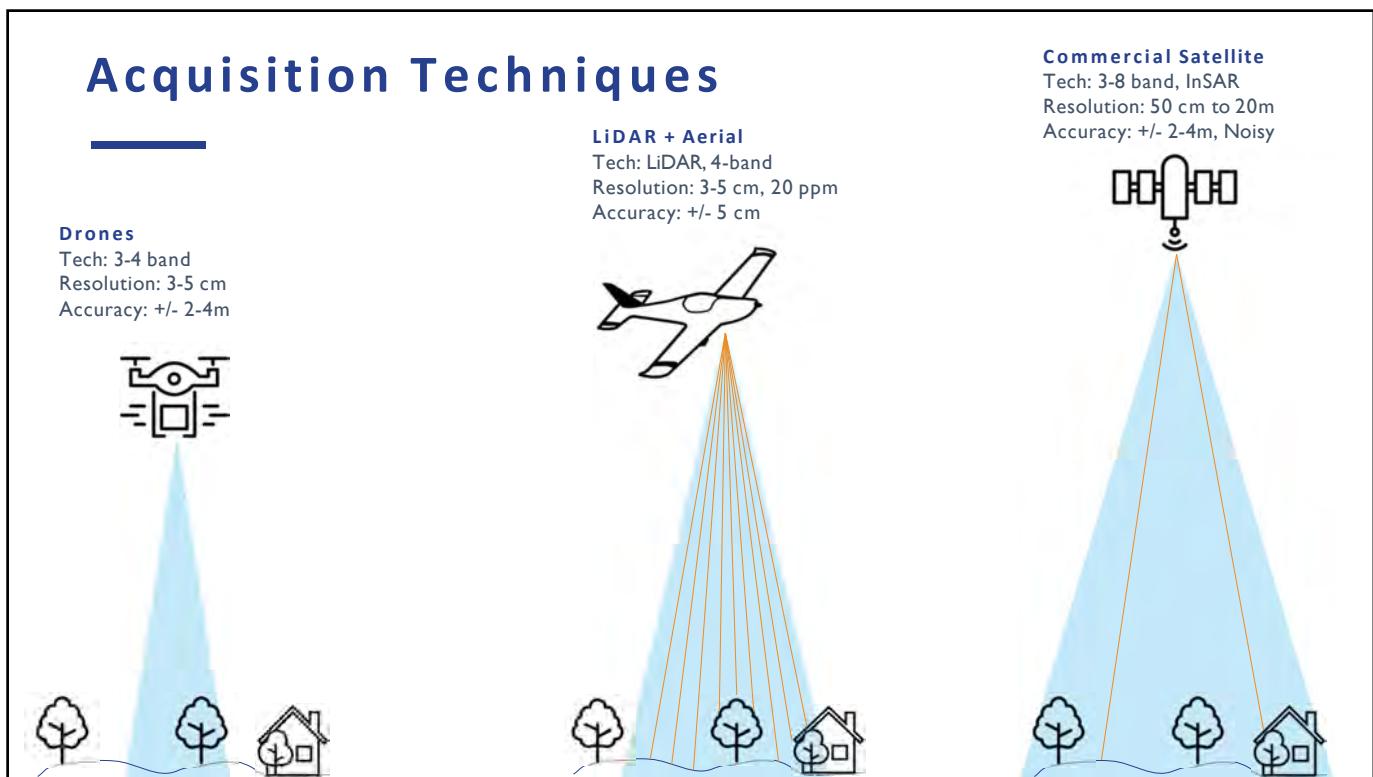

# Hillslope Threats

## Where are Our Greatest Risks?

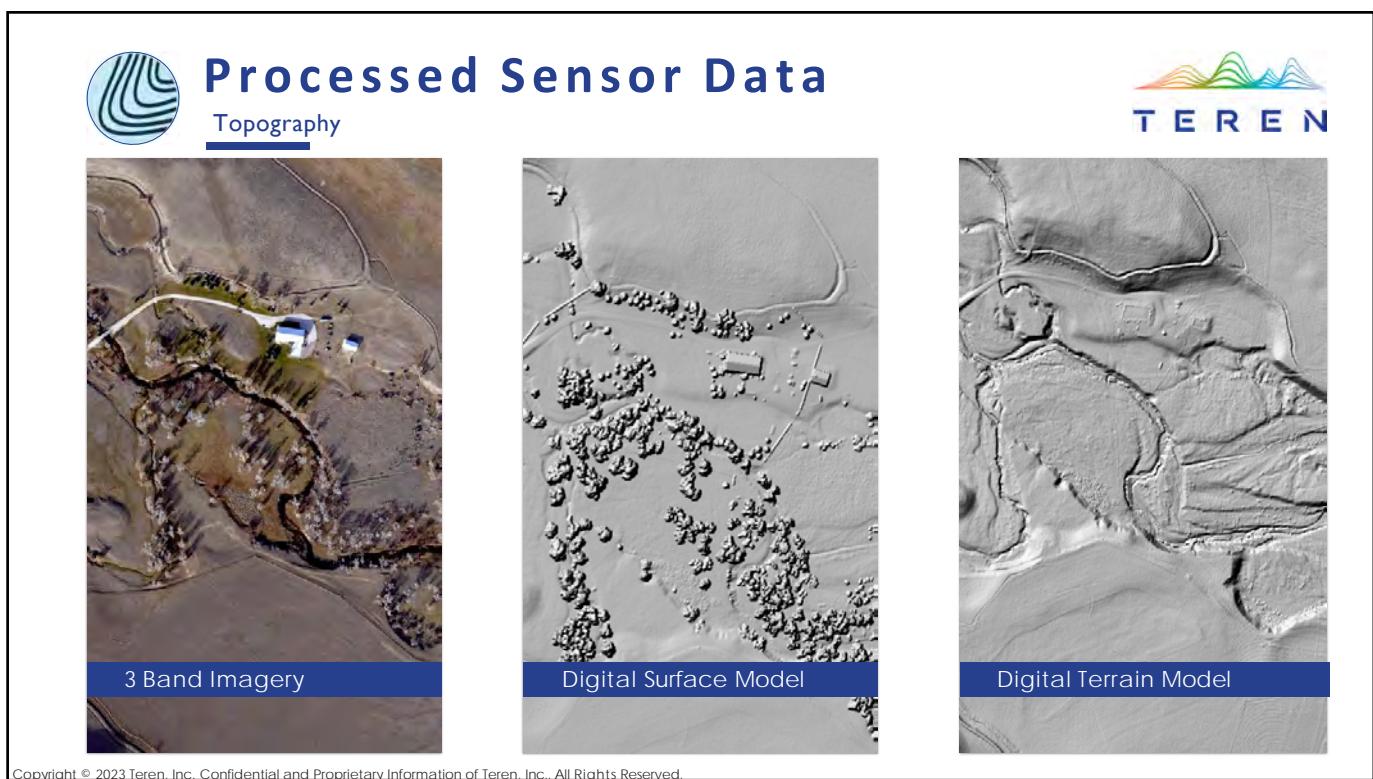

The relative level of threat  
posed by problematic  
hillslopes and existing  
geohazards is summarized to  
the centerline in three-meter  
segments using a sliding  
mile analysis.

6

## Geohazard Identification

 Geohazard Detection & Ranking: Landslide

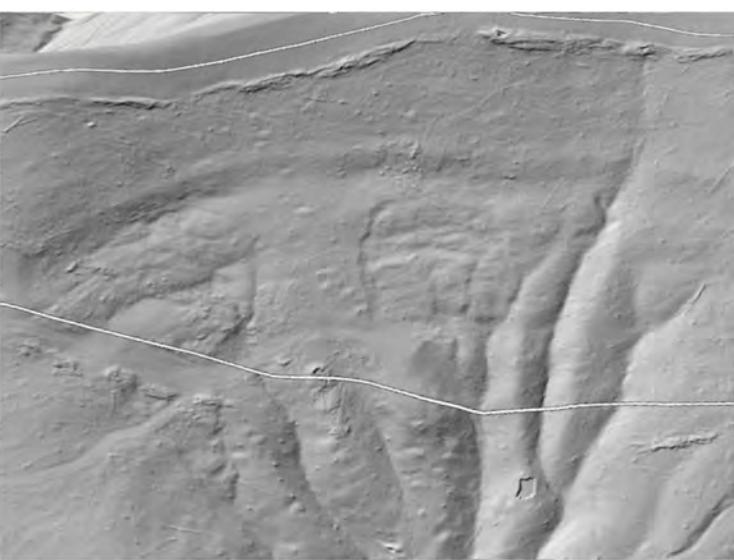

Copyright © 2023, Teren, Inc. Confidential and Proprietary Information of Teren. All Rights Reserved.

13

## Geohazard Assessment

 Geohazard Detection & Ranking

 TEREN

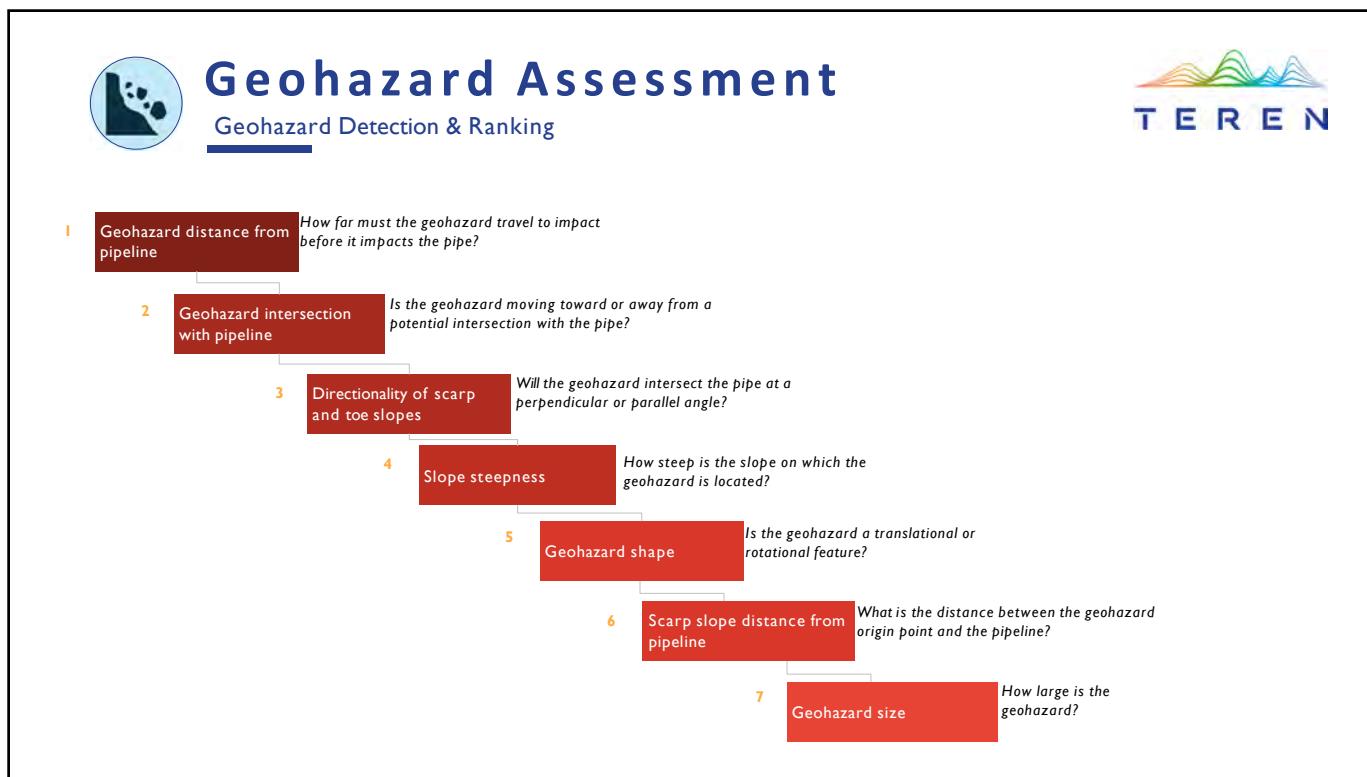

**Geohazard Detection**

- Derived from terrain analysis to identify and delineate boundaries.

**Rule based hazard ranking system**

- Asses physical characteristics
  - Morphology
  - Hillslope steepness
  - Hydrology
- Asses asset hazard characteristics
  - Distance
    - Straight line
    - Flow path
  - Movement
    - Towards or along or away
  - Adjacencies
    - Morphological Intersects
- Reporting and prioritization
  - Characteristic reporting & prioritization score (1 to 10)

14

15

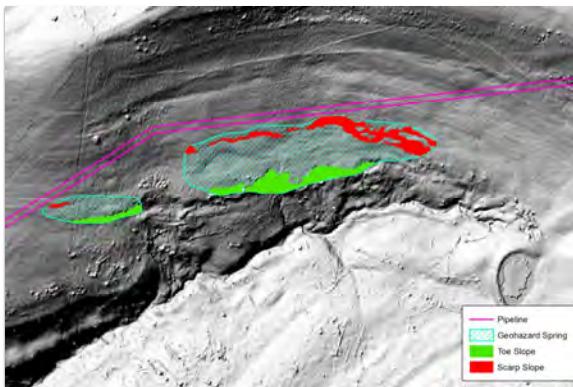

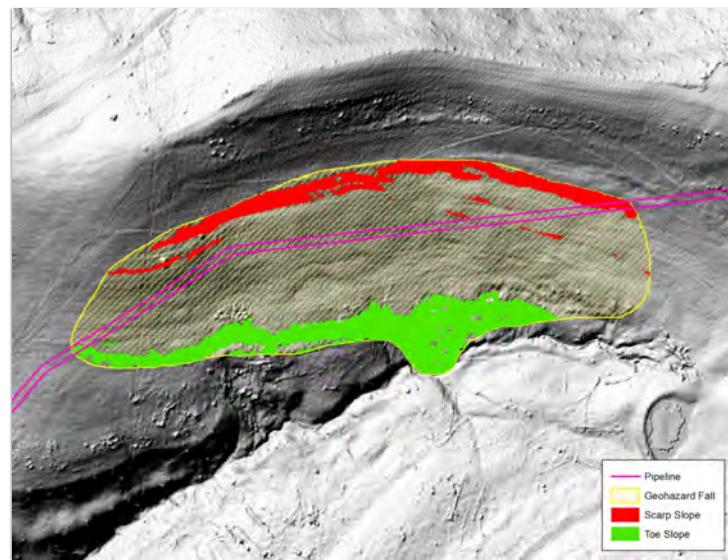

## Geohazard Monitoring and Reporting

### Change Detection

Measurement of geohazard structure enables precision understanding of how geohazard risk determinants change over time.

Spring 2020

Fall 2020

18

9

# Hydrology Analysis

Geohazards

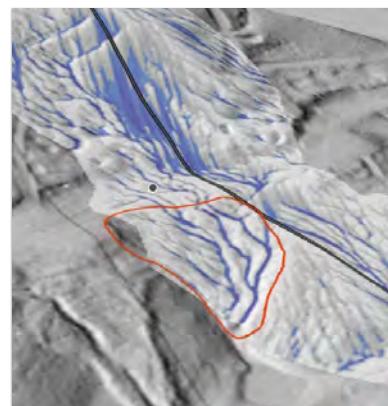

Hydrology Analytics reveal underlying flowpaths contributing to geohazard development and inform precision installation of stormwater controls.

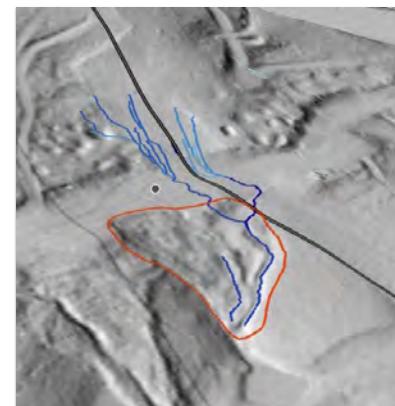

## Identified Geohazard

## Surface Hydrology

## Problematic Flowpaths

Copyright © 2023 Teren, Inc. Confidential and Proprietary Information of Teren, Inc. All Rights Reserved.

19

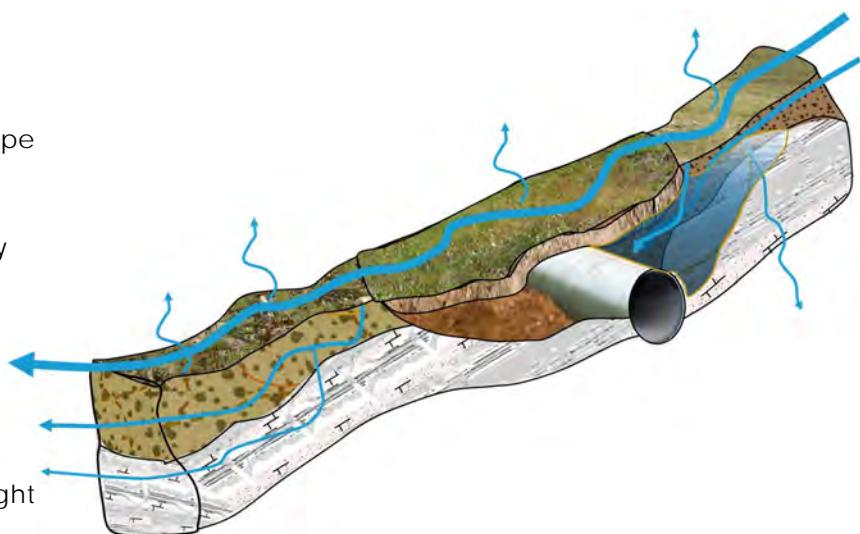

# Hydrology Modeling

Mechanics of Earth Movement

## Hillslope Most At Risk

Lower AIF and Cohesion (i.e., slope stability) due to:

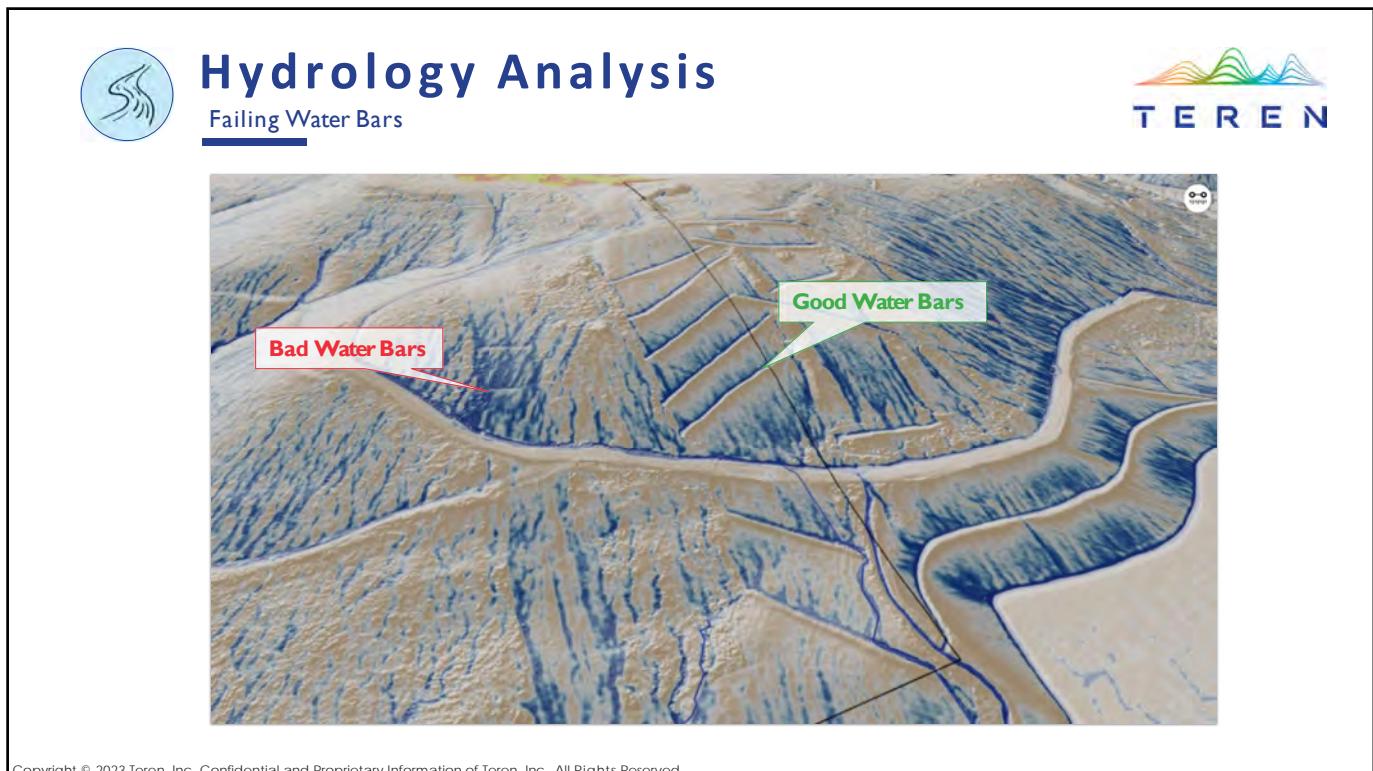

- Increased soil moisture
- Less evapotranspiration by trees
- Area of disturbance
- Tree root removal
- No root channels to move water to ground
- Dam caused by pipe and trench, also increases weight and pore pressure

24

## Hermit's Peak Post-Wildfire Analytics

Terrain, Hydrology, Debris Flow, Sedimentation, Optimal Stabilization, Tree Harvesting, and Permissions Tracking

25

## Summary

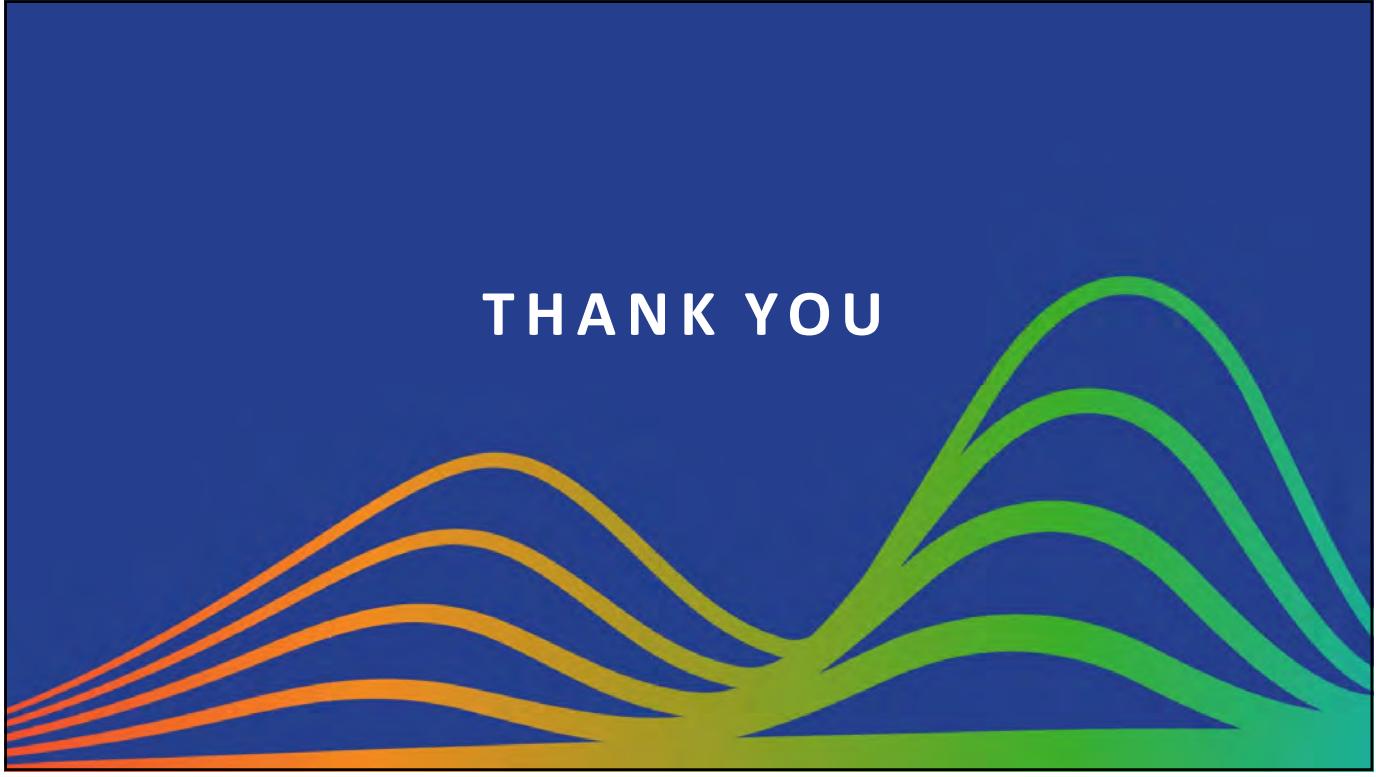

A Closer Look at Geohazards

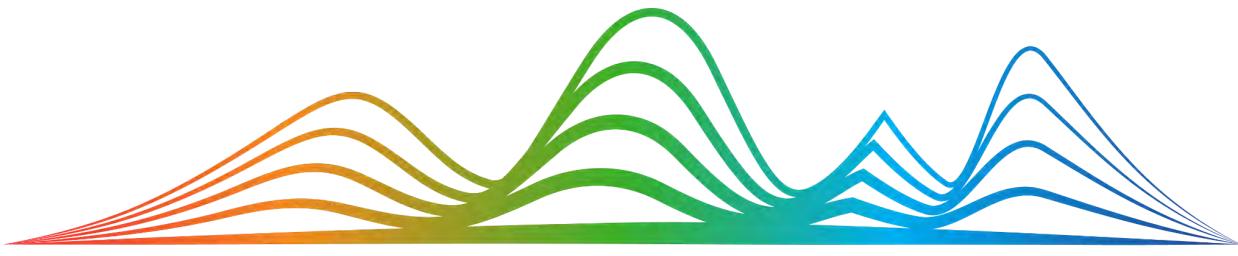

- Teren is providing a platform and framework for assessing risk and building asset resilience over time at scale
- Teren leverages its earth movement mechanics expertise with AI/ML and HPC technologies
- Teren provides the temporal and spatial relevance to geohazard identification, prioritization and monitoring
- Nationwide analytics for broad scale susceptibility assessments and prioritizations of asset threat

## Introduction

Teren is pleased to present our next-generation web map experience. The Teren Viewer provides a plethora of tools for viewing, querying, analyzing, and working with the data provided through the Right-of-Way Integrity Management program. This viewer has been designed to work like many of the web mapping viewers on the market today with the intention of supporting ease of use.

The Teren Viewer is an extensible enterprise platform that will rapidly grow in functionality, with several additional features launching in the next few months.

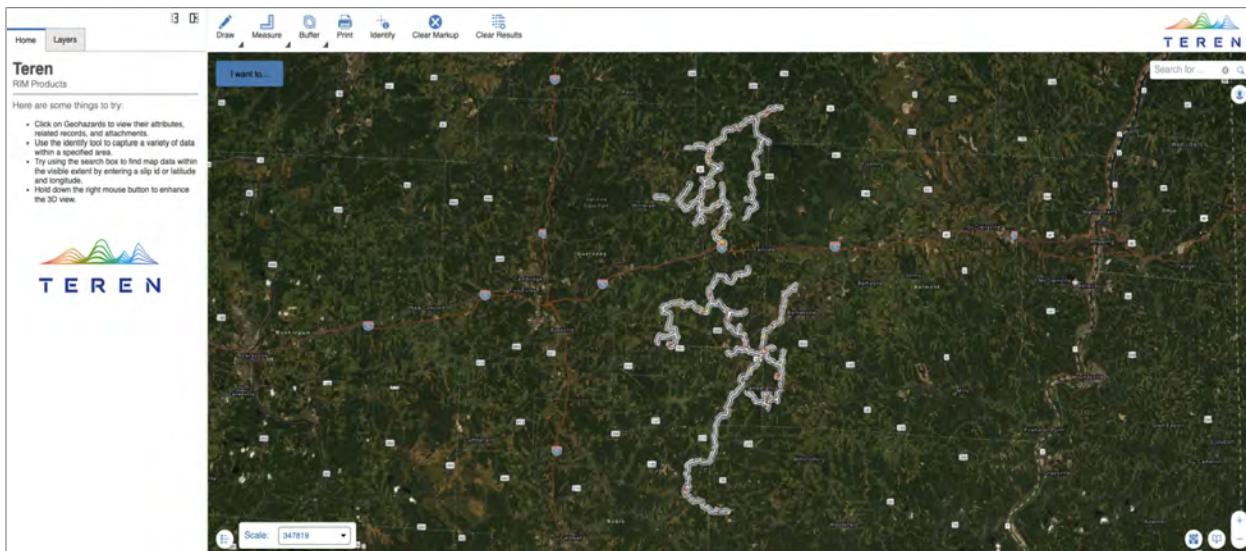

At Teren, user experience is at the forefront of our priorities, and we welcome your feedback and suggestions for features that could improve or enhance your experience with the Teren Viewer. If you have questions, feedback, or suggestions for our team, please contact [support@solspec.io](mailto:support@solspec.io).

This *Quick Start Guide* is intended to help users become familiar with the Teren Viewer while we work toward the release of more in-depth user support documentation. The Teren Viewer *Quick Start Guide* will be updated to reflect new features as they are released.

## Viewer Overview

The Teren Viewer enables you to interact 3-dimensionally with data, view data attributes, filter data, zoom to features, bookmark points of interest, and export results.

After logging into the Teren Viewer with your assigned credentials, you will see a home screen that includes the web map canvas, toolbar (at screen top), and panels (at screen left).

## Panels

When the viewer is initially loaded, the panels appear on the left side of the screen. The panels provide a location to store descriptive information, manage the layers loaded in the webmap, and present other interactive mapping components.

Panels can be hidden, maximizing the map canvas space. In the top-right corner of the panel, highlight the **close panel** or **open panel** icons hide and show the panel (close panel highlighted in blue).

## Home Panel

The Home Panel is reserved to store descriptive information to support engagement with the Viewer. New features will be added to this location.

## Layers

The Layers tab provides a list of all layers loaded in the Web Pap.

### Layer Visibility

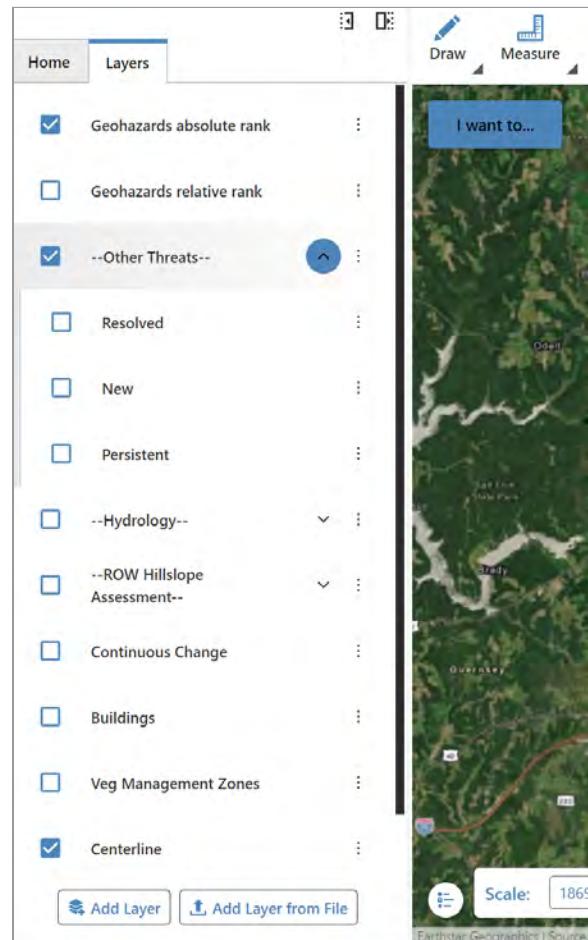

To make a layer visible, ensure the check mark is selected to the left of the layer.

### Grouped Layers

To make the Layers list more organized, layers that share similarity are grouped into categories. These grouped layers are easy to find; the text begins with two dashes ("--") followed by a caret ("^" or "Λ") to the right of the text.

For example the Group Layer called “--Other Threats--” contains many Geohazards layers:

- Resolved
- New
- Persistent

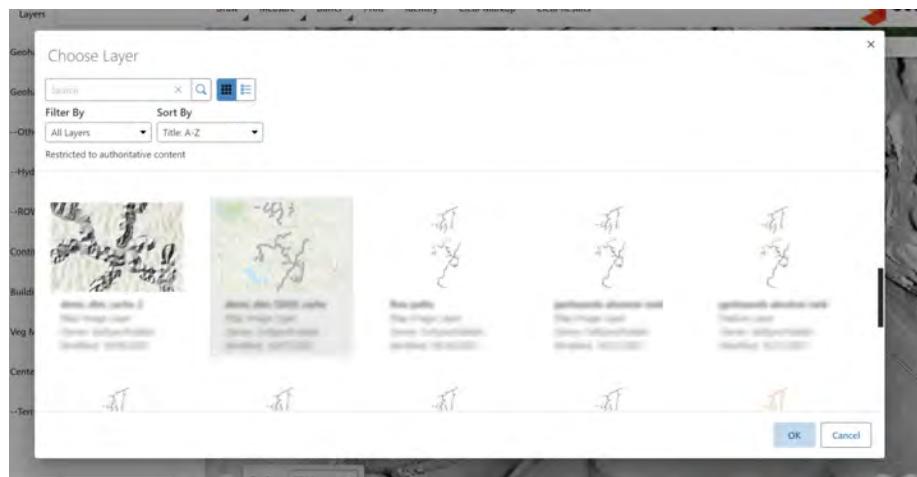

To make any layer within a group of layers visible, ensure the check box to the left of the group layer is checked on.

To expand or contract a grouped layer click the caret (“**v**” or “**^**”) to the right of the grouped layer name.

## Add Layer

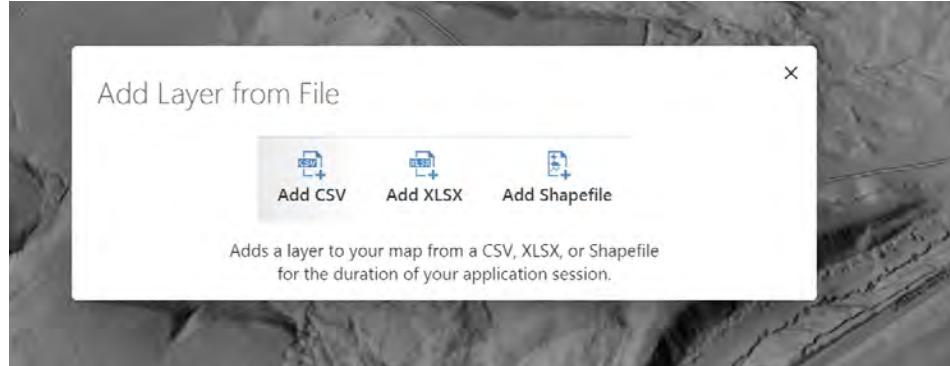

The Viewer environment allows you to load data from previous Right-of-Way Integrity Management acquisitions performed by Teren. Data for the most recent two acquisition and analysis periods will be available through the **Add Layer** menu option located at the bottom of the Layers Panel.

The **Add Layer** feature launches a window that provides visibility to previously loaded analysis results. The window supports search and filter capabilities, allowing you to refine the choices for layers to add to the map.

## Add Layer from File

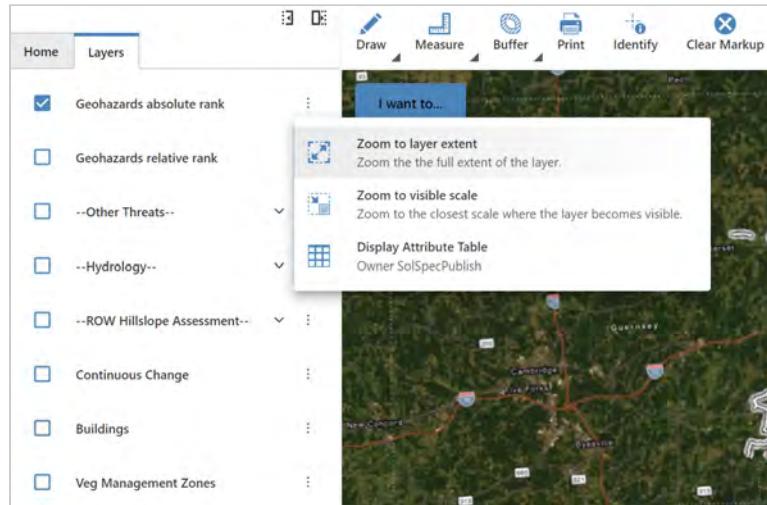

The **Add Layer from File** feature launches a dialog allowing you to upload files to the web environment. The **.CSV** and **.XLSX** options support the upload of point file formats. The **Shapefile** options supports the uploading of points, lines, and polygons. Note that all contents of the Shapefile must first be combined into a **.ZIP** file before uploading them to the Teren Viewer.

## Attribute Table Display

Teren provides a plethora of valuable data with the Right-of-Way Integrity Management analytics suite. There are times when viewing, sorting, and filtering the tabular attribute data provides for valuable assessment of the results.

To open the attribute table for a layer, click the “3 dots” menu to the right of the layer name. Select **Display Attribute Table** from the menu. Note - only the “geohazards absolute/relative rank” have this feature

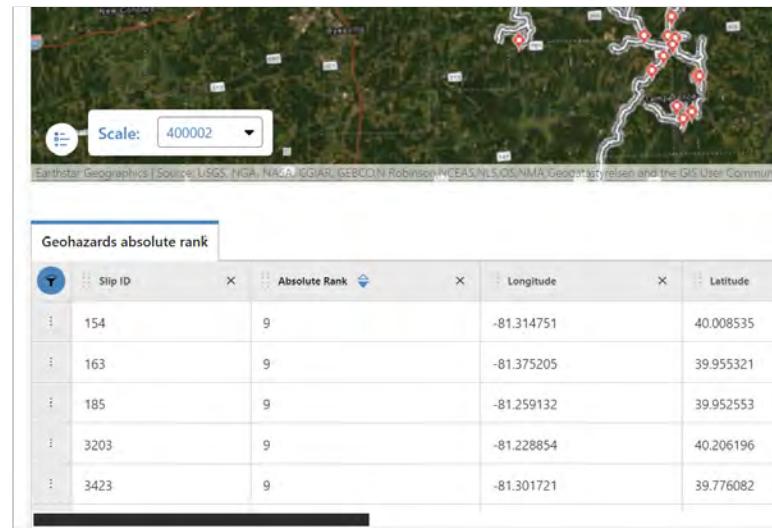

The table appears below the map canvas. Data can be sorted by clicking the up/down arrows at the top of the column header. (Clicking multiple times reverses the sort.)

Data can additionally be filtered by clicking the filter button (highlighted in blue at top left corner of attribute table).

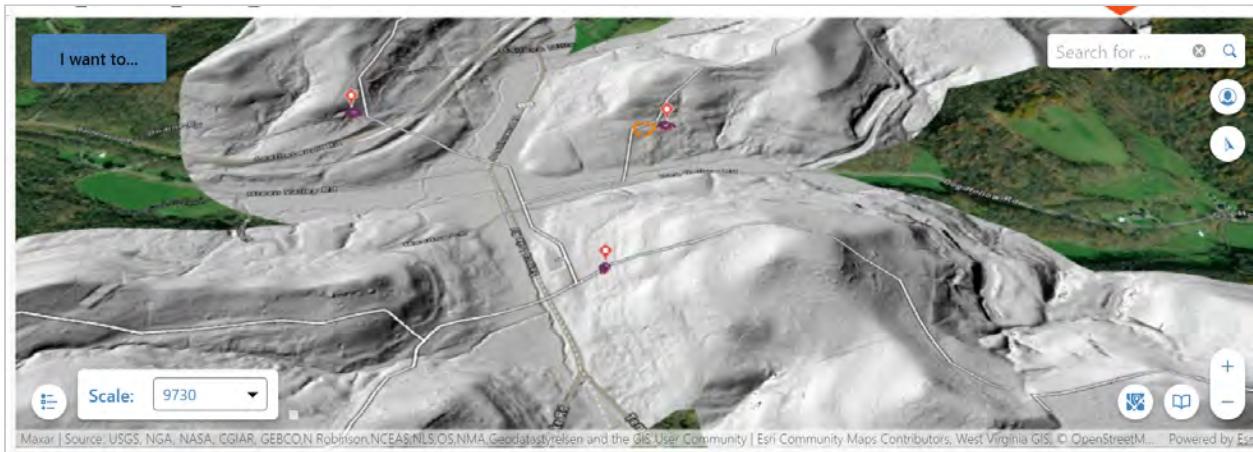

Clicking the three vertical dots located to the left of each row allows you to access a menu of options for exploring a record of interest. Available options include zooming to the feature, filtering the record from the selection set, and exporting the records to a file for further analysis within different applications.

Clicking the three vertical dots at the top-right of the table enables these actions for the entire table.

Slip ID	Absolute Rank	Longitude	Latitude
154	9	-81.314751	40.008535
163	9	-81.375205	39.955321
185	9	-81.259132	39.952553
3203	9	-81.228854	40.206196
3423	9	-81.301721	39.776082

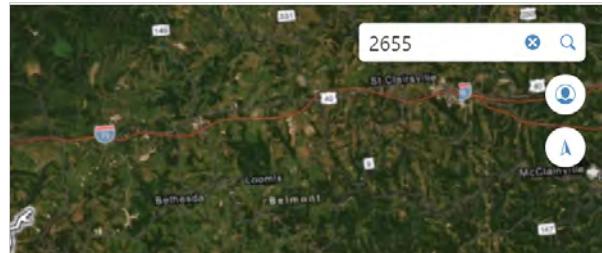

## 3-Dimensional View

The data provided through the Right-of-Way Integrity Management program shines when viewed in an oblique, 3-dimensional view. By default, all data through the Teren Viewer is enabled for 3-dimensional viewing. To access this feature, hold the right button down on your mouse (or alt-select on track pad) and move the cursor. The map will pan and rotate with your mouse.

## Search

The Teren Viewer provides global search functionality, this allows for public address searches, lat/long, and features within our data tables. The search feature executes against all visible layers in the map, and against the Esri world geocoder service (global address service). This allows you to search for attributes within the data.

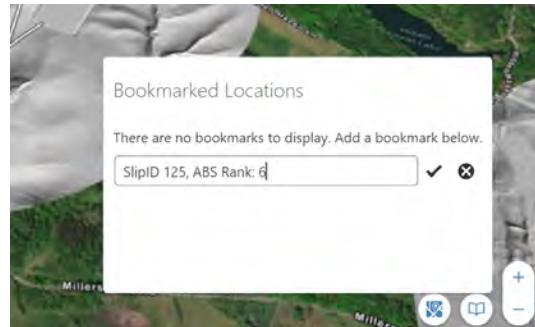

To search, type the value of the attribute you want to see in the Search widget on the map frame. Results will display in the attribute tables below the Viewer.

To search lat/long coordinates, the format is tuned for decimal degrees, Long,Lat. Upon executing the search, an attribute table will pop up from the bottom of the screen. Click the 3 dots to the left and hit “zoom to results”

World Geocoder for ArcGIS					
	Loc_name	Status	Score	Match_addr	LongLabel
: World	M	100	-81.182500 40.096000	40°05'45.599"N 81°10'57.000"W	

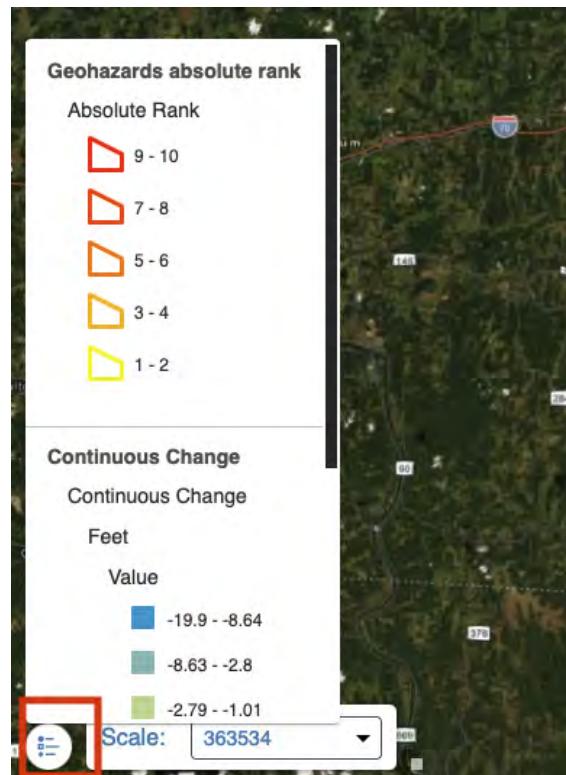

## Bookmark

To save an important location and return to it at a later time, the Teren Viewer enables bookmarking of locations. To bookmark a location, select the bookmark icon in the lower right corner of the map window. Click the **Add Bookmark** button and name the bookmark. This saves the location, angle, orientation of the map at the time of the bookmarking.

## Legend

To display the legend, click on the circular button in the bottom left of the data extent window. This allows the user to view the symbology of the layers turned on.

# **APPENDIX D:**

## **RESOURCES FROM EO59 (INSAR)**

- Hand-off presentation: ODOT Landslides
- Summary table of InSAR data coverage by study region.
- Tables of average velocity and cumulative displacement for each PS point in study region for time period specified by EO59 (SP2016 to SP2023) and for study period (AU2020-SP2023).
