I INTRODUCTION

The purchasing power of a dollar made available to the State for highway construction varies from time to time for any number of reasons. In order that those responsible for long range construction planning may have at their disposal a means of measuring this varying purchasing power at any time and projecting it to any future point in time, a cost index of highway construction has been prepared. This index equates the present cost of highway construction to the cost during the index base period or, in more simple terms, indicates the amount of construction one dollar would have purchased if spent during the base period rather than at the present or some past or future year.

In addition to this means of measuring purchasing power, a properly designed index may be of use in estimating individual projects. Knowing the present value of the index and the anticipated trend, the designer should be able to compute the index for the project estimate and arrive at a logical conclusion regarding the validity of the estimate.

This two fold purpose governed the design of the index.

II INDEX DESIGN

As designed, the index presented here may be defined as: "A weighted average of unit bids submitted by the successful bidders during a selected base period for various items representing substantially all of the construction operations provided for in a highway construction contract."

Index Items

The first step in the design of the index was to select the items to be included. In general terms, highway construction operations may be classified as grading, structures, surfacing and incidentals. Strictly speaking, an index should include

all of the contracted bid items of the base period and conversely, an ideal index would be one which contains only one item representing each of the four generalized construction operations. However, neither of these extremes would be practical since the former would involve several hundred individual bid items and the latter would not be truly representative.

The Bureau of Public Roads maintains a bid price index (See Figure 1) made up of weighted average prices for six items. This index is representative of work involved in grading, structures and surfacing and is apparently quite successful in detecting price trends in the entire nation. However, the absence of an item for flexible base and several other construction operations preclude an identical index for Texas.

The Highway Design Division, Bridge Division and Secondary Roads Division are currently using an index based on the year 1949 which includes all of the contract bid items for that base period. Current projects are compared to similar projects in 1949. However, some items included in this index are outdated since items such as continuously reinforced concrete pavement, upgraded flexible bases, cement stabilized bases and asphaltic concrete pavement were not used extensively in 1949.

The Construction Division's Cost Index as reported in 1953 (See Figure 2) includes eleven items which are a comprehensive representation of highway construction from 1949 through 1953. The items contained in this index were selected for tentative inclusion in the new index. During preparation, some changes were made in the minor index items.

Base Period

The selection of the base period for accumulating the average prices con-

stituted the next step in developing the index. The Bureau of Public Roads Index was originally based on the 1925-29 period but was updated and revised for the period 1957-59 in keeping with the effort of all Federal agencies to base any statistical data on this period. The index used by the Design Divisions is based on the year 1949 and the Construction Division Index is based on a five year period from 1949 through 1953; however, construction innovations and specification changes since that period might produce some fictitious variations in application of the index. The 1957-59 base period was selected in order that the index could be correlated with the BPR Index. Average prices were developed for that period and a possible index prepared. The results were somewhat disappointing in that only approximately 50 percent of the total cost of several projects selected at random were represented in the index. Also, this index appeared to indicate a much greater price rise for 1963 than was reflected by the indices used by the Department. This could be attributed to several factors but is believed to be primarily the result of adoption of the current standard specifications with possibly some influence from changes in design such as the advent of continuously reinforced concrete pavement and upgraded flexible base.

The base period was then moved forward to the years 1961-63. Several factors prompted selection of this period as the base. The 1961 specifications (the forerunner of the current standard specifications) were adopted and put into use early in this period and the bid history for both the 1961 and 1962 specifications was stored on the computer. Also, sufficient bid history had been accumulated on continuously reinforced concrete pavement, high-type flexible base and other relatively recent design innovations to assure reliable averages for these items. Projects governed by the 1951 specifications even though they were let in 1961 are not included in the index.

Statistical Derivations

Figure 3 indicates the composition of the index. The items are divided into four general categories: excavation, base, surfacing and structures with the latter three further separated by generalized pay items.

The area and State average prices for excavation include common and unclassified excavation only; however, in computing the relative weight on an individual project, such items as overhaul, borrow, sprinkling and rolling of embankment material should be included in the item weight.

The itemized breakdown of flexible base was deemed necessary to avoid misleading fluctuations of the index. If only one overall State average for flexible base was included as originally planned, one large project containing a substantial quantity of one of the more expensive bases would result in a fictitious rise in the index for that letting. Separate weighted averages for each flexible base item should counteract this and result in a more stable and accurate index. Average prices are included for various types of flexible base. For most of these items an average price for delivered flexible base is also shown. Since shell with sand admixture and shell with sand and caliche admixture are bid both delivered and with haul paid for separately, the average price includes the volume of shell divided into the sum of shell, sand, caliche and additional quarter mile haul. Therefore, the only prices shown for these items are on a delivered basis. Bid history indicates that cement stabilized base and flexible base used in District 21 are always bid on a delivered basis. A delivered price has not been included for caliche, bankrun gravel or foundation course since a delivered bid history for these items was not available. In the future if these items are bid on a delivered basis, an index price can be established.

All flexible base in the index was computed on a cubic yard basis using a conversion factor of 1.4 from ton to cubic yard for caliche, bankrun gravel, processed gravel, iron ore, crushed stone, foundation course and the delivered base used in District 21. The conversion factor from ton to cubic yard on shell with sand admixture and shell with sand and caliche admixture is 1.12.

The conversion factor from ton to cubic yard for cement stabilized base is 2.0. If cement stabilized base is measured by square yard, the conversion factor is derived from dividing 36 by the depth in inches of the cement stabilized base placed. (Figure 5 indicates the conversion factors for various items of the index.)

Surfacing was divided into four categories with a further breakdown to separate jointed reinforced and continuously reinforced concrete pavement. Aggregate and asphalt for surface treatments include all surfacing aggregates and asphalt for seal coats, one, two and three course surface treatments. The average price for asphaltic concrete pavement includes Hot Mix Asphaltic Concrete Pavement only. However, in calculating the weight of each item and relative weight, cold mix limestone rock asphalt pavement, hot mix-cold laid asphaltic concrete pavement and tack coat should be included. Concrete pavement was divided into two groups because of the price variation for a greater amount of reinforcing steel used in the continuously reinforced design. The average prices for concrete pavement were computed on a cubic yard basis. (See Figure 5 for conversion factors.)

The structural items originally included only reinforcing steel, structural steel and structural concrete. However, it was found that prestressed concrete beams constitutes a large percentage of structural items and was added

to the composition of the index. The item of 24 inch pipe was also added as an indicator item to reflect any price changes in areas of construction not directly related to the major items, although it does not constitute a substantial percentage of the index. In calculating the weight of the item and the relative weight for Pipe 24", all sizes of reinforced concrete and corrugated galvanized metal pipe should be included. The average prices for structural steel were developed from I-Beam Steel and Girder Steel omitting miscellaneous structural steel; however, miscellaneous steel should be used in arriving at the relative weights for structural steel.

The items of sprinkling and rolling were originally included in the index; however, they were deleted since they constituted a very minor percentage and the weighted averages obtained were not realistic.

The average prices indicated are derived by dividing the summation of the total contract cost for each item during the base period by the summation of the quantities for the period. In order to determine the weight each item should be given in the index the total contract cost of similar items of work should be added to the item cost, e.g. overhaul, borrow, etc. added to excavation; tack coat added to asphaltic concrete pavement; etc. as previously discussed. The relative weight for the four general categories is then determined from the total adjustment cost of each item and the total cost in the index. The relative weights computed in this manner should approximate the relative proportions of grading, structures, base and surfacing in an ordinary construction contract as shown in Figure 3. The weight of each item and relative weight shown in the composition of the index is based on construction during the three year base period; however, the weight of each item and relative weight should be calculated on each pro-

ject. To calculate price trends for a given period the weight of each item and relative weight should be adjusted according to construction for that period. (See Figure 8D)

Application

In computing the State index for a monthly letting, or any other period of time, the weighted average unit price for each of the index items is calculated as previously described for the index. The item index is then determined by dividing the average price by the index base period average. The weight of each item for those items constituting the excavation, base, surfacing and structures index is then multiplied by this item index and the summation of these products multiplied by the relative weight to arrive at an index factor percentage. Summation of the four index factor percentages results in the overall index.

Figure 4 illustrates the overall index for each month since 1950.

III AREA INDICES

As previously mentioned, an index which could be applied to individual projects could be of significant benefit to the designer in preparing the estimate for highway construction projects. Knowing the average cost of the project, judgment could then be used to determine probable increased or decreased cost due to conditions peculiar to that project. To develop an index suitable for application to individual projects, weighted average prices equivalent to those developed for the statewide index had to be determined for each area of the State having comparable conditions.

Four factors were selected to determine the groupings. Any one of these factors was considered sufficient justification to warrant a separate area grouping.

1. Usual Construction Practice
2. Climate
3. Geological Formation
4. Usual Type of Project

The first factor alone dictates that each of the various districts be separated since even adjacent districts often use different specification bid items. Consideration of the second factor led to a further separation of the lower counties in the coastal area.

Consideration of the geological formation was on an extremely generalized basis. While the presence of large quantities of rock in certain counties was recognized, there was not sufficient bid history in some of the counties from which reliable weighted averages could be computed. There was also some indication that portions of a county should be grouped separately; however, this would not be a practical grouping for utilizing the computer history.

Consideration of the last factor dictated that the heavy metropolitan areas having expressway type construction under heavy traffic be separated from other counties in that district.

Figure 6 indicates the county groupings which resulted from this process. Forty-two separate groupings are indicated.

The index items which constitute the statewide index were extracted from the bid history for each separate area and weighted averages computed. This resulted in a separate index for each area which, when recombined, is identical in average prices, quantities, relative weights, etc. to the State index.

Figures 7A-7D indicate the weighted average prices for each index item. In several instances where prices are not shown, these areas either did not have a history for the particular bid item or did not have sufficient history to reflect a realistic weighted average. When this occurs, the State average

should be used in computing the index on an individual project until such time as sufficient bid history for this item is established.

Application to Individual Projects

Individual index forms have been prepared for each area for computation of the index for individual projects. Samples of these forms with typical project data inserted are shown in Figures 8A-8C. A form for each area with index list price is included in the Appendix.

Figure 8A indicates the procedure followed in computing the index for a typical grading, structures and surfacing project. The estimate price for each index item contained in the project is entered under "Estimated Cost" and divided by the index list price for the particular area to determine the "Item Index". Where more than one bid item is contained in the project for any index item, such as several types of aggregate for surface treatment, an approximate weighted average price should be determined for use in computing the index. Where more than one item is included for each type of work such as will usually be the case for base, surfacing and structures, the weight to be given each item must be determined. This weight may be an approximation or may be an exact calculation based on the total estimated cost of each of the items. In each case the total weight of each of the four general categories must equal 100 percent. For example Excavation is only one item so it equals 100 percent.

Under flexible base the sum of all base items shall equal 100 percent and the same pertains to the surfacing and structural categories.

The product of the item index and weight of each item is the "Item Index Factor".

These factors, when added, determine the composite item index for each type of construction.

The relative weights shown on figure 8A are those determined from the composition of the index; however, these should be adjusted to correspond with the project. The product of this weight and the composite item index determines the index factor percent which, when added, produces the project index.

Figure 8B and 8C show application of the index to projects having only base and surfacing and surfacing respectively. The procedure to be followed in computing the index is identical to that described above except for relative weight. These weights were adjusted to the actual proportions of the types of construction contemplated in the project.

The index for individual projects is not so critical that strict rules need to be established for its computation. Since one of the functions of the index is to aid the designer in estimating the project, considerable latitude may be exercised in arriving at the weight of each item, adjusted relative weights, etc. The most important factor determined is probably the item index since this figure represents the deviation of the estimated price from the weighted average of past bid history in that area. Judgment and experience can be used to determine if this deviation is justified by conditions peculiar to the project.

IV FUTURE MODIFICATIONS

From time to time it will become apparent that newly developed items should be added to the index. Such construction items as lightweight surfacing aggregates, asphalt stabilized base, etc. will no doubt need to be added

to assure representation of a high percentage of the cost of individual projects. New items may be added to the statewide index or to the area indices at any time by converting the price of the new item back to the base period. However, it will be necessary to accumulate a sufficient price history on a new item to assure a realistic weighted average.
