Foreword/Preface

The wake turbulence bibliography effort traces back to the printed version of "Hallock, J. N., Aircraft Wake Vortices: An Annotated Bibliography (1923 - 1990), DOT-FAA-RD-90-30, 1991". The subsequent enlargement of the material was maintained online on a DOT Volpe Center website until 2020 where a combination of technical and personnel constraints halted the continuation of the effort. It was decided by the FAA Wake Turbulence Research and Development Office (i.e., the sponsor of the wake work at the time of this writing) that although the material is no longer accessible online, it is still of value to make the material up to 2020 available to the wake turbulence community – hence the current electronic publication of the updated Annotated Bibliography. This updated electronic bibliography replaces the earlier printed versions of "Aircraft Wake Vortices: An Annotated Bibliography (1923 - 1990), DOT-FAA-RD-90-30, 1991", "A Summary of Helicopter Vorticity and Wake Turbulence Publications With an Annotated Bibliography, J. J. Shrager, FAA-RD-74-48, 1974", and "Rotorcraft Wakes - An Annotated Bibliography, J. N. Hallock, FA-427-PM-84, 1986". The bibliography consists of abstracts of publications on aircraft wake vortices. This material was developed as part of the Volpe Center support to the sponsoring agencies over time in order to facilitate the understanding of the open literature effort and is not an official nor comprehensive archive.

Like many modern ideas, one of the earliest known references to wake vortices appeared in the notes of Leonardo da Vinci. After the great Leonardo, little was published until Lord Rayleigh described his "vortexes." However, modern aircraft wake vortex history in terms of scientific understanding began with the futile attempts by Lanchester to publish his work in a journal. Fortunately, the material eventually appeared in his book *Aerodynamics*; one of his figures is still used today. Operationally, aircraft wake vortices became a very practical consideration in the 1970s when wide body jets started to be in service, although flight testing on wake vortices appears to trace back to the early 1950s.

To make the task of compiling a bibliography a finite one, certain material was not included. To be considered for this document the publication had to possess a possible implication in the setting of separation standards in the Air Traffic Control System. The bibliography includes theoretical, computational, and experimental work which describes the nature of a vortex (its growth, decay, structure, formation, interaction with the environment, etc.), the effects of vortices on other aircraft, the various means to avoid or to alleviate the severity of a vortex encounter, and technologies that directly contributed to the understanding of the state-of-the-art vortex knowledge. In keeping with the historical term of "wake turbulence", jet-wash and jet-blast related references that have prominent historical significance are included, particularly because operationally wake turbulence separations are often applied to jet-blast in the absence of other guidance. Leading edge or delta wing vortices are considered, but only those that contain relevant information on decays, breakdown and initial circulation estimates are included.

The references are given in the form used by the American Institute of Aeronautics and Astronautics (AIAA). Since material often appeared in more than one publication (such as first in an AIAA paper, then in one of their archival journals), the more accessible source (usually the refereed journal article) was used in this report.

Special thanks to the current and past sponsors that led to the compilation of this material. They include Jillian Cheng, Jeffrey Tittsworth, Paul Strande, Steven Lang and George Greene of the FAA, as well as Wayne Bryant and Edward Johnson of NASA. We also acknowledge the countless contributors over the years that augmented and contributed to the content via correspondence. This compilation is completed under the FAA-Volpe Center Interagency Agreement: A2503-069-069-075840, Order: O2503-069-069-091203.

"EXPERIMENTS USING A THREE-COMPONENT LASER-ANEMOMETRY SYSTEM ON A SUBSONIC FLOW WITH VORTICITY"

RAE T R-8008, June 1980, Royal Aircraft Establishment, Farnborough, England.

Experiments with a three-component laser anemometer on the wake and vortex structure behind a model wing at incidence in a 4ft x 3ft subsonic test section are described. Three colors from the output spectrum of an argon-ion laser were used for the three Doppler-difference arrangements. The complete optical system operated in backscatter and was mounted on a single table which could be translated in three orthogonal directions. An integrated data acquisition and reduction system was used incorporating a photon correlator and a Honeywell 6/36 minicomputer. The output data consisted of mean-velocity and turbulence-intensity values for all three components at each measurement point. From these data, the mean-velocity components in the directions of the conventional tunnel axes could be derived by means of a linear transformation. However, the measured turbulence intensities do not yield the turbulence intensities for these components without additional assumptions or supplementary information.

Abbott, T. S.

"COCKPIT-DISPLAY CONCEPT FOR EXECUTING A MULTIPLE GLIDE-SLOPE APPROACH FOR WAKE-VORTEX AVOIDANCE"

NASA TP-2386, February 1984, NASA Langley Research Center, Hampton, VA.

A piloted simulation study was undertaken to determine the feasibility of utilizing a forward-looking display to provide information that would enable aircraft to reduce their in-trail separation interval, and hence increase airport capacity, through the application of multiple glide-path approach techniques. The primary objective of this study was to determine whether information could be satisfactorily provided on a head-up display (HUD) format to permit the pilot to conduct a multiple glide-slope approach while maintaining a prespecified in-trail separation interval. The tests were conducted in a motion-base cockpit simulator configured as a current-generation transport aircraft and included dynamic effects of the vortices generated by the lead aircraft. The information provided on the HUD included typical aircraft guidance information and the current and past positions of the lead aircraft. Additionally, the displayed information provided self-separation cues that allowed the pilot to maintain separation on the lead aircraft. Performance data and pilot subjective ratings and comments were obtained during the tests. The results of this study indicated that multiple glide-slope approaches, procedurally designed for vortex avoidance, are possible while maintaining pilot work load and performance within operationally acceptable limits. In general, it would seem that multiple glide-slope approaches are possible even under reduced in-trail separation conditions if the pilot is provided with adequate situational information.

Abbott, T. S.

"SIMULATION OF A COCKPIT-DISPLAY CONCEPT FOR EXECUTING A WAKE-VORTEX AVOIDANCE PROCEDURE"

NASA TP-2300, April 1984, NASA Langley Research Center, Hampton, VA.

A piloted simulation study has been undertaken to determine the feasibility and potential benefits of utilizing a forward-looking display to provide information that would enable aircraft to reduce their in-trail separation, and hence increase runway capacity, through the application of multiple glide-path approach techniques. This portion of the study was an initial exploration into a concept in which traffic information was added to a head-up display (HUD) format to allow the pilot to monitor the traffic situation and to self-space on a lead aircraft during a single glide-path approach task. The tests were conducted in a motion-base cockpit simulator configured as a current-generation transport aircraft and include the dynamic effects of the vortices generated by the lead aircraft. The information provided on the HUD included typical aircraft guidance information and the current and past positions of the lead aircraft. Additionally, the displayed information provided self-separation cues which allowed the pilot to maintain separation on the lead aircraft. The results of this study indicate that the display concept could provide sufficient information to the pilot for traffic monitoring and self-separation.

"WIND VELOCITY ESTIMATE AND SIGNAL TO NOISE RATIO ANALYSIS OF AN ALL FIBER COHERENT DOPPLER LIDAR SYSTEM"

16th Coherent Laser Conference, June 2011, Long Beach, CA.

In CDL, a laser pulse is transmitted into the atmosphere and the Doppler shifted signal that scatters off atmospheric aerosol particles is detected by beating this signal with a local oscillator (LO). The resulting RF signal has a Doppler shift proportional to the speed of aerosol particles along the line of sight of the laser beam. In this paper, we present preliminary results from our all fiber 1.5-micron CDL. The range dependence of the theoretical wideband SNR of an atmospheric backscattered signal is compared to experimental results using a 6-inch diameter refractive telescope. The system performance is dependent on optimizing the LO power and our previous research presented a detailed analysis of an optimum LO power and its effect on detector's efficiency.

Abdelazim, S., Santoro, D., Arend, M., Moshary, F. and Ahmed, S.

"ALL-FIBER COHERENT DOPPLER LIDAR FOR WIND SENSING"

15th Coherent Laser Radar Conference Proceedings, June 2009, Toulouse, France, pp. 283-286.

Coherent Doppler LIDAR is being utilized to develop a mobile wind speed measuring station. We are building an all fiber-based eye safe laser system to measure wind speed in urban areas. A 1.5-micron polarization maintained fiber optics master oscillator power amplifier system is used which leverages components from the telecommunication industry. We chose a heterodyne balanced detection to suppress the RIN noise. We have calculated the optimum local oscillator power for maximum optical

detector's efficiency. A/D conversion will be performed at 400 MHz by using a data acquisition card with FPGA on board, which can be programmed to perform autocorrelation and/or FFT onboard for faster performance. This system can be used along with other units on top of high buildings in New York City as a way of detecting wind speed profile for Homeland security.

"TRACKING OF VORTICAL STRUCTURES IN THREE-DIMENSIONAL DECAYING HOMOGENEOUS ISOTROPIC TURBULENCE"

International Journal of Modern Physics C, Vol. 22, Issue 12, 2011, pp. 1373-1391.

Direct numerical simulation of three-dimensional decaying homogeneous isotropic turbulence with a resolution of 128 cubed is carried out using the Lattice Boltzmann Method (LBM). The aim of this paper is to investigate the statistical characteristics of the obtained turbulent flow field and the behavior of the vortical structures. Most of the LBM simulations of decaying turbulence were mainly focused on the statistical results of the velocity field, however the characteristics of the coherent vortices and their time evolution are ignored. In this paper, the statistical properties of the velocity field as well as the extraction and tracking processes of individual vortices are considered. Results show that the present simulation could recover important features of turbulence such as isotropy, skewness, energy spectrum and elongated vortical structures. A vortex ring is identified in the flow field which can be considered as a sign for the existence of vortex rings in homogeneous isotropic turbulence. Forward and reverse tracking of individual vortical structures shows that vortex rings can be generated from the interaction and the overlapping of vortex tubes.

"THE 'MUSICAL' SOUND EMITTED BY A TORNADO"

Monthly Weather Review, Vol. 94, No. 4, April 1966, pp. 213-220

This paper attempts to explain the 'whining' or 'hissing' sound reported from tornadoes. The leading hypothesis is that the air masses involved in the tornado circulation execute some free vibrations. It is found that these vibrations may be in the audible range for a small vortex whose radius is of the order of 10 m. or less. A formula is obtained which relates the frequency of the tone to the inner radius of the vortex. This formula is amenable to experimental verification.

"WAKE DISPLACEMENT MODIFICATIONS TO REDUCE ROTORCRAFT BLADE -- VORTEX INTERACTION NOISE"

Journal of Aircraft, Vol. 41, No. 2, March-April 2004, pp. 290-303

Increasing the vertical separation between the rotor and its wake can reduce the strength of blade-vortex interaction (BVI) noise. A simple, first-order analytical model is developed to estimate the vertical distance between the rotor and the wake at any location of interest in the rotor disk. This model is used as an indicator to evaluate the potential effects of added forces, descent angle, advance ratio, and thrust coefficient on the separation between the wake and the rotor with the aim of identifying strategies that maximize this distance at a particular rotor disk location. The analysis focuses on landing approaches for helicopters and tiltrotors operating near helicopter configuration. The most appropriate strategies to increase this separation at the location of interest are found to depend on whether the wake is initially above or below the rotor. Added drag, added downforce, shallower descents, lower advance ratios, and higher thrust coefficients are shown to be desirable if the wake is initially below the rotor plane at the location of interest; this is the case of tiltrotor approaches and some helicopter descent operations. On the other hand, added thrust, added lift, steeper descents, higher advance ratios, and lower thrust coefficients are usually more appropriate if the wake is initially above the rotor plane at the location of interest; this is the case for other helicopter descent operations.

"THE FORMATION OF VORTEX STREETS"

Journal of Fluid Mechanics, Vol. 13, Issue 1, May 1962, pp. 1-20.

The formation of vortex streets in the wake of two-dimensional bluff bodies can be explained by considering the non-linear interaction of two infinite vortex sheets, initially a fixed distance, h , apart, in an inviscid incompressible fluid. The interaction of such sheets (represented in the calculation by rows of point-vortices) is examined in detail for various ratios of h to the wavelength, a , of the initial disturbance. The number and strength of the concentrated regions of vorticity formed in the interaction depend very strongly on h/a . The non-linear interaction of the two vortex sheets explains both the cancellation of vorticity and vortex-sheet broadening observed in the wakes of bluff bodies.

"AN ESTIMATE OF THE POWER REQUIRED TO ELIMINATE TRAILING VORTICES BY SUCTION"

IEEE Proceedings, Vol. 58, No. 3, March 1970, pp. 326-327.

The feasibility of reducing the hazards of trailing vortices on closely spaced parallel runways is examined. The proposed solution involves the application of suction along the runways. A simplified computer simulation indicated that the application is feasible and that the required horsepower is modest.

Abernathy, F. H., Menkes, J. and Uberoi, M. S.

"AN ESTIMATE OF THE POWER REQUIRED TO ELIMINATE TRAILING VORTICES BY SUCTION"

DOT-1081, Report of Dept. of Transportation Air Traffic Advisory Committee, Vol. 2, Appendix B-4, December 1969, pp. 55-77.

The fullest utilization under IFR conditions of closely spaced parallel runways might very well depend ultimately on our ability to eliminate or at least to control the hazards of wake turbulence. Two parameters determine the severity of the problem: crosswind and aircraft weight. Of all the possible solutions, one of the least promising is to attempt to change the character of the vortex as it leaves the wing. A better approach is to affect the trajectory of the trailing vortices by suction. This solution has the attractive feature that the vortex motion is influenced without relying on viscous dissipating mechanisms. The conceptual scheme involves placing one or more ditches between the runways, covered with a heavy grating, which house the suction blowers.

Abid, M.

"NONLINEAR MODE SELECTION IN A MODEL OF TRAILING LINE VORTICES"

J. Fluid Mech., Vol. 605, 2008, pp. 19-45

Nonlinear mode selection, from initial random Gaussian field perturbations, in a model of trailing line vortices (swirling jets), in the breakdown regime, is addressed by direct numerical simulations with a Reynolds number equal to 1000. A new concept of mode activity in the nonlinear evolution is introduced. The selected modes, according to their activities, are reported and related to strain eigenvectors (with maximum eigenvalues) of the basic flow corresponding to the trailing line vortex under consideration. The selected modes are also related to results from the linear eigenmode (exponential growth) instability theory using the concept of dispersion relation envelope. It is found that the global mode hypothesis of the linear eigenmode theory is violated near the flow axis when the swirl number increases. However, far from the flow axis the linear eigenmode theory is in good agreement with the nonlinear evolution in the breakdown regime. The discrepancy between the nonlinear evolution and the linear eigenmode theory is related to the transient growth of optimal perturbations resulting from the non-normality of the linearized Navier-Stokes equations about shear flows. A clear distinction between an eigenmode, an optimal perturbation (non-modal) and a direct numerical simulation (DNS) mode is made. It is shown that the algebraic (transient) growth contributions from the inviscid continuous spectrum could trigger nonlinearities near the flow axis.

Abid, M. and Brachet, M. E.

"DIRECT NUMERICAL SIMULATIONS OF THE BATCHELOR TRAILING VORTEX BY A SPECTRAL METHOD"

Physics of Fluids, Vol. 10, No. 2, February 1998, pp. 469-475

The nonlinear vorticity dynamics of the Batchelor trailing vortex is presented. Direct numerical simulations of the three-dimensional, incompressible, Navier-Stokes equations by a spectral method are used. It is shown that the initial vortex core is subjected to three transformations: a twisting phase, a lateral expansion of its cross section and formation of a spiral structure. These transformations are accompanied by a gradual deceleration of axial velocity. Mean kinetic energy is

then transferred to radial velocity. When the transfer is maximum a secondary instability is initiated leading to the spiral structure. These transformations agree with vortex breakdown observed in recent experiments.

Abid, M., Andreotti, B., Douady, S. and Nore, C.

"OSCILLATING STRUCTURES IN A STRETCHED-COMPRESSED VORTEX"

J. Fluid Mech., Vol. 450, 2002, pp. 207-233

The dynamics of a vortex subject to a localized stretching is numerically investigated. The structure of the flow is analyzed in the case of an initially two-dimensional vortex surrounded by a periodic array of vortex rings localized far from its core. Amplified oscillations of both the axial vorticity and the stretching are found, in strong contrast with Burgers-like vortices. The resulting dynamics is the appearance, around the vortex, of successive vortical structures of smaller and smaller radius and alternate sign embedded in the previous vortical rings. The frequency scaling of the oscillations is recovered by linear analysis (Kelvin modes) but not the amplification nor the shape of the successive tori. An inviscid model based on structures is presented, which compares better with the numerical computations. These results suggest that the formalism of Kelvin waves is not sufficient to describe the full dynamics, which is instead related to the feedback of rotation on stretching and more conveniently described in terms of localized structures. We finally discuss the relative timescales of vortex stretching and of vortex reaction. The Burgers-like vortices, where there is no such reaction, turn out to correspond to a nearly pure strain field, slightly disturbed by rotation.

Abid, R. and Schmitt, R.

"EXPERIMENTAL STUDY OF A TURBULENT HORSESHOE VORTEX USING A THREE-COMPONENT LASER VELOCIMETER"

AIAA Paper No. 1986-1069, Atlanta, GA, May 1986

The turbulent horseshoe vortex flow generated by a simplified wing-body junction has been experimentally studied. Oil surface flow visualization, static wall pressure measurements, and flow field measurements were made in the separated region upstream of the obstruction leading edge. Mean flow measurements on the plane of symmetry indicate that the three-dimensional separation was confined to a region near the plate. The region of reversed flow was approximately a fifth of the boundary layer thickness. The theoretical streamline pattern suggested by oil surface flow visualization is confirmed.

Aboelkassem, Y.

"BLADE VORTEX INTERACTIONS: EXPERIMENTAL MEASUREMENTS OF THE NEAR-FLOW FIELD"

Journal of Fluid Science and Technology, Vol. 4, No. 1, 2009, pp. 138-155.

The near-field flow structure of an intense streamwise vortex filament encountering normally with a blade tip vortex was investigated experimentally. Three cases were investigated, direct impingement, interactions on the pressure side and interactions over the suction side. The effects of blade-vortex interaction were found to be strongly dependent on whether the vortex filament passed over the pressure or suction side of the blade. In case of zero vortex-blade tip separation (direct impingement), the peak tangential velocity and total circulation of the interaction vortex remained basically unchanged, regardless of downstream distance, but had values larger than the generator vortex, while the core circulation and the core radius increased almost linearly with downstream distance, like an undisturbed generator vortex. The maximum total turbulent energy decreased as x/c increased. In summary, the present experiment deals with the normal interactions of streamwise vortex with another tip vortex shed by a blade end-tip, and focuses on the resultant vortex structures and peak values due to the interaction itself.

Aboelkassem, Y.

"TRAILING VORTEX FILAMENT: A NOVEL SIMILARITY ANALYSIS"

Journal of Aircraft, Vol. 44, No. 2, March-April 2007, pp. 683-687

The classical spatial-decay analysis of a trailing vortex's line filament is extended to include the temporal effects. Based on the order of magnitude argument, the time-dependent governing equations are reduced into a simpler form. New similarity variables are introduced and have been used to transform the time-dependent partial differential equations into an ordinary set. The latter have proven to be identical to the steady analysis given previously by Newman. Consequently, the solution to the time-decay problem is found by analogy to the steady-state subset and without having formally to solve the governing equations. In other words, the time-decay problem is similar to the axial decay one. In addition, the present theoretical study shows the space-time analogy shared by a group of self-similar structure vortices. The steady vortices can be transformed into time decaying and vice versa. This transformation depends solely on the similarity variable. The present results are confirmed by available experimental measurements and have shown that steady and decaying vortices, irrespective of their size, strength, and time level, should collapse into a single curve, that is, the space-time self-similarity hypothesis is indeed validated.

Aboelkassem, Y. and Vatisstas, G. H.

"NEW MODEL FOR COMPRESSIBLE VORTICES"

Journal of Fluids Engineering, Vol. 129, August 2007, pp. 1073-1079

A new analytical solution for self-similar compressible vortices is derived in this paper. Based on the previous incompressible formulation of intense vortices, we derived a theoretical model that includes density and temperature variations. The governing equations are simplified assuming strong vortex conditions. Part of the hydrodynamic problem (mass and momentum) is shown to be analogous to the incompressible kind and as such the velocity is obtained through a straightforward variable

transformation. Since all the velocity components are bounded in the radial direction, the density and pressure are then determined by standard numerical integration without the usual stringent simplification for the radial velocity. While compressibility is shown not to affect the tangential velocity, it influences only the meridional flow (radial and axial velocities). The temperature, pressure, and density are found to decrease along the converging flow direction. The traditional homentropic flow hypothesis, often employed in vortex stability and optical studies, is shown to undervalue the density and greatly overestimate the temperature. Comparable to vorticity diffusion balance for the incompressible case, the incoming flow carries the required energy to offset the contributions of conduction, viscous dissipation, and material expansion, thus keeping the temperature steady. This model is general and can be used to obtain a compressible version for all classical previous incompressible analysis from the literature such as Rankine, Burgers, Taylor and Sullivan vortices.

Aboelkassem, Y., Vatistas, G. H. and Esmail, N.

"VISCOUS DISSIPATION OF RANKINE VORTEX PROFILE IN ZERO MERIDIONAL FLOW"

Acta Mech Sinica, Vol. 21, 2005, pp. 550-556

An analytical solution is given for a time-delay Rankine vortex profile due to viscous effects. The vortex filament is assumed to be isolated, strong, concentrated and having zero-meridional flow (i.e. radial and axial velocities are equal to zero). Zero-meridional renders the governing equations for an unsteady, incompressible and axisymmetric vortex in a simple form. Based on the tangential momentum equation, the spatial-temporal distributions of the swirl velocity are given in terms of Fourier-Bessel series by using separation of variables technique. A general formula is derived by total differentiation of the swirl velocity with respect to time, depicting the viscous dissipation for Oseen and Taylor-like vortex profiles. This analysis is validated by comparison with previous experimental data.

Abramson, S. and Burnham, D. C.

"WIND DATA FROM KENNEDY AIRPORT"

DOT/FAA/ND-97-3, May 1997, DOT Volpe Center, Cambridge, MA.

A 700-foot array of horizontal and vertical single axis anemometers was installed at New York's Kennedy Airport on 30-foot poles under the approach to Runway 31R. One minute average measurements were recorded continuously, with a few breaks, from September 1994 through June 1995. Although the original purpose for the anemometers was to track the lateral position of wake vortices, the measurements also provide a database of wind and turbulence that can be used for other purposes. For example, the crosswind data has been used to evaluate four adaptive wake vortex separation systems based on the measured crosswind. This report documents the data formats and database characteristics and provides information on how to obtain a copy of the data.

Abramson, S. and Burnham, D. C.

"GROUND-BASED ANEMOMETER MEASUREMENTS OF WAKE VORTICES FROM LANDING AIRCRAFT AT AIRPORTS"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 13-1 to 13-7

In 1994 an array of two-axis propeller anemometers was installed at 10-meter height under the approach to Runway 31R at Kennedy Airport. Since the aircraft are typically 50 meters above the ground at the test location, the wake vortices rapidly descend toward the ground where they are readily detected and measured by the anemometers. In 1995 a similar installation was made on Runway 27 at the Memphis Airport. The ultimate goal of this study is to better understand when wake vortices remain in the flight path of following aircraft. The data collection system operates automatically and hence provides wake vortex data under all weather conditions and at all times of day and night with minimal cost. Real-time remote display of the vortex locations was implemented. The anemometers are augmented with additional weather sensors to provide meteorological data with greater detail than the standard surface weather observations. New processing methods for the anemometer data were developed to determine vortex height and strength in addition to the lateral position that was traditionally obtained from ground-based anemometers. The anemometer array is particularly appropriate for studying the interaction of wake vortices with the ground. It readily detects the secondary vortices detached from the boundary layer by the influence of the primary wake vortices; these secondary vortices produce the well known vortex bouncing. Such secondary vortices have not been seen by any other sensing system.

"WAKE BREAKDOWN OF HIGH-FIDELITY SIMULATIONS OF A ROTOR IN HOVER"

AIAA Paper 2019-0593, January 2019, San Diego, CA.

Complete wake breakdown is a well-documented phenomenon associated with computational fluid dynamic hover predictions. As the computational state-of-the-art for hover predictions has progressed, allowing for higher resolution of the rotor wake, this phenomenon has become more severe; thus, resolving this open question has become more important to increase understanding of how and why it occurs and define a path forward. The present work investigates the wake breakdown phenomena using the S-76 isolated rotor. This investigation includes a discussion of physical flow features that are felt to influence both physical and computational wake breakdown as well as an analysis of the computational inputs that can influence these flow features. This includes an analysis of relative vortex core position and strength as a function of wake breakdown and a parameter study to look at off-body grid structure. The grid study employs both cylindrical and Cartesian grids and different grid densities to investigate how these settings influence physical flow features and the initiation of wake breakdown. Rotating and stationary grids are also included in this study. As a result of these studies clear impacts to the wake breakdown have been discovered.

Abuharaz, M. and Ash, R. L.

"A NEW APPROACH FOR MODELING THE UNSTEADY BEHAVIOR OF TRAILING LINE AXIAL VORTICES"

AIAA Paper 2013-3188, June 2013, San Diego, CA.

A state variable procedure has been developed that can be used to study the influence of non-equilibrium pressure gradient forces on the stability of axial trailing-line vortices. In addition to previously-developed modified Navier-Stokes equations, a Poisson equation governing perturbation pressure fluctuations was developed that is of the same differential order as the velocity perturbation equations. A normal mode analysis was utilized to formulate the small perturbations in the vortical flow with radially-varying amplitudes, producing a system of ordinary differential equations governing the evolution of the normal modes in the flow. This has resulted in a more-consistent approach for analyzing the stability and unsteady behavior of these axial vortices.

"EXPERIMENTAL ANALYSIS OF TIP VORTEX BY LASER DOPPLER ANEMOMETRY"

Proceedings of the International Symposium on Applications of Laser Anemometry to Fluid Mechanics, 1984, July 2-5, Lisbon

The aerodynamic performances of aircraft wings, helicopter rotors, marine propellers, and turbomachines are related to the presence of turbulent boundary layers and vortex sheet formation. The mutual interaction between boundary layer makes three-dimensional the phenomenon. This aspect is particularly evident at the wing/body junction and at the extremity of the wings or blades where tip vortices are formed. By means of laser Doppler anemometry, the velocity field is experimentally analyzed close to the tip in the near wake generated by a symmetrical wing with a rectangular plant. The analysis of experimental results shows that there exists a strong axial current in the core of the tip vortex. A velocity logarithmic trend is formed in the zone where there is interaction between the irrotational flow and the core vortex.

Ackroyd, J. A. D.

"THE SPITFIRE WING PLANFORM: A SUGGESTION"

Journal of Aeronautical History, Paper No. 2013/02, 2013, London, U.K.

The paper concerns the aerodynamic design of the Spitfire wing and the involvement of the Canadian-born Beverley Shenstone in this. It is suggested that the wing's distinctive double-ellipse planform could have come from Prandtl's work at Gottingen on finite wing theory.

Acosta, R., Hughes, I. and Petersen, R.

"VISUALIZATION OF WAKE VORTEX EFFECTS ON AIRCRAFT"

B.S. Thesis, June 1998, Hogeschool van Amsterdam, Amsterdam, The Netherlands.

The assignment issued by Dr. J. N. Hallock, manager of the Aviation Safety Division of the Volpe National Transportation Systems Center in Cambridge, Massachusetts, is to visually record aircraft landings at Runway 31R at JFK International Airport. The position and the motion of the aircraft must be retrieved from the recorded images. The data of the motion of all aircraft will be analyzed along with the vortex data gathered by the Volpe Center in order to determine if any aircraft motion is related to wake vortices caused by preceding landing aircraft. After a theoretical analysis a method for recording was chosen involving the use of two cameras. This method is called stereoscopic imaging. The application of stereoscopic imaging as developed does not require input from other systems for its functioning. The accuracy is reliable if the system is calibrated correctly and aligned and stays aligned correctly during recording. The equipment and tools for the system are relatively inexpensive in comparison to having a person analyze recordings of a single imaging system. Of the two test periods that were spent at the JFK test site there were no valuable recordings taken. During the last test period the calibration for both cameras were achieved as well as a measurement of a still object. The error in the measurement proved to be small. The system that is developed and described completely within the contents of this thesis must be set up correctly for it to function adequately. Time as well as money need to be invested into equipment for aligning the cameras correctly to use this system for gaining accurate data, which can then be analyzed in combination with wake vortex data to prove what effect wake vortices have on aircraft.

Adam, I. G.

"VORTEX WAKE AND EXHAUST PLUME INTERACTION, INCLUDING GROUND EFFECT"

Ph.D. Thesis, 1998, Old Dominion University, Norfolk, VA

Computational modeling and studies of the near-field wake-vortex turbulent flows, far-field turbulent wake-vortex/exhaust-plume interaction for subsonic and High-Speed Civil Transport (HSCT) airplane, and wake-vortex/exhaust-plume interaction with the ground are carried out. The three-dimensional, compressible Reynolds-Averaged Navier Stokes (RANS) equations are solved using the implicit, upwind, Roe-flux-differencing, finite-volume, scheme. The turbulence models of Baldwin and Lomax, one-equation model of Spalart and Allmaras and two-equation shear stress transport model of Menter are implemented with the RANS solver for turbulent-flow modeling. For the near-field study, computations are carried out on a fine grid for a rectangular wing with a NACA-0012 airfoil section and a rounded tip. The focus of study is the tip-vortex development, the near-wake-vortex roll-up, and validation of the results with the available experimental data. For the far-field study, the computations of wake-vortex interaction with the exhaust-plume of a single engine of a medium-size subsonic aircraft in a holding condition and two engines of a HSCT in a cruise condition are carried out using an overlapping zonal method for several miles downstream. The overlapping zonal method has been carefully developed and investigated for accurate and efficient calculations of the far-field wake-vortex flow. The results of the subsonic flow are compared with those of a Parabolized Navier Stokes (PNS) solver known as the UNIWAKE code. Next, the problem of wake-vortex/ground interaction is investigated. For the simulation of this problem, typical velocity profiles of a tip vortex with and without the exhaust-plume temperature profiles are used for inflow boundary conditions and the computations are carried out

using the overlapping zonal method for long distances downstream. The effects of the exhaust-plume temperature on the vortex descent, ground boundary-layer separation, vortex rebound and vortex decay are studied and validated with the available experimental data. A parametric study, which covers the effects of atmospheric conditions such as axial wind, crosswind, wind shear, turbulence, and Reynolds number on vortex motion and dynamics near the ground, is also carried out.

Adam, I. G. and Kandil, O. A.

"INVESTIGATION OF THREE-DIMENSIONAL VORTEX-WAKE INTERACTION WITH THE GROUND"

AIAA Paper No. 1998-0594, Reno, NV, January 1998

Three-dimensional, computational study of vortex-wake flow, with and without exhaust plume, near the ground is carried out. The Navier-Stokes (NS) equations are solved using the implicit, upwind, Roe flux-differencing, finite volume scheme. The computations of vortex-wake interaction with the ground are carried out using overlapping zonal method for long distances downstream. Typical velocity profiles of a tip vortex with and without exhaust plume temperature profiles are used for inflow boundary conditions. The effects of the plume temperature on the vortex descent, boundary-layer separation and vortex rebound are studied and validated with the available experimental data. Moreover, the effect of the flow in the axial direction on the vortex descent is studied by using two different axial velocity profiles at the inlet boundaries.

Adams, G. N. and Gilmore, D.C.

"SOME OBSERVATIONS OF VORTEX CORE STRUCTURE"

Canadian Aeronautics and Space Journal, Vol. 18, June 1972, pp. 159-162.

During observation of propeller tip vortex locations by means of smoke and stroboscopic lighting, a fortuitous atmospheric condition resulted in the formation of visible condensation in the vortex cores. The core structure was seen to be extremely complex, with evidence of concentric cells of axial flow, bounded by families of ring vortices. Photographs were taken, and a selection of these is presented here, for the inspiration of fluid dynamicists and the edification of others.

Adamson, D. and Boatright, W. B.

"INVESTIGATION OF DOWNWASH, SIDEWASH, AND MACH NUMBER DISTRIBUTION BEHIND A RECTANGULAR WING AT A MACH NUMBER OF 2.41"

NACA RM-L50G12, 1957, Langley Aeronautical Lab., Langley Field, VA

An investigation of the nature of the flow field behind a rectangular wing of circular arc cross section has been conducted in the Langley 9-inch supersonic tunnel. Pitot- and static-pressure surveys covering a region of flow behind the wing have been made together with detailed pitot surveys throughout the region of the wake. In addition, the flow direction has been measured by means of a

weathercocking vane. Theoretical calculations have been made to obtain the variation of both downwash and sidewash with angle of attack by using the superposition method of Lagerstrom, Graham, and Grosslight. In addition, the effect of wing thickness on the sidewash with the wing at 0 degree angle of attack has been evaluated.

Adamson, H. P. and Morrison, C. F.

"INFRARED AIRBORNE AND GROUND DETECTION OF WAKE VORTICES"

Proceedings of Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, MA, June 1992,

pp. 43-1 - 43-25

Considerable study of aircraft wake vortices has resulted in a large database on these events. However, little useful data exists for the Infrared (IR) community to study. This paper will assess the feasibility and practicality of Infrared detection of these events. The method will be described. The modelling and field data will be presented. The conclusion is that a dedicated program consisting of additional modelling along with a field data collection program is warranted.

"ANALYSIS AND INTERPRETATION OF INSTANTANEOUS TURBULENT VELOCITY FIELDS"

Experiments in Fluids, Vol. 29, 2000, pp. 275-290.

Methods of analyzing and interpreting velocity-field data (both two- and three-dimensional) to understand the kinematics, dynamics, and scales of turbulence are discussed. Reynolds decomposition and vorticity are traditionally used; however, several other methods, including Galilean (constant convection velocity) and LES decompositions (low-pass filtering), in conjunction with critical-point analysis of the local velocity gradient tensor, reveal more about the structure of turbulence. Once the small-scale structures have been identified, it is necessary to assess their importance to the overall dynamics of the turbulence by visualizing the motions they induce and the stresses they impose on other small-scale vortices and on the large-scale field.

"WAKES AND VORTEX STREETS GENERATED BY TRANSLATING FORCE AND FORCE DOUBLET: LABORATORY EXPERIMENTS"

J. Fluid Mech., Vol. 553, 2006, pp. 119-141

Wakes and vortex streets such as those occurring behind towed or self-propelled bodies are generated by moving localized forces in a viscous fluid at moderate values of the Reynolds number. The forcing is provided by an electromagnetic method and allows us to create a 'virtual' body without

introducing any solid objects into the fluid. Characteristics of stable and unstable wakes, particularly the shedding frequency, are measured in the space of control parameters, namely the magnitude of the forcing and the speed of translational motion of the forcing. The results for a single force presented in the dimensionless form of the Strouhal number demonstrate quantitative similarity to those for the classical flow around a cylinder. The problem considered here has an extra degree of freedom compared to the problem of the flow around a cylinder and exhibit a wider array of different regimes. These regimes are documented in both our visualization experiments and particle image velocimetry measurements.

Agnew, P.

"METEOROLOGICAL ASPECTS OF WAKE RELATED CAPACITY GAINS"

Second Workshop WakeNet2-Europe, 'Capacity Gains as Function of Weather and Weather Prediction Capabilities', Langen, November 2004.

The capacity gains anticipated from reductions in wake vortex related spacings are heavily dependent on the skill of forecasting local meteorological conditions. Two classes of weather are particularly important for reduction of the wake vortex threat: cross winds and turbulence. Climatological studies at Heathrow airport have been carried out to investigate the scope for the introduction of reduced spacing rules. An investigation into the influence of winds on aircraft arrival rates have demonstrated the value of high-quality wind forecasting even for normal operations. Profiles of eddy dissipation rates (EDR) from aircraft descents logged in the Heathrow Database (HDB) have been analyzed to investigate the prospects for improved forecasting of turbulence. Finally, results are presented of a study into actual wake vortex encounters in the HDB. Meteorological and aircraft related parameters have been combined to produce a detailed 'snapshot' of a set of around 30 encounters. It is hoped these will provide a basis for further, more detailed studies.

Agnew, P. and Hoad, D. J.

"CLIMATOLOGY STUDY OF WORLD AIRPORTS IN THE CONTEXT OF WAKE VORTEX BEHAVIOR CLASS"

S-Wake Technical Note 132_1, March 2002, Met Office, Bracknell, UK.

Atmospheric conditions play a key role in the evolution of aircraft wake vortices. Earlier work in S-Wake has proposed the introduction of discrete 'wake vortex behavior classes' (WVBC) in which vortices are expected to exhibit differing evolution characteristics. As part of a broader study, we have established climatologies with respect to these WVBC for a variety of airports world-wide. The Met Office Site Specific Forecast Model was used to calculate vertical profiles of meteorological variables over a seven-year period. Synoptic data from each site and forcing data from the ECMWF ERA-15 re-analysis project were used as input to the model. The profiles were used to evaluate the mean WVBC at each site on pressure levels up to a value corresponding to a height of around 2 km. It is found that at many airports, WVBC which favor the rapid dissipation of wake vortices are prevalent for in excess of

30 percent of the time. The implications of these results for future wake vortex separation rules are discussed. [Company Confidential].

"CLIMATOLOGY STUDY OF WORLD AIRPORTS IN THE CONTEXT OF WAKE VORTEX BEHAVIOR CLASS"

13th AMS Conference on Applied Climatology, Paper J1.10, May 2002, Portland, OR

The increasing capacity demands at major airports throughout the world continue to drive research in the civil aviation community into ways of increasing the number of hourly aircraft movements in a safe manner. At busy airports the frequency of movements is restricted by aircraft separation rules imposed due to safety concerns associated with wake vortex encounters. The current separation rules have been highly effective in reducing wake vortex encounters, however there are situations where they appear overly conservative. As a result there is considerable interest in developing a greater understanding of wake vortex evolution in order that a more flexible approach to imposing separations can be implemented. The European S-Wake is a multi-activity research program aimed at addressing these issues and comprises a variety of both experimental and theoretical studies. One important strand is concerned with understanding how local meteorological conditions influence the evolution of vortices. If meteorological conditions can be identified in which wake vortices are known to either dissipate quickly or be swept away from the path of following aircraft, and if those conditions can be reliably forecast sufficiently far ahead, then there exists the basis for a more flexible implementation of aircraft separation rules, which could lead to valuable increases in the frequency of movements in and out of busy airports. This paper describes work concerned with establishing a climatology with respect to wake vortex behavior classes prevalent at any given time. Here we give detailed results available for some major European airports.

Agnew, P., Lunnon, B., Hoad, D., Frech, M., Gerz, T., Carriere, J.-M. and de Bruin, A.

"WAKE VORTEX ALLEVIATION STRATEGIES FOCUS ON INFLUENCE OF WEATHER ON VORTEX BEHAVIOUR"

ICAO Journal, Vol. 56, No. 7, September 2001, pp. 8-10, 28

Current aircraft separation requirements are effective in preventing wake vortex encounters, but are often overly conservative. Scientists are studying vortex behavior in all weather conditions to determine whether separation requirements may be relaxed under certain circumstances.

Agrawal, A.

"MEASUREMENT OF SPECTRUM WITH PARTICLE IMAGE VELOCIMETRY"

Experiments in Fluids, Vol. 39, 2005, pp. 836-840.

The purpose of this paper is to show that the measurement of turbulent spectrum using whole-field velocity techniques such as particle image velocimetry (PIV) is possible. Toward this end, data from the axial plane of a self-similar turbulent axisymmetric jet, at a Reynolds number, based on Taylor microscale of 30 has been analyzed. The two-dimensional velocity data are first high-pass filtered, which reduces the vortices. An automated method is then used to identify the vortices and measure their properties. By directly measuring the energy of the vortices, it is possible to plot the turbulence spectrum. The spectrum presented here shows the presence of energy containing and inertial regimes. However, the smallest scales have not been resolved in the measurements. The slope of the spectrum in the inertial subrange is about -1.6. The number of vortices in the two regimes have also been measured. The number of vortices in the energy containing regime is substantially smaller than those in the inertial subrange. The technique has been verified by analyzing another dataset. These results show that the direct measurement of vortex properties with reasonable confidence is possible using PIV and an appropriate vortex eduction technique.

Agui, J. H. and Andreopoulos, Y.

"AN EXPERIMENTAL STUDY OF THE INTERACTION OF A LONGITUDINAL VORTEX WITH A TRAVELING SHOCK WAVE"

AIAA Paper No. 1999-0149, Reno, NV, January 1999.

The interaction of a planar shock wave with an induced, wing tip generated, vortical flow has been investigated experimentally in the CCNY Shock Tube Research Facility (STURF). A half span NACA-0012 wing at 15 degrees angle of attack generated the vortex in incident flow Mach numbers of 0.31 to 0.45. Measurements of time-dependent total pressure, total temperature, and three-dimensional velocity and vorticity were carried out in the vortex core region. From an analysis of the data before the interaction, it was found that the core exhibited a well-defined total pressure deficit and an increase in mass flux, indicating a well-structured vortex. Mean vorticity and fluctuations were quite significant before and after the interaction with the shock, providing unprecedented experimental data of this kind. Significant enhancement of vorticity fluctuations after the shock interaction were observed in both cases, with increases in rms value of more than 2-fold. A particle flow visualization technique was employed and revealed quite clearly that the core is well defined before the interaction and then becomes diffused with a core growth of approximately 15 degrees shortly after interaction.

"RISK ANALYSIS OF THE PROGNOSIS ALGORITHM AND THE OPERATIONAL USE OF THE WAKE VORTICES WARNING SYSTEM"

B-IT 1029/02, October 1994, DFS Deutsche Flugsicherung, Ottobrunn, Germany

A risk analysis is necessary for the operational use of the wake vortices warning system at Frankfurt Main airport. The results of the risk analysis are presented in this report. The calculated probabilities of forecasting errors are combined with the results of other studies. Using this method, it was possible

to estimate the probability of an accident caused by wake vortices during the operational use of the wake vortices warning system. It is shown that this probability is lower than the accepted risk of single runway operation using wake vortex separation. [In German]

Ahlin, G. A. and Brown R. E.

"PREDICTING THE ONSET OF THE VORTEX RING STATE UNDER ACCELERATED FLIGHT CONDITIONS"

61st Annual National Forum, American Helicopter Society, Grapevine, TX, June 2005

A general method for predicting the onset of the vortex ring state is developed in terms of a model for the propagation and growth of disturbances within the rotor flow. Newman et al.'s engineering model for the onset of the vortex ring state under quasi-steady conditions is shown to be a special case of this approach. A generalization of Newman et al.'s model to the unsteady case is shown to reproduce earlier findings that the onset of the vortex ring state should be postponed to higher descent rates under accelerated flight conditions. Numerical simulations of the onset of the vortex ring state reveal though that the transition into the vortex ring state becomes increasingly gradual as the acceleration of the rotor is increased. Under a combination of high forward speed and vertical acceleration, the vortex ring state may even be replaced by a qualitatively different, highly transient state where the collapse of the wake into the toroidal form that is usually associated with the onset of this flow condition is suppressed. The absence of an abrupt and universal transition marking the onset of the vortex ring state under accelerated flight conditions complicates the application of simple analytical models and implies that the specific details of the time-dependent dynamics of the rotor wake and its interaction with the rotor cannot be ignored when modelling the onset of this flow regime.

Ahlin, G. A. and Brown, R. E.

"WAKE STRUCTURE AND KINEMATICS IN THE VORTEX RING STATE"

Journal of the American Helicopter Society, Vol. 54, No. 3, 2010, pp. 032003-1 - 032003-18.

High-resolution computational simulations of the vortical wake of a rotor operating both near to and within the vortex ring state have been conducted using Brown's vorticity transport model. The nonlinear vortex kinematics of the wake is exposed using three-dimensional visualizations of the simulated flow field. To reveal the vortex dynamics that underpin the highly unsteady flow within the vortex ring state, a rotor with just one blade was modeled. This blade was decoupled aerodynamically from the surrounding velocity field so that it acted merely as a source of trailed vorticity. The investigation identified a significant change in the dominant dynamics of the wake as it swapped from the tubular form that is characteristic of hover or very low speed descent into the toroidal geometry of the vortex ring state. Initial vortex 'pairing' leads to rotation of vortex filaments away from their original attitude. This phenomenon plays an important role in regulating the downwash that the rotor can produce and thus in precipitating the onset of the vortex ring state. The considerable and persistent coherence of the vortical structure of the wake when in the vortex ring state is revealed, despite these disturbances, as are the mechanisms that lead to both small-scale and large-scale wake breakdown

events. Simulations show the balance between the vortex pairing and short-wave instability modes to be different in the vortex ring state at high descent speed, where the wake lies above the rotor, compared to in the vortex ring state at low descent speed when the wake lies predominantly below the rotor. This yields subtle differences to the kinematics and structure of the wake in the two cases.

Ahlin, G. A. and Brown, R. E.

"INVESTIGATING THE PHYSICS OF ROTOR VORTEX RING STATE USING THE VORTICITY TRANSPORT MODEL"

31st European Rotorcraft Forum, Florence, Italy, September 2005

Some of the root causes of the behavior of a helicopter rotor in the vortex ring state are investigated using simulations, conducted using Brown's Vorticity Transport Model, of a two-bladed teetering rotor descending into the vortex ring state under conditions of constant collective pitch. Contrary to some previous reports, the onset of thrust settling on the rotor is found to occur at descent rates much lower than that at which the wake breaks down into the toroidal form that is characteristic of the fully developed vortex ring state. Thrust settling is caused by a loss of loading on the outboard parts of the rotor that is induced initially by compression of the wake below the rotor during low-speed descent. The behavior of the rotor in the vortex ring state appears to be practically insensitive to the twist of the blades, at least for rotors with moderate levels of blade twist. Although blade stall has little effect on the onset of the vortex ring state, it is quite likely that stall on the inner parts of the rotor, even for rotors with moderate levels of blade twist, may modify significantly the behavior of the system during the later stages of the development of the vortex ring state.

"CODE-TO-CODE COMPARISON OF CFD/CSD SIMULATION FOR A HELICOPTER ROTOR IN FORWARD FLIGHT"

AIAA Paper 2011-3819, June 2011, Honolulu, Hawaii.

Two unsteady Reynolds-averaged Navier-Stokes solvers are used to compute the rotor air loads on the UH-60A rotorcraft at several flight conditions across the flight envelope. One code, OVERFLOW, solves the flow equations using either structured grids, or a combination of structured and Cartesian grids. The other solver, FUN3D, uses unstructured grids. Both flow solvers are coupled to the same rotorcraft comprehensive code (CAMRAD II) in order to account for trim and aeroelastic deflections, and both utilize the same loose coupling scheme to transfer data between the flow solver and the comprehensive code. In the process of performing the code-to-code comparison, several small but important details are examined that may sometimes be overlooked when comparing results from rotorcraft simulations using different codes. Computed normal force, pitching moment, and chord force are compared between codes, and also with flight data.

Ahmad, J. U., Yamauchi, G. K. and Kao, D. L.

"COMPARISON OF COMPUTED AND MEASURED VORTEX EVOLUTION FOR A UH-60A ROTOR IN FORWARD FLIGHT"

AIAA Paper 2013-3160, June 2013, San Diego, CA.

A Computational Fluid Dynamics (CFD) simulation using the Navier-Stokes equations was performed to determine the evolutionary and dynamical characteristics of the vortex flow field for a highly flexible aeroelastic UH-60A rotor in forward flight. The experimental wake data were acquired using Particle Image Velocimetry (PIV) during a test of the full-scale UH-60A rotor in the National Full-Scale Aerodynamics Complex 40- by 80-Foot Wind Tunnel. The PIV measurements were made in a stationary cross-flow plane at 90 deg rotor azimuth. The CFD simulation was performed using the OVERFLOW CFD solver loosely coupled with the rotorcraft comprehensive code CAMRAD II. Characteristics of vortices captured in the PIV plane from different blades are compared with CFD calculations. The blade air loads were calculated using two different turbulence models. A limited spatial, temporal, and CFD/comprehensive-code coupling sensitivity analysis was performed in order to verify the unsteady helicopter simulations with a moving rotor grid system.

Ahmad, N. N. and Proctor, F. H.

"ESTIMATION OF EDDY DISSIPATION RATES FROM MESOSCALE MODEL SIMULATIONS"

AIAA Paper No. 2012-0429, January 2012, Nashville, Tennessee.

The Eddy Dissipation Rate is an important metric for representing the intensity of atmospheric turbulence and is used as an input parameter for predicting the decay of aircraft wake vortices. In this study, the forecasts of eddy dissipation rates obtained from the current state-of-the-art mesoscale model are evaluated for terminal area applications. The Weather Research and Forecast mesoscale model is used to simulate the planetary boundary layer at high horizontal and vertical mesh resolutions. The Bougeault-Lacarrere and the Mellor-Yamada-Janjic schemes implemented in the Weather Research and Forecast model are evaluated against data collected during the National Aeronautics and Space Administration's Memphis Wake Vortex Field Experiment. Comparisons with other observations are included as well.

Ahmad, N. N. and Pruis, M. J.

"EVALUATION OF FAST-TIME WAKE MODELS USING DENVER 2006 FIELD EXPERIMENT DATA"

AIAA Paper 2015-3318, June 2015, Dallas, TX.

The National Aeronautics and Space Administration conducted a series of wake vortex field experiments at Denver in 2003, 2005, and 2006. This paper describes the lidar wake vortex measurements and associated meteorological data collected during the 2006 deployment, and includes results of recent reprocessing of the lidar data using a new wake vortex algorithm and estimates of the atmospheric turbulence using a new algorithm to estimate eddy-dissipation rate from the lidar data.

The configuration and set-up of the 2006 field experiment allowed out-of-ground effect vortices to be tracked in lateral transport further than any previous campaign and thereby provides an opportunity to study long-lived wake vortices in moderate to low crosswinds. An evaluation of NASA's fast-time wake vortex transport and decay models using the dataset shows similar performance as previous studies using other field data.

Ahmad, N. N., Proctor, F. H. and Perry, R. B.

"NUMERICAL SIMULATION OF THE AIRCRAFT WAKE VORTEX FLOWFIELD"

AIAA Paper 2013-2552, June 2013, San Diego, CA.

The near-wake vortex flow field from a NACA0012 half-wing was simulated using a fully unstructured Navier-Stokes flow solver in three dimensions at a chord Reynolds number of 4.6 million and a Mach number of approximately 0.15. Several simulations were performed to examine the effects of boundary conditions, mesh resolution, and turbulence scheme on the formation of wingtip vortex and its downstream propagation. The standard Spalart-Allmaras turbulence model was compared with the Dacles-Mariani and Spalart-Shur corrections for rotation and curvature effects. The simulation results were evaluated using the data from an experiment performed at NASA Ames' 32in x 48in low speed wind tunnel.

Ahmad, N. N., Proctor, F. H., Duparcmeur, F. M. L. and Jacob, D.

"REVIEW OF IDEALIZED AIRCRAFT WAKE VORTEX MODELS"

AIAA Paper 2014-0927, January 2014, National Harbor, MD.

Properties of three aircraft wake vortex models, Lamb-Oseen, Burnham-Hallock, and Proctor are reviewed. These idealized models are often used to initialize the aircraft wake vortex pair in large eddy simulations and in wake encounter hazard models, as well as to define matched filters for processing lidar observations of aircraft wake vortices. Basic parameters for each vortex model, such as peak tangential velocity and circulation strength as a function of vortex core radius size, are examined. The models are also compared using different vortex characterizations, such as the vorticity magnitude. Results of Euler and large eddy simulations are presented. The application of vortex models in the post-processing of lidar observations is discussed.

Ahmad, N. N., Proctor, F. H., VanValkenburg, R. L., Pruis, M. J. and Duparcmeur, F. M. L.

"MESOSCALE SIMULATION DATA FOR INITIALIZING FAST-TIME WAKE TRANSPORT AND DECAY MODELS"

AIAA Paper 2013-0510, January 2013, Grapevine, TX.

The fast-time wake transport and decay models require vertical profiles of crosswinds, potential temperature, and the eddy dissipation rate as initial conditions. These inputs are normally obtained from various field sensors. In case of data-denied scenarios or operational use, these initial conditions

can be provided by mesoscale model simulations. In this study, the vertical profiles of potential temperature from a mesoscale model were used as initial conditions for the fast-time wake models. The mesoscale model simulations were compared against available observations and the wake model predictions were compared with the Lidar measurements from three wake vortex field experiments.

Ahmad, N. N., VanValkenberg, R. L., Bowles, R. L., Duparcmeur, F. M. L., Gloudemans, T., van Lochem, S. and Ras, E.

"EVALUATION OF FAST-TIME WAKE VORTEX MODELS USING WAKE ENCOUNTER FLIGHT TEST DATA"

AIAA Paper 2014-2466, June 2014, Atlanta, GA.

This paper describes a methodology for the integration and evaluation of fast-time wake models with flight data. The National Aeronautics and Space Administration conducted detailed flight tests in 1995 and 1997 under the Aircraft Vortex Spacing System Program to characterize wake vortex decay and wake encounter dynamics. In this study, data collected during Flight 705 were used to evaluate NASA's fast-time wake transport and decay models. Deterministic and Monte-Carlo simulations were conducted to define wake hazard bounds behind the wake generator. The methodology described in this paper can be used for further validation of fast-time wake models using en-route flight data, and for determining wake turbulence constraints in the design of air traffic management concepts.

Ahmad, N. N., VanValkenburg, R. L., Pruis, M. J. and Limon Duparcmeur, F. M.

"NASA AVOSS FAST-TIME MODELS FOR AIRCRAFT WAKE PREDICTION: USER'S GUIDE (APA3.8 AND TDP2.1)"

NASA-TM-2016-219353, January 2016, NASA Langley Research Center, Hampton, VA.

NASA's current distribution of fast-time wake vortex decay and transport models includes APA (Version 3.8) and TDP (Version 2.1). This User's Guide provides detailed information on the model inputs, file formats, and model outputs. A brief description of the Memphis 1995, Dallas/Fort Worth 1997, and the Denver 2003 wake vortex datasets is given along with the evaluation of models. A detailed bibliography is provided which includes publications on model development, wake field experiment descriptions, and applications of the fast-time wake vortex models.

Ahmad, N., Barmore, B. and Swieringa, K.

"WIND INFORMATION UPLINK TO AIRCRAFT PERFORMING INTERVAL MANAGEMENT OPERATIONS"

AIAA Paper 2015-3398, June 2015, Dallas, TX.

The accuracy of the wind information used to generate trajectories for aircraft performing Interval Management (IM) operations is critical to the success of an IM operation. There are two main forms of uncertainty in the wind information used by the Flight Deck Interval Management (FIM) equipment. The first is the accuracy of the forecast modeling done by the weather provider. The second is that only

a small subset of the forecast data can be uplinked in the aircraft for use by the FIM equipment, resulting in loss of additional information. This study focuses on what subset of forecast data, such as the number and location of the points where the wind is sampled should be made available to uplink to the aircraft.

Ahmad, N.N., Proctor, F.H., Limon Duparcmeur, F., and Jacob, D.

"Review of Idealized Aircraft Wake Vortex Models"

AIAA Paper No. 2014-0927, January 2014, National Harbor, Maryland

Properties of three aircraft wake vortex models, Lamb-Oseen, Burnham-Hallock, and Proctor are reviewed. These idealized models are often used to initialize the aircraft wake vortex pair in large eddy simulations and in wake encounter hazard models, as well as to define matched filters for processing lidar observations of aircraft wake vortices. Basic parameters for each vortex model, such as peak tangential velocity and circulation strength as a function of vortex core radius size, are examined. The models are also compared using different vortex characterizations, such as the vorticity magnitude. Results of Euler and large eddy simulations are presented. The application of vortex models in the post-processing of lidar observations is discussed.

Ahmad, N.N., VanValkenburg, R.L., and Pruis, M.J.

"NASA AVOSS FAST-TIME WAKE PREDICTION MODELS: USER'S GUIDE, NASA Technical Memorandum NASA/TM-2014-218152"

The National Aeronautics and Space Administration (NASA) is developing and testing fast-time wake transport and decay models to safely enhance the capacity of the National Airspace System (NAS). The fast-time wake models are empirical algorithms used for real-time predictions of wake transport and decay based on aircraft parameters and ambient weather conditions. The aircraft dependent parameters include the initial vortex descent velocity and the vortex pair separation distance. The atmospheric initial conditions include vertical profiles of temperature or potential temperature, eddy dissipation rate, and crosswind. The current distribution includes the latest versions of the APA (3.4) and the TDP (2.1) models. This User's Guide provides detailed information on the model inputs, file formats, and the model output. An example of a model run and a brief description of the Memphis 1995 Wake Vortex Dataset is also provided.

"AN ACCURATE UNSTRUCTURED SIMULATION OF WINGTIP VORTEX"

AIAA Paper 2009, Jan. 2009, Orlando, FL.

Sophisticated techniques for unstructured simulation of a wingtip vortex were developed and demonstrated on stationary NACA0012 airfoil. The techniques were also exemplified for flapping wing

propulsion. Flow parameters were computed at 40 percent chord length downstream to study near field behavior of the vortex. A good agreement of tangential velocity along the vortex core with experimental data was achieved. Surface pressure coefficient, vortex core pressure and vortex diffusion were also found matching with experimental data.

Ahmadi, A. R.

"AN EXPERIMENTAL INVESTIGATION OF BLADE-VORTEX INTERACTION AT NORMAL INCIDENCE"

J. Aircraft, Vol. 23, No. 1, January 1986, pp. 47-55

Blade-vortex interaction (BVI) near and away from the blade tip was experimentally investigated for normal incidence where the vortex is generally parallel to the rotor axis. The experiment was designed to be representative of the chopping of helicopter main rotor tip vortices by the tail rotor. Tip Mach number, radial BVI station, and freestream velocity were varied. Fluctuating blade pressures, far-field sound pressure level and directivity, velocity field of the vortex, and BVI angles were measured. BVI produced impulsive noise and impulsive pressures near the blade leading edge. The radiation pattern for BVI away from the tip was that of a dipole, with the direction of minimum radiation, previously found to be in the plane of the blade, rotated considerably in the direction of negative angle of attack. This is believed to be due to unsteady drag radiation caused by stronger BVIs in the present study. For BVI near the tip, the intensity of the interaction was reduced and the radiation pattern was more complex. Away from the tip, the peak amplitude of fluctuating pressure on the suction side of the blade (near the leading edge) was larger than that on the pressure side, as expected due to the effect of compressibility. This trend was reversed near the tip.

"AN EXPERIMENTAL STUDY ON THE INTERACTION BETWEEN FREE-STREAM TURBULENCE AND A WING-TIP VORTEX IN THE NEAR-FIELD"

Aerospace Science and Technology, Vol. 43, 2015, pp. 395-405.

The effect of external free-stream turbulence was investigated experimentally in the near-field of a wing-tip vortex. A free-stream turbulent flow with 4.6 percent turbulence intensity was created with the aid of a grid turbulence generator, while the turbulence intensity in the base flow case with no grid was approximately 0.5 percent. The experiments were conducted in a closed-circuit wind tunnel while a dynamic force transducer was used to measure the aerodynamic forces on a NACA 0015 wing section in the range of 0 to 25 degrees angle of attack. The wing section with a semi-span aspect ratio of 5.4 spanned approximately half height of the wind tunnel section and fixed vertically to the load cell at the base. Hot-wire anemometry was used to measure the velocity field downstream of the wing at crossflow planes of $x/c = 0.1, 0.42, 0.77$ and 1.03 while the Reynolds number and angle of attack were set at 160,000 and 10 degrees, respectively. The results of aerodynamic force measurement for the no-grid case agree fairly with other experimental and analytical works. In addition, circumferential velocity and circulation profiles inside the vortex flow-field fit well with analytical expressions proposed by

others. The crossflow velocity contours show that the free-stream turbulence tends to increase the vortex diffusion at $x/c = 0.77$ and 1.03 . The inboard and upward movement of the tip vortex downstream of the wing was not significantly affected by the introduction of free-stream turbulence, while external free-stream turbulence increases the turbulence intensity peak. External turbulence also increased the circumferential velocity and vortex circulation with respect to the streamwise distance at radial locations far from the vortex center.

Airbus Industries

"STUDY FOCUSES ON WAKE VORTEX PRODUCED BY DIFFERENT AIRBUS MODELS"

ICAO Journal, Vol. 53, No. 4, May 1998, p. 26

An Airbus Industry sponsored research project which used a ground-based laser to measure the wake vortex left behind each of the manufacturer's aircraft is reviewed. The use of the information gathered during the study in designing future aircraft such as the Airbus A3XX is addressed.

"QUANTIFYING WIND TURBINE WAKE CHARACTERISTICS FROM SCANNING REMOTE SENSOR DATA"

Journal of Atmospheric and Oceanic Technology, Vol. 31, April 2014, pp. 765-787.

Because of the dense arrays at most wind farms, the region of disturbed flow downstream of an individual turbine leads to reduced power production and increased structural loading for its leeward counterparts. Currently, wind farm wake modeling, and hence turbine layout optimization, suffers from an unacceptable degree of uncertainty, largely because of a lack of adequate experimental data for model validation. Accordingly, nearly 100 h of wake measurements were collected with long-range Doppler lidar at the National Wind Technology Center at the National Renewable Energy Laboratory in the Turbine Wake and Inflow Characterization Study (TWICS). This study presents quantitative procedures for determining critical parameters from this extensive dataset - such as the velocity deficit, the size of the wake boundary, and the location of the wake centerline - and categorizes the results by ambient wind speed, turbulence, and atmospheric stability. Despite specific reference to lidar, the methodology is general and could be applied to extract wake characteristics from other remote sensor datasets, as well as computational simulation output. The observations indicate an initial velocity deficit of 50-60 percent immediately behind the turbine, which gradually declines to 15-25 percent at a downwind distance x of 6.5 rotor diameters (D). The wake expands with downstream distance, albeit less so in the vertical direction due to the presence of the ground: initially the same size as the rotor, the extent of the wake grows to $2.7D$ ($1.2D$) in the horizontal (vertical) at $x = 6.5D$. Moreover, the vertical location of the wake center shifts upward with downstream distance because of the tilt of the rotor.

"FIBER LASER COHERENT LIDAR FOR WAKE-VORTEX HAZARD DETECTION"

16th Coherent Laser Radar Conference, Long Beach, CA, June 2011.

We demonstrated a 1.55-micron fiber-optic coherent lidar system with greater than 500 microjoules energy at 25 kHz and about 1.5 MHz Doppler linewidth. We believe this lidar has the potential for aviation applications such as airborne wake-vortex detection.

"PULSED COHERENT FIBER LIDAR TRANSCEIVER FOR AIRCRAFT IN-FLIGHT TURBULENCE AND WAKE-VORTEX HAZARD DETECTION"

Proceedings SPIE, Vol. 8037, Laser Radar Technology and Applications XVI, June 2011, pp. 80370R-1 - 80370R-10.

We report on the development of a fiber-optic pulsed coherent lidar transceiver for wind-velocity and aircraft wake-vortex hazard detection. The all-fiber 1.5-micron transmitter provides up to 560 microjoule energy at 25 kHz with 800 ns pulse width (pump limited). Performance simulations indicate wake-vortex hazard signature detection up to about 2.5 km range with a receiver sensitivity of about 2 fW (SNR=6), suited for an aircraft landing scenario. Furthermore, the transceiver is implemented using a high-speed FPGA based control and digital-signal-processing, enabling its use as a flexible pulse-format multi-function in-flight lidar sensor. We present the latest laboratory results and preliminary testing of this pulsed coherent lidar transceiver, along with the lidar performance simulation of wake-vortex eddy models.

"EXPERIMENTAL STUDY OF SELF-OSCILLATIONS DEVELOPING IN A SWIRLING-JET FLOW"

Fluid Dynamics, Vol. 39, No. 3, 2004, pp. 406-413

The results of an experimental investigation of the periodic pressure oscillations developing in a submerged swirling jet flowing out into an open space are presented. The main governing parameters of the process are determined and a general dependence relating the oscillation frequency with the governing parameters over a wide range of parameter variation is established experimentally. Based on this dependence, an empirical formula for calculating the oscillation frequency is proposed.

Akinjanju, T.

"GROUND EVALUATION OF SEEDING AN IN-FLIGHT WINGTIP VORTEX USING INFRARED IMAGING FLOW VISUALIZATION TECHNIQUE"

NASA/American Soc. Eng. Education Summer Faculty Fellowship Program, September 1989, Old Dominion Univ., Norfolk, VA, pp. 38-40

An experimental simulation of an in-flight wingtip vortical flow visualization technique uses infrared imaging to observe strong and concentrated vortices. This experiment is phase 1 of a two-phase infrared evaluation program. The system includes a vortex generator (model 320 Vortec Vortex Tube) which generates the required vortex. The mouth of the unit is mounted close to the free end of a half-inch diameter, sixteen and a half foot long stainless-steel tubing (sized after tubing currently installed in the wings of an experimental Beechcraft Sundowner 180 aircraft). Dichloro difluoromethane (Freon-12) is entrained into the generated vortex. A breakdown of the vortices is indicated by the rapid diffusion and the resulting pattern is tracked using the infrared imager and video systems. Flow rates (volume and mass) are estimated at the laboratory and proposed flight conditions. The nominal flight altitude is expected to be 2500 feet.

Akinyanju, T.

"GROUND EVALUATION OF SEEDING AN IN-FLIGHT WINGTIP VORTEX USING INFRARED IMAGING FLOW VISUALIZATION TECHNIQUE"

NASA CR-181894, September 1989, Norfolk State University, Norfolk, VA.

An experimental simulation of an in-flight wingtip vortical flow visualization technique uses infrared imaging to observe strong and concentrated vortices. This experiment is phase I of a two-phase infrared evaluation program. The system includes a vortex generator (model 320 Vortec Vortex Tube) which generates the required vortex. The mouth of the unit is mounted close to the free end of a half-inch diameter, sixteen and a half foot long stainless-steel tubing (sized after tubing currently installed in the wings of an experimental Beechcraft Sundowner 180 aircraft). Dichloro difluoromethane (Freon-12) is entrained into the generated vortex. "RECONNECTIONS OF VORTEX FILAMENTS"

Fluid Dynamics Research, Vol. 3, 1988, pp. 239-246.

The process of break-down and reconnection of vortex filaments is considered by the method of three-dimensional vortex singularities (vortons) in various situations, including oblique interaction of a vortex ring with a boundary in shear flow, shedding of a vortex ring from a horseshoe vortex, instability of elliptic vortex ring, Crow instability of two perturbed antiparallel vortex filaments, merging and subsequent splitting of vortex rings. Special attention is paid to the global integrals (vorticity, momentum, angular momentum) and to the inviscid dissipation of energy. The visualization of the effective vortex core, created by the interference of the vorticity fields of vortons, is presented. The

comparisons with other methods of simulation of three-dimensional vortex interactions and with the observations have been made.

"TRAILING VORTEX DETECTION AND QUANTITATIVE EVALUATION OF VORTEX CHARACTERISTICS BY PIV TECHNIQUE"

20th International Congress on Instrumentation in Aerospace Simulation Facilities, August 2003, Gottingen, Germany

This paper summarizes the activities performed to investigate the formation, motion and persistence of trailing vortices released by large commercial aircraft. Two different experimental test campaigns were carried out in two different large towing tank facilities performing PIV measurements. The lesson learned by the first investigation and by the experience of the scientific community, the solution adopted to characterize the wake vortex by the initial formation phase down to wake collapsing in the far-wake region are illustrated. Together with the adopted technical solution, with the selected experimental facility and with the improved measurement system, a particular care is taken: on the data analysis description, on the importance of advanced PIV algorithms and on the selected post-processing methods for evaluating the main magnitudes characterizing the vortex structures.

"COMPARISON OF LIDARS, GERMAN TEST STATION FOR REMOTE WIND SENSING DEVICES"

9th German Wind Energy Conference, DEWEK, November 2008, Bremen, Germany.

Deutsche WindGuard is involved in the test of lidar based wind measurement devices since 2005. At current status, there are two lidar systems commercially available, the British ZephIR and the French Windcube system. The Windcube has reached an excellent accuracy, reproducibility, and availability in flat terrain, even at 135m measurement height above ground, while the ZephIR has problems to reach high accuracy in large measurement heights. The German Test Station for Remote Wind Sensing Devices has been initiated to provide the wind industry the possibility to have tested lidars or sodars prior to the application in the field, like cup anemometer calibrations. Furthermore, the test station is intended to be used for the type specific classification of remote wind sensing devices.

Aleksander, B.

"THREE-DIMENSIONAL ROTOR FLOW CALCULATIONS"

FME Transactions, Vol. 33, No.1, 2005, pp. 33-39

This paper presents the numerical model developed for rotor blade aerodynamics loads calculation. The model is unsteady and fully three-dimensional. Helicopter blade is assumed to be rigid, and its motion during rotation is modeled in the manner that rotor presents a model of rotor of helicopter

Aerospatiale SA 341 Gazelle (the blade is attached to the hub by flap, pitch and pseudo lead-lag hinges). Flow field around the blade is observed in succession of several azimuth locations. Flow field around helicopter rotor is modeled as fully three-dimensional, unsteady and potential. Blade aerodynamics is modeled using a lifting surface model. Rotor wake is generated from the straight elements of constant vorticity, released from the trailing edge, at fixed azimuth angles. These vortices represent both trailed and shed wake components, and are allowed to freely convect along local velocity vectors. Wake is modeled as free one, and its shape at certain moment can be calculated from simple kinematics laws applied on collocation points of the wake. Wake distortion is calculated only in the rotor near-field, i.e. in finite number of rotor revolutions. Vortex elements are modeled with vortex core. The radius of the vortex core is assumed independent of time, and it depends on circulation gradient at the point of vortex element released from the blade.

"METHOD AND ON-BOARD SYSTEM FOR ENSURING THE MINIMUM LONGITUDINAL SEPARATION DISTANCE UNDER WAKE TURBULENT CONDITIONS"

US Patent 9,466,220 B2, October 2016.

Standardized distance minima for longitudinal separation is ensured during flight of a second aircraft behind a first aircraft on take-off or landing of the aircraft on one runway or on two parallel runways located near to each other, or during flight one behind the other at near altitude levels in condition where there is the risk of turbulence from the vortex wake of the first aircraft possibly being present along the direction of movement of the second aircraft. Continuous monitoring of the level of wake vortex flight safety of the second aircraft is carried out in a buffer zone which surrounds the aircraft and is selected on the basis of the direction of the aircraft outside the standardized distance minimum, taking into account pilot reaction time and the time for the system for controlling the second aircraft to respond to a command to change speed.

"EXPERIMENTAL INVESTIGATION OF VORTEX FLOWS NEAR LOW-ASPECT-RATIO WINGS AND CIRCULAR CONES AT MACH TWO"

Akademiia Nauk. SSR, Izvestiia, Mekhanika Zhidkosti i Gaza, September-October 1967, pp. 113-121

Application of a flow-visualization method to the investigation of the flow pattern resulting from the interaction of wing-tip vortices with the boundary layer. The method employed makes use of a stable luminosity that appears (because of a predischage) when a high voltage is applied to electrodes situated in an airflow. Photographs (on which the shock waves from the electrodes and flow separation region are clearly seen against the interelectrode luminosity) showing the trajectories of the vortex streets are obtained for low-aspect-ratio wings and circular cones situated at various angles of attack in a flow with $M=2$ and $Re=0.9 \times 10^6$.

Alford, Jr., W. J.

"THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE SUBSONIC-FLOW FIELDS BENEATH SWEEPED AND UNSWEEPED WINGS WITH TABLES OF VORTEX-INDUCED VELOCITIES"

NACA TR-1327, August 1956, Langley Aeronautical Laboratory, Langley Field, VA

The flow-field characteristics beneath swept and unswept wings as determined by potential-flow theory are compared with the experimentally determined flow fields beneath swept and unswept wing-fuselage combinations. The potential-flow theory utilized considered both spanwise and chordwise distributions of vorticity as well as the wing-thickness effects. The perturbation velocities induced by a unit horseshoe vortex are included in tabular form. The results indicated that significant chordwise flow gradients existed beneath both swept and unswept wings at zero lift and throughout the lift range. The theoretical predictions of the flow-field characteristics were qualitatively correct in all cases considered, although there were indications that the magnitudes of the downwash angles tended to be overpredicted as the tip of the swept wing was approached and that the sidewash angles ahead of the unswept wing were underpredicted. The calculated effects of compressibility indicated that significant increases in the chordwise variation of flow angles and dynamic-pressure ratios should be expected in going from low to high subsonic speeds.

"SELF-SIMILAR BEHAVIOUR OF A ROTOR WAKE VORTEX CORE"

Journal of Fluid Mechanics, Vol. 740, 2014, pp. R1-1 to R1-12.

We report a self-similar behavior of solutions (obtained numerically) of the Navier-Stokes equations behind a single-blade rotor. That is, the helical vortex core in the wake of a rotating blade is self-similar as a function of its age. Profiles of vorticity and azimuthal velocity in the vortex core are characterized, their similarity variables are identified and scaling laws of these variables are given. Solutions of incompressible three-dimensional Navier-Stokes equations for Reynolds numbers up to $Re = 2000$ are considered.

Alim, A.

"A PHYSICAL COMPREHENSIVE DEFINITION OF A VORTEX BASED ON THE LAMB VECTOR"

Algerian Journal of Applied Fluid Mechanics, Vol. 1, 2007, pp. 1-5.

Although the concept of a vortex is an essential tool in the comprehension of fluid dynamics, it is still very difficult to find a universal definition for a vortex. In the present study, we elected to propose a simple physical comprehensive definition for a vortex. A vortex is defined using the Lamb vector as a low velocity noisy structure. This new definition has been applied to a theoretical Oseen vortex and to experimental flows obtained from particle image velocimetry (PIV) images. The vortex center was defined as the location of the highest noise source and the vortex core was delimited by the two extrema of the spatial derivative of the divergence of the Lamb vector. A very good correlation was

found between the new method proposed and the standard eigenvalue method. The extension of the method to complex flows was possible by introducing a threshold function. It was, therefore, possible to extract the maximal number of vortex structures from the velocity field.

Alix, D. and Simich, P.

"ACOUSTIC CHARACTERIZATION OF WAKE VORTICES IN-GROUND-EFFECT"

Report, Aero 16.622 Spring 2004, May 2004, MIT, Cambridge, MA.

Recent theoretical work suggests that aircraft wake vortices produce a low frequency acoustic signal when they descend in ground effect. To date, only high frequency signals have been observed, and no studies have been done on acoustic behavior in ground effect. The ability to detect vortices using acoustic methods could lead to reliable vortex sensors for high traffic airports. In this experiment, an array of four directional microphones was used to record acoustic signals from vortices IGE. The data was analyzed with Fast Fourier Transform techniques that revealed the presence of acoustic signals in 6 of the 26 aircraft recorded. Although low frequency background noise made signals hard to detect, the aircraft recorded did show acoustic signals above 500 Hz. One aircraft showed a signal below 200 Hz; however, results for these low frequencies are still inconclusive due to background noise.

Alix, D. C., Simich, P. D., Wassaf, H. and Wang, F. Y.

"ACOUSTIC CHARACTERIZATION OF WAKE VORTICES IN GROUND EFFECT"

AIAA Paper No. 2005-0260, Reno, NV, January 2005

The experience and findings of an exploratory effort to characterize the sound emitted by aircraft wake vortices near the ground are presented. A line array of four directional microphones was deployed and recorded the wakes of several commercial aircraft in the approach phase with particular attention being paid to the characterization of background noise. It is found that vortices near the ground emit broadband sound with frequency contents ranging from below 100 Hz to near 2000 Hz and possibly beyond. However, addressing the degree of consistency of the vortex sound would require deployment of a larger array. The mechanism of vortex sound generation and suggestions on future studies are discussed.

Alksne, A. Y.

"DETERMINATION OF VORTEX PATHS BY SERIES EXPANSION TECHNIQUE WITH APPLICATION TO CRUCIFORM WINGS"

NACA TR-1311, 1957, Ames Aeronautical Laboratory, Moffett Field, CA

A series method of determining two-dimensional vortex paths is considered and applied to the computation of vortex positions behind a slender equal-span cruciform wing at any angle of bank as a function of the distance behind the trailing edge. Calculated paths are shown for four bank angles. For

a bank angle of 45 deg. comparison is made with the results of a closed expression given in NACA TN 2605. For other bank angles water-tank experiments provide qualitative comparison. Satisfactory agreement is found for a sufficient distance downstream to include most practical missile-tail positions. The interference forces on an equal-span interdigitated cruciform tail behind a slender equal-span cruciform wing are calculated for four angles of bank from the vortex positions found by use of the series.

"HIGH ANGLE OF ATTACK HELICOPTER BLADE-VORTEX INTERACTION; NUMERICAL STUDIES USING LES"

AIAA Paper No. 2011-3208, June 2011, Honolulu, Hawaii.

The influence of angle of attack on the helicopter blade-vortex mechanism of interaction is investigated using large eddy simulation (LES). The LES technique provides a promising tool for obtaining the unsteady wall-pressure fields, aerodynamic coefficients, and the acoustic source functions. A large eddy simulation is carried out for a two-dimensional Blade-Vortex Interaction problem, for a chord-based Reynolds number of 1300000. Computations are carried out to investigate the influence of angle of attack (0, 5 and 10 degrees) on the aerodynamic coefficients and acoustic field.

Allan, S. S. and Dacey, T. J.

"AN ANALYSIS OF THE IMPACTS OF WAKE VORTEX RESTRICTIONS AT LGA"

Report ATC-305, Sept. 2002, MIT Lincoln Laboratory, Lexington, MA.

Wake vortex restrictions at New York's La Guardia airport cause a significant reduction in capacity when aircraft land on runway 22 and depart on runway 31. This report presents an analysis of the annual delay cost at LGA associated with the wake vortex restrictions. We find that the delay due to these restrictions exceeds 4000 hours annually, and that these restrictions cause a significant workload increase to controllers at both La Guardia and the New York TRACON. If traffic levels were to increase 10 percent from their February 2001 levels, the corresponding increase in delay due to the wake vortex restrictions would rise from 30 hours a day to over 400 hours a day in this runway configuration. It is also found that for a meaningful increase in passenger capacity in this runway configuration to be achieved as demand grows, restrictions must be reduced from their current levels. If the percentage of heavy/757s doubled at LGA, there would be no increase in passenger capacity while daily delays in this runway configuration due to current wake vortex separation standards would increase by 250 hours.

"INVESTIGATION ON AN ACTIVE WINGLET INFLUENCING THE WAKE OF A LARGE TRANSPORT AIRCRAFT"

ICAS 2006, Paper 2006-3.8.2, Sept. 2006, Hamburg, Germany.

The flow field behind a Very Large Transport Aircraft is investigated at several cross-flow planes. The amplification of instability mechanisms using an active rudder on a large winglet will be discussed. Results will be shown for the baseline and cases of passive and active rudder deflections using hot-wire anemometry.

Allen, A. and Breitsamter, C.

"LANDING GEAR INFLUENCE ON THE WAKE VORTEX OF A LARGE TRANSPORT AIRCRAFT"

Journal of Aircraft, Vol. 45, No. 4, July-August 2008, pp. 1367-1372.

An experimental investigation on the wake vortex formation and evolution of a four-engine large transport aircraft model in the near field and extended near field has been conducted by means of hot-wire anemometry in a wind tunnel. The half-model used has a scale of 1:19.25 and the tests focus on the high-lift case of a typical landing configuration at a Reynolds number of 520,000 based on the wing mean aerodynamic chord. The flow field is investigated up to 4.7 spans downstream of the model, which is investigated with and without landing gear. Based on the measured time-dependent velocity components, the wake flow field is analyzed by distributions of vorticity, turbulence intensities, and spectral densities. The landing gear consists of a stay and four wheels, which create a bluff-body wake that interferes with the shear layer caused by the wing and wing junction. The landing gear creates a low-energy vortex system and a highly turbulent wake. Due to the landing gear, the main vortex centers are located slightly further outboard and the roll-up process is retarded, especially the inboard movement of the horizontal tail plane vortex. The velocity spectra of the landing gear wake show broadband characteristics with some moderate narrowband energy concentrations in the close near field, which do not enhance inherent wake instabilities. Although the turbulence caused by the landing gear is still present in the extended near field, only a small influence on the overall vortex system of the entire aircraft can be found. The landing gear influence is therefore negligible in the context of reducing minimum aircraft separation distances.

Allen, A. and Breitsamter, C.

"TRANSPORT AIRCRAFT WAKE INFLUENCED BY A LARGE WINGLET AND WINGLET FLAPS"

J. Aircraft, Vol. 45, No. 2, March-April 2008, pp. 686-699

Detailed flow fields of a wind-tunnel investigation are discussed presenting the wake vortex development and evolution in the near field and extended near field behind a four-engine large transport aircraft model fitted with a large winglet. The tests use a half-model of 1:32 scale focusing on the high-lift case of a typical approach configuration at a Reynolds number of 500,000 based on the wing mean aerodynamic chord and at an angle of attack of 7 deg. Flow-fields are carefully inspected by advanced hot-wire anemometry at seven crossflow planes up to 5.6 spans downstream of the model. Based on the measured time-dependent velocity components, the wake flow-field is analyzed by distributions of mean velocity and vorticity, turbulence intensities, and spectral densities. The near-field wing vortex sheet is dominated by seven main vortical structures, namely the winglet vortex, the

wing tip vortex, the outboard flap vortex, the outboard and inboard nacelle vortices, and the vortices shed at the wing-body junction and the horizontal tail plane. In the extended near field, these vortices roll up and merge to form the remaining rolled-up vortex. The deflection of winglet flaps produces additional vortices influencing the wing tip near field and enhancing the overall merging process. Especially for the cases with asymmetrical flap deflection, the remaining rolled-up vortex shows a significant narrowband concentration of turbulent kinetic energy which may result in an amplification of inherent far-field instabilities.

Allen, A. and Breitsamter, C.

"EXPERIMENTAL INVESTIGATION OF COUNTER-ROTATING FOUR VORTEX AIRCRAFT WAKE"

Aerospace Science and Technology, Vol. 13, 2009, pp. 114-129. [Also, 1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-181, September 2007, pp. 3413-3421.

An experimental investigation on the wake vortex formation and evolution of a four-vortex system of a generic model in the near field and extended near field as well as the behavior and decay in the far field region has been conducted by means of hot-wire anemometry in a wind tunnel. The results were obtained during an experimental campaign as part of the EC project FAR-Wake. The model used consists of a wing-tail plane configuration with the wing producing positive lift and the tail plane negative lift. The circulation ratio of tail to wing is -0.3 and the span ratio is 0.3. Thus, a four-vortex system with counter-rotating neighboring vortices exists. The model set-up was chosen on the condition to create a most promising four vortex system with respect to accelerate wake vortex decay by optimal perturbations enhancing inherent instability mechanisms. The flow field has been investigated up to a distance of 48 span dimensions downstream of the model and the results obtained at 1, 12, 24 and 48 span distances are shown as non-dimensional axial vorticity and vertical turbulence intensities. A significant decay in peak vorticity is observable during the downward motion of the vortices. Spectral analysis of the unsteady velocity data reveals a peak in the power spectral density distributions indicating the presence of a dominating instability. Cross spectral density distributions have also been extracted from the data gathered from two hot-wire probes, which highlight the co-operative instability leading to a rapid wake vortex decay within 30 span dimensions downstream.

Allen, C. B.

"PARALLEL SIMULATION OF LIFTING ROTOR WAKES IN FORWARD FLIGHT"

International Journal of Numerical Analysis and Modeling, Vol. 4, No. 1, 2007, pp. 1-15.

A finite-volume implicit, unsteady, multiblock, multigrid, upwind solver, and structured multiblock grid generator for rotors are presented, and applied to lifting rotors in forward flight. These flows are particularly expensive to compute as the accurate capture of the detailed vortical wake requires fine meshes away from the blades and, hence, a parallel version of the code has been developed allowing the use of very fine meshes. Parallel performance of the code is presented, and grid dependence of the computed blade loads and wake analyzed, by considering wake capturing, total blade load and

sectional load variation around the azimuth. It is demonstrated that the vortical wake capture is severely influenced by grid density, and even with 32 million points grid convergence is not approached. It is also shown that if blade loads only are of interest the vorticity dissipation is not a severe problem, and coarser meshes can be used. However, if more detail is required, for example blade-vortex interaction or aero-acoustic analysis, it would appear very difficult to capture the wake to any reasonable accuracy.

Allen, J. J. and Naitoh, T.

"EXPERIMENTAL STUDY OF THE PRODUCTION OF VORTEX RINGS USING A VARIABLE DIAMETER ORIFICE"

Physics of Fluids, Vol. 17, No. 6, June 2005, 061701-1-061701-4

A method for producing a vortex ring with an apparatus that utilizes a time varying aperture that closes during ring production is shown to have the capability for the production of rings of low nondimensional energy similar to a Hill's spherical vortex. This represents a difference of more than 50%, in terms of the nondimensional energy, of those which have been produced with fixed diameter generators. Experiments show that modulation of the rate at which the vortex ring generator produces kinetic energy, circulation, and impulse is the critical factor in determining what type of ring is formed.

Allen, K.

"AIRCRAFT WING TIP VORTEX TESTING METHODOLOGY, SIMULATION AND ANALYSIS TECHNIQUES"

AIAA Paper 2017-3888, June 2017, Denver, CO.

User requirements prompted new field testing procedures to collect and examine the behavior of wing tip vortices that are generated by large aircraft, such as the United States Air Force C-17 Globemaster III. This study describes the unique test methodology, rationale, and data analysis of wing tip vortices recorded in a series of flight tests that occurred at U.S. Army Yuma Proving Ground, AZ in April 2014. The study provides lessons learned, conclusions, and recommendations for future studies. Empirical wing tip vortex data was then used to perform an initial validation of a Vortex Modeling Tool to determine its accuracy in predicting actual wing tip vortex behavior. Although this study was performed in a personnel parachute airdrop environment, data and test techniques discussed have potential benefits in commercial passenger and cargo aircraft flight planning, which are also significantly affected by wing tip vortices.

"WAKE VORTEX ENCOUNTERS IN A FLIGHT SIMULATOR"

Aeronautical Journal, Vol. 114, No. 1159, September 2010, pp. 579-587.

A real-time model of a wake vortex has been developed for an engineering flight simulator, which enables studies to be undertaken into the effects of wake vortex encounters with civil transport aircraft. A brief summary of the methods used to create a vortex model and integrate it with a real-time flight simulator is presented. Tools have been developed to determine the structural loads on an aircraft during a simulated wake vortex encounter and to visualize the airframe loads. Four wake vortex encounters were flown with different pilot recovery strategies and automatic flight controls. It is clear from analysis of these results that it is difficult for a pilot to appreciate the margin of tail loading during an encounter and a prototype training display is outlined to enable pilots to fully understand the effects of rudder inputs in recovery from these events.

"SAN FRANCISCO INTERNATIONAL AIRPORT SIMULTANEOUS OFFSET INSTRUMENT APPROACH CEILING REDUCTION TO 1600 FEET"

Report DOT-FAA-AFS-410-03, October 2011, FAA Flight Technologies and Procedures Division, Washington, DC.

As part of the Safety Management System process this Operational Safety Assessment was completed in conjunction with Technical Report DOT FAA-AFS-440-76; Evaluation to determine if pilots can develop a wake turbulence avoidance strategy while conducting Simultaneous Offset Instrument Approaches (SOIA) at San Francisco International Airport (SFO) with a ceiling of 1,600 feet. The conclusion of this assessment is that pilots are able to develop a wake turbulence avoidance strategy with a ceiling of 1,600 feet and no new mitigations are required.

"AUTOMATIC IDENTIFICATION OF WAKE VORTEX TRAVERSE BY TRANSPORT AIRCRAFT USING FUZZY LOGIC"

4th International Conference on Soft Computing and Machine Intelligence, November 2017, Port Louis, Republic of Mauritius, pp. 133-139.

Aircraft trailing vortices result sometimes in significant disturbance to following aircraft. Separation standards between leading and following aircraft are sometimes over estimated, hence reducing airport capacity. An important contribution to the formation and revision of vortex separations lies in the recognition of wake vortex traverse by pilot reports together with a manual analysis of the flight data routinely recorded by flight data recorders (FDRs). This process has many disadvantages and, therefore, it is desirable to have an automatic identification technique, which can save time, and is both accurate and simple to implement. In this paper, fuzzy logic (FL) is used to model and identify vortex encounters. FL tolerates data imprecision and cope well with complexities in modeling the vortex encounters. Fuzzy linguistic variables are used to model FDR data. Fuzzy rules are derived from a collection of 54 pilot reports of vortex encounters and 210 flight records from FDRs. FL identification models are analyzed and the fuzzy rule base is optimized. An average success rate of identification of

83.7 percent is obtained. This automatic identification system should enable the aviation authorities to review regularly the appropriateness of wake vortex separation criteria to enhance safety and increase airport capacities.

"NEURO-FUZZY TECHNIQUES FOR THE IDENTIFICATION OF AIRCRAFT WAKE VORTEX ENCOUNTERS"

Advances in Science, Engineering and Technology Conference (ASET 2018), February 2018, Dubai, UAE.

The automatic identification of aircraft vortex encounters by soft-computing techniques, such as fuzzy systems, gives better identification results than when performed by subjective manual approaches. However, the construction of the fuzzy rules heavily depends on a thorough understanding of vortex aerodynamics and aircraft response to a vortex encounter. Moreover, it requires a detailed analysis of flight data records and pilot reports, which all help in the proper selection of the critical fuzzy input variables. However, the automatic identification of vortex encounters by fuzzy logic can be greatly influenced by the shape and distributions of membership functions. Artificial neural networks integrated with fuzzy systems have been used as a solution in the automatic tuning of the membership functions of fuzzy linguistic variables. In this paper, a hybrid Adaptive Neuro-Fuzzy Inference System (ANFIS) is selected to automatically tune the parameters of the fuzzy membership functions. Various neuro-fuzzy models having different sets of parameters and factors are investigated. Simulation results with an average identification accuracy of 84.2 percent is obtained. The neuro-fuzzy hybrid model can also be used in the identification of other aircraft flight events such as wind shear and hard landing.

Al-Mahadin, A. and Dalkilic, S.

"INVESTIGATION OF FACTORS AFFECTING AIRCRAFT VORTEX ENCOUNTERS"

Advances in Science, Engineering and Technology Conference (ASET 2018), February 2018, Dubai, UAE.

Large aircraft wake vortices may sometimes cause significant disturbance to following aircraft. Separation standards between landing and following aircraft are proven to be overestimated in some cases, and therefore reducing airport capacity. Other times they are underestimated and hence causing aircraft incidences and accidents. An important contribution to the formation and revision of vortex separations depends on the recognition of vortex traverse by analysis of pilot reports together with a manual examination of data from flight data recorders (FDRs). However, the current process of flight events analysis is sometimes subjective and time consuming. Furthermore, there is sometimes disagreement between pilot reporting and analysis of flight data from FDR. Hence the current process requires improvement. This paper examines 54 pilot reports of transport aircraft vortex encounters to establish factors affecting the encounters. The research findings help the aviation authorities to impose new requirements such as training for pilots and FDR analysts on vortex identification. Findings can also contribute to enhance safety, improve operation efficiency and help revision of the appropriateness of regulations of vortex separations. This paper also indicates further investigation areas that are essential for aircraft wake vortex analysis, identification and severity mitigation.

"A FAST ADAPTIVE VORTEX METHOD IN THREE DIMENSIONS"

Journal of Computational Physics, Vol. 113, 1994, pp. 177-200

The method of local corrections (MLC) developed by Anderson for two spatial dimensions is a particle-particle particle-mesh method, in which the calculation of the velocity field induced by a collection of vortices is split into two parts: (i) a finite difference velocity field calculation using a fast Poisson solver, the results of which are used to represent the velocity field induced by vortices far from the evaluation point; and (ii) an N-body calculation to compute the velocity field at a vortex induced by nearby vortices. We present a fast vortex method for incompressible flow in three dimensions, based on the extension of the MLC algorithm from two to three spatial dimensions and the use of adaptive mesh refinement in the finite difference calculation of the MLC. Calculations with a vortex ring in three dimensions show that the break-even point between the MLC with AMR and the direct method is a N about 3000 on a Cray Y-MP; for N about 64,000 MLC with AMR can be 12 times faster than the direct method. Results from calculations of two colliding inviscid vortex rings demonstrate the increased resolution which can be obtained using fast methods.

Alonso, C. M.

"UAS SENSITIVITY TO WAKE TURBULENCE FOR ESTABLISHING SAFETY DISTANCE REQUIREMENTS"

MS Thesis, September 2014, Universitat Politècnica de Catalunya, Barcelona, Spain.

Nowadays, the aviation industry is one of the most important sectors in our society with a great variety of aircraft. Its development and evolution have brought the appearance of new aircraft and, consequently, an increase in the number of aircraft operations in both air and on the ground. Increasing the number of activities in both Air Traffic Management (ATM) and Air Traffic Flow Management (ATFM) has also led to a greater use of the airspace capacity. What it means is that the capacity has been optimized to perform more aircraft operations per minute without considering the aerial rules and regulations already established. One of the consequences of the optimization of the airspace capacity was the closer approximation between aircraft, or in other words, a reduction of the distance between the leading and the following aircraft. The approximation, which was carried out without considering any law, led to some dangerous situations between aircraft due to the appearance of an effect on the following aircraft, called turbulences or shaking effects, which had never experienced before and which led them to be crashed. Thus, scientists established an uncertainty area, called Wake Turbulence, which should be avoided by all aircraft flying behind another aircraft in order to prevent such dangerous situations. Consequently, the aim of this thesis is to understand what a wake turbulence is and to establish safety distances requirements between aircraft. On the one side, what it is going to be studied is what a wake turbulence is, including its properties and characteristics, for a better understanding of what it is. On the other side, a type of modeling of the wake turbulence done previously is going to be studied to know how much the wake turbulence descends and moves and, once it is done, a new modeling of the wake turbulence is going to be performed basing on

previous studies. In addition to it, another simulation is going to be performed to see some collision scenarios between aircraft where the wake turbulence is involved. And, finally, once it is done, the minimal safety distance that UAS will have to maintain respect to other aircraft may be estimated.

Aloysius, S. S. and Wrobel, L. C.

"ON THE USE OF NEAR FIELD COMPUTATIONAL FLUID DYNAMICS FOR IMPROVING AIRPORT RELATED DISPERSION MODELS"

3rd International Conference on Research in Air Transportation, June 2008, Fairfax, VA, pp. 413-420.

This paper discusses one of the major problems concerning current dispersion modelling techniques used around airports; the source dynamics characterization. Due to the lack of information and non-availability of experimental data, common dispersion models rely on very simple source approximations. Through a staged process, the paper shows a more accurate representation of the plume dynamics of an aircraft during the take-off phase. Using Computational Fluid Dynamics, useful data can be collected to represent and understand the fluid mechanics associated with the dispersion process. The results can help dispersion modelers with better source dynamics representation and benefit the management of aircraft time separation delays in the take-off and landing phases.

Aloysius, S. S. and Wrobel, L. C.

"LARGE EDDY SIMULATION OF PLUME DISPERSION BEHIND AN AIRCRAFT IN THE TAKE-OFF PHASE"

Environ. Fluid Mechanics, Vol. 9, 2009, pp. 457-470.

The aim of this paper is to provide an investigation, using large eddy simulation, into plume dispersion behind an aircraft in co-flowing take-off conditions. The complete geometry of a Boeing 737 is modelled and investigated. The current work represents a contribution towards a better understanding of the source dynamics behind an airplane jet engine during the take-off and landing phases. The information provided from these simulations will be useful for future improvements of existing dispersion models.

Aloysius, S. S., Pearce, D. and Wrobel, L. C.

"COMPARISON OF CFD AND LAGRANGIAN METHODS -- SIMPLE SCENARIO DURING TAKE-OFF"

EuroControl Report EEC/SEE/2007/001, 2007, Brunel University, Uxbridge, UK.

This report aims to simulate the dispersion of NO_x from an aircraft engine during the take-off phase, and to provide information on source dynamics for future improvements of existing dispersion models. The dispersion of a single engine, typical of the B-737, was simulated first, followed by the simulation of a twin engine. The results are discussed in detail and compared with results from other papers dealing with related problems, in order to correlate some of the findings. The method employed to characterize the plume dynamics employs state-of-the-art CFD software packages, which represent the

most advanced mathematics that can be applied to the simulation of fluid flow. The Large Eddy Simulation turbulence model was used to model the smaller eddies present within the grid resolution, and to solve explicitly the large eddies contained outside it. The conclusions from the report highlight the importance of two parameters, namely wind data and vortical structures, for both simulations. Another important parameter for the double engine simulation relates to the interaction effects between the two engines. The implication of the results will also be of benefit to air traffic management, for the efficient prediction of time separation delays between aircraft in the take-off and landing phases.

"CURIE: A NEW CLEAR AIR DOPPLER RADAR DEDICATED TO THE LOWER PART OF THE ATMOSPHERIC BOUNDARY LAYER (20M - 750M)"

14th International Symposium for the Advancement of Boundary Layer Remote Sensing, IOP Conf. Series: Earth and Environmental Science, Vol. 1, 2008, pp. 012015-1 to 012015-7.

A new X-band mini-radar, CURIE radar (Canopy Urban Research on Interactions and Exchanges), mainly adapted to low Atmospheric Boundary Layer sounding has been developed at CETP. After a brief description of the opportunity and working conditions in a turbulent atmosphere, main characteristics are presented. Though this radar works in presence of precipitation as all X-band radar can do, this paper is more dedicated to clear air used in the turbulent atmospheric boundary layer. We are presented comparisons with UHF observations and boundary layer information which can be inferred from CURIE as entrainment across the inversion layer.

Alsayed, O. A., Asrar, W. and Omar, A. A.

"EVALUATION OF AIRCRAFT WING-TIP VORTEX USING PIV"

10th Asian International Conference on Fluid Machinery, CP 1225, AIP Conference Proceedings, Vol. 1225, 2010, pp. 382-390.

The formation and development of a wing-tip vortex in a near and extended near field were studied experimentally. Particle image velocimetry was used in a wind tunnel to measure the tip vortex velocity field and hence investigate the flow structure in a wake of aircraft half-wing model. The purpose of this investigation is to evaluate the main features of the lift generated vortices to find ways to alleviate hazardous wake vortex encounters for follower airplanes during start and approach such that the increase in airport capacity can be achieved. First the wake structure at successive downstream planes crosswise to the axis of the wake vortices was investigated by measuring parameters such as core radius, maximum tangential velocities, vorticities, and circulation distributions. The effect of different angles of attack setting on vortex parameters was examined at one downstream location. In very early stages the vortex sheet evolution makes the tip vortex to move inward and to the suction side of the wing. While the core radius and circulation distributions hardly vary with the downstream distance, noticeable differences for the same vortex parameters at different angles of

attack settings were observed. The center of the wing tip vortices scatter in a circle of radius nearly equal to 1% of the mean wing chord and wandering amplitudes shows no direct dependence on the vortex strength but linearly increase with the downstream distance.

Alsayed, O. A., Asrar, W., Omar, A. A., Kwon, K. and Jung, H.

"EXPERIMENTAL INVESTIGATION OF WING TIP VORTEX"

AIAA Paper 2009-1486, Jan. 2009, Orlando, FL

Particle image velocimetry was used in a low-speed wind tunnel to investigate and characterize wing tip vortex structures. A rectangular wing of a SWIM model was used as a vortex generator in two different configurations, (i) plain wing and (ii) flapped wing with trailing edge flap extended at 20 degrees. Vortex flow quantities and their dependence on angle of attack at a chord base Reynolds Number of 32800 and 43800 were evaluated. Assessment of measured data reveals that the peak values of tangential velocities, vortex strength and vorticities are directly proportional to the angle of attack. The vortex core radius value grows slowly as the angle of attack is increased. Both plain and flapped configurations showed similar trends. The peak tangential velocities and circulation distributions doubled when the flapped configuration was used instead of the plain wing.

Altaf, A., Omar, A. A., Asrar, W. and Jamaluddin, H. B. L.

"STUDY OF THE REVERSE DELTA WING"

Journal of Aircraft, Vol. 48, No. 1, January-February 2011, pp. 277-286.

Particle image velocimetry was used in a low-speed wind tunnel to investigate the vortex structure of a slender reverse delta wing at various angles of attack and roll. This work investigates the characteristics of the vortices generated downstream in planes perpendicular to the freestream direction and their dependence on angles of attack and roll at a chord-based Reynolds number of $Re = 382,000$. The peak tangential velocities at an angle of attack greater than 5 degrees show a trend like a delta wing. A six-component balance was used to obtain the aerodynamic coefficients for a reverse delta wing as well as a delta wing for comparison. A simulation of streamlines, velocity vectors, and surface pressure contours was carried out using computational fluid dynamics software to show the characteristics of the flow over a reverse delta wing.

Altaf, A., Thong, T. B., Omar, A. A. and Asrar, W.

"EXPERIMENTAL INVESTIGATION OF THE INFLUENCE OF A REVERSE DELTA TYPE ADD-ON DEVICE ON THE FLAP-TIP VORTEX OF A WING"

3rd International Conference on Mechanical, Automotive and Aerospace Engineering, in IPO Conf. Series: Materials Science and Engineering, Vol. 184, 2017, Kuala Lumpur, Malaysia, pp. 012002-1 to 012002-11.

Particle Image Velocimetry was used in a low-speed wind tunnel to investigate the effect of interactions of vortices produced by an outboard flap-tip of a half wing (NACA 23012 in landing condition) and a slender reverse delta type add-on device, placed in the proximity of the outboard flap-tip, on the upper surface of the half wing. This work investigates the characteristics of the vortex interactions generated downstream in planes perpendicular to the free stream direction at a chord-based Reynolds number of $Re = 274,000$. It was found that the add-on device significantly reduces the tangential velocity magnitude and enlarges the vortex core of the resultant vortex by up to 36.1% and 36.8%, respectively.

Altaf, A., Thong, T. B., Omar, A. A. and Asrar, W.

"INFLUENCE OF A REVERSE DELTA-TYPE ADD-ON DEVICE ON WAKE VORTEX ALLEVIATION"

AIAA Journal, Vol. 54, No. 2, February 2016, pp. 625-636.

Particle image velocimetry was used in a low-speed wind tunnel to investigate the effect of interactions of vortices produced by a wingtip of a half-span wing (NACA 23012 in landing condition) and a slender reverse delta-type add-on device placed near the tip on the upper surface of the half-span wing. This work investigates the characteristics of the vortex interactions generated downstream in planes perpendicular to the freestream direction and their dependence on angles of attack at a chord-based Reynolds number of $Re = 275,000$. It was found that the add-on device significantly reduced the tangential velocity, vorticity, and circulation magnitude by up to 82.9, 92.6, and 42.8 percent, respectively, and increased the resultant vortex core radius by a factor of 6.57. A six-component force balance was used to obtain the aerodynamic performance of the half-span wing model with a reverse delta-type add-on device. It was found that the reverse delta-type add-on device marginally affected the aerodynamic performance of the half-span high-lift configuration wing model.

"3-D PERSPECTIVE PRIMARY FLIGHT DISPLAYS FOR AIRCRAFT"

Proceedings of the IEA 2000/HFES 2000 Congress, July 2000, San Diego, CA, pp. 3-29 to 3-32.

Using a 3-D perspective display, Stanford University has flown numerous approaches and missed approaches. The system has been flown extensively on a Beechcraft Queen Air in the working air traffic environment. Inflight evaluations included tunnel approaches overlaid on existing non-precision procedures, curved and segmented approaches, traffic patterns flown by instrument reference, and skywriting with GPS. Augmentations to the perspective flight display, including perspective terrain and dynamic terrain alerting, are viable and improve pilots' situational awareness.

Alter-Gartenberg, R.

"STEREO-VIDEO DATA REDUCTION OF WAKE VORTICES AND TRAILING AIRCRAFTS"

NASA/CR-1998-208719, September 1998, Computer Sciences Corp., Hampton, VA

This report presents stereo image theory and the corresponding image processing software developed to analyze stereo imaging data acquired for the wake-vortex hazard flight experiment conducted at NASA Langley Research Center. In this experiment, a leading Lockheed C-130 was equipped with wing-tip smokers to visualize its wing vortices, while a trailing Boeing 737 flew into the wake vortices of the leading aircraft. A Rockwell OV-10A airplane, fitted with video cameras under its wings, flew at 400 to 1000 feet above and parallel to the wakes, and photographed the wake interception process for the purpose of determining the three-dimensional location of the trailing aircraft relative to the wake. The report establishes the image-processing tools developed to analyze the video flight-test data, identifies sources of potential inaccuracies, and assesses the quality of the resultant set of stereo data reduction.

Althaus, W. and Weimer, M.

"REVIEW OF THE AACHEN WORK ON VORTEX BREAKDOWN"

IUTAM Symposium on Dynamics of Slender Vortices, Aachen, Germany, August 31-September 3, 1997

Results of the numerical simulations and of the experimental investigations of vortex breakdown are presented. This paper focuses on the development of physical understanding of the breakdown process. Simulations of axisymmetric flows suggested that the Navier-Stokes equations for time-dependent, three-dimensional flows should be solved to describe the breakdown process. The simulation of a free vortex showed bubble- and spiral-type breakdown and the transition between these states. The comparison with the experimental visualization showed a good agreement, thus the analysis of the physical mechanisms of breakdown were based on the numerical results. The initiation and growth of the bubble are described by a feedback mechanism. The shedding of high axial velocity structures is explained. The growing asymmetry of the internal bubble structure and the subsequent transition to spiral-type breakdown are described. Simulating vortex breakdown in a slightly diverging tube showed stable bubble and further downstream spiral-type breakdown. The location and internal structure of the bubble corresponds to experimental results. The results of the application of flow visualizations and Particle-Image-Velocimetry are presented.

Althaus, W., Krause, E., Hofhaus, J. and Weimer, M.

"BUBBLE- AND SPIRAL-TYPE BREAKDOWN OF SLENDER VORTICES"

Experimental Thermal and Fluid Science, Vol. 11, 1005, pp. 276-284.

Bubble- and spiral-type breakdown and periodic transition between the two were visualized by varying the volume flux in a transparent, low-speed, vertical water tunnel with a diffuser inset. A feedback model for the initiation and development of bubble-type breakdown is proposed, and the transition from bubble- to spiral-type breakdown is explained by an asymmetry of the circumferential vorticity distribution. Both are qualitatively confirmed by experimental flow visualization. The initiation of the bubble-type breakdown and its transition to the spiral-type were successfully simulated by

solving the Navier-Stokes equations for three-dimensional, unsteady, and incompressible flow with boundary conditions similar to those of an experimental investigation. Hence, for the first time it was possible to compare the results of numerical and experimental flow visualizations and therefore to draw a conclusion about the reliability of simulating vortex breakdown numerically.

Altman, A.

"DESIGN METHODOLOGY FOR LOW SPEED HIGH ALTITUDE LONG ENDURANCE UNMANNED AERIAL VEHICLES"

21st International Council of the Aeronautical Sciences Congress ICAS, September 1998, Melbourne, Australia.

High Altitude Long Endurance (HALE) Unmanned Aerial Vehicles (UAV's) are increasingly being considered to perform a wide range of tasks. Recent years have seen greater value of UAV's in the military reconnaissance arena, first in the Persian Gulf war, with the use of small UAVs, and more recently over Bosnia with medium sized UAVs.

Alvarez, E. J. and Ning, A.

"DEVELOPMENT OF A VORTEX PARTICLE CODE FOR THE MODELING OF WAKE INTERACTION IN DISTRIBUTED PROPULSION"

AIAA Paper 2018-3646, June 2018, Atlanta, GA.

Recent developments in electric aircraft technology have enabled the use of distributed propulsion for the next generation of vertical lift vehicles. However, the ability to rapidly assess the performance of these design concepts, with sufficient fidelity, is a current weakness of this nascent industry. This paper explores the capacity of the viscous Vortex Particle Method (VPM) to model wake interactions found in distributed propulsion. The elements of the vortex particle method are summarized, and a new approach for the calculation of vortex stretching through the complex-step derivative approximation is presented. Preliminary validation is performed on vortex ring cases resembling the fundamental dynamics encountered in propeller wakes. Unsteady wake dynamics of individual propellers are successfully modeled, replicating the instabilities that lead to vortex breakdown as observed experimentally. Comparing the method with results from momentum theory, it is shown that VPM is consistent with theoretical values of near and far field induced velocities, and a notable feature is its ability to model near/far field transition. Furthermore, VPM is able to fully characterize induced velocities across the entire wake, from the stable region where momentum theory operates, through instability transition and eventual vortex breakdown. The simulation of a multirotor configuration of two tip-to-tip propellers is shown, displaying the capacity of VPM to model wake mixing. The results presented here are intermediate steps in the development of a mid-fidelity modeling tool for the early design stages of distributed-propulsion electric aircraft.

Amelsberg, S.

"THE CREDOS PROJECT: PILOT MODEL FOR WAKE VORTEX ENCOUNTER SIMULATIONS FOR TAKE-OFF AND DEPARTURE"

CREDOS Report D3-6, November 2009.

A pilot model (PM) is developed for fast-time Monte Carlo Simulations with varying wake vortex encounter conditions for safety analyses. The model consists of different submodules to perform the take-off run, rotate, follow a standard instrument departure route and recover and stabilize the aircraft during and after a wake vortex encounter. The PM generates sidestick pitch, sidestick roll, pedal, throttle lever, flap lever, and landing gear lever commands and manipulates those control elements as a pilot would do. For design and validation of the PM, data was generated in a certified A330 Full Flight Simulator and on A320 development simulator with licensed commercial airline pilots. For final validation, the PM was implemented into the flight simulation to compare it with recorded pilot reactions.

Amelsberg, S.

"WAKE VORTEX ENCOUNTER SEVERITY CRITERIA FOR TAKE-OFF AND DEPARTURE"

CREDOS Report D3-5, November 2009, Technical University of Berlin, Berlin, Germany.

Criteria shall be identified that quantify the severity of a Wake Vortex Encounter during takeoff and departure. This paper describes the development process of suitable metrics that can estimate the hazard of a wake vortex encounter situation based on objective aircraft state parameters. It is applicable for Monte Carlo simulation and suitable for risk assessments. The hazard estimation based on the identified criteria is verified with the hazard ratings of human pilots. The reference data were gathered during piloted simulator tests.

Amelsberg, S.

"TRAJECTORY MODELS FOR TAKEOFF AND DEPARTURE"

CREDOS Report D3-1, September 2007, Technical University of Berlin, Berlin, Germany.

The European Commission funded CREDOS (Cross wind reduced separations for departure operations) project aims to demonstrate the validity of reducing departure separations under conditions of sufficient crosswind. For this validation a safety assessment is required, which will be performed by Monte Carlo Simulation (MCS) of aircraft departure trajectories. This paper describes the development of an aircraft trajectory model, which is a part of the MCS. The requirement to generate trajectories for different kind of aircraft can be fulfilled by a simple point mass model (3DoF) consisting of three main parts: (i) A database of all relevant aircraft parameters, nominal departure route information, meteorological conditions, (ii) pilot model, (iii) and the description of the aircraft behavior with the equations of motion. The simulated flight path is subdivided into the following segments

which describe the different kinds of flight phases: lift-off, unsteady climb, steady climb, acceleration, and transitions between these phases.

Amelsberg, S.

"ADDENDUM FOR TRAJECTORY MODELS FOR TAKE-OFF AND DEPARTURE"

CREDOS Report D3-1, November 2007, Technical University of Berlin, Berlin, Germany.

This addendum documents the validation of the Boeing 737-300, Airbus 300-600, and the Airbus 340-300. It is an addition to Appendix A of the deliverable D3-1.

Amelsberg, S. and Kauertz, S.

"PILOTED WAKE VORTEX ENCOUNTER SIMULATOR TESTS FOR DEPARTURE"

CREDOS Report D3-4, November 2008, Technical University of Berlin, Berlin, Germany.

Piloted simulator tests were carried out to study and assess the safety hazard imposed by wake vortices during departures. The tests were conducted in Hamburg at the A320 THOR simulator and in Berlin at the A330 full-flight simulator with several rated airline pilots. On one hand, objective parameters of the pilot's response in wake vortex encounter conditions and resulting aircraft reactions were recorded and on the other hand the pilots subjective ratings of the encounter severity were documented. The hazard rating scale ranges from slight aircraft upsets with no pilot reaction required up to extreme disturbances with temporary loss of control. Test planning, accomplishment and the first steps of parameter correlation are discussed.

Amelsberg, S. and Luckner, R.

"PARAMETRIC AIRCRAFT TRAJECTORY MODEL FOR TAKEOFF AND DEPARTURE"

1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-273, September 2007, pp. 785-795

The European Commission funded CREDOS (Cross wind reduced separations for departure operations) project aims to demonstrate the validity of reducing departure separations under conditions of sufficient crosswind. For this validation a safety assessment is required that computes encounter probabilities and encounter severity by means of Monte Carlo Simulation (MCS). This paper describes the development of an aircraft trajectory model for departure of vortex generating and following aircraft. This model is a part of the MCS. The requirement to generate trajectories for different aircraft types can be fulfilled by a simple point mass model consisting of three main parts: (i) a database of all relevant aircraft parameters, nominal departure route information, meteorological conditions, (ii) pilot model, and (iii) the description of the aircraft dynamic by the equations of motion. The simulated flight path is subdivided into segments that are described by the following flight phases: lift-off, unsteady climb, steady climb, acceleration, and transitions between these phases. Finally,

results of a deterministic model validation based on high-fidelity flight simulation for a specific aircraft as well as the model validation based on aircraft trajectories measured at Frankfurt airport are presented.

Amromin, E.

"ANALYSIS OF VORTEX CORE IN STEADY TURBULENT FLOW"

Physics of Fluids, Vol. 19, 2007, pp. 118108-1 to 118108-3.

Profiles of velocity and pressure for the vortex core in turbulent flow were obtained by solving Reynolds equation for the circumferential component of the fluid momentum. The viscous core radius is defined as a function of viscosity coefficient, vortex intensity, and a Reynolds stress component. The obtained velocity profiles are in much better agreement with known experimental data than are the Rankin vortex profiles.

An, R., Kontis, K. and Edwards, J. A.

"COMPRESSIBLE VORTEX-RING INTERACTION STUDIES WITH A NUMBER OF GENERIC BODY CONFIGURATIONS"

AIAA Paper No. 2005-1044, Reno, NV, January 2005

An experimental study has been conducted to examine compressible vortex ring structure and propagation, and the interaction of vortex ring with generic-body configurations. The experiments used a circular 30mm internal diameter and 38mm outer diameter shock-tube. The driver and driven gas was air. A vortex ring was generated by the impulse of the shock wave emerging from the open end of the shock-tube. High-speed schlieren photography was employed. Both side view and 45 degrees oblique photographs were taken. The interactions with generic shape objects, which were a circular cone, a sphere, a cube, and a plane-wall, were studied. Three different driver pressures of 12, 8, and 4 bars were tested with driven gas at 1 bar; the shock wave Mach number inside the tube was 1.63, 1.52 and 1.25 respectively.

Anand, G. and Graham, W. R.

"VORTEX FILAMENT SIMULATION OF TRAILING VORTEX MERGER"

AIAA Paper No. 2005-4854, Toronto, Canada, June 2005

Aircraft in high-lift configuration shed multiple vortices. These generally merge to form a downstream wake consisting of two counter-rotating vortices of equal strength. The understanding of the merger of two co-rotating trailing vortices is important in evaluating the separation criteria for different aircraft to prevent wake vortex hazards during landing and take-off. There is no existing theoretical method on the basis of which such norms can be set. The present study is aimed at gaining a better understanding of the behavior of wake vortices behind the aircraft. Two dimensional studies are carried out using the

vortex blob method and compared with Bertenyi's experiment. It is shown that inviscid two-dimensional effects are insufficient to explain the observations. Three dimensional studies, using the vortex filament method, are applied to the same test case. Two Lamb-Oseen profile vortices of the same dimensions and initial separation as the experiment are allowed to evolve from a straight starting condition until a converged steady flow is achieved. The results obtained show good agreement with the experimental distance to merger. Core radius and separation behavior is qualitatively like experiment, except for rapid increases at first. This may be partially attributable to the choice of filament-element length, and recommended further work includes a convergence study for this parameter.

"NONLINEAR INTERACTION OF A VORTEX PAIR WITH CLEAN AND SURFACTANT-COVERED FREE SURFACES"

Wave Motion, Vol. 19, 1994, pp. 343-365.

Two-dimensional unsteady viscous-flow problem associated with the normal incidence of a counter-rotating vortex pair on a free surface is analyzed. Effects of surface tension and insoluble surfactants on the generation of free-surface vorticity and surface waves are investigated. A recently developed finite-difference method based on boundary-fitted coordinates is used to solve the fully-nonlinear problem. Results show that in the absence of surfactants and at low Froude number (based on circulation strength and initial separation distance of the vortex pair), waves of short lengths are generated. However, secondary vorticity generated in this case is not strong enough to affect the outward translation of the primary vortices. At intermediate Froude number, a transient wave developing outboard of the primary vortex becomes steep, and eventually breaks because of local instability. Consequently, free-surface vorticity inhibits the outward translation of the primary vortices. Surface tension in a clean free surface dampens the steep short waves, hence also the generation of free-surface vorticity. However, variation in surface tension induced by surfactants intensifies the generation of surface vorticity, thereby causing the primary vortices to rebound. The increase in the rotational part of wave motion results in the dampening of overall free-surface deformations. However, it is found that the shear stress associated with a large gradient of surfactant concentration could cause local steepening of the short-wave generated outboard of the primary vortex.

Ananthan, S.

"ANALYSIS OF ROTOR WAKE AERODYNAMICS DURING MANEUVERING FLIGHT USING A FREE-VORTEX WAKE METHODOLOGY"

PhD Thesis, 2006, University of Maryland, College Park, MD.

The problem of helicopter rotor wake aerodynamics during maneuvering flight conditions was analyzed using a time-accurate, free-vortex wake methodology. The free-vortex method consists of a Lagrangian representation of the rotor flow field using vortex elements, where the evolution of the

flow field is simulated by tracking the free motion of these vortex elements and calculating their induced velocity field. Traditionally, free-vortex methods are inviscid, incompressible models, but in the present approach the viscous effects are incorporated using a viscous splitting method where the viscous and inviscid terms are modeled as successive sub-processes. The rotor aerodynamics and rigid blade flapping dynamics are closely coupled with the wake model and solved for in a consistent manner using the same numerical scheme. Validations of the methodology with experimental data were performed to study the wake response to perturbations in collective and cyclic pitch inputs. The numerical simulations captured all the essential wake dynamics observed in flow visualization. The predictions of the transient inflow and air loads response were found to be in excellent agreement with the available experimental measurements. It was observed that the rotor wake was extremely sensitive to perturbations in collective and cyclic blade pitch inputs. The characteristic wake response was found to be the bundling of the wake vorticity into a vortex ring structure. The evolution, convection and subsequent breakdown of this bundled ring of tip-vortices was found to be highly nonlinear, and occurs with a temporal lag. The nonlinear induced velocity field associated with unsteady wake evolution can cause considerable fluctuations in the rotor air loads time-history if the bundled tip-vortex structure comes near the rotor blades.

Ananthan, S. and Leishman, J. G.

"TRANSIENT HELICOPTER ROTOR WAKES IN RESPONSE TO TIME-DEPENDENT BLADE PITCH INPUTS"

Journal of Aircraft, Vol. 41, No. 5, September-October 2004, pp. 1025-1041

A time-accurate, free-vortex method was used to predict the evolution of a helicopter rotor wake and the corresponding unsteady rotor air loads in response to time-varying changes in blade pitch. Both steady and maneuvering flight conditions were examined. The modeling was validated using measured rotor responses to transient increases in collective pitch and also for oscillatory collective and cyclic blade pitch inputs. In each case the results showed that there was a temporal lag in the growth and convection of vorticity into the rotor wake, causing significant unsteady effects at the rotor. For transient blade pitch inputs, the calculated results showed the bundling of individual vortex filaments below the rotor into vortex rings, a result also verified experimentally. These vortex rings, however, subsequently break down through the development of Kelvin waves. A simulated piloted pull-up maneuver from descending flight was studied, producing evidence that maneuvers can also cause wake vorticity to bundle below the rotor. Large unsteady rotor air loads were produced as the blades encountered this accumulated wake vorticity. A study was also conducted to examine the effects of small-amplitude, low-frequency blade pitch inputs, typical of pilot control inputs during flight. Overall, it is apparent that even moderate control inputs can have a significant impact on the temporal developments of the rotor wake.

"THE ROLE OF FILAMENT STRETCHING IN THE FREE-VORTEX MODELING OF ROTOR WAKES"

58th Annual Forum and Technology Display of the American Helicopter Society International, Montreal, Canada, June 2002

The problem of filament strain or flow field 'stretching' effects are discussed within the context of time-marching, free-vortex filament modeling of rotor wakes. It is shown that for most practical rotor flight conditions, wake distortions create velocity fields that impose three-dimensional strain on the vortex filaments, stretching these filaments, and changing their vorticity and induced velocity field. Such strain or stretching effects are not easily neglected without proper justification. The basic approach used here to model these effects, applies a Prandtl-type decomposition of the inviscid and viscous contributions into successive sub-processes, with a recombinant solution to give a consistent level of approximation to the rotor wake problem. A parsimonious model based on an equivalent diffusion time is developed to account for and couple the effects of filament straining into the viscous part of the solution. Examples of wake predictions are shown for rotors operating in hover, forward flight, flight near the ground, and during descending flight. It is shown that even for benign flight conditions, strain effects on vortex filaments can be significant, and including the effects of strain on the viscous characterization of the vortices is important for predictions of the rotor wake development.

Anderson, C. R., Chen, Y.-C. and Gibson, J. S.

"CONTROL AND IDENTIFICATION OF VORTEX WAKES"

Transactions of the ASME, Vol. 122, June 2000, pp. 298-305

In this paper, control and identification methods for vortex wakes are investigated. The problem studied concerns the stabilization of vortices behind a flat plate, using backside suction as an actuator. The flow dynamics are modeled with a discrete vortex method. Feedback control results for a linear PI controller are presented as well as identification results for a class of input/output models that can be used to design more sophisticated controllers.

Anderson, E. A. and Lawton, T. A.

"CORRELATION BETWEEN VORTEX STRENGTH AND AXIAL VELOCITY IN A TRAILING VORTEX"

Journal of Aircraft, Vol. 40, No. 4, July-August 2003, pp. 699-704

The vortices that trail from the wingtips of a large aircraft provide a significant hazard to an aircraft that follows in its wake. The objective is to contribute to the understanding of these vortices by identifying the conditions where an axial velocity in excess of the freestream value will be generated in the core of a trailing vortex. The axial velocity near the core of a trailing vortex was measured using a triple-sensor hot-wire probe and compared with measured values of vortex circulation strength. The vortex was generated in a wind tunnel using a NACA 0015 wing model with a semispan aspect ratio of 0.80. A linear relationship between the axial velocity and a nondimensional circulation parameter is indicated. For small values of the circulation parameter, the axial velocity shows a velocity deficit. An increase in circulation strength results in a progressive increase in axial velocity, which can exceed the freestream velocity by as much as 70%. The results indicate that the magnitude of the axial velocity is

sensitive to the two end-cap configurations, flat and rounded, that were tested. It was found that scaling the circulation parameter by the vortex radius collapses the data from both configurations to a single linear curve.

Anderson, E. A. and Lawton, T. A.

"EFFECT OF WING LOADING ON AXIAL VELOCITY IN A WINGTIP VORTEX"

AIAA Paper No. 2001-0578, Reno, NV, January 2001

Theories pertaining to the cause of an axial velocity excess in a free trailing vortex are evaluated and compared to experimental measurements. It was found that several previous analyses contain an inconsistency that leads to the conclusion that an axial velocity excess will occur in the core of a line vortex. In the current study 3-component hot-wire velocity measurements were used to calculate the circulation strength in a trailing vortex generated by a NACA 0015 wing. The results were compared to the measured axial velocity near the center of the vortex. A strong correlation between wing loading as defined by a non-dimensional circulation parameter and the axial velocity was determined. For low circulation parameter values, below approximately 0.1, the axial velocity was less than the freestream value or 'wake-like'. For larger parameter values the axial velocity exceeded the freestream resulting in 'jet-like' behavior. A linear relationship between circulation strength and axial velocity was found. It is concluded that the cause of the velocity excess is streamwise directed downwash.

Anderson, E. A., Wright, C. T. and Lawton, T. A.

"EXPERIMENTAL STUDY OF THE STRUCTURE OF THE WINGTIP VORTEX"

AIAA Paper No. 2000-0269, Reno, NV, January 2000

The development of a wingtip vortex in the region adjacent the wing end-cap to approximately two chord lengths downstream from the trailing edge is strongly influenced by Reynolds number, angle-of-attack, and end-cap treatment. This study primarily focuses on the role of wing end-cap geometry on the initial development of the tip vortex and how that development is altered by angle-of-attack. The velocity field in the vicinity of the end-cap of a NACA 0015 wing section was measured using a triple-sensor hot wire probe and compared to flow visualization results. The results indicate that a 'jet-like' axial velocity profile will be generated for loading parameter values of the order 0.2 while much lower loading will produce a 'wake-like' profile. In addition, the flat end-cap geometry produced multiple, relatively strong vortices in the near-field as opposed to the single vortex generated using the rounded end-cap configuration. These different structures influenced the downstream development of the wingtip vortex.

"CALCULATION OF EXHAUST PLUME STRUCTURE AND EMISSIONS OF THE ER 2 AIRCRAFT IN THE STRATOSPHERE"

Journal of Geophysical Research, Vol. 101, No. D2, February 1996, pp. 4025-4032.

Calculations are presented for the NASA ER 2 aircraft at high altitude to simulate measurements taken of its own emissions during a wake-crossing event. Results are presented for a Mach = 0.71 case in the lower stratosphere with an engine NO_x emission index of 4.6 corresponding to the measured value. A series of codes was used in the analysis to calculate the flow field and chemical kinetics, from the engine combustor out to a distance of about 20.2 km (97 s). Initial plume properties were calculated with a two-dimensional computational fluid dynamics code with finite rate chemistry. The results of the plume code initialized a three-dimensional parabolized Navier-Stokes reacting flow solution, where the plume dynamics interacting with the aircraft wake were calculated out to the region of plume breakup. Results show that the early shape and mixing rate of the engine exhaust plume are dominated by the presence of the aircraft vortex wake. Model results for NO_x emissions compare well to in situ measurements taken in the field. Calculated exhaust species evolutions predict several species ratios in good agreement with field data. The mixing rate of the engine plume was also predicted to be consistent with dilution measured in the field.

Anderson, M. R., Miaki-Lye, R. C., Brown, R. C. and Kolb, C. E.

"NUMERICAL MODELING OF REACTING ENGINE PLUMES AND AIRCRAFT WAKE INTERACTIONS"

AIAA Paper No. 1996-0948, Reno, NV, January 1996

The effects of aircraft emissions on the chemical balance of the atmosphere has gained increasing attention in recent years. New generations of higher speed aircraft which would fly up into the stratosphere have been a particular concern. A host of experimental and analytical efforts to quantify these effects is being pursued through NASA's Atmospheric Effects of Aviation Program as well as other international efforts. Proper numerical analysis of the reacting near field region of the engine plume(s) presents several challenges. Chemical models must be constructed which are valid in the atmospheric temperature and pressure range and must include the relevant nitrogen, carbon, and sulfur species. In addition, flow field modeling is complicated by the interaction which occurs between the engine plume and the aircraft wake vortices which roll off the wings. This phenomenon substantially affects the mixing and dilution of the plume. Results are presented here for several aircraft of various designs, speeds, and altitudes. The analysis consists of a Parabolized Navier-Stokes CFD approach coupled with a specially developed finite rate chemistry model. The focus will be on the external near field region from the exit plane of the engine to the point of wake breakup several kilometers downstream. Comparisons of analytical results to field data are shown for the ER-2, Boeing 747, and Concorde aircraft.

"MOBILE COHERENT DOPPLER LIDAR SYSTEM FOR WIND SENSING"

17th Coherent Lidar Conference, June 2013, Barcelona, Spain.

We have developed ultra compact all-fiber Coherent Doppler LIDAR (CDL) system for wind sensing, called Man-pack LIDAR. The dimension of the Man-pack LIDAR is 40x30x16.5 cm, its weight is 13.9 kg and its power consumption is only 46.7 W. Thanks to low power consumption optical transmitter/receiver unit, this new CDL system can be operated by two Lithium polymer batteries, and it can continue to measure over two hours without exchanging batteries. This Man-pack LIDAR has also successfully marked the maximum range for wind velocities more than 1 km as long as our conventional all-fiber CDL product.

"VORTICITY DYNAMICS IN INTERACTIONS OF SHOCK OR EXPANSION WAVES WITH TURBULENCE AND VORTICES"

AIAA Paper No. 2006-706, Reno, NV, January 2006

The interaction of planar shock waves or expansion waves with homogeneous and isotropic turbulence and induced longitudinal and spanwise vortices generated by a wing have been investigated experimentally in the CCNY Shock Tube Research Facility at several Reynolds numbers. A custom made hot-wire vorticity probe was designed and developed capable of measuring the time-dependent highly fluctuating three-dimensional velocity and vorticity vectors, and associated total temperature, in non-isothermal and inhomogeneous flows with reasonable spatial and temporal resolution. These measurements allowed the computations of the vorticity stretching/tilting terms, vorticity generation through dilatation terms, full dissipation rate of kinetic energy term and full rate-of-strain tensor. These results indicate that the outcome of the interaction depends strongly on the upstream turbulence of the flow.

Andreotti, B., Maurer, J., Couder, Y. and Douady, S.

"EXPERIMENTAL INVESTIGATION OF TURBULENCE NEAR A LARGE SCALE VORTEX"

European Journal of Mechanics, B/Fluids, Vol. 17, No. 4, 1998, pp. 451-470.

The influence of a strong large-scale vortex on neighboring turbulence is investigated. For this purpose, the statistical properties of the tangential velocity fluctuations are systematically investigated as a function of the distance to the vortex core. Far from the vortex, the characteristics usually found in isotropic homogeneous turbulence are approximately obtained. In the central region of the vortex a strong decrease of the amplitude of the velocity fluctuations and of the dissipation is observed. However, in this region of space the flow is not smooth: the energy spectrum $E(k)$ still exhibits the equivalent of an inertial range but with a slope which can range from k to -1.25 power to k to -1 power instead of the classical k to $-5/3$ power. Furthermore, the intermittence is much weaker inside the vortex central region: the velocity differences PDFs no longer exhibit long stretched tails and are more self-similar from scale to scale. In between these two regions, at the periphery of the vortex, the intermittence is strongly increased. It is shown that this increase is due to the mixing in the velocity signal of the two types of statistics (the strongly fluctuating bulk turbulence and the weakly fluctuating

vortex flow). This situation is analyzed using a variant of extended self-similarity that we call LSS (loose self-similarity) which lends itself to the analysis of situations where a clear scaling is not obvious.

Andrews, D. R.

"A FLIGHT INVESTIGATION OF THE WAKE BEHIND A METEOR AIRCRAFT, WITH SOME THEORETICAL ANALYSIS"

A.R.C. Current Paper 282, December 1954, Royal Aircraft Establishment, Farnborough, England.

An experimental investigation of the wake behind a Meteor-4 aircraft has been carried out, and theory used wherever possible to confirm and extend the results obtained. Tests with a Vampire flying in the wake of the Meteor show that the strength of the vortices fall to about one-half its initial value by 8000 feet behind the aircraft. Theory and flight test experience showed that the rolling moment imposed on a tracking aircraft constituted the most serious disturbance from the vortices.

Andrews, W. H.

"FLIGHT EVALUATION OF THE WING VORTEX WAKE GENERATED BY LARGE JET TRANSPORTS"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 287-288

A flight program has been conducted to update the current knowledge relative to the behavior of wing wake vortices generated by existing large transport aircraft and future jumbo jet transports. The tests were conducted to evaluate the wake location, persistence, apparent intensity and influence out of ground effect and primarily under terminal area configuration and operational conditions. Test aircraft included a DC-9, CV-990, and a C-5A. The wake behavior was evaluated by measuring aircraft response and controllability of a series of probe airplanes flying in the generating aircraft wake at separation ranges of 1 to 15 nautical miles.

Andrews, W. H., Drinkwater, F. J., Krier, G. E. and Robinson, G. H.

"FLIGHT-TEST EVALUATION OF THE WING VORTEX WAKE GENERATED BY LARGE JET-TRANSPORT AIRCRAFT"

FAA Compilation of Working Papers Concerning Wake Turbulence Tests, April 1970.

An evaluation of the behavior of the wing vortex wake of large, jet transport airplanes is presented. The primary objectives of the test program were to provide preliminary information to establish a logical terminal-area airspace separation criterion for all types of aircraft operating in the proximity of large transports. The flight tests were conducted to obtain data for the determination of the wing vortex wake location, persistence, and intensity behind the generating airplanes. In addition, a portion of the testing was directed toward evaluating the effects of the wing vortex wake on several different classes of aircraft.

Andrews, W. H., Robinson, G. H. and Larson, R. R.

"AIRCRAFT RESPONSE TO THE WING TRAILING VORTICES GENERATED BY LARGE JET TRANSPORTS"

NASA Aircraft Safety and Operating Problems, NASA SP-270, Vol. 1, 1971, pp. 115-126

The paper summarizes the NASA effort to evaluate the effect of the wing-tip vortex wake generated by large jet transport airplanes on a variety of smaller airplanes. The investigation was designed to obtain data essential to the determination of the wing-wake location relative to the generating aircraft and the apparent strength and dissipation of the vortex at a specified point along the wake trail. An additional objective was to evaluate the upset potential and subsequent recovery capability of a variety of airplanes penetrating the vortex system.

Andrews, W. H., Robinson, G. H. and Larson, R. R.

"EXPLORATORY FLIGHT INVESTIGATION OF AIRCRAFT RESPONSE TO THE WING VORTEX WAKE GENERATED BY JET TRANSPORT AIRCRAFT"

NASA TN D-6655, March 1972, NASA Flight Research Center, Edwards, CA

The effect of intercepting wing tip vortices generated by large jet transports, including jumbo jets, over separation distances from 1 nautical mile to 15 nautical miles is evaluated based on the response of a vortex probe airplane in the roll mode. The vortex probe test aircraft included a representative general aviation airplane, an executive jet, a fighter, and light and medium weight jet transports. The test conditions and airplane configurations were comparable to those normally used during takeoff, landing, or holding pattern operations. For flight safety the tests were performed at altitudes from 9500 feet to 12,500 feet. In addition to an evaluation of the probe airplane response, a flight test technique is suggested for determining minimum separation distance, using as variables the ratio of vortex-induced roll acceleration to maximum lateral control acceleration and the gross weight of the generating aircraft.

Andrews, W. H., Tymczyszyn, J. J., Jacobsen, R. A. and Drinkwater, F. J.

"FLIGHT INVESTIGATION OF THE RESPONSE OF WIDE-BODY TRI-JET TO THE WING VORTEX WAKE GENERATED BY LARGE TRANSPORT AIRCRAFT"

FWP-35, February 1973, NASA Flight Research Center, Edwards, CA

A flight test program was conducted which included a Lockheed C-5A and a McDonnell Douglas DC-10-40 airplane as the vortex wake generating airplanes. The vortex wake probe airplanes consisted of a DC-10-10, a DC-9-10, L-1011, and a Learjet-23. The data analysis was based on the probe airplane roll response resulting from the wake vortex of the generating airplane and the corresponding probe airplane lateral power available to oppose the induced vortex rolling moment.

Angelucci, S. B.

"A MULTIVORTEX METHOD FOR AXISYMMETRIC BODIES AT ANGLE OF ATTACK"

Journal of Aircraft, Vol. 8, No. 12, December 1971, pp. 959-966

A multi-vortex model made up of many discrete free vortices has been used to represent the actual vortex sheets shed from the lee side of a slender body at an angle of attack. Circulation, strength, and position of the vortices, together with the induced normal forces, are evaluated at various axial positions along the body axis. The viscous inputs to the analysis are the separation or feeding points which are provided by experiment or semi-empirical theories. A discussion of the numerical computations and a comparison with experimental data are presented.

Anmin, Q.

"NUMERICAL STUDY OF WAVE PROPAGATION ON VORTEX FILAMENTS"

Journal of Computational Physics, Vol. 104, 1993, pp. 185-210

Simulations of a vortex tube in unbounded, inviscid, incompressible fluid flow using three-dimensional vortex filament methods are presented. The numerical parameters that determine accuracy are investigated. Methods to deal with the truncated ends, which arise in the simulation of a part of a vortex tube, are developed. The non-monotonic response of the vortex filament evolution using the vortex method to variation of core size is observed. The effect of a small torsion of a wave on vortex stretching is discussed. The long-time propagation of a periodic wave of constant helical shape along a vortex tube is illustrated.

"WAKE TURBULENCE EVENT, SYDNEY AIRPORT, NSW, 3 NOVEMBER 2008"

Australian Transport Safety Report, Investigation AO-2008-077, November 2009.

On 3 November 2008, a SAAB Aircraft Company 340B-229, registered VX-ORX, was conducting a regular public transport flight from Orange, NSW to Sydney. The crew reported that at about 0724 Eastern Daylight-saving Time, when tracking to join a 7 NM (13 km) final for runway 34 Right (34R), a passenger sustained minor injuries following a possible wake turbulence event that resulted in a momentary loss of control of the aircraft. Examination of the available radar, meteorological and aircraft operational data identified that the momentary upset probably resulted from wake turbulence, which was generated by an Airbus Industrie A380-800 (A380) that was conducting a parallel approach to runway 34 Left (34L). There was a 35 kt left crosswind affecting both aircraft's approaches.

"STANDARDS DEVELOPMENT ACTIVITIES FOR USING NEAR REAL-TIME AIRCRAFT-DERIVED DATA IN FUTURE APPLICATIONS"

DO-360, RTCA, September 2015, RTCA, Washington, DC.

The Wake Vortex Tiger Team (WVTT) accomplished an extensive review of the current state of wake vortex research along with an assessment of current and planned wake vortex mitigation applications. Extensive domestic and international participation on the WVTT contributed to broad support of the Findings and Recommendations. In addition, the WVTT considered the needs of Air Traffic Management and weather applications, all of which will benefit from a rich environment of near real-time reporting from aircraft. The WVTT attempted to lay out a logical framework of Findings and Recommendations which can be acted upon, and believe there is much opportunity to improve the safety and efficiency of air traffic management systems in the future by incorporating more frequent and near real-time weather reports from aircraft.

"AVIATION INVESTIGATION REPORT: ENCOUNTER WITH WAKE TURBULENCE, AIR CANADA, A319-114, C-GBHZ, WASHINGTON STATE, UNITED STATES"

Report A08W0007, 2008, Transportation Safety Board of Canada, Ontario, Canada.

On 10 January 2008, the Air Canada Airbus A319-114 (registration C-GBHZ, serial number 0813), operating as flight ACA190, was en route from Victoria International Airport, British Columbia, to Toronto Lester B. Pearson International Airport, Ontario on a regularly scheduled flight with 83 passengers and 5 crew members on board. The aircraft was at flight level (FL) 350 and following a United Airlines Boeing 747-400, flight UAL896, in level cruise at FL 370 over the state of Washington, United States (U.S.). When separation had increased to 8.1 nautical miles (nm), with UAL896 in the lead, U.S. air traffic control cleared ACA190 to climb from FL 350 to its flight planned altitude of FL 370. At 0648 Pacific standard time, as ACA190 was climbing through FL 366, 10.7 nm behind UAL896, sharp jolts were felt in ACA190, followed by a series of rolls. During the roll oscillations, the aircraft continued the climb to FL 369 and then descended to FL 355, where the crew regained straight and level flight. The crew declared an emergency and diverted the flight to Calgary International Airport, Alberta where it landed uneventfully at 0728. Eight passengers and crew received minor injuries and three received serious injuries due to falls and collisions with aircraft furnishings.

"FAA REPORT ON AIRPORT CAPACITY, VOLUME II - EIGHT AIRPORT SURVEY"

FAA-EM-74-5, II, January 1974, FAA Office of Systems Engineering, Washington, DC.

This study analyzes the impact of FAA programs on airport capacity over the next ten years. The results are reported in two volumes. The first volume forms a summary of the findings of the study; the second volume presents the detailed examinations of each of the selected airports. Eight major airports (Atlanta, Chicago O'Hare, Denver, Los Angeles, Miami, New York Kennedy, Philadelphia, and San Francisco) were examined in detail. The study found that these programs will have substantial benefits at the airports surveyed. VFR capacities will increase about 25 percent over today, and IFR about 50 percent. A major requirement will be the metering and spacing and wake vortex avoidance systems programs. With these systems in place, IFR capacity will rise from its present level of 75 percent of VFR capacity to about 90 percent, thus increasing the ability to maintain sustained all-weather operations. If these improvements are achieved, no airport surveyed will in the long term (1979-82) experience peak hour VFR saturation, and only one airport is projected to experience peak hour IFR saturation.

"ENVIRONMENTAL FACTORS AFFECTING LOSS OF CONTROL IN-FLIGHT: BEST PRACTICE FOR THREAT RECOGNITION AND MANAGEMENT"

Report, International Air Transport Association, 2016, Montreal, Quebec, Canada.

In the IATA 2015 Safety Report, less than one tenth of accidents in the period 2011-2015 were categorized as Loss of Control (LOC-I) but approaching a half of all fatal accidents in the period were found to be LOC-I. Environmental threats were identified in a significant proportion of all LOC-I accidents and therefore a strong link can be drawn between environmental factors and fatal accidents. IATA has prepared this guidance material to bring together industry knowledge and identified best practices in a single document. For the purposes of the document the environmental factors to be considered are meteorological phenomena such as convective weather and the associated conditions, turbulence in clear air and turbulence from aircraft wake vortices.

"TECHNICAL SUPPORT PACKAGE FOR LAR-14568 OFF-SURFACE FLOW VISUALIZATION USING SULFUR HEXAFLUORIDE GAS AND INFRARED IMAGING"

NASA Langley research Center, TSP LAR-14568, 1993.

A new off surface flow visualization technique that consists of seeding the vortex (or other off-surface flow phenomenon) with a gas that has a strong infrared absorbing/emitting characteristic and then visualizing the flow with an IR imaging system is described. The example highlighted involves using sulfur hexafluoride gas entrained into a wing tip vortex. This gas has a strong absorption/emission characteristic in the 8 to 12 micrometer range, and therefore an IR imager of the same wavelength range is used to visualize the flow. The technique was illustrated on a NASA P-28 research aircraft.

"NTSB URGES GREATER SEPARATION FOR SOME AIRCRAFT BEHIND B-757's"

ITSA Report, Vol. 1, No. 1, March 1994

Greater separation distances have been recommended by the U.S. NTSB for following Boeing 757 s. This was precipitated by a series of accidents involving planes following B-757's on landing approaches. These accidents were caused by wake vortices. The new separation distances are greatest for very small aircraft and smallest for aircraft nearing the weight of 757's. The NTSB also called for: better and more established air traffic control procedures and information for pilots of B-757 and similar weight aircraft on proper flight path guidance during landing approaches; prohibition of visual approach clearances for IFR aircraft landing behind larger airplanes in the large or heavy category until the airplane is in-trail and the closure rate is such that the pilot can maintain the minimum IFR separation without excessive maneuvering; issuance of information by controllers to VFR landing aircraft about wake turbulence, name of aircraft manufacturer and model, separation distance, and other data relevant to wake turbulence avoidance; and expanded training and information for controllers and pilots about the wake vortex problem and avoidance procedures.

Anon.

"LASER RADAR SCANS THE SKY"

Design Engineering, July/August 1997, pp. 17-18.

Discusses the use of laser radar in the study and monitoring of the wake vortex produced by an aircraft. The research work about vortices by DERA/Malvern at Heathrow Airport is described.

Anon.

"AVOIDING WAKE TURBULENCE"

Flight Deck, Issue 31, Spring 1999, pp. 40-45.

The FAA has issued a 'Wake Turbulence Training Aid' manual. This training resource was developed to reduce the number of wake turbulence accidents and incidence. The newly revised data and procedures should be useful to pilots.

"TECHNICAL CONFERENCE ON THE EFFECTS OF HELICOPTER DOWNWASH ON FREE PROJECTILES"

U.S. Army Aviation Systems Command, St. Louis, MO, November 1975

Proceedings of a conference on the effects of helicopter downwash on free projectiles. A chronological bibliography on rotor downwash from 1922 to 1975 is included.

Anon.

"LONDON CITY AIRPORT WAKE TURBULENCE STUDY"

Final Report, December 2010, Halcrow Group Limited, London, England.

The purpose of this study is to satisfy obligations in the Agreement which accompanies the planning permission granted by the London Borough of Newham (LBN) on 9 July for an increase in permitted annual aircraft movements to 120,000. The planning agreement requires London City Airport to submit a Wake Turbulence Study to LBN. The purpose of the study is to investigate any damage arising to buildings around the Airport because of wake turbulence, together with recommendations to address each damage or the risk of such damage and procedures that should be adopted to handle any claims for compensation arising from such damage. Because damage has only been reported at one location near the Airport the assessment of risk must be based on a combination of empirical research and experience from airports with a record of turbulence damage. The sensitivity of the issue makes access to data on vortex damage incidence at other airports difficult. Studies have therefore had to rely on sources in the public domain, including industry and academic research, public inquiry evidence, and airport publications such as consultative committee minutes.

"WAKE VORTEX CAPACITY BENEFITS FOR SIMULTANEOUS APPROACHES AT ST. LOUIS AIRPORT"

FTA-TM-506-1, June 1994, Flight Transportation Associates, Inc., Cambridge, MA

This paper details the results of FTA's investigation into the potential capacity gains of applying 1.5 nautical mile (NM) diagonal separation between parallel arrival operations at St. Louis Lambert International Airport (STL). Currently, dependent parallel arrivals are permitted only when runways are separated by 2,500 feet or more due to concern over wake vortex turbulence. If conditions exist which eliminate or reduce this effect, the application of diagonal separation may be permitted between runways separated by less than 2,500 feet. A similar study was completed for Boston's Logan International Airport and much of the material in this memorandum reflects the previous Logan analysis. The way the runways are used is dependent upon several factors including weather, traffic demand, and the type of aircraft operation (e.g. jet versus propeller). Information on STL operations was obtained from the STL Tower and the Air Traffic Division of the FAA Central Region Office.

"WAKE VORTEX LIDAR SYSTEM REPORT AND DOCUMENTATION: THE AVOSS DEMONSTRATION AT DALLAS/FORT WORTH INTERNATIONAL AIRPORT JUNE-JULY 2000"

RTI/7473/1002-03, Research Triangle Institute, Raleigh-Durham, N. C., October 2000

In response to the reduced spacing operations element of the NASA Terminal Area Productivity program, the Wake Vortex Lidar (WVL) at NASA Langley Research Center (LaRC) has developed and extensively field-tested an experimental 2-micron 100 Hertz ground-based pulsed coherent lidar system for aircraft wake vortex and turbulence detection. The goal of the project is to provide wake vortex and atmospheric wind measurement support to the Aircraft Vortex Spacing System (AVOSS). The WVL Project developed a detection system that supported the wake vortex detection and weather measurement functions of AVOSS.

Anon.

"VORTEX RESEARCH BUILDS"

Jane's Airport Review, Vol. 6, No. 7, September 1994, pp. 60-61

The National Aeronautics and Space Administration (NASA), in conjunction with the FAA, is conducting an aggressive wake vortex research program related to the Terminal Area Productivity Program. According to the director of the NASA program, the purpose is to increase airport capacity by accurately predicting safe separation distances using real-time data of atmospheric conditions and data specific to the airplane model.

Anon.

"RUSSIANS HELP CANADA PREDICT WAKE TURBULENCE"

Aviation Week & Space Technology, Vol. 140, No. 6, 7 February 1974, p. 24

Transport Canada is working with a Russian institute to perfect computer software designed to predict where wake turbulence vortices will move on an airfield. The objective of the project is to shift a Russian developed computer model onto western digital computers to see if a real-time predictive system could be developed for certification and use at airports.

"WAKE TURBULENCE TRAINING PROGRAMME IS DESIGNED TO EDUCATE BOTH PILOTS AND AIR TRAFFIC CONTROLLERS"

Boeing Aero, December 1995, pp. 23, 29

A Boeing-led team, under the sponsorship of the Air Transport Association of America (ATA) and in conjunction with the U.S. Department of Transportation, completed development of the industry's most authoritative and extensive wake turbulence training aid in April 1995. Designed to educate both pilots and air traffic controllers, the informative training aid focuses on procedures that can help in avoiding encounters with wake turbulence.

"DOCUMENTATION FOR THREE WAKE VORTEX MODEL DATA SETS FROM SIMULATION OF FLIGHT 587 WAKE VORTEX ENCOUNTER ACCIDENT CASE"

RTI/8438/006/-02F, January 2003, RTI International, Research Triangle Park, NC.

This document contains a general description for data sets of a wake vortex system in a turbulent environment. The turbulence and thermal stratification of the environment are representative of the conditions on November 12, 2001 near John F. Kennedy International Airport. The simulation assumes no ambient winds. The full three-dimensional simulation of the wake vortex system from a Boeing 747 predicts vortex circulation levels at 80 percent of their initial value at the time of the proposed vortex encounter. The linked vortex oval orientation showed no twisting, and the oval elevations at the widest point were about 20 meters higher than where the vortex pair joined. Fred Proctor of NASA's Langley Research Center presented the results of this work at the NTSB public hearing that started 29 October 2002. This document contains a description of each data set including: variables, coordinate system, data format, and sample plots. Also included are instructions on how to read the data.

"IN-FLIGHT SEPARATION OF VERTICAL STABILIZER, AMERICAN AIRLINES FLIGHT 587 AIRBUS INDUSTRIE A300-605R, N14053, BELLE HARBOR, NEW YORK, NOVEMBER 12, 2001"

NTSB/AAR-04-04, 2004, National Transportation Safety Board, Washington, DC.

This report explains the accident involving American Airlines flight 587, an Airbus Industrie A300-605R, N14053, which crashed into a residential area of Belle Harbor, New York, following the in-flight separation of the airplane's vertical stabilizer and rudder. The safety issues discussed in this report focus on characteristics of the A300-600 rudder control system design, A300-600 rudder pedal inputs at high airspeeds, aircraft-pilot coupling, flight operations at or below an airplane's design maneuvering speed, and upset recovery training programs. Safety recommendations concerning these issues are addressed to the Federal Aviation Administration and the Direction General de l'Aviation Civile.

Anon.

"WAKE VORTEX MINIMIZATION"

NASA SP-409, 1977, NASA Headquarters, Washington, DC

The purpose of this conference is to present a status report on research directed at reducing the disturbances to the air behind aircraft as they fly through the atmosphere. The objective of such a reduction is to minimize the hazard to smaller aircraft that might encounter these wakes. The general guidelines given this research are that natural atmospheric motions be assumed negligible so that the alleviation schemes will be effective on calm days when the wakes are believed to be most persistent. A further restriction is that the alleviation is to be achieved by aerodynamic means, hopefully to be accomplished by changes on the wake-generating aircraft that are easy to retrofit onto existing aircraft.

Anon.

"ENGINEERING AND DEVELOPMENT PROGRAM PLAN - WAKE VORTEX"

FAA-ED-21-1A, 1977, FAA, Washington, DC

This Engineering and Development Program Plan defines the current research efforts investigating the wake vortex phenomenon. The overall objectives of the program are the design, development, testing, and prototyping of a system(s) to increase runway capacity by minimizing wake vortex effects as an impediment to efficient and effective traffic management in the terminal environment. The plan identifies and discusses the three major work areas: Vortex Advisory System, Wake Vortex Avoidance System, and Vortex Alleviation Research. Prior developments and related research are reviewed and future research requirements identified.

"AIRCRAFT ACCIDENT REPORT - AIR PENNSYLVANIA 501, PIPER PA-31-350, N5MS, PHILADELPHIA, PENNSYLVANIA, JULY 25, 1980"

NTSB AAR-81-1, January 1981, NTSB, Washington, DC

On July 25, 1980, at 0713, Air Pennsylvania 501, a Piper PA-31-350 Navajo aircraft, crashed while making a visual approach to runway 27R at Philadelphia International Airport, Pennsylvania. The aircraft, a scheduled commuter flight from Reading, Pennsylvania, arrived in the Philadelphia Approach Control area as a VFR 'pop-up' flight and was sequenced to land behind United Flight 555, a Boeing 727 IFR arrival, on runway 27R. Witnesses stated that, when Flight 501 was about 1/2 mile on final approach, it rolled from side to side, pitched up, rolled inverted to the left, and flew into the ground nose first. All three persons aboard the aircraft were killed and the aircraft was destroyed. The National Transportation Safety Board determines that the probable cause of the accident was the loss of aircraft control due to an encounter with wake turbulence from the preceding aircraft at an altitude too low for recovery and the pilot's failure to follow established separation and flightpath selection procedures for wake turbulence avoidance.

Anon.

"SAFETY ISSUES RELATED TO WAKE VORTEX ENCOUNTERS DURING VISUAL APPROACH TO LANDING"

NTSB/SIR-94-01, February 1994, NTSB, Washington, D.C

The Safety Board conducted a special investigation to examine in detail the circumstances surrounding five recent accidents and incidents in which an airplane on approach to landing encountered the wake vortex of a preceding Boeing 757. Thirteen occupants died in two of the accidents. The encounters, which occurred during visual conditions, were severe enough to create an unrecoverable loss of control for a Cessna Citation, a Cessna 182, and an Israel Aircraft Industries Westwind. Additionally, there were significant but recoverable losses of control for a McDonnell Douglas MD-88 and Boeing 737 (both required immediate and aggressive flight control deflections by their flight crews). The safety issues discussed in this special investigation report are: the adequacy of the current aircraft weight classification scheme to establish separation criteria to avoid wake vortex encounters, the adequacy of air traffic control procedures related to visual approaches and visual flight rules operations behind heavier airplanes, pilot knowledge related to the avoidance of wake vortices, and the lack of available data to analyze the history of wake vortex encounters in the United States. Recommendations concerning these issues were made to the Federal Aviation Administration.

Anon.

"BOEING 757 WAKE TURBULENCE: A REVIEW OF THE ACTIONS OF THE FEDERAL AVIATION ADMINISTRATION"

DOT Office of the Secretary of Transportation, July 1994

On June 10, 1994, Secretary of Transportation Federico Pena and FAA Administrator David Hinton directed a review of the FAA's actions regarding wake turbulence associated with the Boeing 757. This was in response to public concern regarding the timeliness of the agency's actions in this area over the past several years. This was not a technical review of wake vortex research, air traffic control procedures, National Transportation Safety Board recommendations, or B757 wake vortices. The review instead focused on responses to issues raised by the B757 wake vortex and on the decision-making processes used by the agency in dealing with these issues.

Anon.

"WAKE TURBULENCE TRAINING AID"

DOT/FAA/RD-95/6, April 1995, DOT Volpe National Transportation Systems Center, Cambridge, MA

The goal of the Wake Turbulence Training Aid is to reduce the number of wake turbulence related accidents and incidents by improving the pilot's and air traffic controller's decision making and situational awareness through increased and shared understanding and heightened awareness of the factors involved in wake turbulence. The major three objectives of the Wake Turbulence Training Aid are: (1) to educate pilots and air traffic controllers on wake turbulence and avoidance of the phenomenon; (2) to increase the wake-turbulence situational awareness of pilots and air traffic controllers; and (3) to provide usable information to develop a ground training program.

"VORTEX WAKE TURBULENCE - FLIGHT TESTS CONDUCTED DURING 1970"

FAA-FS-71-1, February 1971, FAA/NASA/Boeing Task Force, Washington, DC

The summary report covers the 1970 flight test program conducted by the Federal Aviation Administration in joint participation with the National Aeronautics and Space Administration and the Boeing Company. The objective was to update the interim air traffic separation standards issued on 21 January 1970 restricting the airspace behind the B-747 and C-5A aircraft. Flight tests were conducted at three locations: At Edwards Air Force Base, a CV-990 and F-104 probed the vortices of a C-5A. At Seattle, a B-707 and B-737 and F-86 probed the vortices of a B-747. In addition, approach, landing, takeoff, and crossing runway tests were conducted with a B-737 trailing a B-747. At Idaho Falls, aircraft were flown past an instrumented tower to obtain measurements of vortex core diameters and tangential velocities.

"FAA SYMPOSIUM ON TURBULENCE"

Federal Aviation Administration, Washington, DC, March 1971

The Federal Aviation Administration sponsored Symposium on Turbulence was conducted in Washington, DC, 22-24 March 1971. Subjects covered at the Symposium included wake turbulence, clear air turbulence, wind shear, upsets, thunderstorms, and turbulence plotting.

Anon.

"A LASER-TELESCOPE SYSTEM TO ENHANCE AIRPORT SAFETY"

Optical Spectra, September 1971, p. 12

A pulsed argon laser with two reflecting telescopes is being used to develop techniques for measuring the velocities of vortices generated by jet aircraft. Preliminary results indicate the feasibility of applying the newly developed doppler shift technique to airport use.

Anon.

"ENGINEERING AND DEVELOPMENT PROGRAM PLAN: AIRCRAFT WAKE VORTEX AVOIDANCE SYSTEM"

FAA-ED-21-1, February 1973, Federal Aviation Administration, Washington, DC

Efforts to develop a Wake Vortex Avoidance System (WVAS) are discussed. The basic objective of the program is the design of a system to increase runway capacity by removing the capacity-restrictive

large spacings now required between aircraft to avoid wake vortex hazards. These large spacings will be replaced by separations tailored to aircraft type and prevailing meteorological conditions. In addition, by using vortex sensors, safety will be increased in the terminal area by warning of the existence of vortices in the aircraft approach and departure paths. The program consists of three major task areas: sensor development, vortex behavior, and hazard definition. These tasks will be integrated into an overall system design. Although the program will require up to five years to complete, interim capabilities specifically directed toward safety will be available in useable form in advance of the completion date.

Anon.

"AIR VORTEX WAKES AND THEIR CAUSE"

NASA-TT-F-14288, June 1972, Scientific Translation Service, Santa Barbara, CA

The dangers of air vortex wakes caused by jumbo jets such as the B-747 to air traffic are discussed. The effects of these wakes on other aircraft is described and safety measures are presented.

Anon.

"VORTEX HAZARD INDEX"

FAA Compilation of Working Papers Concerning Wake Turbulence Tests, April 1970

Equations are proposed for determining the vortex hazard index for the encountering aircraft. Equations are developed for calculating the vortex strength when the aerodynamic and inertia characteristics of the probe aircraft are known. It is concluded that further data is required to clarify the effect of the span of the encountering aircraft.

Anon.

"SYMPOSIUM ON AIRCRAFT WAKE TURBULENCE"

D1-82-0993, September 1970, Boeing Scientific Research Labs., Seattle, WA

Session topics: Fundamental problems; experimental methods; flow visualization, presentations, and results; wake formation and character; stability and decay of trailing vortices; aircraft response to wake turbulence; and control and use of trailing vortices.

Anon.

"AIRCRAFT ACCIDENT REPORT: DELTA AIR LINES, INC., MCDONNELL DOUGLAS DC-9-14 N3305L, GREATER SOUTHWEST INTERNATIONAL AIRPORT, FORT WORTH, TEXAS, 30 May 1972"

NTSB-AAR-73-3, March 1973, NTSB, Washington, DC

The crash of a DC-9 aircraft at Fort Worth, Texas airport on 30 May 1972 is reported. The crash occurred during an attempted go-around following a landing approach. The landing approach was normal, but the aircraft began oscillating after passing the runway threshold and finally struck the runway in an extreme right wing low attitude. It was determined that the cause of the accident was an encounter with a trailing vortex generated by a large jet aircraft which preceded the DC-9 to the runway.

"SUBSONIC LIFT-DEPENDENT DRAG DUE TO THE TRAILING VORTEX WAKE FOR WINGS WITHOUT CAMBER OR TWIST"

ESDU-AERO-W.02.01.02, October 1974, Engineering Science Data Unit, London, England

A numerical expression for the lift-dependent drag coefficient due to the wing trailing vortex wake at subsonic speeds is derived. The data apply to unencumbered untwisted wings with straight leading and trailing edges and streamwise tips. The theory from which the data were obtained is linearized and relates to inviscid flow. Additional mathematical relationships are developed for wings with different planforms. Graphs of the drag coefficient for various wing shapes and airspeed conditions are provided.

Anon.

"VORTEX WAKES OF LARGE AIRCRAFT"

American Institute of Aeronautics and Astronautics, New York, NY, 1974

The aircraft trailing vortex problem is examined along with the behavior of vortex systems, rapid scanning three-dimensional hot-wire anemometer surveys of wing-tip vortices, axial flow in trailing line vortices, stability theory for a pair of trailing vortices, and studies of the stability of a vortex pair. Other subjects considered are related to flight test studies of the formation and dissipation of trailing vortices, aircraft wake dissipation by sinusoidal instability and vortex breakdowns, observations of atmospheric effects on vortex wake behavior, the decay of an isolated vortex, and the relationship between eddy transport and second-order closure models for stratified media and for vortices.

"BIG PLANE TURBULENCE CAN CAUSE A FLIGHT HAZARD"

Safety Suggestions, No. 8, 1952, Beech Aircraft Corp., Wichita, KS.

A collection of pilot reports discussing experience pilots may have had in encountering turbulence in landing behind large aircraft. The reports comment on: what causes the hazard, what type of airplanes do the vortices affect, and what types of planes are reported to have caused the turbulence.

Anon.

"A PRELIMINARY STUDY OF THE EFFECT OF JET BLAST OR WAKE ON OTHER AIRCRAFT"

Beech Aircraft Corp., Wichita, KS, July 1955

This is a summary report of an industry survey of available technical information of the potential hazards of encountering the blast and/or wake of a preceding or passing jet aircraft and similar propeller-driven aircraft.

Anon.

"COMPILATION OF WORKING PAPERS CONCERNING WAKE TURBULENCE TESTS"

Federal Aviation Administration, Washington, DC, April 1970

The compilation contains four papers: (1) Flight-Test Evaluation of the Wing Vortex Wake Generated by Large Jet-Transport Aircraft by Andrews, Robinson, Krier and Drinkwater of NASA; (2) Results of the Boeing Company Wake Turbulence Test Program by Condit of Boeing; (3) Measurements of the Vortex Wake Characteristics of the Boeing 747, Lockheed C-5A, and Other Aircraft, data report by Garodz of DOT; and (4) Vortex Hazard Index.

Anon.

"WAKE TURBULENCE IS DANGEROUS"

Aviation Safety Digest Publication, Dept. of Civil Aviation, Melbourne, Australia, 1970

The hazards posed by wing tip vortices of large aircraft to light aircraft taking off or landing are discussed. Examples and illustrations of the phenomena are given. Flight rules are suggested for light aircraft to prevent accidents. These rules include: avoidance of flight below and behind large aircraft on takeoff, starting the takeoff run from the end of the runway to be airborne before the point where heavy aircraft have lifted off, and maintaining an above and beyond position during final landing approach. Air traffic control procedures are also discussed.

Anon.

"AIR VORTEX WAKES AND THEIR CAUSE"

Verband Deutscher Flugleiter E. V., 1971

The dangers of air vortex wakes caused by jumbo jets such as the B-747 to air traffic are discussed. The effects of these wakes on other aircraft is described and safety measures are presented.

Anon.

"AIRCRAFT WAKE TURBULENCE"

FAA Advisory Circular No. 90-23E, October 1991

The Advisory Circular alerts pilots to the hazards of aircraft trailing vortex and wake turbulence, and recommends related operational procedures.

"VORTEX PROBE FLIGHT TEST (B-767 AIRCRAFT)"

Wake Vortex Research Data Package No. FAA/ACD-1, Feb. 1991, FAA Technical Center, Atlantic City Int'l Airport, NJ.

This document contains the processed data from probe testing of wake vortices of a Boeing 767 aircraft conducted during a 1990 fall series of flight tests. These tests were held at the NOAA test facility located near Idaho Falls, Idaho; also shown are the flight paths used for the test aircraft. Described herein are the aircraft and equipment used, in addition to the techniques for data collection and analysis. A representative set of data is also provided consisting of probe aircraft data, both instrumented (data collection and video) and knee-pad and chase aircraft data (video). Although no flow visualization was available for the testing, several vortex encounters were experienced by the probe aircraft, one of which was considered significant and is the subject of this data package.

Antkowiak, A. and Brancher, P.

"TRANSIENT ENERGY GROWTH FOR THE LAMB-OSEEN VORTEX"

Physics of Fluids, Vol. 16, No. 1, January 2004, pp. L1-L4

The transient evolution of infinitesimal flow disturbances which optimally induce algebraic growth in the Lamb-Oseen (Gaussian) vortex is studied using a direct-adjoint technique. This optimal perturbation analysis reveals that the Lamb-Oseen vortex allows for intense amplification of kinetic energy for two-dimensional and three-dimensional perturbations of azimuthal wavenumber $m = 1$. In both cases, the disturbances experiencing the most growth initially take the form of concentrated spirals at the outer periphery of the vortex which rapidly excite bending waves within the vortex core. In the limit of large wavelengths, the optimal perturbation leads to arbitrarily large growths via an original scenario combining the Orr mechanism with vortex induction.

Antkowiak, A. and Brancher, P.

"ON VORTEX RINGS AROUND VORTICES: AN OPTIMAL MECHANISM"

J. Fluid Mech., Vol. 578, 2007, pp. 295-304

Stable columnar vortices subject to hydrodynamic noise (e.g. turbulence) present recurrent behaviors, such as the systematic development of vortex rings at the periphery of the vortex core. This phenomenon lacks a comprehensive explanation, partly because it is not associated with an instability *stricto sensu*. The aim of the present paper is to identify the physical mechanism triggering this intrinsic feature of vortices using an optimal perturbation analysis as a tool of investigation. We find that the generation of vortex rings is linked to the intense and rapid amplification of specific disturbances in the form of azimuthal velocity streaks that eventually evolve into azimuthal vorticity rolls generated by the rotational part of the local Coriolis force. This evolution thus appears to follow a scenario opposite to the classical lift-up view, where rolls give rise to streaks.

Antonov, V. A., Baranov, A. S. and Kondrat'ev, B. P.

"LOCAL VORTICES IN A DIFFERENTIALLY ROTATING FLOW"

Fluid Dynamics, Vol. 40, No. 1, 2005, pp. 71-82.

A time-dependent local elliptic vortex in a differential two-dimensional incompressible fluid flow is considered. Nonlinear oscillations of vortices of the cyclonic and anticyclonic types are described. It is found that the evolutionary tracks can be both closed and unclosed. The former corresponds to the azimuthal oscillations of the principal axis and the latter to the complete rotational state of the elliptic vortex. Steady-state solutions are also obtained; they are represented by ellipses elongated or compressed along the flow. Small oscillations of the vortex equilibrium figures are investigated and a general dispersion relation for arbitrary perturbations is derived. The stability criterion is found.

Anusonti-Inthra, P. and Floros, M.

"COUPLED CFD AND PARTICLE VORTEX TRANSPORT METHOD: WING PERFORMANCE AND WAKE VALIDATIONS"

AIAA Paper 2008-4177, June 2008, Seattle, WA

The development of a new hybrid CFD approach using fully coupled Reynolds-Averaged Navier-Stokes (RANS) and Particle-based Vorticity Transport Method (PVTM) solvers is summarized in this paper. The methodology is applied to predict the performance and wake parameters of an isolated wing in low-speed flow condition. The approach divides the flow field into several regions and uses appropriate flow solvers according to the dominant physical features of the flow in each region. The near body flow field, which is dominated by the effect of viscosity and geometry, is resolved using a 3D compressible RANS solver. The flow field outside of the RANS regions, which is primarily dominated by the vortices being shed from aerodynamic surfaces, is simulated using a viscous implementation of the PVTM method. The results obtained using the coupled RANS/PVTM analysis compare well with experimental

data, in particular the pressure distribution, sectional load, and tip vortex parameters (swirl velocity, core location, and core size).

Aono, H., Shyy, W. and Liu, H.

"NEAR WAKE VORTEX DYNAMICS OF A HOVERING HAWKMOTH"

Acta Mechanica Sinica, Vol. 25, No. 1, 2009, pp 23-36.

Investigation of vortex dynamics in near wake of a hovering hawkmoth and hovering aerodynamics is conducted to support the development of a biology-inspired dynamic flight simulator for flapping wing-based micro air vehicles. Realistic wing-body morphologies and kinematics are adopted in the numerical simulations. The computed results show 3D mechanisms of vortical flow structures in hawkmoth-like hovering. A horseshoe-shaped primary vortex is observed to wrap around each wing during the early down- and upstroke; the horseshoe-shaped vortex subsequently grows into a doughnut-shaped vortex ring with an intense jet-flow present in its core, forming a downwash. The doughnut-shaped vortex rings of the wing pair eventually break up into two circular vortex rings as they propagate downstream in the wake. The aerodynamic yawing and rolling torques are canceled out due to the symmetric wing kinematics even though the aerodynamic pitching torque shows significant variation with time. On the other hand, the time-varying aerodynamics pitching torque could make the body a longitudinal oscillation over one flapping cycle.

Appleman, H.

"THE FORMATION OF EXHAUST CONDENSATION TRAILS BY JET AIRCRAFT"

Bulletin American Meteorological Society, Vol. 34, No. 1, January 1953, pp. 14-20.

This paper defines the meteorological state of the atmosphere which will give rise to the formation of condensation trails (contrails) as the exhaust from an aircraft engine mixes with and saturates the environment. Three basic assumptions were made with regard to the formation of visible contrails: (1) contrails are composed of ice crystals; (2) water vapor cannot be transformed into ice without first passing through the liquid phase, thus necessitating an intermediate state of saturation with respect to water; (3) a minimum visible water content of 0.004 gm per square m is required for a faint trail and 0.01 gm per square m for a distinct trail. This last requirement proved of no importance in determining whether a trail would form, but did affect its persistence. Curves were constructed showing the critical temperature for the formation of a visible trail as a function of the pressure and relative humidity of the environment and the amount of air entrained into the exhaust. It is shown that these curves are applicable to any aircraft which has the same water to heat ratio in its exhaust as the case discussed in this report. In general, this ratio is fairly constant regardless of the type of airplane, control settings, or fuel. The major exception occurs with aircraft powered by reciprocating engines in which case a considerable portion of the heat produced may be dissipated outside of the trail. A separate, but similar, study would be necessary for each aircraft with a significantly different proportion of such heat loss.

"HIGH-ORDER COMPACT DIFFERENCE SCHEME APPLIED TO DOUBLE-DELTA WING VORTICAL FLOWS"

Journal of Aircraft, Vol. 41, No. 4, July-August 2004, pp. 953-956

The sixth-order compact difference scheme was applied to the flow simulation over a double-delta wing and accuracy was investigated. The scheme captured two vortices without excessive dissipations, and the secondary separation vortex near the leading edge is also properly evaluated. The resulting pressure distributions on the wing showed much better agreement with the experiment than those by use of Roe's third-order scheme. The remaining problem is the accuracy of the vortex-merging location, and further investigations are necessary to improve the reliability of the simulations.

Arcas, D. R. and Redekopp, L. G.

"ASPECTS OF WAKE VORTEX CONTROL THROUGH BASE BLOWING/SUCTION"

Physics of Fluids, Vol. 16, No. 2, February 2004, pp. 452-456

Numerical simulations are used to explore the effect of blowing/suction on the characteristics of vortex shedding from a plane forebody with a rectangular base. The distribution of blowing/suction is varied to assess its role in either enhancing or suppressing the strength of shed vortices in the wake. It is shown that the amplitude of vortices in the near wake, and the required fluxes to suppress vortex shedding, scale differently depending on whether the control is exercised with blowing or with suction. These differences are rationalized in terms of local instability properties of mean velocity profiles in the near wake.

Ardonceanu, P. and Amani, G.

"REMARKS ON THE RELATION BETWEEN LIFT INDUCED DRAG AND VORTEX DRAG"

European Journal of Mechanics, B/Fluids, Vol. 11, No. 4, 1992, pp. 455-460

Among the numerous concepts which emerge from a drag analysis, some are mathematically well-defined, such as the pressure drag or the friction drag. Others of great practical interest often have a somewhat hazy definition for a real viscous fluid. The relation between the so-called 'vortex-drag' and 'lift-induced drag' is pointed out in a recent paper [Chometon and Laurent, 1990]. This short note is intended to give further clarification of the subject and some results from a relevant experimental investigation are presented. It is pointed out that the momentum balance in the wake of a lifting wing gives a correct estimate of the lift induced drag, provided that the survey area is large enough to include all the vortex energy.

Aref, H.

"VORTEX DYNAMICS OF WAKES"

Nelineinaga Dinamika, Vol. 2, No. 4, 2006, pp. 411-424.

Several problems related to the dynamics of vortex patterns as observed in wake flows are addressed. These include: The universal Strouhal-Reynolds number relation. The Hamiltonian dynamics of point vortices in a periodic strip, both the classical two-vortices-in-a-strip problem, which gives the structure and self-induced velocity of the traditional vortex street, and the three-vortices-in-a-strip problem, which is argued to be relevant to the wake behind an oscillating body. The bifurcation diagram for wake structure found experimentally by Williamson and Roshko is addressed theoretically.

Aref, H., Brens, M. and Stremler, M. A.

"BIFURCATION AND INSTABILITY PROBLEMS IN VORTEX WAKES"

Second International Symposium on Instability and Bifurcation in Fluid Dynamics, August 2006, Technical University of Denmark, Copenhagen; Journal of Physics: Conference Series, Vol. 64, 2007, 01205.

A number of instability and bifurcation problems related to the dynamics of vortex wake flows are addressed using various analytical tools and approaches. We discuss the bifurcations of the streamline pattern behind a bluff body as a vortex wake is produced, a theory of universal Strouhal-Reynolds number relation for vortex wakes, the bifurcation diagram for 'exotic' wake patterns behind an oscillating cylinder first determined experimentally by Williamson and Roshko, and the bifurcations in topology of the streamlines pattern in point vortex sheets. The Hamiltonian dynamics of point vortices in a periodic strip is considered. The classical results of von Karman concerning the structure of the vortex sheet follow from the two-vortices-in-a-strip problem, while the stability results follow largely from a four-vortices-in-a-strip analysis. The three-vortices-in-a-strip problem is argued to be relevant to the wake behind an oscillating body.

Aref, H., Stremler, M. A. and Ponta, F. L.

"EXOTIC VORTEX WAKES - POINT VORTEX SOLUTIONS"

Journal of Fluids and Structures, Vol. 22, Issues 6-7, August-October 2006, pp. 929-940.

Von Karman was the first to present a quantitative model of the 'vortex street' wake as a double row of point vortices, to determine which configurations propagate in the direction of the rows, and to consider the linear stability theory for such states. In the early literature one works with infinite rows of vortices. The vortex street is assumed to continue to infinity both upstream and downstream. Another analytical approach is to use periodic boundary conditions in the direction of the wake. This representation was used by Domm in his analysis of the instability of the Karman vortex street. Birkhoff and Fisher in 1959 were the first to treat vortices in a periodic strip as a dynamical system in its own right. We have used the periodic system to address problems of vortex wake patterns, in

particular vortex wakes that are more complicated than the traditional two-vortices-per-strip configurations. We use the term 'exotic' for such wakes. We submit that this approach can yield a number of insights, including results of direct relevance to experiments, in the same sense that von Karman's analysis has been helpful to the understanding of the regular vortex street wake, and we present the results obtained to date following this program.

"A DISCRETE VORTEX MODEL FOR PREDICTING WING ROCK OF SLENDER WINGS"

AIAA Paper No. 1992-4497, August 1992, Hilton Head, SC.

An unsteady, discrete vortex model has been developed in order to identify the fluid mechanisms responsible for generating wing rock of slender, sharp-edged delta wings. The solution of the unsteady flow field is coupled with the rigid body equation of motion in roll to allow for self-induced oscillations. The model has qualitatively captured all the primary flow field and motion characteristics observed in experiment. Combination of experimental and computational results indicate that wing rock is sustained by a lag in the position of the leading-edge vortices normal to the surface. Damping necessary to obtain a limit cycle is provided by rate dependent damping on the bottom surface of the wing, and damping 'lobes' generated by unsteady behavior of vortex strength.

"DEVELOPMENT OF A FIBER BASED EYE SAFE COHERENT WIND LIDAR SYSTEM FOR URBAN WIND FIELD MEASUREMENTS"

Proceedings of the SPIE, Vol. 7832, October 2010, pp. 783206-1 to 783206-6.

A compact coherent wind lidar system has been developed and is being tested in an urban environment. We use polarization maintaining fiber throughout the system to improve the stability of the heterodyne detected return signal. The 1.54-micron transmitter is designed using a master oscillator and pulsed power amplifier configuration. The receiver is operated in a coaxial arrangement and balanced detection is employed to reduce the effects of relative intensity noise, allowing for operation in the shot noise limited region. Development and verification of the lidar system is enhanced by taking advantage of a set of ground based sodar, radar wind profiler and building top anemometers that are part of the New York City Meteorological Network. Operation in a coastal urban environment with a complex terrain such as New York City requires that the system be flexible enough to allow for adjustable operating conditions, tunable signal processing algorithms and user defined data products, so that the optimal performance can be chosen with a variety of practical applications in mind.

Arend, M., Campmier, M., Fernandez, A. and Moshary, F.

"APPLICATION OF LIDAR AND OTHER PROFILING TECHNIQUES TO STUDY THE IMPACT THAT SEVERE WEATHER HAZARDS HAVE ON THE NEW YORK CITY BUILT ENVIRONMENT"

28th International Laser Radar Conference, June 2017, Bucharest, Romania, published in EPJ Web of Conferences, Vol. 176, 2018, pp. 06003-1 to 06003-4.

The complexity of urban boundary layer dynamics poses challenges to those responsible for the design and regulation of buildings and structures in the urban environment. Lidar systems in the New York City Metropolitan region have been used extensively to study urban boundary layer dynamics. These systems, in conjunction with other sensing platforms can provide an observatory to perform research and analysis of turbulent and inclement weather patterns of interest to developers and agencies.

"PARTICLE IMAGE VELOCIMETRY MEASUREMENTS OF VORTEX RINGS HEAD-ON COLLISION WITH A HEATED VERTICAL PLATE"

Physics of Fluids, Vol. 22, 2010, pp. 053604-1 - 053604-8.

We report particle image velocimetry measurements of the collision of a vortex ring with a heated wall kept at a constant temperature. We consider the case when both the vortex ring and the thermal boundary layer generated by the vertical heated wall are stable and laminar prior to any interaction. The impingement process can be divided into two parts. (i) A ring-driven stage, where the vortex ring grows in diameter while approaching the wall and therefore it sweeps progressively an increased surface on the wall. (ii) A boundary layer-driven stage, where the vortex ring moves upward due to the thermal convective motion generated by the heated wall. In some cases, the head-on collision triggers the ring's azimuthal instability as revealed by the formation of vortical structures arranged on a wavy starlike pattern and confirmed by flow visualization. A single collision generates important velocity gradients and shear stresses along the wall accompanied with the creation of local vorticity normal to the vertical heated wall. Peak wall shear stresses occur near the point of impact of the vortex ring core.

"TEMPERATURE PROFILES BY GROUND-BASED REMOTE SENSING AND IN SITU MEASUREMENTS"

14th International Symposium for the Advancement of Boundary Layer Remote Sensing, published in IOP Conf. Series: Earth and Environmental Science, Vol. 1, 2008, pp. 012025-1 - 012025-9.

This study focuses on the accuracy of the temperature profiles measured with a Doppler Radio-Acoustic Sounding System and a Microwave Temperature Profiler during a period of about 3 months in winter 2007-2008. The experiment was carried on at the experimental facility of the Institute of Atmospheric Sciences and Climate (ISAC) of the Italian National Research Council (CNR). The temperature data measured with remote sensors were verified with in situ measurements on a mast as

well as with tethered balloon data. The facimile echograms obtained with the ISAC Doppler SODAR were analyzed to understand to which extent the RASS and Radiometer temperature profiles behavior can represent the real thermal structure of the atmosphere.

Ariyur, K. B.

"PREDICTION OF DYNAMIC GROUND EFFECT THROUGH MODIFIED LIFTING LINE THEORY"

AIAA Paper 2005-4610, June 2005, Toronto, Canada.

We propose a systematic procedure for predicting ground effect forces and moments for fixed wing aircraft in subsonic flight, the first that explicitly accounts for non-zero rise/sink rates. The method extends Prandtl's lifting line theory by using an image vortex system with lifting line and trailing vortex sheet under the ground to satisfy zero normal velocity at the ground. A modified lifting line equation is obtained for the distribution on the lifting line. This is used to calculate the distribution of lift and induced drag on the wing in ground effect. Pitching moment and control surface effectiveness in ground effect are estimated using the available lift slope and pitching moment slope with the modified angles of attack in ground effect. A further extension is also made to use an image lifting surface under the ground to give more precise estimates of pitching moment and of the effects of control surface deflections in ground effect. An example calculation with an elliptical wing is used to illustrate the results and compare with available experimental results in the literature.

Arkind, K. D.

"RAYTHEON'S ADVANCED CONCEPT DEVELOPMENT ACTIVITIES IN AIR TRAFFIC MANAGEMENT"

AIAA Paper No. 2003-5771, Austin, TX, August 2003

Raytheon is participating in the NASA Virtual Airspace Modeling and Simulation program to develop new concepts in Air Traffic Management as well as building the simulation capability needed to verify these future ATM concepts. A novel approach is introduced to eliminating the constraints imposed by wake vortex avoidance, using Flight Corridors and closely spaced parallel runways to double the capacity of today's airports.

Arkind, K. D.

"REQUIREMENTS FOR A NOVEL TERMINAL AREA CAPACITY ENHANCEMENT CONCEPT IN 2022"

AIAA Paper No. 2004-5411, Providence, RI, August 2004

A primary constraint on the capacity of the National Airspace System capacity is the arrival and departure rates at our major hub airports. Raytheon has developed a novel concept for terminal area operations that significantly increases arrivals and departures. The Terminal Area Capacity Enhancing Concept (TACEC) can double the number of aircraft arriving and departing by allowing very closely spaced parallel runway usage coupled with a unique wake vortex avoidance solution. Ongoing

development efforts have included a NAS wide simulation to evaluate the potential capacity increases that TACEC can provide, as well as the feasibility of implementation at the nation's busiest airports. In addition, an analysis of the terminal airspace performance requirements for aircraft and ATM operations provides the basis for a technology roadmap exercise that delineates the necessary developments for implementation by 2022. Finally, an ongoing safety analysis provides an evaluation of the operational risks.

Arndt, R. E. A. and Keller, A. P.

"WATER QUALITY EFFECTS ON CAVITATION INCEPTION IN A TRAILING VORTEX"

Transactions of the ASME, Vol. 114, September 1992, pp. 430-438.

Tip vortex cavitation studies were made with a hydrofoil that was elliptical in planform, with an aspect ratio of 3, and having a modified NACA 662-415 profile. LDV measurements of the tangential velocity component in the vortex were used to determine that the maximum pressure in the vortex varies with lift coefficient squared, i.e., that the incipient cavitation number should follow a C_L^2 relation. This is in contradiction to previous observations that the tip vortex cavitation index varied approximately with lift coefficient to the power 1.4. By carefully monitoring the tensile strength of the water, i.e., its susceptibility to cavitation, the discrepancy was traced to the capability of the test water to sustain a tensile stress. Cavitation in 'weak' water (no tensile strength) does follow the C_L^2 relationship, whereas observations in 'strong' water (rupture considerably below vapor pressure) more closely followed the previously observed variation of C_L to the 1.4 power. Since the structure of the vortex cannot be affected by changes in the water quality, the discrepancy can be explained only by the amount of tension that can be sustained by the test water before inception occurs. Apparently a relatively larger value of tension can be sustained in the vortex as the strength of the vortex is increased. This would explain the observed deviation from the expected C_L^2 law for water with measurable tensile strength.

"ACOUSTIC SPECTRAL ANALYSIS OF THREE TORNADOES"

Journal of Acoustical Society of America, Vol. 60, No. 3, September 1976, pp. 584-593.

Three sound recordings of tornadoes have been spectrally analyzed over the frequency interval between 100 and 2000 Hz. The low-frequency analysis was limited by the response of the microphones used for the recordings; the upper frequency limit was imposed on both the microphone response and the low-signal level. One recording was made of a tornado which passed through Clay Center, Kansas on 25 September 1973. A second sound recording was made of a tornado that passed through Guin, Alabama on 3 April 1974, and a third recording was made of a tornado in Tulsa, Oklahoma on 8 June 1974. All of the recordings are of low quality and the audio information required major spectral corrections, but the data analysis does indicate that the audio emissions from the tornadoes decrease in intensity as a function of increasing frequency. An attempt has been made to correlate the data with

real (and conjectured) physical characteristics of the tornadoes and attendant atmospheric phenomena. It is clear to us from an objective analysis (and the more difficult subjective evaluation of the recordings) that identification of tornadoes based on acoustic emissions is possible.

Arntz, A. and Hue, D.

"ENERGY-BASED PERFORMANCE ASSESSMENT OF THE NASA COMMON RESEARCH MODEL"

AIAA Journal, Vol. 54, No. 1, January 2016, pp. 88-100.

Aircraft have evolved into extremely complex systems that require adapted methodologies and tools for efficient design processes. A theoretical formulation based on energy management has been recently proposed by Arntz et al. for assessing the aero-thermo-propulsive performance of future aircraft configurations. The present article focuses on the validation of its numerical implementation in a FORTRAN code for the postprocessing of Reynolds-averaged Navier-Stokes flow solutions. The flow around the wing-body NASA Common Research Model is assessed in terms of energy destruction. A 2 MW work potential associated with the lift-induced vortices is identified in the wake of the airplane. Subsequently, a six-level grid convergence study enables determining the robustness and accuracy of the energy postprocessing code. The introduction and calibration of a numerical correction allows to account for the spurious numerical vortex dissipation and to obtain an accuracy similar to the traditional near-field drag method. Finally, the postprocessing code is validated for drag prediction against computational fluid dynamics and experimental wind-tunnel data.

Arthur, W. R.

"APPLICATION OF TWO-DIMENSIONAL VORTEX THEORY TO THE PREDICTION OF FLOW FIELDS BEHIND WINGS OF WING BODY COMBINATIONS AT SUBSONIC AND SUPERSONIC SPEEDS"

NACA TN-3227, September 1954, NACA Langley Aero. Lab., Langley Field, VA

A theoretical investigation has been made of a general method for predicting the flow field behind the wings of plane and cruciform wing and body combinations at transonic or supersonic speeds and slender configurations at supersonic speeds. The wing trailing-vortex wake is represented initially by line vortices distributed to approximate the spanwise distribution of circulation along the trailing edge of the exposed wing panels.

"THE INFLUENCE OF PRESSURE RELAXATION ON THE STRUCTURE OF AN AXIAL VORTEX"

Physics of Fluids, Vol. 23, 2011, pp. 073101-1 to 073101-12.

Governing equations including the effects of pressure relaxation have been utilized to study an incompressible, steady-state viscous axial vortex with specified far-field circulation. When sound generation is attributed to a velocity gradient tensor-pressure gradient product, the modified

conservation of momentum equations that result yield an exact solution for a steady, incompressible axial vortex. The vortex velocity profile has been shown to closely approximate experimental vortex measurements in air and water over a wide range of circulation-based Reynolds numbers. The influence of temperature and humidity on the pressure relaxation coefficient in air has been examined using theoretical and empirical approaches, and published axial vortex experiments have been employed to estimate the pressure relaxation coefficient in water. Non-equilibrium pressure gradient forces have been shown to balance the viscous stresses in the vortex core region, and the predicted pressure deficits that result from this non-equilibrium balance can be substantially larger than the pressure deficits predicted using a Bernoulli equation approach. Previously reported pressure deficit distributions for dust devils and tornados have been employed to validate the non-equilibrium pressure deficit predictions.

Ash, R. L.

"AXIAL VORTICES: DID RANKINE ALMOST GET IT RIGHT?"

AIAA Paper 2017-3263, June 2017, Denver, CO.

W. J. M. Rankine's 1869 axial vortex model is still in use today. By embedding a rigidly-rotating fluid cylinder within an inviscid axial vortex, the salient features of long-lived axial vortices are preserved. While that model does not predict dissipation, it also does not suffer from the non-physical core dilation behavior exhibited typically by computational fluid dynamics codes. This presentation will discuss research that has been conducted by the author, along with his colleagues and former students, focused on gaining a better understanding of the mechanisms responsible for axial vortex coherence. While we did not set out to justify Rankine's vortex model, our work on the non-equilibrium behavior of incompressible axial vortices can be employed to show how simple fluids, when subjected to potential vortex flow conditions, generate vortex cores similar to a Rankine vortex. Since the requisite non-equilibrium parameters controlling the core size and intensity are based on classical acoustic measurements for moist air, this presentation will discuss how actual weather conditions around airports can be employed to assess the potential severity of proximate vortex hazards.

Ash, R. L. and Zheng, Z. C.

"NUMERICAL SIMULATIONS OF COMMERCIAL AIRCRAFT WAKES SUBJECTED TO AIRPORT SURFACE WEATHER CONDITIONS"

Journal of Aircraft, Vol. 35, No. 1, January-February 1998, pp. 18-26

Using tower fly by data, we have developed a two-dimensional numerical simulation of wake vortex motion and decay for representative commercial aircraft. Our simulations support Squire's conjecture that the ratio of eddy viscosity to kinematic viscosity should scale linearly with circulation, which yields a nominally constant equivalent Reynolds number for all commercial aircraft sizes. We have tested the constant eddy viscosity approximation for three different aircraft configurations and six surface weather states, showing the utility of the approach in predicting wake vortex motion and decay. Subsequently,

we have shown how data from one aircraft flight test can be used to infer the decay behavior of another and we have examined the influence of the six surface weather states on the vortex decay behavior predicted for a large commercial aircraft.

Ash, R. L. and Zheng, Z. C.

"INITIALIZATION AND SIMULATION OF THREE-DIMENSIONAL AIRCRAFT WAKE VORTICES"

NASA-CR-204437, May 1997, Old Dominion Univ., Norfolk, VA

This paper studies the effects of axial velocity profiles on vortex decay, in order to properly initialize and simulate three-dimensional wake vortex flow. Analytical relationships are obtained based on a single vortex model and computational simulations are performed for a rather practical vortex wake, which show that the single vortex analytical relations can still be applicable at certain streamwise sections of three-dimensional wake vortices.

Ash, R. L., Zheng, Z. C. and Greene, G. C.

"CROSS WIND EFFECTS ON TURBULENT AIRCRAFT WAKE VORTICES NEAR THE GROUND"

AIAA Paper No. 1994-2381, Colorado Springs, CO, June 1994

A Reynolds stress transport turbulence model has been used to simulate the two-dimensional behavior of aircraft wake vortices, subjected to cross winds near the ground. The simulations have shown that turbulence effects alter vortex behavior but the direct influence of turbulence on vortex trajectories and lifetimes (near the ground) is only moderate. This study has investigated various characteristics of the atmospheric boundary layer, in order to identify the ambient variables that influence the wake vortex hazard and subsequent lifetime. Finally, an improved method for wake vortex hazard assessment has been described that can provide a more reliable estimate of the hazard.

Ashford, R.

"TERMINAL AREA PRODUCTIVITY OVERVIEW"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 1-4

Under the Terminal Area Productivity Program, NASA is developing technologies to improve airport throughput in instrument meteorological conditions (IMC). It is estimated that 60% of airborne delays are due to conducting approaches to airports under IMC. In visual terminal operations, responsibility for maintaining safe separation during takeoff, initial climb-out, approach, landing and roll out rests with the flight crew of each airplane. Conversely, in non-visual terminal operations, responsibility for maintaining safe separation rests with Air Traffic Control. The result is a set of separation standards that varies significantly between visual and non-visual conditions. A major part of the program is devoted to safely optimizing longitudinal and lateral spacing between aircraft to approach that

attainable in visual conditions. This work includes both flight deck and ground-based advanced automation to improve pilot and controller situational awareness and decision making capabilities. Technologies to expedite surface operations in low visibility conditions are also being developed.

Ashkenas, I. L. and Johnson, W. A.

"WAKE VORTEX HAZARD DEFINITION PROGRAM"

TR-1025-3, July 1974, Systems Tech. Inc., Hawthorne, CA

This report documents the development of a vortex hazard definition program. Implementation of this program will provide an important step toward the realization of an ultimate system that will safely provide reduced traffic separations at congested airports. The problem is conceptually a simple one: with reduced separations there is a greater potential hazard from vortex encounters. The main point is that we need to assure safe operations with minimum separations that are tailored to the actual hazard. In order to do this we must consider the possibility of a worst case encounter; and if such encounters are potentially catastrophic, we must assure that the probability of such an event is acceptably small. To do this requires a more precise definition of hazard than simple rules of thumb. The central role of appropriate computer simulation and analysis is emphasized. All program elements feed into a progressively improved simulation, where critical interactions are assessed in the presence of all other inputs. We must depend on computer modeling because of the many possible critical situations; we must consider the pilot's probable (recovery) control behavior; and we must predict vortex location and strength with minimum uncertainty. Then we must establish realistic, tailored hazard volumes.

Ashley, S.

"QUIETING KILLER WAKES"

Scientific American, Vol. 286, No. 2, February 2002, pp. 24-25

Engineers are working on ways to detect hazardous wake vortices so pilots can avoid them or to design aircraft that leave safer skies behind them. If implemented, these new technologies could boost the number of planes that airports could handle, thus cutting delays and enabling increased commercial air traffic in coming years.

"DATA PROCESSING AND DISPLAY OF LASER DOPPLER EXPERIMENTAL RESULTS, VOLUME 1"

NASA-CR-150441, September 1976, Arkansas Univ., Fayetteville, A.

Contract activities performed in developing a laser Doppler system for detecting, tracking, and measuring aircraft wake vortices are summarized. The computer program for processing and displaying the Dust Devil experimental data is presented. Program listings are included in the appendix.

Ashok, A. and Smits, A. J.

"THE TURBULENT WAKE OF A SUBMARINE MODEL IN PITCH AND YAW"

AIAA Paper 2013-1121, January 2013, Grapevine, TX.

The objective of the present study is to understand how the pitch and yaw angle affect the mean flow and turbulence in the wake of the DARPA SUBOFF, an idealized submarine model. Measurements in the wake were performed at $Re = 2,400,000$. Mean velocity and one-component turbulence measurements were performed using Pitot probes and single normal hot wires in the span-wise plane, 10 diameters downstream of the trailing edge. The range of measured angles of attack and yaw angles were limited to between 0 and 12 degrees in part to avoid wind tunnel interference effects. Flow visualization in water at $Re = 4,000$ was also performed to inform the wake patterns observed at higher Reynolds number.

Asselin, D. J. and Williamson, C. H. K.

"VORTEX PAIR IMPINGING ON A HORIZONTAL GROUND PLANE"

Physics of Fluids, Vol. 25, No. 9, 2013, pp. 091104-1 to 091104-2.

In this work, we employ a water tank equipped with a long set of computer-controlled flaps. These flaps are lowered into the tank and closed, much as one would close a book, to generate a counter-rotating vortex pair. This primary vortex pair then descends under its own induced velocity toward a transparent acrylic ground plane. Upon interaction with the boundary, the vortices drive fluid in a boundary layer against an adverse pressure gradient. This ultimately causes flow separation and the rollup of a secondary vortex pair of opposite sign vorticity. Two principal phenomena are observed. The first is significant axial flow in each vortex tube. Because the Crow instability causes displacements in a plane oriented at approximately 45 degrees to the horizontal, the 'troughs' of the sinusoidal vortex tube, at which the vortices are closest together, interact with the ground before the 'peaks.' The result is a strong motion of the fluid away from the region of closest approach, producing bulbous regions of vorticity at the peaks of the vortex. The second phenomenon occurs in the secondary vorticity. Here, structures that appear to be rebounding vortex rings, located between the deformed primary vortices, are clearly observed. It is particularly important to note that the precise structures produced are highly dependent on the extent to which the Crow instability has developed prior to contact with the boundary.

Asselin, D. J. and Williamson, C. H. K.

"VORTEX PAIR IMPINGING ON A HORIZONTAL GROUND PLANE"

Physics of Fluids, Vol. 25, No. 9, 2013, pp. 091104-1 to 091104-2.

In this work, we employ a water tank equipped with a long set of computer-controlled flaps. These flaps are lowered into the tank and closed, much as one would close a book, to generate a counter-rotating vortex pair. This primary vortex pair then descends under its own induced velocity toward a transparent acrylic ground plane. Upon interaction with the boundary, the vortices drive fluid in a boundary layer against an adverse pressure gradient. This ultimately caused flow separation and the rollup of a secondary vortex pair of opposite sign vorticity. Visualization of the primary vortices is achieved through laser induced fluorescence of dye, which is painted onto the inside surface of the flaps prior to running an experiment. To visualize the secondary vortices, our laboratory has developed a novel technique. Prior to the experiment, dye is pooled on the ground plane and allowed to settle in a thin sheet. Consequently, this dye marks the secondary vortices, which may be visualized separately or concurrently with the primary vorticity.

Asselin, D. J. and Williamson, C. H. K.

"FORMATION OF SMALL-SCALE VORTEX RINGS FROM VORTEX PAIRS CLOSE TO THE GROUND"

66th Annual Meeting of the APS Division of Fluid Dynamics, Vol. 58, No. 18, November 2013, Pittsburgh, PA.

In this research, we examine the effect of a solid boundary on the dynamics and instabilities of a pair of counter-rotating vortices. An isolated vortex pair is subject to a short-wave elliptic instability and a long-wave Crow instability. Near a wall, the boundary layer between the primary vortices and the wall can separate, leading to the generation of secondary vorticity. These secondary vortices can be subject to small-scale instabilities as they come under the influence of the primary vortices. In contrast, in the present study we are interested in the long-wave Crow instability interrupted by interaction with a wall. This can cause significant axial flow, resulting in a periodic concentration of fluid containing vorticity at the peaks of each wavy vortex tube and a corresponding evacuation of fluid containing vorticity from the troughs. It appears that this axial flow is driven at least in part by the formation of vortex ring-like structures in the secondary vortex as it is deformed by the primary vortex. Furthermore, additional small scale-vortex rings evolve from the secondary vorticity and from the concentrated vortical regions in the primary vorticity. In both cases, these rings cause vorticity to rebound away from the ground.

"FINAL REPORT WP1000 SYSTEMS REQUIREMENTS"

IST-2001-34729, May 2003, National Aerospace Laboratory, Amsterdam, The Netherlands

This document constitutes the final report from ATC-WAKE WP 1000 dedicated to the specification of Operational Requirements, Operational Concept and Procedures, User Requirements and System Requirements for an ATC system integrating wake vortex prediction and detection capabilities.

Atashbaz, G. and Ommian, M.

"EXPERIMENTAL INVESTIGATION OF VORTEX FLOW OVER AN 80 DEGREE/60 DEGREE DOUBLE DELTA WING AT SIDESLIP"

Journal of Aircraft, Vol. 43, No. 3, May-June 2006, pp. 840-842.

A series of qualitative and quantitative experimental investigations into the effect of angle of attack and sideslip on the aerodynamic behavior of a sharp leading-edge 80 deg/60 deg double delta wing were conducted. Surface oil-flow and laser light sheet visualizations, as well as surface pressure measurements, were performed on the strake and wing upper surface. The following observations are made. (1) Suction peak increases with increasing angle of attack symmetrically on both sides of the double delta wing before vortex breakdown occurs. (2) Increasing sideslip will cause strong asymmetric vortices over starboard and port sides of the wing, which causes different lift characteristics and as a result causes rolling moment. This may produce difficulties in stability and control of the wing.

Atassi, O. V., Bernoff, A. J. and Lichter, S.

"INTERACTING VORTEX AND VORTEX LAYER: HOW LENGTH SCALE AFFECTS ENTRAINMENT AND EJECTION"

AIAA Journal, Vol. 36, No. 6, June 1998, pp. 924-928

A contour dynamics model of the interaction between a point vortex and a layer of constant vorticity, bounded below by a slip wall and above by irrotational flow, is studied. The height of the vortex above the layer establishes a length scale that is found to have a strong influence on both the evolution of the layer and the vertical displacement of the vortex. A vortex far above the boundary layer generates long-wavelength disturbances. These exhibit early-time growth, which saturates, taking on the shape of a vortex-like structure, suggesting that a vortex far above a boundary layer can create another one within the layer. Concurrently, entrainment of irrotational flow deep into the layer occurs within a narrow crevice. Alternatively, for a vortex initially placed close to the layer, a short-scale disturbance occurs that exhibits rapid, continuous growth that eventually rolls up around the vortex. Here, accounting for the vertical displacement of the vortex is necessary to accurately determine the interface evolution. The results support the contention that a vortex can induce ejection and roll up of the boundary layer and entrainment of irrotational flow into the layer.

Atassi, O. V., Lichter, S. and Bernoff, A J.

"THE INTERACTION OF A POINT VORTEX WITH A BOUNDARY LAYER LEADING TO ERUPTION"

AIAA Paper No. 1996-2140, New Orleans, LA, June 1996

A model for entrainment of irrotational flow into a boundary layer, and the eruption and rollup of vorticity away from the wall, is studied. The model consists of a point vortex and a layer of constant vorticity, bounded below by a wall and above by an irrotational flow. Contour dynamics is used to compute the pathline of the vortex and the evolution of the interface which delineates vortical flow from irrotational flow. Four cases are studied for which the ratio of vortex strength to initial distance of

the vortex above the interface is kept fixed. With this constraint, the initial vortex-induced velocity evaluated at a scaled distance along the interface is equal in all cases. Consequently, a vortex far above the boundary layer generates long-wavelength disturbances on the interface. These exhibit early-time growth which saturate as their amplitude becomes large. The interface takes the shape of a vortex-like structure as it overturns, suggesting that a vortex far above a boundary layer can create another one within the layer. Concurrently, entrainment of irrotational flow deep into the layer occurs within a narrow crevice. Though the vortex moves towards the layer during the course of its interaction, the change in its induced velocity on the interface is not dynamically significant. Alternatively, for a vortex initially placed close to the layer, a short-scale disturbance occurs for which the change in induced velocity due to the vertical displacement of the vortex is significant. The disturbance exhibits rapid, continuous growth that eventually rolls up around the vortex.

Atias, M. and Weihs, D.

"MOTION OF AIRCRAFT TRAILING VORTICES NEAR THE GROUND"

Journal of Aircraft, Vol. 21, No. 10, October 1984, pp. 783-786

A theoretical study of the motion of a two-dimensional vortex pair, such as obtained in a subsonic aircraft wake moving near the ground, is described. The wake motion, analyzed by a discrete vortex method, is shown to be characterized by a repeating rebounding phenomenon, resulting in a spiral path, with a general upward and outward motion, after the initial approach to the ground. It is shown that the cause of the rebounding and the oscillations observed in the trajectories of such vortex pairs is the boundary layer generated near the ground. This vorticity separates and gyrates around the vortices of the pair.

"A META-HEURISTIC APPROACH TO AIRCRAFT DEPARTURE SCHEDULING AT LONDON HEATHROW AIRPORT"

9th International Conference on Computer-Aided Scheduling of Public Transportation, San Diego, CA, August 2004

London Heathrow airport is one of the busiest airports in the world. Moreover, it is unusual among the world's leading airports in that it only has two runways. At many airports the runway throughput is the bottleneck to the departure process and as such it is vital to schedule departures effectively and efficiently. For reasons of safety, separations need to be enforced between departing aircraft. The minimum separation between any pair of departing aircraft is determined not only by those aircraft but also by the flight paths and speeds of aircraft that have previously departed. Departures from London Heathrow are subject to physical constraints that are not usually modelled in departure runway scheduling models. There are many constraints which impact upon the orders of aircraft that are possible and we will show how these constraints either have already been included in the model we present or can be included in future. The runway controllers are responsible for the sequencing of the

aircraft for the departure runway. This is currently carried out manually. In this paper we propose a metaheuristic-based solution for determining good sequences of aircraft in order to aid the runway controller in this difficult and demanding task. Finally, some results are given to show the effectiveness of this system and we evaluate those results against manually produced real world schedules.

Attwooll, V. W.

"SEPARATION CRITERIA FOR SUPERSONIC TRANSPORTS AND OTHER ASPECTS OF TRAFFIC CONTROL"

Journal of the Institute of Navigation, Vol. 15, No. 2, Summer 1968, pp. 199-204.

This paper discusses the studies made of the traffic system for the supersonic transport at the RAE. We first discuss the design for the oceanic traffic system having regard to the performance characteristics of the aircraft, to the characteristics of the atmosphere at the heights to be flown and to possible restriction of supersonic flight overland. Cost effectiveness studies give desirable values for oceanic separation minima. We then consider the desirable navigation specification to achieve these minima. Finally, we discuss the control of the aircraft during the domestic oceanic transition and in the terminal area.

Attwooll, V. W.

"THE EFFECTS OF TRAILING VORTICES ON THE SAFE CAPACITY OF AIR ROUTES AND AIRPORTS"

Tech. Memo. Math 6702/2, July 1967, Royal Aircraft Establishment, Farnborough, England

Although the danger to aircraft of flying into the trailing vortex shed by another aircraft has been stressed many times, there is still too little known about the characteristics of vortices to enable the relation between the vortex hazard and the separation minima used by Air Traffic Control to be expressed in quantitative terms. The memorandum shows that present knowledge is insufficient to eliminate the possibility that the vortex hazard could have a marked effect both on the capacity of airports and on the lethal risk attendant on a close approach following inadvertent loss of separation between two aircraft en route.

"EXPERIMENTAL STUDY ON THE WIND TURBINE WAKE MEANDERING WITH THE HELP OF A NON-ROTATING SIMPLIFIED MODEL AND OF A ROTATING MODEL"

AIAA Paper 2011-0460, January 2011, Orlando, FL.

The present work completes a previous study of the present authors that compared, through wind tunnel experiments, the wake properties of a model of a 3-blade rotating wind turbine and of a porous disc made of metallic mesh. The main goal is to determine, in the context of numerical or experimental approaches, the acceptable degree of modelling of the wind turbine to study in the far-wake. The previous study showed that the wake expansion was similar for both models and the specific signatures

induced by a rotating wind turbine (tip vortices and add of rotational momentum) were indiscernible from $x = 3D$ downstream of the rotating model. The present results show that the wake meandering due to the large turbulence length scales of the freestream ABL-like flow is detected and its amplitude is similar for both models. Furthermore, the meandering process detected in the present study is proven to be horizontal and not vertical. To conclude, one can notice that no discrepancy is detected in the meandering process of the wake downstream of a porous disc or of a rotating wind turbine in the present experimental conditions. It tends to prove that modelling a turbine through the actuator disc concept is adequate to study the turbine far-wake in many situations (on condition that the freestream turbulence intensity is relatively high).

Audenaerd, L.

"CHARACTERIZATION OF SURFACE AND ALOFT WINDS FOR ADVANCED PARALLEL RUNWAY OPERATIONS"

Journal of the Transportation Research Board, Vol. 2300, Issue 1, December 2012, pp. 49-58.

The increase in demand for air travel throughput has resulted in an effort to identify novel techniques for improving efficiency. One such effort targets the barrier imposed by wake turbulence separation standards -- reducing inter-aircraft spacing during radar operations. Recently, concepts have focused on exploiting the effects of wake transport under wind fields by developing wind-dependent procedures that mitigate wake hazards during favorable wind conditions. However, the challenge regarding computing benefits during conditional time epochs requires methodology designed for a niche modeling area that even sophisticated airport capacity simulation models lack. This work attempts to augment the capacity computation by presenting a characterization of the favorable crosswind availability across a range of thresholds and aloft monitoring heights based on Rapid Update Cycle and aviation system performance measure weather data. The focus is on presenting a generalization of wind behavior and on providing insight into the effects of the wind on the applicability of wind-dependent wake-based procedures. Data for nine major U.S. airports currently operating closely spaced parallel runways are analyzed.

Audenaerd, L.

"ESTIMATING APPROACH PATH COVERAGE OF AIRCRAFT-DERIVED METEOROLOGICAL DATA IN ADVANCED AIR TRAFFIC MANAGEMENT APPLICATIONS"

Journal of the Transportation Research Board, No. 2449, 2014, pp. 53-63.

If appropriately equipped, aircraft traveling throughout the global air space have the unique capability to measure and report high-resolution meteorological data, under all weather conditions. These data can have high economic value for both aviation and nonaviation uses by communicating a dense picture of weather conditions from thousands of ad hoc sensors operating daily in the global air space over areas of an aviation operational interest. However, ensuring that the technology provides adequate levels of service and safety requires a clear understanding of system performance

characteristics in conjunction with sensor and data link capabilities, broadcast frequencies, equipage rates, and operational service environmental requirements. This paper explores the density of coverage as a measure of performance by presenting the problem as a stochastic area coverage model of a homogeneous dynamic wireless ad hoc sensor network. A model was developed to relate the density needs of various advanced air traffic management applications to the spatial and temporal coverage of aircraft-sensed meteorological data in the airport terminal area. A comprehensive experimental design is presented with varying aircraft equipage rates, message broadcast frequencies, coverage granularities, and traffic demand levels. Infrastructure and sensor limitations are included to capture some realism within the model. Results are determined by solving this variation on a traditional set covering model using Monte Carlo simulation techniques.

"APPLYING IMPROVED WIND AND AIRCRAFT PERFORMANCE DATA IN WAKE PROCEDURE CONCEPTS"

2014 Integrated Communications Navigation and Surveillance (ICNS) Conference, April 2014, Herndon, VA.

As NextGen concepts seek increasing airport throughput, separation from naturally occurring wake turbulence becomes a limiting factor in the pursuit of capacity improvements in many cases. In recent years, the implementation of fixed procedural changes that reduce wake separations while maintaining safety have been very successful. Further opportunities for reducing wake constraints have led to exploiting specific meteorological conditions to mitigate wake hazards. As an example, one such program, entitled Wake Turbulence Mitigation for Departures, ensures safe reduction of successive departure separations based on dynamic crosswind conditions. Availability of these conditions, however, is limited by the abilities of the wind detection system -- its sensing ability, data reliability and forecasting accuracy. Recent efforts are addressing these limitations by exploring how the use of better knowledge of wind and aircraft performance can increase availability or enable the design of further wake turbulence mitigation arrival and departure procedures. Additionally, recent advancements in aircraft flight track data assimilation have led to a deeper understanding of aircraft operational behavior during landing and take-off cycles. The confluence of these efforts is currently being leveraged to develop more sophisticated wake mitigation applications. This paper provides an overview of recent progress in developing broad data access and collection of weather and aircraft positional data; prospective applications that would leverage these data; and the relationship between the data density, or supply-side, requirements and the associated application demand needs.

"INCREASING AIRPORT ARRIVAL CAPACITY IN NEXTGEN WITH WAKE TURBULENCE AVOIDANCE"

Integrated Communications, Navigation and Surveillance Conference, May 2009, Arlington, VA.

Arrival capacity at major airports is a primary constraint that must be overcome to reach the Next Generation Air Transportation System (NextGen) capacity goals. At the nation's busiest airports with

closely spaced parallel runways for arrivals, capacity can be reduced significantly when weather at these airports falls below visual approach minima. When visual approaches can be used for arriving aircraft, pilots can apply their experience and judgment to position their aircraft to avoid wake turbulence generated by other aircraft they are following to the airport. This practice allows for the best arrival capacity to be achieved in good weather. When ceiling and visibility fall below that required for visual approaches, airports that would normally arrive on two parallel runways spaced less than 2500 feet apart, must discontinue parallel approaches, thus reducing the arrival rate to what can be achieved with a single runway. This reduction in capacity is due to the air traffic control requirement that parallel runways spaced this closely must be treated as one runway for application of wake turbulence separation. A new wake turbulence procedure has recently been approved for use at several airports that allows arrivals at these airports to reduce separation between aircraft on parallel approaches in weather below visual approach minima using a parallel dependent stagger arrival operation. This procedure, documented in JO 7110.308, allows aircraft to arrive in staggered pairs, with Large and Small wake category aircraft in the lead. With this procedure, approximately half of the capacity normally lost due to deteriorating weather can be regained. Additional procedures are being explored, such as Wake Turbulence Mitigation for Arrivals (WTMA) that will allow additional gains in capacity by including additional airports with more closely spaced runways, and additional wake category aircraft participating as leaders in this parallel dependent stagger approach procedure. This paper provides an overview of the WTMA concept and describes analysis techniques used to develop initial estimates of the capacity improvement that various phases of WTMA will provide.

"SCHLIEREN TECHNIQUES IN COMPARISON: THE BACKGROUND ORIENTED METHOD VERSUS VISUALIZATION WITH HOLOGRAPHIC FILTERS"

4th International Symposium on Particle Image Velocimetry, Paper 1191, September 2001, Gottingen, Germany.

Within this paper two recently developed visualization techniques are presented. The results of the Background Oriented Method, are compared to the flow-field visualizations, obtained by using the holographic filters from ISL. Both, the background oriented schlieren technique as well as the visualization with holographic filters were used to represent the index gradients of aerodynamic flows. The investigations have been carried out in the ISL blow-down wind tunnel at a Mach number of 3. A canard-wing combination was used in order to study the shock-vortex interaction phenomenon.

"1.5 MICRON LIDAR FOR HELICOPTER BLADE TIP VORTEX DETECTION"

Advanced In-Flight Measurement Techniques, Research Topics in Aerospace, edited by F. Boden et al, 2013, Springer-Verlag Berlin Heidelberg, pp. 187-194.

The objective in the ONERA study in the project 'Advanced In-flight Measurement Techniques' is to assess the capability of an on-board LIDAR technique to investigate in-flight tip vortices behavior. This paper presents the design of a 1.5 micron LIDAR sensor dedicated to tip vortex characterization and tests on ground during trials on a DLR helicopter in hover flight. The relevant information resulting from these trials is the tip vortex velocity field as well as the time evolution of the vortex. The technical challenge here is to characterize a very small phenomenon at short range: the core radius varies from typically 10 to 30 mm as the vortex ages. The study results show that LIDAR technique is promising for onboard measurement during flight. The velocity measurement is direct and absolute (no calibration needed) and its accuracy can be up to 0.25 m/s and commonly 1 m/s. However, seeding is necessary to realize a compact and reliable LIDAR system with components 'off the shelf': in the framework of flight trials, clouds could provide efficient seeding enabling the use of LIDAR as a powerful technique for tip vortex characterization.

"THREE-DIMENSIONAL WIND MEASUREMENTS WITH THE FIBERED AIRBORNE COHERENT DOPPLER WIND LIDAR LIVE"

Atmosphere, Vol. 10, No. 549, September 2019.

A three-dimensional (3D) wind profiling Lidar, based on the latest high power 1.5 μ m fiber laser development at Onera, has been successfully flown on-board a SAFIRE (Service des Avions Français Instrumentés pour la Recherche en Environnement) ATR42 aircraft. The Lidar called LIVE (Lidar VEnt) is designed to measure wind profiles from the aircraft down to ground level, with a horizontal resolution of 3 km, a vertical resolution of 100 m and a designed accuracy on each three wind vector components better than 0.5 m.s⁻¹. To achieve the required performance, LIVE Lidar emits 410 J laser pulses repeating at 14 KHz with a duration of 700 ns and uses a conical scanner of 30° total opening angle and a full scan time of 17 s.

"CFD ANALYSIS OF WINGLETS AT LOW SUBSONIC FLOW"

Proceedings of the World Congress on Engineering 2011, Vol. 1, July 2011, London, U.K.

A winglet is a device attached at the wingtip, used to improve aircraft efficiency by lowering the induced drag caused by wingtip vortices. It is a vertical or angled extension at the tips of each wing. Winglets work by increasing the effective aspect ratio of a wing without adding greatly to the structural stress and hence necessary weight of the wing structure. This paper describes a CFD 3-dimensional winglets analysis that was performed on a rectangular wing of NACA65,218 cross sectional airfoil. The wing is of 660 mm span and 121 mm chord and was analyzed for two shape configurations, semicircle and elliptical. The objectives of the analysis were to compare aerodynamic characteristics of the two winglet configurations and to investigate the performance of the two winglets shape simulated at

selected cant angle of 0, 45 and 60 degrees. The computational simulation was carried out by FLUENT 6.2 solver using Finite Volume Approach. The simulation was done at low subsonic flow and at various angles of attack using Spalart-Allmaras couple implicit solver. A comparison of aerodynamics characteristics of lift coefficient, drag coefficient and lift to drag ratio, L/D was made and it was found that the addition of the elliptical and semi-circular winglet gave a larger lift curve slope and higher Lift-to-Drag Ratio in comparison to the baseline wing alone. Elliptical winglet with 45-degree cant angle was the best overall design giving about 8 percent increase in lift curve and the best Lift-to-Drag Ratio.

"RESPONSE OF A HELICOPTER PENETRATING THE TIP VORTICES OF A LARGE AIRPLANE"

Vertica, Vol. 11, No. 1/2, 1987, pp. 65-76.

The dynamic response of helicopters penetrating a pair of trailing vortices of a jumbo jet is analyzed. The rotor aerodynamic forces which are fully coupled with the body motion with six degrees of freedom are calculated by using the local momentum theory (LMT). The wake vortices of the jumbo jet are assumed to be a frozen gust and are disturbed by the blade motion. The time histories of the dynamic behaviors of the helicopter as well as the blade motion are presented for the various parameters such as the distance between the helicopter and the jumbo jet, the type of helicopter rotor, and the flight path angle with respect to the trailing vortex of the jumbo jet.

"EVALUATING VISUALIZATION MODES FOR CLOSELY-SPACED PARALLEL APPROACHES"

Proceedings of the Human Factors and Ergonomics Society 49th Annual Meeting, 2005, pp. 35-39

Raytheon's TACEC (Terminal Area Capacity Enhancement Concept) proposes to increase airspace capacity by using closely-spaced formations of arriving and departing aircraft to greatly increase airport capacities. However, a blunder in a tightly-spaced formation could cause a collision with another aircraft or its wake vortices. Therefore, humans need tools and visualization aids to detect and respond to blunders. This paper is the first in a series of experiments to evaluate the ability of different visualization modes to enable detection of lateral blunders. We tested four viewpoints, one warning aid, and three blunder speeds in a within-subjects design. This study had twelve participants. The main result was that changing the viewpoint made a large difference; the cockpit view was by far the worst. Blunder detection varied by speed and was difficult in the presence of noise. Future experiments should use more realistic simulators and pilots as participants.

Baals, D. B. and Mourhess, M. J.

"NUMERICAL EVALUATION OF THE WAKE-SURVEY EQUATIONS FOR SUBSONIC FLOW INCLUDING THE EFFECT OF ENERGY ADDITION"

NACA ARR-L5H27, October 1948, Langley Aeronautical Lab., Langley Field, VA

Direct-reading tables and charts are presented for determining the drag or thrust coefficients from wake-survey measurements in the subsonic speed range. For flows wherein no energy is added, the point drag coefficient is shown to be an explicit function of the stream Mach number, the static-pressure coefficient at the wake station, and the total-pressure-loss coefficient. Values of the point drag coefficient are tabulated for a wide range of values of these parameters. Inasmuch as the tabulated coefficients (either drag or thrust) represent the point values, which are independent of the integration of the wake, the charts or tables in the form presented are general in application. For flows wherein energy is added, such as flows behind propellers or heated radiators, an additional parameter, which is a function of the stagnation-temperature rise, must be considered. Values of the point drag coefficient that include the effects of the addition of energy are tabulated.

Baart, D., Monk, H. and Schweiker, M. L.

"AIRPORT CAPACITY AND DELAY ANALYSES"

DOT-FAA-CT-TN91/18, April 1991, FAA Technical Center, Atlantic City, NJ

The benefits achievable in terms of reduced delay and capacity gained at several major airports if products of the Wake Vortex Program were implemented resulting in reduced intrail separation standards is addressed. These theoretical separation standards were developed from products of the Wake Vortex Program and were used in a simulation of runway operations at John F. Kennedy (JFK), Boston (BOS), and St. Louis (STL) airports. These products include Vortex Advisory System (VAS), Wake Vortex Avoidance System (WVAS), Wake Vortex Detection/Monitoring System. In addition to site specific airports, generic runway configurations were explored as a means of grouping many airports with similar configurations. The estimates derived include delay time saved in dollars per day and capacity gained in operations per hour for each airport evaluated. Considerable benefits to the airlines and the economy could be achieved if these wake vortex products were implemented resulting in reduced separation standards.

Baart, D., Rovinsky, R. B., Monk, H. and Schweiker, M.

"EFFECT OF REDUCED INTRAIL SEPARATIONS ON CAPACITY"

Proceedings of the Aircraft Wake Vortices, Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 27-1 - 27-22

Alleviating the congestion of our airports has been a major concern of the FAA and the airlines. Conservative separation standards, now in effect, increase arrival and departure delay and reduce airport capacity. Several products of the FAA's Wake Vortex Program, if implemented, will permit reduced separation standards in terminal areas, in addition to improving safety. Using the Runway Delay Simulation (RDSIM) Model, which emulates runway operations based on historical data, we examined these theoretical separation standards on capacity and delay at John F. Kennedy (JFK), Boston (BOS), and St. Louis (STL) airports. Generic runway configurations were also explored as a means of

grouping many airports with similar runway configurations. We also used SIMMOD, which provides considerable detail on the airfield and airspace of an airport, to analyze the benefits possible at Dallas Fort Worth (DFW) and Chicago O'Hare (ORD) from developing and installing future wake vortex detection/monitoring systems as well as changing future separations standards. This paper presents the results of the above analyses, which indicate that the reduced separation standards can produce significant benefits to the aviation industry and economy. However, these benefits can only be realized by safely coordinating operational changes with air traffic procedures.

Babie, B. M.

"AN EXPERIMENTAL AND ANALYTICAL STUDY OF THE STABILITY OF COUNTER-ROTATING VORTEX PAIRS WITH APPLICATIONS FOR AIRCRAFT WAKE TURBULENCE CONTROL"

Ph.D. Thesis, April 2008, Notre Dame, Indiana.

Three principal objectives served to focus the research project that is presented in this dissertation. The first two objectives were to develop an improved understanding of the wake configurations that were conducive to large instability growth rates and to subsequently use quantitative methods to identify the instability modes that dominate the far-field wake dynamic. With a clear understanding of the physics of an unstable aircraft wake, the third objective was to use this newly attained information to recommend methods for a reliable wake control strategy. A compilation of flow visualization results shows a design space of counter-rotating wake configurations, defined by the circulation and span ratios, where rapidly amplifying instabilities are consistently seen to exist. This design space is also seen to encompass rigidly-translating wake systems. A combination of quantitative flow visualization estimates, hot-wire anemometry and an analytical stability analysis was successful in identifying two forms of bending wave instability, namely the long and short-wave modes. Having identified two bending instability modes in the experimental wake, it was possible to suggest a strategy by which these modes could be exploited for the control of aircraft wakes.

Babie, B. M. and Nelson, R. C.

"FLOW VISUALIZATION STUDY OF FAR FIELD WAKE VORTEX INTERACTIONS"

11th International Symposium on Flow Visualization, Notre Dame University, Notre Dame, IN, August 9-12, 2004

An experiment to study the interaction of a wake consisting of four vortices is currently under development in the Hessert Laboratory at the University of Notre Dame. The four vortices are created by an apparatus consisting of four half span high aspect ratio wings. Each wing is mounted to a stepper motor that permits accurate control of the wing angle of attack. Furthermore, the lateral spacing between the wings can be manually adjusted. Thus, the spacing, circulation and sense of rotation of each vortex in the wake can be controlled. The goal of this study is to investigate how a wake consisting of four vortices can be made unstable so that it decays rapidly in the downstream direction. The vortex instability modes under investigation generally occur at large distances downstream from

the origin of their generation. The primary method of validating the new multiple vortex interaction facility is through visualization of the vortices. A major challenge in observing the extent of attenuation in the far field of the wake is in maintaining seeding of the vortex structures at large distances downstream. Methods for achieving such a flow seeding will be discussed in detail. The visualization method that has shown the most promise for tracking multiple vortices many span lengths downstream of the wake generating device is through helium bubble visualization. This paper discusses the use of helium bubbles to mark the vortices, lighting and other issues that needed to be resolved to be able to track the vortex wake evolution.

Babie, B. M. and Nelson, R. C.

"AN EXPERIMENTAL INVESTIGATION OF BENDING WAVE INSTABILITY MODES IN A GENERIC FOUR-VORTEX WAKE"

Physics of Fluids, Vol. 22, 2010, pp. 077101-1 - 077101-15.

An experimental study of a planar wake consisting of four vortices that simulate the trailing vortex wakes generated by transport airplanes in either takeoff or landing configurations is presented. The objective of this study was to examine naturally occurring wake instabilities. Specifically, the focus of the study was centered on bending wave instabilities of which the Crow instability represents a particular case. A unique method of generating a four-vortex wake was developed for this study. The four-vortex wake generating device permitted direct variation of the spacing between vortices as well as control over the vortex circulation strength. Two quantitative flow visualization experiments were instrumental in identifying wake configurations that were conducive to the rapid growth of bending wave modes and in the identification of the long-wavelength mode. Detailed experiments were also conducted to examine the flow structure in the near-field or roll-up region using a four sensor, hot-wire probe that could measure all three velocity components in the wake simultaneously. The results of both the flow visualization and hot-wire experiments indicate that the long-wavelength mode and the first short-wavelength mode likely dominate the far-field wake physics and may potentially be utilized in a wake control strategy.

Babie, B. M. and Nelson, R. C.

"WAVELENGTH AND AMPLITUDE MEASUREMENT OF AN UNSTABLE WAKE VORTEX BENDING MODE VIA HELIUM-BUBBLE VISUALIZATION"

13th International Symposium on Flow Visualization, Nice, France, July 2008

This paper describes a research study that examines the potential of exciting instability modes in a trailing vortex wake to cause breakup and decay of these hazardous wake structures. A four-vortex model has been selected for this study as it is representative of a landing aircraft wake; a flight stage that is most prone to wake encounters. Previous work done by the authors has resulted in the identification of a region of counter-rotating wake configurations that are conducive to large temporal instability growth rates. This region is also observed to include those configurations which are known

to translate rigidly. The driving hypothesis of the current work is that the observed unstable motion is a long-wavelength instability that is driven by the mutual interaction of the tip/flap vortex pair on each side of the wake centerline. The helium-bubble visualization technique has been used as an effective tool for the identification of the long-wavelength instability. The data attained from visual images of the wake have been used to obtain quantitative estimates of the bending mode wavelength and amplitude for comparison with linear stability theory.

Babie, B. M. and Nelson, R. C.

"AN EXPERIMENTAL STUDY OF WAKE VORTEX INSTABILITIES"

AIAA Paper 2008-363, Reno, NV, Jan. 2008

An investigation of the stability of a four-vortex wake has been conducted in the atmospheric boundary layer wind tunnel at the University of Notre Dame. Four independent wing models were used to create a generic four-vortex wake, such that the effects of circulation strength and vortex span could easily be studied. Helium bubble flow visualizations provide sufficient evidence of the persistence of a long-wavelength instability driven primarily by the strain field between the inboard-outboard vortex pair for a specific set of wake configurations. A quantitative investigation into the near-field development of these wakes via hot-wire anemometry further indicates the development of the elliptical form of short-wavelength instability. The experimental measurements of a short-wavelength perturbation frequency was found to compare favorably to that predicted by theory.

Babigian, R. and Hayashibara, S.

"COMPUTATIONAL STUDY OF THE VORTEX WAKE GENERATED BY A THREE-DIMENSIONAL WING WITH DIHEDRAL, TAPER, AND SWEEP"

AIAA Paper 2009-4107, June 2009, San Antonio, Texas.

A preliminary CFD study was conducted to compare the wingtip vortices and induced drag generated by three wing-configurations at cruise conditions. The geometry for a clean wing, a wing with winglets, and a wing with raked wingtips were modeled in CATIA and numerically analyzed using FLUENT CFD software. The results produced detailed contour and vector plots of the wingtip vorticity magnitudes created by each wingtip configuration. Results revealed two techniques used by wingtip devices to reduce the wingtip vortices and thus the induced drag on a wing. Winglets exhibited the potential for creating a force component in the direction of an aircraft's thrust, counteracting the drag on the wing. Alternately, raked wingtips displayed a tendency for reducing the overall magnitude of the tip vortices. Although both concepts are aerodynamically beneficial, the raked wingtip is a promising innovation for future use on passenger aircraft.

Back, L. H.

"OPTICAL AND PHYSICAL REQUIREMENTS FOR FLUID PARTICLES MARKING TRAILING VORTICES FROM AIRCRAFT"

Journal of Aircraft, Vol. 13, No. 7, July 1976, pp. 483-489

A theoretical study of the optical and physical requirements of marking trailing vortices that emanate from aircraft wings was carried out by considering particulate light-scattering properties, ability of particles to follow trailing vortices, and survival time of particles to vortex dissipation. Liquid droplets undergoing evaporation and molecular dispersion were investigated. Droplets should have lifetimes of about 300 sec. Droplet size should be about 1 micron to maximize light scattering with the minimum mass of liquid required. Droplets of this small size would spiral outward very slowly and essentially remain in the vortex cores. Nontoxic hygroscopic liquids, having an affinity for moisture in the air, have been identified. These liquids have relatively low vapor pressures of order 10⁻⁵ mm Hg that would ensure droplet persistence long enough to mark trailing vortices.

Backstein, S. and Staufenbiel, R.

"SOME EXPERIMENTAL RESULTS ON SPIRAL VORTEX BREAKDOWN"

Z. Flugwiss Weltraumforsch, Vol. 19, 1995, pp. 359-365

Columnar vortices which are embedded in a flow field with increasing pressure in axial direction tend to vortex breakdown. Moderate adverse pressure gradients induce breakdown in form of a 'spiral' type at free vortices, without neighboring surfaces. To study this phenomenon in detail, experiments were conducted in a water tunnel with a tip vortex stimulated to spiral-type breakdown. For varying pressure gradients continuously and smoothly, a special test setup was developed. The vortex center was visualized by small hydrogen bubbles. By means of flow visualization and LDV measurements, the transition of the slender vortex into a spiral breakdown domain was studied. To analyze the experimental results, a simulation model was developed which permitted to reconstruct vortex structure and center position. It is shown that this type of vortex breakdown is not an abrupt structural change as the 'classical' definition proposes, but more a smooth transformation from one state to another. It is characterized by turning the vortex center into a spiral path, without an essential modification of the vortex structure, before the ordered structure is destroyed by self-induction. Moreover, it can be shown that the appearance of stagnation or reversal of the axial flow, which are stated generally as secondary effects of vortex breakdown, is not an essential feature of spiral breakdown.

Backstein, S. H.

"EXPERIMENTAL AND NUMERICAL RESULTS ON SPIRAL VORTEX BREAKDOWN"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 32-1 to 32-7

Experiments and numerical simulations have been performed to investigate the spiral breakdown of a wing tip vortex in flow fields of adverse axial pressure gradient. The basic idea was to stretch the transition domain by a reduction of the imposed pressure gradient. Embedding the vortex in a flow field with only gradual axial retardation, a stretching could be achieved in both, experiment and calculation, giving some interesting insight into the mechanism of vortex breakdown. The appearance of reversed axial flow, upstream of the spiral, is identified as the distinctive feature of vortex breakdown, that must lead to the loss of axial symmetry and to an unsteady flow.

Baek, K.-H.

"SIMULATIONS OF SHEAR LAYER EFFECTS AND CROW INSTABILITY ON AIRCRAFT WAKE VORTICES"

M.S. Thesis, 1998, University of South Alabama, Mobile, AL

Effects of shear layers on aircraft wake vortices are numerically studied, using a two-dimensional point vortex model. It is found that the mechanism responsible for the asymmetric behaviors of a wake vortex pair can be deduced from inviscid interactions with shear layers. On the other hand, atmospheric turbulence can have effects on the decay of wake vortices by inducing vortex instabilities. Viscous effects on Crow (or sinusoidal) instability are investigated for three-dimensional wake vortices with initial disturbances and axial velocities at the center of vortices. Simulation results suggest that viscous effects tend to decrease the unstable wavelength from Crow's inviscid stability criteria. It is also addressed that the presence of the axial velocities uniquely developed in flow fields during the instability process can decrease the vortex strength at some degree.

Baffico, M. and Lund, F.

"MULTIPLE SCATTERING OF ULTRASONIC WAVES BY SLENDER VORTICES"

Proceedings IUTAM Symposium on Dynamics of Slender Vortices, September 1997, Aachen, Germany.

The propagation of ultrasound through a flow that is made up of many slender, randomly distributed vortices, is studied in a multiple scattering approximation. Effective medium equations are derived. They yield an effective speed of sound, as well as an attenuation length. As an example, these quantities are explicitly calculated when the vortices are vortex rings.

Bagai, A. and Leishman, J. G.

"FLOW VISUALIZATION OF COMPRESSIBLE VORTEX STRUCTURES USING DENSITY GRADIENT TECHNIQUES"

Experiments in Fluids, Vol. 15, 1993, pp. 431-442

Mathematical results are derived for the schlieren and shadowgraph contrast variation due to the refraction of light rays passing through two-dimensional compressible vortices with viscous cores. Both standard and small-disturbance solutions are obtained. It is shown that schlieren and shadowgraph

produce substantially different contrast profiles. Further, the shadowgraph contrast variation is shown to be very sensitive to the vortex velocity profile and is also dependent on the location of the peak peripheral velocity (viscous core radius). The computed results are compared to actual contrast measurements made for rotor tip vortices using the shadowgraph flow visualization technique. The work helps to clarify the relationships between the observed contrast and the structure of vortical structures in density gradient based flow visualization experiments.

"ROTOR FREE-WAKE MODELING USING A PSEUDOIMPLICIT RELAXATION ALGORITHM"

J. Aircraft, Vol. 32, No. 6, November-December 1995, pp. 1276-1285

A pseudo-implicit predictor-corrector relaxation algorithm with five-point central differencing in space has been developed for the solution of the governing differential equations of the helicopter rotor free-wake problem. This new approach is compared and contrasted with more conventional explicit-type free-wake algorithms. A convergence analysis shows that the new algorithm provides for much more rapid convergence characteristics compared to explicit methods, with improvements in numerical efficiency and predictive accuracy.

Baggaley, A. W. and Barenghi, C. F.

"TURBULENT CASCADE OF KELVIN WAVES ON VORTEX FILAMENTS"

Journal of Physics, Conference Series, Vol. 318, 13th European Turbulence Conference, 2011, p. 062001.

By numerically integrating in time the motion of vortex filaments, we study how the nonlinear interaction of Kelvin waves along vortices generates Kelvin waves of larger and larger wavenumbers (smaller and smaller wavelength). At sufficiently large wavenumbers the angular velocity of the vortices is large enough that kinetic energy is lost by sound emission. This turbulent cascade of Kelvin waves should explain why turbulence, generated in superfluid helium at very low temperature near absolute zero, quickly decays, despite the lack of any viscous dissipation.

Baggs, C.

"THE WAKE VORTEX REPORTING PROGRAMME: A BRIEF HISTORY AND EXPLANATION OF INCIDENT REPORTING AND DATA CAPTURE"

ATCEU Memorandum No. 177, July 1991, Air Traffic Control Evaluation Unit, National Air Traffic Services, Christchurch, Dorset, UK

This memorandum describes the wake vortex incident database which has been established at the ATCEU since October 1989. It provides an overview of the procedures used for capturing and recording

data from reported wake vortex incidents. Statistical data will be extracted from the database at regular intervals.

Baggs, C.

"THE WAKE VORTEX REPORTING PROGRAMME: ANALYSIS OF INCIDENTS REPORTED BETWEEN JANUARY 1990 AND DECEMBER 1991"

ATCEU Memorandum No. 184, June 1992, Air Traffic Control Evaluation Unit, National Air Traffic Services, Christchurch, Dorset, UK.

This memorandum provides a statistical review of wake vortex incidents which were reported to the ATCEU in the period January 1990 to December 1991. A total of 86 incidents were reported in 1990 and a total of 87 incidents were reported in 1991. The memorandum also summarizes the methods used for capturing and analyzing such data.

"AFTERBODY AERODYNAMIC OPTIMIZATION DESIGN OF TRANSPORT AIRPLANE CONSIDERING WING WAKE FLOW"

Acta Aerodynamica Sinica, Vo. 33, No. 1, February 2015, pp. 134-141.

The aerodynamic optimization design of typical transport afterbody considering the influence of the wing wake flow is studied. An optimization framework is established for the aircraft configuration and used for afterbody optimization at cruising status. The objective of this framework is to optimize the afterbody considering the influence from other parts of aircraft and the engineering constraints simultaneously. The spatial property of the afterbody in spatial control frame is established by implementing the free form deformation (FFD) approach. The NURBS spline is chosen as the basis function, which can represent the property of spatial control element and is suitable for afterbody geometry. Infinite interpolation deforming grid technique is adopted to update spatial grid with high efficiency and mesh quality. The modified Kriging surrogate model and quantum particle swarm algorithm are included in the optimization system to increase efficiency and ability to find global optimal solution. To reduce drag at cruising status, unswept angle and cross section shape are optimized as the main afterbody configuration parameters. The result of the case shows that the aerodynamic performance of the transport's body is improved after the optimization.

"MULTIPLE PRECISION, MULTIPLE PROCESSOR VORTEX SHEET ROLL-UP COMPUTATION"

RNR-92-028, October 1992, NASA Ames Research Center, Moffett Field, CA

This paper describes a vortex sheet roll-up computation using multiple precision arithmetic on a highly parallel computer (an Intel iPSC/860).

Bailey, Jr., W. H. and Durham, T. A.

"AIRCRAFT WAKE INVESTIGATION"

Journal of Aircraft, Vol. 18, No. 2, February 1981, pp. 67-68

The Air Force Weapons Laboratory conducted a test to determine the wake characteristics of a B-52 in flight. Variations in the ambient atmosphere introduced by an aircraft wake manifested by increased wind velocities and gas constituents can cause fluctuations in laser beam propagation. By flying a B-52 upwind of a highly instrumented meteorological tower, wake vortex wind speeds and gas concentrations of the exhausts were obtained. The test was conducted in crosswinds as high as 80 ft/s which allowed the inspection of wakes 5 s in age and 2000 ft behind the aircraft. In this region it was found that the vortex contained: 1) wind speeds more than 210 ft/s and 2) a 250% increase in the concentrations of CO₂. The implication of these results is that propagation of high-energy lasers through aircraft wakes could be seriously degraded.

Bailey, Jr., W. H. and Durham, T. A.

"B-52 WAKE INVESTIGATION"

LOG-C3932, March 1980, Air Force Academy, Colorado Springs, CO

The wake characteristics of a B-52 in flight are determined. Of specific concern is the fact that variations in the ambient atmosphere introduced by an aircraft wake manifested by increased wind velocities and gas constituents can cause fluctuations in laser beam propagation. By flying a B-52 upwind of a highly instrumented meteorological tower, wake vortex wind speeds and gas concentrations of the exhaust were obtained. The test was conducted in crosswinds as high as 80 ft/sec which allowed the inspection of wakes 5 seconds in age and 2000 feet behind the aircraft. In this region, it was found that the vortex contained: (1) wind speeds more than 210 ft/sec and (2) a 250 percent increase in the concentrations of CO₂. The implication of these results is that propagation of high energy lasers through aircraft wakes could be seriously degraded.

"B-52 TOWER FLYBY"

AFWL-TR-78-162, April 1979, Air Force Weapons Lab., Kirtland AFB, NM

A tower flyby test was conducted to determine the wake characteristics of the B-52 bomber. Such information was required for Air Force Weapons Laboratory studies on laser beam propagation. Of particular interest were wake velocities, engine exhaust composition and general wake geometry. The approach was to fly a B-52 crosswind and upstream of an instrumented tower. Measurements were then made as the wake was transported through the tower by the crosswind -- its magnitude, direction

and chemical composition -- together with the flight trajectory of the airplane then allows a spatial sampling of the wake. In addition, a series of flow visualization runs were made using tower and airplane smoke to characterize wake geometry. Crosswinds on the order of 80 feet per second allowed penetrations as close as 2000 feet behind the aircraft. Peak wake velocities of 210 feet per second and CO₂ exhaust concentrations of 250 percent above the ambient condition were recorded.

"MEASUREMENTS OF THE VELOCITY FIELD OF A WING-TIP VORTEX, WANDERING IN GRID TURBULENCE"

J. Fluid Mech., Vol. 601, 2008, pp. 281-31.

Velocity measurements were performed in a wing-tip vortex wandering in free-stream turbulence using two four-wire hot-wire probes. Vortex wandering was well represented by a bi-normal probability density with increasing free-stream turbulence resulting in increased amplitude of wandering. The most dominant wavelength of wandering was found to remain unaffected by free-stream conditions. Two-point velocity measurements were used to reconstruct the vortex velocity profile in a frame of reference wandering with the vortex. Increasing turbulence intensity was found to increase the rate of decay of the vortex peak circumferential velocity while the radial location of this peak velocity remained unchanged. These results are consistent with several possible decay mechanisms, including the stripping of vorticity by azimuthally aligned vortical structures, transfer of angular momentum from the vortex to these structures during their formation and the deformation and breakup of the vortex by strong free-stream eddies.

Bailey, S. C. C., Tavoularis, S. and Lee, B. H. K.

"EFFECTS OF FREESTREAM TURBULENCE ON WING-TIP VORTEX FORMATION AND NEAR FIELD"

Journal of Aircraft, Vol. 43, No. 5, September-October 2006, pp. 1282-1291.

The formation and near-field development of a wing-tip vortex under the influence of freestream turbulence were examined using flow visualization and hot-wire anemometry. A low turbulence freestream as well as two cases of grid turbulence with different intensities and length scales were considered. In all cases the tip vortex was found to form from three smaller vortices, but the turbulence in its core was found to intensify with increasing freestream turbulence. The vortex trajectory was found to be unaffected by freestream turbulence, but the wing wake that was rolling up around the vortex was observed to have a curvature that decreased as freestream turbulence increased. The mean axial velocity distribution in the low-turbulence case was neither jet-like nor wake-like but had an annular shape. Time-averaged velocity profiles measured in the turbulent freestream cases were wake-like, and it was inferred that the instantaneous profiles would be significantly affected by vortex meandering. Mean circumferential velocity distributions in the vortex core displayed self-similar developments in all cases examined. Finally, it was found that the apparent diffusion in the shear layer shed from the wing increased with increasing freestream turbulence.

"OBJECT-ORIENTED SIMULATION OF PARATROOPER-VORTEX INTERACTIONS"

Proceedings of the Winter Simulation Conference, 1997, pp. 903-910.

The C-17 Airdrop Model provides the Air Force and Army test and evaluation community with the capability to (i) assess the risk of vortex encounters, and (ii) predict ground dispersal patterns on the drop zone. Written in MODSIM III, aircraft vortices and paratroopers are modeled as objects whose behavior accurately reflects their real-world counterparts using pre-validated aerodynamic and trajectory equations within the objects' methods. This model has provided the joint airborne community with a preliminary estimate of paratrooper/vortex encounter rates and locations as a function of formation element separation and wind conditions, as well as a tool for simulating alternative C-17 aircraft formation configurations prior to actual flight. Future use of the model suggests simulating brigade-size operations; expanding to include equipment drops, new parachute deployment systems, and precision airdrop visualization; and, evaluating new airborne combat tactics.

"THEORY OF NON-AXISYMMETRIC BURGERS VORTEX WITH ARBITRARY REYNOLDS NUMBER"

Proceedings IUTAM Symposium on Dynamics of Slender Vortices, September 1997, Aachen, Germany, pp. 193-202.

We develop an asymptotic theory of the steady state of a rectilinear vortex in linear straining flow. In the special case of axisymmetric strain, the solution is the familiar Burgers vortex. In the more general non-axisymmetric situation, the asymptotic theories were developed for low Reynolds number (Robinson and Saffman 1984) and for high Reynolds number (Moffatt, Kida and Ohkitani 1994). In the present paper we develop a new expansion in the parameter λ which characterizes the departure from axisymmetry. Hence we obtain an expansion valid uniformly for all Reynolds numbers and thus bridging the gap between the low and the high Reynolds number theories. In practice the new expansion is useful when the non-axisymmetric deformation of the vortex is not too large.

"VORTEX MOTION IN A WEAK BACKGROUND SHEAR FLOW"

J. Fluid Mech., Vol. 509, 2004, pp. 281-304

A point vortex is introduced into a weak background vorticity gradient at finite Reynolds number. As the vortex spreads viscously so the background vorticity becomes wrapped around it, leading to enhanced diffusion of vorticity, but also giving feedback on the vortex and causing it to move. This is investigated in the linear approximation, using a similarity solution for the advection of weak vorticity around the vortex, at finite and infinite Reynolds number. A logarithmic divergence in the far field

requires the introduction of an outer length scale and asymptotic matching. In this way results are obtained for the motion of a vortex in a weak vorticity field modulated on the large scale and these are confirmed by means of numerical simulations.

Baker, G. R.

"ROLL UP OF A VORTEX SHEET USING THE 'CLOUD-IN-CELL' TECHNIQUE"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 124-13.

The problem of the roll up of a two-dimensional vortex sheet generated by a wing in an ideal fluid is phrased in terms of the stream function and the vortex sheet strength. A numerical method is used to calculate the time evolution of the vortex sheet by adapting the 'Cloud-In-Cell' technique introduced in solving many particle simulations in plasma physics. Two cases are considered for the initial distribution of circulation, one corresponding to an elliptically loaded wing and the other simulating the wing with a flap deployed. Results indicate that small scale behavior plays an important part in the roll up. Typically, the small-scale perturbations evolve into ever increasing larger structures by vortex amalgamation. Conclusions are given from several tests exploring the validity of the method. Briefly, small scale perturbations are introduced artificially by the grid, but the emerging large-scale behavior is relatively insensitive to it. Since clearly defined structures result from the application of this method, it promises to aid considerably in understanding the behavior of vortex wakes.

Baker, G. R. and Pham, L. D.

"A COMPARISON OF BLOB METHODS FOR VORTEX SHEET ROLL-UP"

J. Fluid Mech., Vol. 547, Jan. 2006, pp. 297-316

The motion of vortex sheets is susceptible to the onset of the Kelvin-Helmholz instability. There is now a large body of evidence that the instability leads to the formation of a curvature singularity in finite time. Vortex blob methods provide a regularization for the motion of vortex sheets. Instead of forming a curvature singularity in finite time, the curves generated by vortex blob methods form spirals. Theory states that these spirals will converge to a classical weak solution of the Euler equations as the blob size vanishes. This theory assumes that the blob method is the result of a convolution of the sheet velocity with an appropriate choice of a smoothing function. We consider four different blob methods, two resulting from appropriate choices of smoothing functions and two not. Numerical results indicate that the curves generated by these methods form different spirals, but all approach the same weak limit as the blob size vanishes. By scaling distances and time appropriately with blob size, the family of spirals generated by different blob sizes collapse almost perfectly to a single spiral. This observation is the next step in developing an asymptotic theory to describe the nature of the weak solution in detail.

"LASER ANEMOMETER MEASUREMENTS OF TRAILING VORTICES IN WATER"

J. Fluid Mech., Vol. 65, Part 2, August 1974, pp. 325-336

A series of measurements of trailing vortices behind lifting hydrofoils is described. These measurements were made in the Caltech Free-Surface Water Tunnel, using a laser-Doppler velocimeter to measure two components of velocity in the vortex wake. Two different model planforms were tested, and measurements were made at several free-stream velocities and angles of attack for each. Velocity profiles were measured at distances downstream of the model of from five to sixty chord lengths. The theory of trailing vortices is discussed. The effects of 'vortex wandering' upon the measurements are computed, and the corrected results are seen to be in reasonable agreement with the theory.

"INVESTIGATION OF THE EFFECTS OF MASS INJECTION TO RESTRUCTURE A TRAILING TIP VORTEX AT TRANSONIC SPEEDS"

RASA-73-03M, February 1973, Rochester Applied Science Assoc., Rochester, NY

This report describes the results of an experimental research program which was conducted to assess the effects of mass injection in the tip vortex on airfoil performance in transonic flow. Balance data and Schlieren photographs were taken for a rectangular semispan model with a full-span aspect ratio of 7.35 in the Mach number range of 0.553 to 1.0. The results of the investigation indicates that mass injection of the concentrated tip vortex does not generate any significant change in airfoil performance at transonic speeds for the configuration tested. Schlieren photographs of the compressible flow field showed that the near field flow characteristics of the airfoil were not influenced by mass injection or by passive nozzle characteristics at transonic speeds.

"WIND TURBINE WAKE STABILITY INVESTIGATIONS USING A VORTEX RING MODELLING APPROACH"

The Science of Making Torque from Wind 2012, published in IOP Journal of Physics: Conference Series Vol. 555, 2014, pp. 012111-1 - 012111-10.

In the present study, a simple inviscid vortex ring (VR) modelling approach is used to represent the developing rotor wake. This allows a straightforward investigation and comparison of the impact of uniform, yawed and sheared flow conditions on the development of the rotor wake, with the additional possibility of including ground effect. The effect of instabilities on the development of the wake is manually introduced in the form of perturbations of strength, ring position and size. The phenomenon of vortex filament interaction or leapfrogging could play a role in the observation of unsteady phenomena and is therefore also addressed. Such a study is hence performed considering recent conflicting views on the causes of wake meandering: is the observed dynamic wake behavior a result of large-scale turbulent forcing or do more subtle and intrinsic wake instabilities play a role? This study

concludes that the presence of the ground and external perturbations, most notably changes in the wake pitch and the rotor thrust coefficient, can significantly affect the steady development of the wake. The mutual vortex pairing instability, whilst displaying interesting periodic behavior, does not correlate with periodic wake behavior reported by Medici et al. However, in the absence of unsteady inflow, it is shown that the wake of a Horizontal Axis Wind Turbine (HAWT) is certainly prone to displaying unstable, dynamic behavior caused by these additional factors.

"DECAY OF FAR FLOW FIELD IN TRAILING VORTICES"

NASA TN-D-7568, February 1974, NASA Ames Research Center, Moffett Field, CA

A finite difference machine code is used in the wake vortex problems in the quasi-cylindrical boundary layer approximation. A turbulent energy model containing new features is developed that accounts for the major effects disclosed by more advanced models in which the parameters are not yet established. Several puzzles that arose in previous theoretical investigations of wake vortices are resolved.

Baldwin, B. S., Chigier, N. A. and Sheaffer, Y. S.

"DECAY OF FAR-FLOWFIELD IN TRAILING VORTICES"

AIAA Journal, Vol. 11, No. 12, December 1973, pp. 1601-1602

Methods for reduction of velocities in trailing vortices of large aircraft are of current interest; finite-difference calculations of the flow in turbulent wake vortices were done as an aid to interpretation of wind-tunnel and flight experiments directed toward that end.

Baldwin, B. S., Sheaffer, Y. S. and Chigier, N. A.

"PREDICTION OF FAR FLOW FIELD IN TRAILING VORTICES"

AIAA Paper No. 1972-0989, Palo Alto, CA, 1972

A finite-difference machine code is brought to bear on the wake-vortex problem in the quasi-cylindrical boundary-layer approximation. A turbulent-energy model containing new features is developed. Parameters of the model are evaluated by comparison of calculated velocities and turbulent intensities with measurements in an axisymmetric wake. Comparisons are made with a previous calculation of the decay of an isolated vortex and with wind tunnel and flight measurements in trailing vortices. A self-similar solution develops at large axial distance that decays with the square root of distance. A slower decay occurs in the preceding transition region.

Ball, C. T.

"CHICAGO O'HARE INTERNATIONAL AIRPORT CAPACITY ANALYSIS"

FAA-RD-75-205, November 1975, Federal Aviation Administration, Washington, DC.

A task force comprised of representatives from the FAA, airlines, and the City of Chicago was formed in December of 1974 to study the present and future capacity and delay of the Chicago O'Hare International Airport. The task force effort concentrated on two future air traffic control environments: One consisting of basic metering and spacing and wake, one consisting of basic metering and spacing and a wake vortex predictive system; the other consisting of advance metering and spacing, a discrete address beacon system, and a wake vortex predictive system. January 1975 schedule information was used to determine the present future capacity of the airport.

"SYSTEMATIC DIFFERENCES IN AIRCRAFT AND RADIOSONDE TEMPERATURES"

Bulletin American Meteorological Society, November 2008, pp. 1689-1708.

Automated aircraft temperatures exhibit considerable variance with aircraft models and on average they are warmer than radiosonde temperatures; therefore, field studies and bias corrections for NWP models are recommended.

Balmforth, N. J., Smith, S. L. and Young, W. R.

"DISTURBING VORTICES"

Journal of Fluid Mechanics, Vol. 426, 2001, pp. 95-133.

Inviscid spatially compact vortices (such as the Rankine vortex) have discrete Kelvin modes. For these modes, the critical radius, at which the rotation frequency of the wave matches the angular velocity of the fluid, lies outside the vortex core. When such a vortex is not perfectly compact, but has a weak vorticity distribution beyond the core, these Kelvin disturbances are singular at the critical radius and become 'quasi-modes'. These are not true eigenmodes but have stream function perturbations that decay exponentially with time while the associated vorticity wraps up into a tight spiral without decay. We use a matched asymptotic expansion to derive a simplified description of weakly nonlinear, externally forced quasi-modes. We consider the excitation and subsequent evolution of finite-amplitude quasi-modes excited with azimuthal wavenumber 2. Provided the forcing amplitude is below a certain critical amplitude, the quasi-mode decays and the disturbed vortex returns to axisymmetry. If the amplitude of the forcing is above critical, then nonlinear effects arrest the decay and cat's eye patterns form. Thus the vortex is permanently deformed into a tripolar structure.

Balser, M., McNary, C. A. and Nagy, A. E.

"ACOUSTIC ANALYSIS OF AIRCRAFT VORTEX CHARACTERISTICS"

FAA-RD-72-81, July 1972, Xonics Inc., Van Nuys, CA

A program of field measurements at NAFEC and related analysis has been carried out as part of the development of acoustic radar for aircraft vortex turbulence detection. Spectra of acoustic signals scattered from the vortices were found to agree in form with those derived from a model, and yielded velocities that generally agreed with those observed by the NAFEC tower instrumentation. Consistent quantitative measurements of circulation, the quantity most closely related to hazard, were obtained for several different aircraft. Confident vortex tracks were obtained for aircraft (a DC-6) altitudes up to 1500 ft, with the vortex detected at about 1300 ft and tracked for about a minute until it passed out of the coverage region.

Balser, M., McNary, C. A. and Nagy, A. E.

"ACOUSTIC BACKSCATTER RADAR SYSTEM FOR TRACKING AIRCRAFT TRAILING VORTICES"

Journal of Aircraft, Vol. 11, No. 9, September 1974, pp. 556-562

The safety hazard posed by potential encounters with invisible vortices from preceding aircraft imposes stringent limitations on aircraft spacing in the terminal area, hence on traffic-handling capacity. An acoustic back-scatter radar system has been developed to detect and track such vortices, and thereby provide the information for more advanced air traffic procedures that would eliminate the uncertainty and delay caused by vortices. The system is fully engineered and operates in real time. Examples of the real-time display and of vortex tracks from Boeing 747's landing at the Los Angeles International Airport are given in the paper.

Balser, M., Nagy, A. E. and Proudian, A. P.

"VORTEX OBSERVATIONS BY THE XONICS ACOUSTIC RADAR AT NAFEC"

FAA-RD-71-103, December 1971, Xonics Inc., Van Nuys, CA

A series of flight tests was conducted in order to demonstrate feasibility of the concept of the Xonics acoustic vortex detector. The first tests consisted of simultaneous observations in close proximity by both the Xonics equipment and the instrumented tower of vortices shed by a low-flying aircraft. Except for the few cases where data was lost through equipment misalignment or malfunction or operator error, vortex returns were observed on virtually all of the runs. A total of 55 runs, which represents a substantial fraction of all the data gathered, were selected for analysis. The vortex velocity measurements exhibit a clear correlation with aircraft configuration, and appear to confirm their use as a valid indicator of vortex intensity.

Balser, M., Nagy, A. E. and Proudian, A. P.

"AIRCRAFT VORTEX DETECTION SYSTEM"

US Patent 3,735,333, May 1973

An improved system for detection and measurement of aircraft wing tip vortices over a wide area. An acoustic echo system with transmitter and receiver spaced from each other in a plane perpendicular to the flight path for illuminating the vortex and picking up scattering of the transmitter signal produced by the vortex, using Doppler frequency spectrum analysis with the maximum and minimum frequencies providing measure of vortex intensity. A plurality of receivers operating with a common transmitter providing coverage of an area of interest along a flight path. A transmitter covering a broad area by a broad beam acoustic transducer or a plurality of narrow beams, and means for identifying a specific zone within the broad area occupied by the vortex being analyzed.

"AIRCRAFT WAKE VORTEX PARAMETRIZATION BASED ON 1.5-MICRON COHERENT DOPPLER LIDAR DATA"

27th ILRC International Laser Radar Conf., July 2015, New York City, NY.

A strategy of measurement by a 1.5-micron pulsed coherent Doppler lidar 'Stream Line' has been developed, and a method for estimation of aircraft wake vortices from the lidar data has been proposed. The principal possibility of obtaining the information about the vortex situation over an airport airfield with the Stream Line lidar has been demonstrated.

Banakh, V. A. and Smalikho, I. N.

"ESTIMATION OF THE TURBULENCE ENERGY DISSIPATION RATE FROM THE PULSED DOPPLER LIDAR DATA"

Atmospheric and Oceanic Optics, Vol. 10, No. 12, December 1997, pp. 957-965.

Based on the results of numerical modeling we have analyzed the possibility and calculated the errors of estimating turbulence kinetic energy dissipation rate from data of pulsed Doppler lidar. Compared are the accuracies of estimation of wind velocity spatial structure function from Doppler lidar data obtained by the method of correlation function argument and the method of maximum likelihood. It is shown that, when using sufficiently large number of sample data, the relative error in estimation of turbulence energy dissipation rate with a pulsed Doppler lidar must be below 15-20 percent at signal-to-noise ratio equal or greater than unity.

Banakh, V. A., Brewer, A., Pichugina, E. L. and Smalikho, I. N.

"MEASUREMENTS OF WIND VELOCITY AND DIRECTION WITH COHERENT DOPPLER LIDAR IN CONDITIONS OF A WEAK ECHO SIGNAL"

Atmospheric and Oceanic Optics, Vol. 23, No. 5, 2010, pp. 381-388.

The possibility of measuring the wind velocity and direction with 2-micron pulsed coherent Doppler lidar in conditions of a weak echo signal is investigated. It is shown that the use of the filtered sine wave fitting of the lidar-measured radial wind velocities allows for the estimation of the wind velocity vector components with an acceptable accuracy at a low signal-to-noise ratio up to values of -20 dB.

Banakh, V. A., Smalikho, I. N. and Falits, A. V.

"ESTIMATION OF THE TURBULENCE ENERGY DISSIPATION RATE IN THE ATMOSPHERIC BOUNDARY LAYER FROM MEASUREMENTS OF THE RADIAL WIND VELOCITY BY MICROPULSE COHERENT DOPPLER LIDAR"

Optics Express, Vol. 25, No. 19, September 2017, pp. 22679-22692.

The accuracy of the method of azimuth structure function for estimation of the dissipation rate of the kinetic energy of turbulence from an array of radial velocities measured by low-energy micropulse coherent Doppler lidars with conical scanning by a probing beam around the vertical axis has been studied numerically. The applicability of the method in dependence on the turbulence intensity and the signal-to-noise ratio has been determined. The method of azimuth structure function was applied for estimation of the turbulent energy dissipation rate from radial velocities measured by the lidar in the experiments on the coast of Lake Baikal. Two-dimensional time-height patterns of the wind turbulence energy dissipation rate were obtained. Part of them were obtained in presence of the atmospheric internal waves (AIWs) and low-level jet streams. It is observed that the wind turbulence in the area occupied by jet streams is very weak. In the process of dissipation of AIWs the wind turbulence strength increases.

Banakh, V. A., Smalikho, I. N., Pichugina, E. L. and Brewer, W. A.

"REPRESENTATIVENESS OF MEASUREMENTS OF THE DISSIPATION RATE OF TURBULENCE ENERGY BY SCANNING DOPPLER LIDAR"

Atmospheric and Oceanic Optics, Vol. 23, No. 1, 2010, pp. 48-54.

The representativeness of measurements of the dissipation rate of atmospheric turbulence energy by 2-micron pulsed coherent Doppler lidar scanning in the vertical plane is studied experimentally. A comparison of the results of simultaneous measurements of the dissipation rate at different altitudes in the atmospheric boundary layer by lidar and four sonic anemometers has shown that the lidar estimate has a small bias and its relative error does not exceed 25 percent.

Banakh, V. A., Smalikho, I. N., Pichugina, Y. L. and Brewer, W. A.

"ESTIMATION OF THE TURBULENCE ENERGY DISSIPATION RATE FROM THE PULSED COHERENT DOPPLER LIDAR DATA MEASURED AT THE CONICAL SCANNING"

9th International Symposium on Tropospheric Profiling (ISTP), September 2012, University of L'Aquila, L'Aquila, Italy.

In this paper we present the basic relations for the estimation of the turbulence energy dissipation rate from the transverse and longitudinal structure function of the radial wind velocity measured by pulsed coherent Doppler lidar (CDL) at the conical scanning (both one full scan and multiple sectorial scanning). We compare the results of the pulsed CDL profiling the dissipation rate in the ABL by these methods with the estimation of the dissipation rate obtained from the sonic anemometer data. We present the results of estimating the dissipation rate at the given height from the transverse and from the longitudinal structure function calculated based on the same data of the radial wind velocity measured by CDL during long temporal period and compare these results with each other.

Bandyopadhyay, P. R., Stead, D. J. and Ash, R. L.

"ORGANIZED NATURE OF A TURBULENT TRAILING VORTEX"

AIAA Journal, Vol. 29, No. 10, October 1991, pp. 1627-1633

Experiments have been carried out into the turbulence structure of a low-Reynolds-number trailing vortex produced at the juncture of a flow aligned cylinder and a pair of oppositely loaded airfoils. Five different types of screens are placed ahead of the vortex generator. Components of the mean velocity, Reynolds stress flux, and quasiperiodic large-scale wavelengths have been measured. The turbulence structure varies with Rossby number. The vortex core is not a benign solid body of rotation. It has intermittent patches of turbulent and laminar fluid. The shear-stress-rich low-momentum core fluid intermittently ejects outwards in the direction of vortex rotation.

"3D VOLUMETRIC ANALYSIS OF WIND TURBINE WAKE PROPERTIES IN THE ATMOSPHERE USING HIGH-RESOLUTION DOPPLER LIDAR"

Journal of Atmospheric and Oceanic Technology, Vol. 32, 2015, pp. 904-914.

Wind turbine wakes in the atmosphere are three-dimensional (3D) and time dependent. An important question is how best to measure atmospheric wake properties, both for characterizing these properties observationally and for verification of numerical, conceptual, and physical (e.g., wind tunnel) models of wakes. Here a scanning, pulsed, coherent Doppler lidar is used to sample a turbine wake using 3D volume scan patterns that envelop the wake and simultaneously measure the inflow profile. The volume data are analyzed for quantities of interest, such as peak velocity deficit, downwind variability of the deficit, and downwind extent of the wake, in a manner that preserves the measured data. For the case study presented here, in which the wake was well defined in the lidar data, peak deficits of up to 80 percent were measured 0.6-2 rotor diameters (D) downwind of the turbine, and the wakes extended more than 11D downwind. Temporal wake variability over periods of minutes and the effects of atmospheric gusts and luffs in the inflow are demonstrated in the analysis. Lidar scanning trade-offs important to ensuring that the wake quantities of interest are adequately sampled by the

scan pattern, including scan coverage, number of scans per volume, data resolution, and scan-cycle repeat interval, are discussed.

Bao, F. and Vollmers, H.

"ALLEVIATION OF END-EFFECT IN FACILITIES FOR FAR WAKE INVESTIGATIONS"

AIAA Paper No. 2005-0907, Reno, NV, January 2005

This paper deals with the end-effect problem encountered in the wake vortex researches in test facilities with limited length. The disturbances produced during the launching and recovering of a/c models may propagate along the vortex core and introduce a helical instability which will burst off the vortex core. When the disturbances reach the measurement region, the results will be spoiled. Investigations were made in a water towing tank, which was instrumented with a stereo PIV system and visualization devices. Methods for alleviating the end-effect were studied and one effective setup was patented.

Bao, F., Liu, J., Zhu, H., Jiang, J. and Wang, J.

"CONTROL METHOD FOR AIRCRAFT WAKE VORTEX BASED ON RAYLEIGH-LUDWIG INSTABILITY"

Journal of Beijing University of Aeronautics and Astronautics, Vol. 41, No. 8, August 2015, pp. 1381-1387.

The aircraft wake vortex is an inherent flow phenomenon due to the lift generation mechanism, which has a negative impact on the flight safety. By adding a set of specially designed spoiler, a rectangular wing was designed to generate a pair of weaker vortices, which had different sizes and opposite direction compared to main wing vortices, thereby constructing a self-destructive four-vortex wake system to induce Rayleigh-Ludwig instability. Under different experimental conditions, in terms of changing the size or shape of the spoiler, towing speed and angle of attack, the wake vortex development of the test model, that both with and without spoiler, as well as the circulation analysis, were acquired particle image velocimetry (PIV) measurements under the Reynolds number. The study demonstrates that the decrease in circulation was 35 percent to 55 percent in 45 wingspans when spoilers are introduced, whereas the counterpart of the baseline airfoil, without spoilers, is nearly kept steadily, which reveal the application possibility of Rayleigh-Ludwig instability in alleviating the wake vortex. As the initial circulation ratio equals to -0.489 and the initial distance ratio is 0.5, the circulation of the primary vortex reduces most significantly (55.9 percent) in 45 wingspans. Results would provide a scheme in the design of airfoils with weaker vortices.

"EXPERIMENTAL STUDY ON RAYLEIGH-LUDWIG INSTABILITY OF AIRCRAFT WAKE VORTEX"

Acta Aeronautica et Astronautica Sinica, Vol. 36, No. 7, July 2015, pp. 2166-2176.

Based on the fact that the main wing and tail would produce counter-rotating vortices in the process of taking-off and landing, a set of double vortex generators are designed. Under two different experimental conditions, in terms of changing the position and initial intensity ratio of the double vortex, the wake vortex development of the test mode is acquired, including flow visualizations and particle image velocimetry (PIV) technology. Research reveals that the introduction of a weaker vortex, with a proper position and initial intensity ratio, would change the main vortex original trajectory and promotes its dissipation. However, it does not present an obvious linear relationship between them. The analysis results of vortex trajectory could be used in improving the efficiency of taking-off and landing in airports, the experiments also provide a reference for the overall design of aircrafts: when the requirement for flight mechanics design is satisfied, optimizing the overall aerodynamic layout will have a significant effect on alleviating the intensity of aircraft wake. [In Chinese.]

"EXPERIMENTAL STUDY ON CONTROLLING WAKE VORTEX IN WATER TOWING TANK"

Proceedings 20th International Congress on Instrumentation in Aerospace Simulation Facilities 2003, Gottingen, Germany, August 25-29, 2003, pp. 214-223

An experimental study was carried out to establish a self-destructing vortex wake. Sets of horizontal tail plains were employed to generate additional vortex sheet interacting with the wing vortex sheet of a rectangular wing. The study was made in the water towing tank in Gottingen (WSG), which was instrumented with 2D/3C PIV system, balance and flow visualization devices. The tailoring of 4 vortices wake systems was achieved by varying horizontal tail plains with different aspect ratios with various incidences, generating various destabilizing effects. The study exhibited that the interaction of tail vortices with tip vortices may result in a promising self-destructive mechanism within the wake system in the sense that the vortex core experiences an instability and decay abruptly. Typically, the wake vortex cores could be destabilized by as early as in 30 wing spans downstream with suitable tail settings, instead of more than 100 wing spans for that of a 'clean model'. The possible influence from the finite movement in the water tank due to transient processes of the model (end-effect) was investigated. The influence of the bottom and side wall effects was estimated from comparison of results from a larger water towing tank (HSVA).

"FOUR-VORTEX SYSTEM RECONSTRUCTION AND EXPERIMENTAL STUDY OF ITS WAKE FEATURES"

Acta Aeronautica et Astronautica Sinica, Vol. 36, No. 5, May 2015, pp. 1491-1499.

The aircraft wake vortex is a coherent flow phenomenon due to the lift generation mechanism, which threatens the flight safety and limits airport operation efficiency. By mounting a vortex generator onto the wingtip of a rectangular airfoil, a secondary vortex that rotated reversely to the primary vortex is produced, thereby constructing a self-destructed four-vortex system to accelerate the dissipation of the primary vortex. Combined with flow visualizations and particle image velocimetry (PIV) measurements,

a parametric study of the spatial evolution and vorticity development of the four-vortex system in 25 wingspans, as well as the circulation reduction rate in 45 wingspans, is conducted. The results exhibit that the interaction instability of the wake vortex is triggered by the secondary vortex in advance, resulting in the premature breakdown of the primary vortex, resulting in the decline of its vorticity. As the initial circulation ratio is -0.581 and the initial distance ratio is 0.5, the circulation of the primary vortex is reduced most significantly (34.7%) in 45 wingspans. The results would provide a scheme for the design of airfoils with weaker vortices. [In Chinese.]

Baranov, N. A.

"WAKE VORTEX DYNAMICS STUDY IN TEMPERATURE INVERSION CONDITIONS"

WMO Technical Conference on Meteorological and Environmental Instruments and Methods of Observation, September 2016, Madrid, Spain.

The presented results have been obtained following numerical modeling of aircraft wake vortex dynamics in the conditions of surface temperature inversion of the atmosphere. Modeling was based on data from surface temperature profile monitoring, which took place in winter and spring at Sochi airport using MTP-5 meteorological temperature profiler. A comparative analysis of the wake vortex dynamics in the absence and presence of a side wind of varying intensity was carried out for a number of temperature inversion cases, such as surface inversion, elevated inversion with different layer altitude inversion, elevated inversion with surface isothermy.

"METHOD AND SYSTEM FOR PREVENTING AN AIRCRAFT FROM PENETRATING INTO A DANGEROUS TRAILING VORTEX AREA OF A VORTEX GENERATOR"

US Patent 7,333,030 B2, February 2008

The invention relates to methods and devices for aircraft's safe operation and is embodied in the form of a method and system for informing a user, for example an aircraft crew and/or a flight controller, on the probable penetration of the aircraft into dangerous areas of the vortex shedding of vortex generators which are located near the aircraft at a forecast time when the aircraft passes through a simulated control plane situated at a preventive distance in the direction of motion of the aircraft, said distance being calculated on a basis of a sufficient forecast period so that the aircraft carries out a flight evasive maneuver. The preventive system defines the trajectory and intensity of the vortex shedding of the vortex generators, the co-ordinates of intersecting points of the vortex sheddings with a control plane, the geometric parameters of the dangerous areas thereof according to danger criteria specified by a user, forms a warning area in said control plane, an area of the forecast positions of the aircraft and dangerous vortex shedding areas at a forecast time, follows up the events of crossing the warning area and/or the area of the aircraft forecast positions associated with the dangerous vortex shedding areas and draws attention of the user to said event with the aid of display devices and a visualization device.

Baranov, N. A., Belotserkovski, A. S., Kanevski, M. I. and Pasekunov, I. V.

"INTEGRATED SYSTEM FOR AIRCRAFT VORTEX SAFETY"

US Patent Application 2007/0103340 A1, May 2007.

The invention relates to systems for preventing off-normal situations when there is a possibility that an aircraft penetrates a dangerous area of the vortex shedding of a vortex generator. The inventive system consists of information sub-systems for recording and storing information on the expected relative position of the aircraft and trailing vortex areas in line with danger criteria which are specified by a user and concern dangerous aerodynamic forces and torques effecting the aircraft and induced by the trailing vortex of vortex generators, and for conveying said information to said user, who can be the aircraft crew and/or flight attendants, at a preventive distance from the aircraft and at a forecast moment. Said information can be visualized in a human-readable form and in a volume sufficient for forming a directive signal for carrying out a flight maneuver by the aircraft to move away from the dangerous trailing vortex area.

"WIND SPEED VECTOR RESTORATION ALGORITHM"

28th International Laser Radar Conference, June 2017, Bucharest, Romania, published in EPJ Web of Conferences, Vol. 176, 2018, pp. 06012-1 to 06012-4.

Impulse wind lidar (IWL) signal processing software developed by JSC <<BANS>> recovers full wind speed vector by radial projections and provides wind parameters information up to 2 km distance. Increasing accuracy and speed of wind parameters calculation signal processing technics have been studied in this research. Measurement results of IWL and continuous scanning lidar were compared. Also, IWL data processing modeling results have been analyzed.

"EXPERIMENTAL STUDY OF A GROUND VORTEX: THE EFFECT OF THE CROSSFLOW VELOCITY"

Journal of Aircraft, Vol. 50, No. 1, January-February 2013, pp. 298-302.

Laser-Doppler measurements of the velocity characteristics of a ground vortex flow resulting from the collision of a wall jet with a boundary layer were reported for velocity ratios equal to 0.5 and 0.62. Two secondary vortices were found upstream of the separation point for the highest velocity ratio. These vortical structures affect the interaction zone and the separation point in the wall jet side moves upstream. The angle of deflection of the upwash flow was found to decrease with the velocity ratio. The turbulent structure of the collision zone is not substantially affected by the velocity ratio, but important changes occur above the wall jet for the higher velocity ratio. The flow remains essentially isotropic everywhere except near the separation point.

Barata, J. M. M., Durao, D. F. G., Santos, P. J. C. T. and Silva, A. R. R.

"TURBULENT ENERGY BUDGETS OF A GROUND VORTEX FLOW"

15th International Symposium on Applications of Laser Techniques to Fluid Mechanics, July 2010, Lisbon, Portugal.

Turbulent kinetic energy budgets are presented for a highly curved flow generated by the collision of plane wall turbulent jet with a low-velocity boundary layer. The different terms are obtained in the vertical plane of symmetry by quadratic interpolation of the LDV measurements, for a wall jet-to-boundary layer velocity ratio of 2. The results, which have relevance to flows encountered by powered-lift aircraft operating in ground effect, quantify the structure of the complex ground vortex flow resulting from the collision of a wall jet with a boundary layer. The analysis of turbulent energy equation terms using the measured data revealed that production by normal and shear stresses are both very important to the turbulent structure of the impact zone of the ground vortex. The analysis of turbulent kinetic energy indicates the modeling of turbulence of deflected flow resultant from the collision between the wall jet and the boundary layer this may require an adequate treatment.

Barba, L. A., Leonard, A. and Allen, C. B.

"VORTEX METHOD WITH MESHLESS SPATIAL ADAPTION FOR ACCURATE SIMULATION OF VISCOUS, UNSTEADY VORTICAL FLOWS"

International J. for Numerical Methods in Fluids, Vol. 47, March 2005, pp. 841-84.

A vortex method has been developed where spatial adaption of the Lagrangian vortex particles is provided by the technique of radial basis function interpolation. In this way, the meshless formulation of the vortex method is preserved throughout. Viscous effects are provided by the core spreading method, where core size control is accomplished in the spatial adaption, thus ensuring convergence. Numerical experiments demonstrate considerable increase in accuracy, in comparison with standard remeshing schemes used with vortex methods. Proof-of-concept is achieved successfully on a problem of quasi-steady tripole vortex flow, and parallel implementation of the method has permitted high accuracy computations of vortex interactions at high Reynolds number.

Barbagallo, D., De Gregorio, F. and Tino, N.

"HELICOPTER WAKE INVESTIGATIONS BY MEANS OF PIV AND HW MEASUREMENT TECHNIQUES"

9th International Symposium on Flow Visualization, Paper No. 415, 2000, pp. 415-1 - 415-16

During the first two weeks of November 1998, a measurement campaign was conducted to investigate the reliability of the Particle Image Velocimetry and the Hot Wire Anemometer techniques on high unsteady phenomena in an industrial facility. At the same time the aerodynamics interaction phenomenon occurring between the helicopter rotor and the tailplanes, better known as pitch-up phenomenon, was studied. Time-average and unsteady velocity flow field measurements were carried out at different chordwise stations on different horizontal tailplane positions, for different values of the advance ratio. The results have shown that the PIV can be a powerful tool in the experimental aerodynamics field, especially to investigate high unsteady phenomena. The comparison of the time-averaged velocity field by PIV and HW results have shown good agreement. The pitch-up phenomenon was measured and the advance ratio values relative to the wake impinging on the tailplanes were detected. The main rotor tip vortex has been measured and for some test cases the PIV measurement system was phase locked to the helicopter main rotor in order to investigate the velocity behavior related to the rotor azimuth position.

Barbaresco, F.

"AIRPORT RADAR MONITORING OF WAKE VORTEX IN ALL WEATHER CONDITIONS"

Proceedings of the 7th European Radar Conference, September 2010, Paris, France, pp. 85-88.

To assess maturity and capability of X-band radars to monitor wake roll-ups in all weather conditions, radar data were collected on airports, near runway at Orly airport and just under its ILS Interception Area. Additional trials took place on Paris-CDG Airport to benchmark Lidar and Radar Technologies. Continuous detection, characterization, and profiling capabilities of wake vortices, up to a range of 2000 m, have been proved in clear air and rainy weather. Recorded data have been correlated with electromagnetic and fluid mechanical models of wake turbulences for better and more accurate understanding of roll-ups radar cross section and Doppler signature. X-band radar has been proved to be a full-fledged alternative, which can make a significant contribution to a wake vortex alert system,

but to achieve as much reliability as possible, collaborative electro-optical and electromagnetic sensors solution is envisaged encapsulated in a Wake Vortex Advisory System. These sensors could be used to permanently monitor turbulence on runways.

Barbaresco, F.

"METHOD FOR RADAR MONITORING OF WAKE TURBULENCE"

US Patent Application 2010/0117892 A1, May 2010.

The present invention relates to a method for detecting and grading the state and the evolution of wake turbulence caused by an aircraft, based on the radar signals reflected by this turbulence, these signals being analyzed through analysis cells of given dimension in terms of distance and bearing. This method mainly comprises: a first preliminary detection step proper for detecting and locating turbulence in a cell, a second step for determining the strength of the detected turbulence, and a third step for determining the age of the detected turbulence as well as the geometric parameters which characterize it. The method according to the invention advantageously makes it possible to detect wake turbulence and to determine at one and the same time the position and the strength of the latter as well as its stage of evolution. The invention applies in particular to the field of air traffic control and air safety in general.

"RADAR WAKE-VORTICES CROSS-SECTION/DOPPLER SIGNATURE CHARACTERISATION BASED ON SIMULATION AND FIELD TEST TRIALS"

IET Radar, Sonar and Navigation, 2015, pp. 1-15.

Runway operation is the limiting factor for the overall throughput of airports. Today the International Civil Aviation Organization (ICAO) imposes wake vortex separation minima between following aircrafts that are based on simple pair-wise rules. However, the lifetime of wake vortices results from a much

broader basis of factors, that ranges from a large set of aircraft parameters to meteorological conditions and traffic mix. In particular, atmospheric conditions can significantly reduce wake hazard, for instance, in case of strong turbulence or crosswinds. While such situations could allow a reduction of the separation minima, safety reasons and the current technical challenges of detecting and managing such scenarios leads to the strict application of the ICAO standards. With the aid of accurate wind data and precise measurements of wake vortices, more efficient intervals could be set, particularly when weather conditions turn unfavorable. Depending on traffic intensity, these adjustments could enhance airport capacity, and generate major commercial benefits. This study deals with recent development in the radar technology to attain such goals. It presents (i) the trials of an electronic scanning radar to be used in a future wake turbulence advisory system and (ii) theoretical and numerical analysis of the radar response in clear air and in rainy weather. Part of this work has been achieved with the support of the European ATM research program SESAR.

"RADAR SENSORS FOR WIND & WAKE-VORTEX MONITORING ON AIRPORT: FIRST RESULTS OF SESAR P12.2.2 XPO TRIALS CAMPAIGN AT PARIS CDG AIRPORT"

7th European Conference on Radar in Meteorology and Hydrology (ERAD), June 2012, Toulouse, France.

This paper will present European SESAR P12.2.2 project that develops a verified wake turbulence system according to related operational concept improvements to, punctually or permanently, reduce landing and departure wake turbulence separations and, therefore, to increase the runway throughput in such a way that it safely absorbs arrival demand peaks and reduces departure delays. This global objective will be achieved by means of Radar sensors to deliver in real time position and strength of the wake vortices and to assess wind conditions including ambient air turbulence by EDR. This paper will present the Radar component of sensors trials campaign, performed at CDG Airport in Spring 2011, providing results of statistical analyses of two UHF wind Profilers Radars and one X-band Wake-Vortex Monitoring Radar data collection, respectively benchmarked with Sodar/Lidar Profiler and 3D Wake-Vortex Monitoring Lidar. The main results were convincing in terms of wake vortex detection. Most of wake vortices were detected in both critical areas. Results show that Radar and Lidar are complementary depending on weather conditions. X-band Radar performances are optimal under rainy conditions when Lidar performances are optimal in dry air. For wind, the overall availability of UHF Wind Profiler Radars data as a function of the height above the surface will be presented (the percentage of the time that reflectivity was sufficient to make a measurement and that the atmosphere was sufficiently homogeneous and stable). The statistical comparison between two UHF profilers (and with Sodar/Lidar Profilers) will be based on histograms of interpolated data availability, wind velocity and direction profiles in specific periods, calculation of bias, standard deviation and correlation for wind velocity and direction by altitude. Using combinations of sensors, models, and real measurements, and thanks to some improved sensors already planned within the project (X-band E-scanning radar), it should be possible to reach operational needs for the Wake-Vortex Advisory system.

"RADAR 3D MONITORING OF WAKE-VORTEX HAZARDS, CIRCULATION AND EDR RETRIEVAL/CALIBRATION; SESAR P12.2.2 AND FP7 UFO SENSORS TRIALS AT PARIS-CDG AND TOULOUSE AIRPORTS"

International Radar Conference, Lille, France, 2014.

At airports, runway operation is the limiting factor for the overall throughput; specifically, the fixed and overly conservative ICAO wake turbulence separation minima. The wake turbulence hazardous flows can dissipate quicker because of decay due to air turbulence or be transported out of the way on oncoming traffic by cross-wind, yet wake turbulence separation minima do not consider wind conditions. Indeed, for safety reasons, most airports assume a worst-case scenario and use conservative separations; the interval between aircraft taking off or landing therefore often amounts to several minutes. However, with the aid of accurate wind data and precise measurements of wake vortex by radar sensors, more efficient intervals can be set, particularly when weather conditions are stable. Depending on traffic volume, these adjustments can generate capacity gains, which have major commercial benefits. This paper presents electronic scanning radar trials as Safety Net of a wake turbulence system supporting increased throughput as part of the European ATM research program SESAR, and complementary study UFO (Ultra-Fast wind sensors for wake-vortex hazards mitigation) funded by European FP7 program, on Radar EDR retrieval and Calibration.

Barbaresco, F., Jeantet, A. and Meier, U.

"WAKE VORTEX X-BAND RADAR MONITORING: PARIS-CDG AIRPORT 2008 CAMPAIGN RESULTS AND PROSPECTIVES"

2009 International Radar Conference, October 2009, Bordeaux, France.

In order to improve the capacity of airports in view of the expected increasing amount of traffic the knowledge about the safety issues caused by wake vortices has to be improved. The final goal is to build up a wake vortex alert system to ensure the application of appropriate but not oversized safety distances in all weather conditions. Lidar systems are able to deliver very accurate data, but are also sensitive to the weather conditions like rain and fog. We did trials with the X-band radar BOR-A 550 on Paris-CDG Airport in June 2008 to benchmark Lidar and Radar Technologies. Continuous detection, characterization (strength: circulation) and profiling (age: young/mature/old/decaying) capabilities of wake vortices up to a range of 1500 m have been proved in clear air and rainy weather. The Doppler resolution of around 0.2 m/s used with regularized high Doppler resolution techniques can characterize the wake vortex speed distribution in detail. X-band radar is a full-fledged alternative, which can make a significant contribution to a wake vortex alert system.

Barbaresco, F., Jeantet, A. and Meier, U.

"WAKE VORTEX DATA COLLECTION AND ANALYSIS USING X-BAND RADAR"

1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-004, September 2007, pp. 1061-1064

In order to improve the capacity of airports in view of the expected increasing amount of traffic the knowledge about the safety issues caused by wake vortices must be improved. The final goal is to build up a wake vortex alert system to ensure the application of appropriate but not oversized safety distances all the time. It is necessary to perform long time data collections of wake vortex encounters on one or more large airports. Lidar systems can deliver very accurate data, but are also sensitive to the weather conditions like rain and fog. THALES did trials with the X-band radar BOR-A 550 on Orly Airport in November, 2006. It was possible to detect wake vortices up to a range of 700 m. The Doppler resolution of around 0.2 m/s used with regularized high Doppler resolution techniques can characterize the wake vortex speed distribution in detail. X-band Radar is a full-fledged alternative, which can make a significant contribution to a wake vortex alert system.

Barbaresco, F., Jeantet, A. and Meier, U.

"WAKE VORTEX DETECTION AND MONITORING BY X-BAND DOPPLER RADAR: PARIS ORLY RADAR CAMPAIGN RESULTS"

The IET International Conference on Radar Systems, Edinburgh, Scotland, October 2007.

Lidar Sensors has been used to collect data on Wake Turbulence and deliver accurate measurements, but their uses is limited to clear air conditions and are not operational in Rain and Fog weathers. On the other hand, Radar is a good complimentary sensor, which can be used for turbulence remote sensing as well. To mature this last solution, THALES did trials on Paris Orly airport in November 2006, and has proved that X-band Doppler Radar was able to detect wake vortexes up to a range of 700 m. Furthermore, the Doppler resolution of around 0.2 m/s used with Regularized High Doppler resolution techniques was able to characterize wake vortex speed distribution in detail. These first trials showed the usability of X-band Radar as an appropriate sensor in different weather conditions like fog, rain, and dry/wet air. Long time data collection trials are planned for different airports to mature this new technology of wake vortex monitoring. The results of the trials that have been performed up to now will be presented. Moreover, the application of methods to match the recorded data with the current knowledge of the fluid mechanics will be shown. As a conclusion, X-band Radar is a full-fledged alternative to a Lidar system, which can make a significant contribution to the improvement of airport capacity and Safety.

"WAKE VORTEX DETECTION, PREDICTION AND DECISION SUPPORT TOOLS IN SESAR PROGRAM"

32nd Digital Avionics Systems Conference, Paper 6B1, October 2013, East Syracuse, NY.

This paper presents the developments of a wake turbulence system supporting increased throughput as part of the European ATM research program SESAR. This wake turbulence system is designed to, punctually or permanently, reduce landing and departure wake turbulence separations, thus increasing the runway throughput in such a way that arrival demand peaks and departure delays are safety absorbed. This global objective is by deploying radar sensors to deliver real-time position and strength information of the wake vortices and to assess wind conditions including ambient air turbulence via Eddy Dissipation Rate. To further address the optimization of throughput, two extensions for the use of wake turbulence system are considered for the terminal area and the runway rollout. These extensions connect the ground system with the aircraft to maximize benefits. The first application is the optimization of aircraft sequence via point-merge procedure, which is part of interval management operational improvement. The second application relates to the optimization of runway exit based on assessment of runway condition and aircraft-based braking capability to select the best runway exit for both the aircraft objectives and the runway throughput.

Barbaresco, F., Juge, P., Klein, M., Ricci, Y., Schneider, J.-Y. and Moneuse, J.-F.

"OPTIMISING RUNWAY THROUGHPUT THROUGH WAKE VORTEX DETECTION, PREDICTION AND DECISION SUPPORT TOOLS"

ESAV'11 Workshop, September 2011, Capri, Italy.

Currently at many airports, runway is the limiting factor for the overall throughput. Among the most important parameters are the fixed wake turbulence separation minima expressed in time for take-off clearance and by distance for arrivals on final approach. This wake turbulence separation limits the arrival and departure flow on many airports in Europe already today. Existing departure and arrival wake turbulence separations are sometimes considered over conservative as they do not take into

account meteorological conditions likely to shift, reduce or alleviate their circulations. This paper will present the main aspects of a SESAR project that defines, analyses and develops a verified wake turbulence system according to related operational concept improvements in order to, punctually or permanently, reduce landing and departure wake turbulence separations and, therefore, to increase the runway throughput in such a way that it safely absorbs arrival demand peaks and/or reduces departure delays. This global objective will be achieved by means of developing a wake vortex decision support system able to deliver in real time position and strength of the wake vortices and to predict their behavior and potential impact on safety and capacity, taking in account actual weather information as well as the airport specific climatological conditions, aircraft characteristics (generated wake vortex and wake vortex sensitivity) and airport runways layout. These functionalities will be progressively included in the wake vortex decision support system to be validated and deployed on airports in order to optimize the runway throughput and reduce delays.

Barbaresco, F., Juge, P., Klein, M., Ricci, Y., Schneider, J.-Y. and Moneuse, J.-F.

"OPTIMISING RUNWAY THROUGHPUT THROUGH WAKE VORTEX DETECTION, PREDICTION AND DECISION SUPPORT TOOLS"

Journal of Air Traffic Control, Vol. 54, No. 3, Summer 2012, pp. 21-37.

Aircraft creates wake vortices in different flying phases. To avoid jeopardizing flight safety by wake vortices encounters, time/distance separations have been conservatively increased, thus restricting runway capacity. The concern is higher during taking off and landing phases, as aircraft are less easy to maneuver. These vortices usually dissipate quickly (decay due to air turbulence or transport by cross-wind), but most airports operate for the safest scenario, which means the interval between aircraft taking off or landing often amounts to several minutes. However, with the aid of accurate wind data and precise measurements of wake vortex, more efficient intervals can be set, particularly when weather conditions are stable. Depending on traffic volume, these adjustments can generate capacity gains, which have major commercial benefits. Wake vortices are a natural byproduct of lift generated by aircraft and can be considered as two horizontal tornados trailing behind the aircraft. A trailing aircraft exposed to the wake vortex turbulence of a lead aircraft can experience an induced roll moment (bank angle) that is not easily corrected by the pilot or the autopilot. However, these distances can be safely reduced with the aid of smart planning techniques of future Wake Vortex Decision Support Systems based on Wake Vortex detection/monitoring and Wake Vortex Prediction (mainly transport estimation by cross-wind), significantly increasing airport capacity. This limiting factor will be significantly accentuated soon with the arrival of new heavy aircraft: Airbus A380, a stretched version of Boeing B747-8. Radar and Lidar sensors are low-cost technologies with highly performing complementary wake vortex detection capability in all weather conditions compared to others sensors that suffer of limited one. Radar and Lidar are promising sensors for turbulence remote sensing on airport, for all kinds of aviation weather hazards (wake vortex, windshear, micro-bursts, atmospheric turbulences) with ability to work operationally in a collaborative way, in different severe weather conditions like fog, rain, wind, and dry air.

Barbaresco, F., Thobois, L., Dolfi-Bouteyre, A., Jeannin, N., Wilson, R., Valla, M., Hallermeyer, A., Feneyrou, P., Brion, V., Besson, L., Cariou, J. P., Leviandier, L., Pillet, G. and Dolfi, D.

"MONITORING WIND, TURBULENCE AND AIRCRAFT WAKE VORTICES BY HIGH RESOLUTION RADAR AND LIDAR REMOTE SENSORS IN ALL WEATHER CONDITIONS"

Probe Material by Electromagnetic Waves, Union Radio-Scientifique Internationale, Paris, France, March 2015, pp. 81-110.

Air flows in the troposphere have a major impact on air traffic safety and operations. By air flows, several phenomena can be distinguished with different spatial and temporal characteristic scales: the mean wind itself, its rapid fluctuations, called turbulence, and wake vortices which are structured motions generated by each aircraft. At low altitudes, during take-off or landing phases, distance separations between aircrafts that limit today airport capacities were set up forty years ago to prevent the risk of wake vortices encounters in worst conditions. These out-of-date distance separations must be optimized since strength and lifetime of wake vortices vary a lot with weather conditions, like winds and turbulence. At high altitudes, during enroute flight phase, wake vortices as well as clear air turbulence can have a dramatic impact on aircraft safety. In this study, the way to measure wind, turbulence and wake vortices with new remote sensing techniques, 1.5 micron Coherent Doppler LIDAR, X-Band RADAR, and UV direct detection LIDAR, is detailed for ground-based or airborne applications. Sensor simulation tools and post-processing algorithms have been developed to retrieve wind, turbulence, especially EDR (eddy dissipation rate) and wake vortices parameters from sensors data and to assess their accuracy.

"WAKE VORTEX MONITORING & PROFILING BY DOPPLER X-BAND RADAR IN ALL WEATHER CONDITIONS"

6th EUROCONTROL Innovative Research Workshop & Exhibition, December 2007, Bretigny sur Orge, France, pp. 225-236.

To improve the capacity of airports in view of the expected increasing amount of traffic the knowledge about the safety issues caused by wake vortices must be improved. The final goal is to build up a wake vortex alert system to ensure the application of appropriate but not over-sized safety distances in all weather conditions. Lidar systems can deliver very accurate data, but are also sensitive to rain and fog. THALES did trials with the X-band radar BOR-A 550 on Orly Airport in November 2006 at Initial Take-Off and in September 2007 at ILS Interception Area. Operational continuous Detection, characterization (strength: circulation) and profiling (age: young/mature/old/decaying) capabilities of wake vortices up to a range of 1500 m have been proved in clear air and rainy weather. Opportunity detection of wake vortex was also obtained at long range until 7 Km in clear air. The Doppler resolution of around 0.2 m/s used with regularized high Doppler resolution techniques can characterize the wake vortex speed distribution in detail. X-band Radar is a full-fledged alternative, which can make a significant contribution to a wake vortex alert system.

"STUDY OF WAKE VORTEX ROLL UP SPIRAL GEOMETRY BASED ON REAL CONDITIONS AIRPORT DOPPLER RADAR TRIALS (NEAR THE GROUND ALONG RUNWAY AND IN GLIDE SLOPE)"

Int'l. Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

High Doppler resolution of X-band Radar can characterize wake vortex spiral geometry. Wake vortex Doppler radar signature can estimate: tangential speed in wake roll-up, wake vortex strength by circulation estimations, wake vortex age, and wake vortex spiral geometry. These radar trials have been made in real conditions at Paris Orly Airport in two phases: horizontal scanning of runways and vertical scanning of ILS interception area (entrance of glide slope), in wet and dry conditions. Additional trials are scheduled in 2008 at Paris CDG Airport.

"FLIGHT TEST OF SMALL UAS WAKE VORTEX ENCOUNTERS -- PART 1: CONTROL SYSTEM DEVELOPMENT AND EVALUATION"

AIAA Paper 2017-0957, January 2017, Grapevine, TX.

An exponential growth in the number of unmanned aircraft systems (UAS) operating within U.S. national airspace is projected through the next two decades. Regulations for small UAS weighing under 55 pounds have been enacted per Federal Aviation Regulations (FAR) part 107. Without specific authorization through a certificate of operation or section 333 exemption, small UAS will initially be restricted from integrating with controlled air traffic due to see and avoid criteria. As UAS are

developed with robust see and avoid capability, integration into the national airspace is inevitable. Wake vortex encounters of similarly sized small UAS could prove problematic in a future, integrated national airspace scenario. Historical data has shown that wake vortex encounters most frequently occur during the takeoff, approach, and landing phases of flight. Flight testing of small UAS is planned to characterize and provide recommendations regarding wake vortex encounters of fixed wing and rotary aircraft during each phase of flight. Part one of this paper offers discussion of flight test methodology and specific operational procedures that were developed as part of the test campaign.

"WAKE VORTEX ATTENUATION FLIGHT TESTS: A STATUS REPORT"

The 1980 Aircraft Safety and Operating Problems Conf., Part 2, March 1981, NASA Langley Research Center, pp. 387-408

Flight tests were conducted to evaluate the magnitude of aerodynamic attenuation of the wake vortices of large transport aircraft that can be achieved using static spoiler deflection and lateral control oscillation. These methods of attenuation were tested on Boeing B-747 and Lockheed L-1011 commercial transport aircraft. Evaluations were made using probe aircraft, photographic and visual observations, and ground-based measurements of the vortex velocity profiles. The magnitude of attenuation resulting from static spoiler deflection was evaluated both in and out of ground effect. A remotely piloted QF-86 drone aircraft was used to probe the attenuated vortices in flight in and out of ground effect, and to make landings behind an attenuated B-747 airplane at reduced separation distances.

"VORTEX ATTENUATION FLIGHT EXPERIMENTS"

Proceedings Wake Vortex Minimization Symposium, NASA, SP-409, 1977, pp. 369-403

Flight tests evaluating the effects of altered span loading, turbulence ingestion, combinations of mass and turbulence ingestion, and combinations of altered span loading turbulence ingestion on trailed wake vortex attenuation were conducted. Span loadings were altered in flight by varying the deflections of the inboard and outboard flaps on a B-747 aircraft. Turbulence ingestion was achieved in flight by mounting splines on a C-54G aircraft. Mass and turbulence ingestion was achieved in flight by varying the thrust on the B-747 aircraft. Combinations of altered span loading and turbulence ingestion were achieved in flight by installing a spoiler on a B-747 aircraft. The characteristics of the attenuated and unattenuated vortices were determined by probing them with smaller aircraft. Acceptable separation distances for encounters with the attenuated and unattenuated vortices are presented.

"FLIGHT TEST INVESTIGATION OF THE VORTEX WAKE CHARACTERISTICS BEHIND A BOEING 727 DURING TWO-SEGMENT AND NORMAL ILS APPROACHES"

FAA-NA-75-151, January 1975, NASA Dryden Flight Research Center, Edwards, CA

A series of flight tests were performed to evaluate the vortex wake characteristics of a Boeing 727 (B727-200) aircraft during conventional and two-segment ILS approaches. Twelve flights of the B727, equipped with smoke generators for vortex marking, were flown wherein its vortex wake was intentionally encountered by a Lear Jet model 23 (LR-23) or a Piper Twin Comanche (PA-30); and its vortex location during landing approach was measured using a system of photo-theodolites. The tests showed that at a given separation distance there were no readily apparent differences in the upsets resulting from deliberate vortex encounters during the two types of approaches. Timed mappings of the position of the landing configuration vortices showed that they tended to descend approximately 91 meters (300 feet) below the flight path of the B727. The flaps of the B727 have a dominant effect on the character of the trailed wake vortex. The clean wing produces a strong, concentrated vortex. As the flaps are lowered the vortex system becomes more diffuse. Pilot opinion and roll acceleration data indicate that 4.5 nautical miles would be a minimum separation distance at which roll control could be maintained during parallel encounters of the B727's landing configuration wake by small aircraft. This minimum separation distance is generally in scale with results determined from previous tests of other aircraft using the same roll control criteria.

"DOWNSTREAM EVOLUTION OF WINGTIP VORTICES PRODUCED FROM AN INVERTED WING"

The Aeronautical Journal, Vol. 119, No. 1216, June 2015, pp. 747-763.

Counter-rotating vortices form from the opposite edges of lifting surfaces, and gradually move laterally and dissipate as they travel downstream (as seen in a wing-fixed reference frame). Under ground-effect conditions, the vortex from a lifting wing -- such as that used in an aircraft application -- moves laterally outboard from the wingtip as it progresses downstream; for a downforce wing in ground effect -- such as that used in an automotive application -- the vortex moves laterally inboard. An interesting case is the situation where the inboard moving vortices become near each other. The objective of the present study was to investigate counter-rotating vortices produced from a low aspect ratio downforce wing operating in ground effect. The pair of vortices move towards each other and mutually induce an upwards directed motion which in turn reduces the inboard movement driven by the ground effect. Experimental data gained from three-dimensional Laser Doppler Anemometry in a moving ground wind-tunnel was used to validate a Large Eddy Simulation computational result.

"QUALITY CONTROL ALGORITHMS FOR THE KENNEDY SPACE CENTER 50-MHZ DOPPLER RADAR WIND PROFILER WINDS DATABASE"

Journal of Atmospheric and Oceanic Technology, Vol. 29, December 2012, pp. 1731-1743.

This paper presents the process used by the Marshall Space Flight Center Natural Environments Branch (EV44) to quality control (QC) data from the Kennedy Space Center's 50-MHz Doppler radar wind profiler (DRWP) for use in vehicle wind loads and steering commands. The database has been built to mitigate limitations of using the currently archived databases from weather balloons. The DRWP database contains wind measurements from approximately 2.7- to 18.6-km altitude at roughly 5-min intervals for the August 1997-December 2009 period of record, and the extensive QC process was designed to remove spurious data from various forms of atmospheric and non-atmospheric artifacts. The QC process is largely based on DRWP literature, but two new algorithms have been developed to remove data contaminated by convection and excessive first-guess propagations from the median filter/first guess algorithm. In addition to describing the automated and manual QC process in detail, this paper describes the extent of the data retained. Roughly 58 percent of all possible wind observations exist in the database with approximately 100 times as many complete profile sets existing relative to the EV44 balloon databases. This increased sample of near-continuous wind profile measurements may help to increase launch availability by reducing the uncertainty of wind changes during launch countdown.

Barkel, B.

"SIMULATION OF A HELICOPTER/LIGHT AIRCRAFT WAKE ENCOUNTER"

MS Thesis, September 2011, Univ. of Liverpool, Liverpool, England.

This project is investigating the effect of light helicopter wakes using computer-based simulation methods. A literature survey was conducted to study current vortex models and numerical techniques for vortex modeling and wake encounter simulation. Simple numerical models for vortex trajectory and induced velocities were written for both fixed-wing aircraft and rotorcraft. The fixed-wing program uses the method of images to simulate the ground and an iterative Biot-Savart computation scheme to develop the vortex trajectories. The rotorcraft wake is based on the Beddoes prescribed wake model, and calculates the trajectories of the vortices based on mathematical equations derived from experimental data. Each model can be used to generate both time-varying and static wakes, where the induced velocities are calculated on a grid using the Biot-Savart law with Scully vortex cores superimposed over the vortex filaments. These wakes are then inserted into FLIGHTLAB for real-time flight simulation. Preliminary tests found that the magnitude of the response from the following aircraft largely depends on the length of time it spends within the wake; encounters where the aircraft is traveling slower and enter the wake from directly behind pose more danger than those where the aircraft is traveling faster and encounter the wake at an angle. Crosswinds play a relatively minor role, as they can affect the trajectory of the wake but, due to the simplicity of the current models, they do not affect the structure of the core or alter the induced velocities by a significant amount relative to the aircraft's speed. A methodology for modifying the FLIGHTLAB fixed-wing model architecture to accept time-varying wakes was developed.

"WAKE SENSOR EVALUATION PROGRAM AND RESULTS OF JFK-1 WAKE VORTEX SENSOR INTERCOMPARISONS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 324-332

In November 1996, several sensing technologies (in situ anemometers, cw lidar, fan-beam sodar, RASS, and scintillometer) was deployed at JFK airport to evaluate their potential for meeting the wake sensing requirements of the AVOSS system. Of particular interest were sensors that can detect meteorological conditions as well as detect wake vortices. The tests were conducted near the middle marker of Runway 31R, where landing aircraft are about 50 m above the ground. Based on the test results, an additional test was scheduled for May 1997.

Barker, B. C., Koch, G. J. and Nguyen, D. C.

"AN OPERATIONAL WAKE VORTEX SENSOR USING PULSED COHERENT LIDAR"

Proceedings of 19th International Laser Radar Conf., Part 2, July 1998, pp. 681-684

NASA and FAA initiated a program in 1994 to develop methods of setting spacings for landing aircraft by incorporating information on the real-time behavior of aircraft wake vortices. The goals of this effort are to ensure that separation standards are adequate for safety and to reduce aircraft spacing for higher airport capacity. Preliminary studies indicate that the airline industry would save considerable money and incur fewer passenger delays if a dynamic spacing system could reduce separations at major hubs during inclement weather to the levels routinely achieved under visual flight conditions. The sensor described herein may become part of the dynamic spacing system known as the 'Aircraft VORtex Spacing System' (AVOSS) that will interface with a future air traffic control system. The wake vortex sensor will periodically provide data to validate AVOSS predictions. The first measurements of wake vortices using a pulsed lidar were made by Coherent Technologies, Inc. using a 2-micron solid-state, flashlamp-pumped system operating at 5 Hz. This system was first deployed at Denver's Stapleton Airport. Pulsed lidar has been selected as the baseline technology for an operational sensor due to its longer-range capability.

"LASER RADAR WATCHES THE FRIENDLY SKIES"

Photonics Spectra, Vol. 31, No. 4, April 1997, pp. 94-98

Lasers are probing aircraft wake vortex effects to improve commercial airline safety and traffic. Laser radar is studying wake vortices to help determine whether planes at busy airports can safely fly closer together during bad weather -- thus reducing delays.

Barker, S. J. and Crow, S. C.

"THE MOTION OF TWO-DIMENSIONAL VORTEX PAIRS IN GROUND EFFECT"

PR-4, May 1976, Poseidon Research, Sherman Oaks, CA

A new technique for generating a pair of line vortices in the laboratory has been developed. The mean flow of these vortices is highly two-dimensional, although most of the flow field is turbulent. This two-dimensionality permits the study of vortex motions in the absence of the Crow mutual induction instability and other three-dimensional effects. The vortices are generated in a water tank of dimensions 15 x 122 x 244 cm. They propagate vertically and their axes span the 15 cm. width of the tank. One wall of the tank is transparent, and the flow is visualized using fluorescein dye. High speed photography is used to study both the transition to turbulence during the vortex formation process and the interaction of the turbulent vortices with a simulated ground plane. The interaction of the vortex pair with the ground plane does not follow the predictions of potential flow theory for line vortices. Although total circulation is apparently conserved, the vortices remain at a larger distance from the ground than expected and they eventually 'rebound' or move away from the ground. Differences between a free surface boundary condition and a smooth or rough ground plane are discussed. The ground plane interaction is qualitatively very similar to that of aircraft trailing vortices observed in recent flight tests.

Barker, S. J. and Crow, S. C.

"THE MOTION OF TWO-DIMENSIONAL VORTEX PAIRS IN A GROUND EFFECT"

J. Fluid Mech., Vol. 82, Part 4, 1977, pp. 659-671

A new technique for generating a pair of line vortices in the laboratory has been developed. The mean flow of these vortices is highly two-dimensional, although most of the flow field is turbulent. This two-dimensionality permits the study of vortex motions in the absence of the Crow mutual induction instability and other three-dimensional effects. The vortices are generated in a water tank of dimensions 15 x 122 x 244 cm. They propagate vertically and their axes span the 15 cm width of the tank. One wall of the tank is transparent, and the flow is visualized using fluorescein dye. High speed photography is used to study both the transition to turbulence during the vortex formation process and the interaction of the turbulent vortices with a simulated ground plane. Transition occurs first in an annular region surrounding the core of each vortex, starting with a shear-layer instability on the rolled-up vortex sheet. The turbulent region then grows both radially inwards and radially outwards until the entire recirculation cell is turbulent. A 'relaminarization' of the vortex core appears to take place somewhat later. The interaction of the vortex pair with the ground plane does not follow the predictions of potential-flow theory for line vortices. Although the total circulation is apparently conserved, the vortices remain at a larger distance from the ground than is expected and eventually 'rebound' or move away from the ground. Differences between a free-surface boundary condition and a smooth or rough ground plane are discussed. The ground-plane interaction is qualitatively very similar to that of aircraft trailing vortices observed in recent flight tests.

"CORE INSTABILITIES OF A VORTEX PAIR"

Bull. Am. Physical Society, Vol. 20, No. 11, November 1975, p. 1428

Aircraft wake vortices have stimulated great interest in the means by which vortex pairs decay. The mechanism of vortex decay outside ground effect can be divided into two classes: mutual induction instability and vortex core instability. The present study looks at the second class both experimentally and analytically. By the Rayleigh criterion, isolated vortices are stable to small axisymmetric disturbances. However, it is shown that a wrapped-up vortex sheet is unstable to helical disturbances having azimuthal wavenumbers greater than three. Any tangential velocity distribution with an inflection point in the rotational region is unstable to such disturbances. The experiment used to visualize the instabilities is a two-dimensional analog of the vortex wake, in which distance behind the aircraft is represented by time from the creation of the vortex pair. The experiment takes place in a water tank of dimensions 0.5 by 4 by 8 feet. The vortices are oriented across the 0.5 feet width of the tank, visualized by dye injection, and photographed by a high-speed movie camera.

"PIV MEASUREMENTS OF THE VORTICAL WAKE BEHIND TILT-ROTOR BLADES"

13th International Symposium on Applications of Laser Techniques to Fluid Mechanics, Paper No. 1072, Lisbon, Portugal, June 2006

This paper concerns a collaborative research work between DLR of Gottingen and LABM of Marseille which aims to create a new experimental data base characterizing the tilt-rotor wake and the associated vortex structures. This study will provide detailed flow data on the aerodynamic interactions causes which occur on a tilt-rotor aircraft including a rotor, a nacelle, a fixed wing and an end plate simulating the fuselage. Experiments have been performed in the LABM S1L wind-tunnel at 3 different flight configurations which correspond to hover, conversion and cruise flights. The stereoscopic PIV system generates an illuminating laser sheet in a Z-plane normal to the uniform free stream velocity. PIV measurements have been performed at different Z-planes distributed at different distance downstream the rotor (in the wake region between the rotor and the wing and above the fixed wing) in both the conversion and cruise flight configurations and for different parametric conditions of the rotor shaft angle, the blade rotational frequency, the upstream velocity, the advancing parameter, and the collective pitch angle value. For these different parametric conditions, the tip vortex path and the associated 3C velocity field shed from the blade have been determined in the early stages of the tip vortex shedding corresponding to 3 azimuth positions and in a fixed downstream plane located at $Z/R=0$. The XY-plots of the velocity vector clearly show the flow perturbation generated by the blade passage and the vortex development and propagation from the tip of the emitting blade. Moreover, from such PIV measurements performed at different downstream distances from the rotor and at different blade azimuth positions the tip vortex paths have been reconstructed both in the wake region between the rotor and the wing and above the wing surface. The wake data provide a better understanding on both the vortex dynamics and the behavior of vortical structures interacting with the wing on a tilt-rotor configuration.

"INVESTIGATION OF AEROELASTIC EFFECTS IN STREAMWISE-ORIENTED VORTEX/WING INTERACTIONS"

AIAA Paper 2014-1281, January 2014, National Harbor, MD.

This work explores the interaction of streamwise vortices generated by a leader wing on rigid and flexible follower wings in a close homogeneous V-formation. Computations are performed using high-fidelity implicit LES simulations coupled with a geometrically nonlinear Reissner-Mindlin finite element plate model. Several areas are explored in order to provide a better understanding of the unsteady flow structure, aerodynamic loading, and aeroelastic response that might be encountered by light-weight high aspect ratio wings in close-formation. First, exploration of positioning between rigid wings shows interaction between the incident streamwise vortex and follower wing tip vortex. These effects include vortex-dipoles, instability of the vortex cores, and bifurcation which can all significantly reorient wake features with a small change in lateral or vertical positioning. Each case demonstrates an enhanced lift-to-drag ratio while unsteady loading remains comparable to that of a single wing. This suggests fluctuations in the incident vortex due to atmospheric disturbances or unintended/uncontrollable aircraft motion might be a more dominant source of buffeting behavior in the case of flexible wings. Such an effect would be magnified in the presence of a stronger incoming vortex as shown in the case of increasing the leader-wing angle of attack. Second, computation of flexible wings in close-formation primarily results in static-aeroelastic spanwise deflection of the wing and repositioning of the vortex-encounter. Consequently, large changes in flow structure and loading result from small static spanwise bending deformations. A small dynamic response is observed in the twisting-mode of the moderately flexible case which amplifies pitching-moment fluctuations and would have implications on the fatigue life of the wing structure. Interestingly, this source of unsteadiness was diminished on the vortex-encounter side of the wing.

Barnes, C. J., Visbal, M. R. and Huang, G. P.

"EFFECT OF BENDING OSCILLATIONS ON A STREAMWISE-ORIENTED VORTEX INTERACTION"

AIAA Paper 2015-3303, June 2015, Dallas, TX.

This work explores the feedback response and unsteady flow structure due to forced bending oscillations on a q -vortex impinging on a flat plate wing inboard of the wingtip and aligned with the leading-edge. The effects of bending amplitude are explored for A/c greater than or equal to 0.025 and less than or equal to 0.1 at a bending frequency of $f_{sub b} = f_c/(U_{sub infinity}) = 0.5$. The low-frequency motion requires a large amplitude to provide significant impact to the general flow structure. Low-frequency, large-amplitude motion provides several important effects. Upstream of the leading-edge, bending oscillations alleviate the upstream influence experienced in the static rigid wing case consequently diminishing helical instability in the impinging vortex. This observation suggests a favorable application of wing dynamics in vortex-surface interactions. Very close to the leading-edge the vortex is forced between adverse and favorable pressure gradients which alternately promote growth and removal of helical instability, respectively. Above the wing, the initially coherent vortex is

shown to decompose into a series of spanwise substructures when it passes over and then pinches off from the suction-side. The effects of bending frequency are evaluated for f_{sb} greater than or equal to 0.5 and less than or equal to 2 at an amplitude of $A/c = 0.025$. Bending oscillations of $f_{sb} = 1$, close to the instability frequency $S t_c = 0.9$, could impose a slight shift in vortex behavior causing the instability to lock into the bending frequency. High-frequency, low-amplitude motion inhibits coherent propagation of the incident vortex over either side of the wing, but fails to induce higher-modal instability upstream of the leading edge.

Barnes, J. R.

"SIDE FORCE ON A WING BODY COMBINATION DUE TO TRAILING VORTICES"

ARC Report CP-669, July 1962, Royal Aircraft Establishment, Farnborough, England. (Also, RAE Tech. Note Aero. 2834.)

A long cylindrical body has two wings attached symmetrically but set at equal and opposite angles relative to its axis. When this system is placed at incidence in a uniform flow a side force is experienced. The purpose of this note is to make some estimate of the magnitude of this side force. The vortices shed by the wings are assumed to have rolled up at the trailing edge and their paths are calculated using slender body theory. Expressions are given for the forces experienced by the body aft of the wings, and some numerical calculations made.

Baron, A., Boffadossi, M. and Deponte, S.

"NUMERICAL SIMULATION OF VORTEX FLOWS PAST IMPULSIVELY STARTED WINGS"

AGARD Vortex Flow Dynamics, Politecnico di Milano, Milan, Italy, July 1991

A nonlinear unsteady vortex lattice method is used to predict the geometry of the wakes and the distribution of the aerodynamic loads on impulsively started wings. The wings are assumed to have negligible thickness, arbitrary aspect ratio, and planform. They can undergo a general unsteady motion. Multi-wing configurations can be treated. Wakes can be released in the flow field from any of the sharp edges of the lifting surfaces, depending on planform, aspect ratio, and attitude of the wings. Particular emphasis is placed on the simulation of vortex core diffusion which is regarded as a prominent factor in a correct development of unsteady wakes. A vortex core diffusion model is proposed which seems to be able to deal even with the severe roll-up of the shear layers past highly swept multi-wing configurations with leading edge separation. The prediction capabilities of the method are verified by comparison of the numerical results with experimental data published by various authors.

Baronti, P. and Elzweig, S.

"FOG FORMATION AND DISPERSAL BY TRAILING VORTICES"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 561-573.

A model is presented to explain why fogs can be maintained for extended periods of time. The model considers fog as a dynamical system whereby droplets depletion through fall is balanced by a continuous process of evaporation and condensation. The controlling parameters of the process are indicated. Possible means of fog dispersal by the velocity field induced by trailing vortices are suggested.

Barre, S., Bogey, C. and Bailly, C.

"DNS OF A HIGH-ASPECT-RATIO ELLIPTIC VORTEX AND ITS GENERATED NOISE"

AIAA Paper No. 2005-2956, Monterey, CA, May 2005

The aerodynamic evolution and the acoustic radiation of elliptic vortices with various aspect ratios are investigated by solving numerically the full compressible Navier-Stokes equations. Three behaviors are observed according to the aspect ratio a/b where a and b are the major and minor semi-axes of the vortices. At the small aspect ratio (1.2) the vortex rotates at a constant angular velocity and radiates like a rotating quadrupole. The acoustic radiation is in very good agreement with a reference analytical solution. At the moderate aspect ratio (5.0), the vortex is initially unstable. However, its aspect ratio decreases due to an axisymmetrization process, which inhibits the growth of instabilities. The noise level then decreases and the radiation frequency increases. The far-field is found to be in good agreement with the reference solution, which has been modified to take into account the evolution of the shape of the vortex. For vortices with larger aspect ratios (6 or more), axisymmetrization does not occur quickly enough to stop the growth of instabilities, which splits the vortices. Then various mergings are found to occur. For instance, in the case of aspect ratio 6, several successive switches between an elliptic state and a configuration of two co-rotating vortices are observed. The sound field remains weakly affected by the switches. The present results show that the initial value of the aspect ratio yields the relative weight of the axisymmetrization which stabilizes the vortex, and of the growth of instabilities which tends to split it.

Barre, S., Bogey, C. and Bailly, C.

"DIRECT SIMULATION OF ISOLATED ELLIPTIC VORTICES AND OF THEIR RADIATED NOISE"

Theoretical Computational Fluid Dynamics, Vol. 22, 2008, pp. 65-82.

The aerodynamic evolution and the acoustic radiation of elliptic vortices with various aspect ratios and moderate Mach numbers are investigated by solving numerically the full compressible Navier-Stokes equations. Three behaviors are observed according to the aspect ratio a/b where a and b are the major and minor semi-axes of the vortices. At the small aspect ratio (1.2) the vortex rotates at a constant angular velocity and radiates like a rotating quadrupole. At the moderate aspect ratio (5.0), the vortex is initially unstable. However, the growth of instability waves is inhibited by the return to axisymmetry which decreases its aspect ratio. The noise level becomes lower with time and the radiation frequency increases. For vortices with larger aspect ratios (6 or more), the return to

axisymmetry does not occur quickly enough to stop the growth of instabilities, which splits the vortices. Various mergers are then found to occur. For instance, in the case of aspect ratio 6, several successive switches between an elliptic state and a configuration of two co-rotating vortices are observed. The present results show that the initial value of the aspect ratio yields the relative weight between the return to axisymmetry which stabilizes the vortex and the growth of instabilities which tends to split it.

"CONCEPT FOR USING MULTIPLE GLIDE SLOPE ANGLES FOR WAKE VORTEX AVOIDANCE ON PARALLEL IFR APPROACHES"

FAA-DL5-86-3, November 1986, Mitre Corp., McLean, VA

For parallel runways separated by less than 2500 feet, the longitudinal separation between aircraft on adjacent approaches must be maintained at the same distance as if the aircraft were on a single runway. The hazard associated with trailing wing tip vortices is the major hindrance to reducing separation distances during instrument approaches. This report shows how separations can be safely reduced on closely spaced parallel runways. The analysis exploits the use of staggered runway thresholds, multiple glide slope angles, and wind measurement devices to ensure vortex avoidance. The analysis is applied to Denver Stapleton International Airport.

"IMPACT OF AIRCRAFT PLUME DYNAMICS ON AIRPORT LOCAL AIR QUALITY"

Atmospheric Environment, Vol. 74, 2013, pp. 247-258.

Air quality degradation in the locality of airports poses a public health hazard. The ability to quantitatively predict the air quality impacts of airport operations is of importance for assessing the air quality and public health impacts of airports today, of future developments, and for evaluating approaches for mitigating these impacts. However, studies such as the Project for the Sustainable Development of Heathrow have highlighted shortcomings in understanding of aircraft plume dispersion. Further, if national or international aviation environmental policies are to be assessed, a computationally efficient method of modeling aircraft plume dispersion is needed. To address these needs, we describe the formulation and validation of a three-dimensional integral plume model appropriate for modeling aircraft exhaust plumes at airports. We also develop a simplified concentration correction factor approach to efficiently account for dispersion processes particular to aircraft plumes. The model is used to explain monitoring station results in the London Heathrow area showing that pollutant concentrations are approximately constant over wind speeds of 3-12 m/s, and is applied to reproduce empirically derived relationships between engine types and peak NO_x concentrations at Heathrow. We calculated that not accounting for aircraft plume dynamics would result in a factor of 1.36-2.3 over-prediction of the mean NO_x concentration (depending on location), consistent with empirical evidence of a factor of 1.7 over-prediction. Concentration correction factors

are also calculated for aircraft takeoff, landing, and taxi emissions, providing an efficient way to account for aircraft plume effects in atmospheric dispersion models.

"ONERA/DLR ACTIVITIES ON DOPPLER GLOBAL VELOCIMETRY AND ITS QUALIFICATION FOR WIND TUNNEL APPLICATIONS"

3rd ONERA-DLR Aerospace Symposium, June 2001, Paris, pp. S4-4/1-10.

Two Doppler Global Velocimetry Systems (DGV) have been set-up in the scope of the DLT-ONERA co-operation. Both systems are capable to perform planar three component velocity measurements in air flows. The system set-up by the ONERA was designed with special regards on wind tunnel applications, while the DLR system is slightly more dedicated to turbo-machinery flows. The technical performance of these systems will be reported as well as the successful application of both systems in wind tunnel flows. DGV measurements were performed in the wake region of a car model and in the flow above a delta wing. Both measurements were cross-checked with LDA data. The common effort is now aimed at defining a concept for a DGV-system for large wind tunnels.

"SIMPLIFIED METHODS OF PREDICTING AIRCRAFT ROLLING MOMENTS DUE TO VORTEX ENCOUNTERS"

AIAA Paper 1976-0061, January 1976, Washington, DC.

Computational methods suitable for fast and accurate prediction of rolling moments on aircraft encountering wake vortices are presented. Appropriate modifications to strip theory are developed which account for the effects of finite wingspan. It is shown that in the case of an elliptic wing the aspect ratio correction to the lift curve slope should be based on the semi-span. A reciprocal theorem is used to relate the rolling moment on a wing in an arbitrary downwash field to that on a wing in steady rolling motion. Calculations are presented for a wing encountering a vortex with a Betz velocity distribution. It is shown that the ratio of the spans of the generating and encountering aircraft is the most significant parameter in determining the possible hazard.

"3D WIND AND TURBULENCE CHARACTERISTICS OF THE ATMOSPHERIC BOUNDARY LAYER"

Bulletin American Meteorological Society, Vol. 95, No. 5, May 2014, pp. 743-756.

The 3D wind and turbulence characteristics of the atmospheric boundary layer experiment (3D Wind) was conducted to evaluate innovative remote sensing and in situ platforms for measurements of wind and turbulence regimes. The experiment is part of a planned series that focuses on quantifying wind and turbulence characteristics at the scales of modern wind turbines and wind farms and was conducted in northern Indiana in May 2012. 3D Wind had the following specific objectives: (i) intercomparison experiments evaluating wind speed profiles across the wind turbine rotor plane from traditional cup anemometers and wind vanes on a meteorological mast and from a tethered balloon, sonic anemometers (mast mounted and on an unmanned aerial vehicle), three vertical-pointing (continuous wave) lidars and a pulsed scanning lidar, and (ii) integrate these measurements and output from 3-km-resolution (over the inner domain) simulations with the Weather Research and Forecasting Model to develop a detailed depiction of the atmospheric flow, upwind, within, and downwind of a large, irregularly spaced wind farm. This paper provides an overview of the measurement techniques, their advantages and disadvantages focusing on the integration of wind and turbulence characteristics that are necessary for wind farm development and operation. Analyses of the measurements are summarized to characterize instrument cross comparison, wind profiles, and spatial gradients and wind turbine wakes.

"BEST PRACTICE FOR MEASURING WIND SPEEDS AND TURBULENCE OFFSHORE THROUGH IN-SITU AND REMOTE SENSING TECHNOLOGIES"

Report, July 2016, Department of Energy grant EE0005379, Cornell University, Ithaca, NY.

The purpose of this document is to briefly review some applications of in-situ and remote sensing technologies to atmospheric flow conditions in the offshore environment with a specific focus on the wind energy industry. Special emphasis is placed on providing illustrative examples of previous research, and to use those to contextualize and summarize best practice recommendations for the offshore wind energy industry, for obtaining wind speeds and turbulence characterizations.

Barthlott, C. and Fiedler, F.

"TURBULENCE STRUCTURE IN THE WAKE REGION OF A METEOROLOGICAL TOWER"

Boundary-Layer Meteorology, Vol. 108, 2003, pp. 175-190.

A meteorological tower significantly modifies the air flow, the mean wind speed and wind direction as well as the turbulence structure of the air. Such changes can be noticed in particular in the wake region of the tower. Measurements on the 200 m tower of Forschungszentrum Karlsruhe were carried out using Solent sonic anemometers in the lee of the tower and cup anemometers on both sides. In the wake region, spectral energy density is increased in the high-frequency range. Superposition of this disturbance spectrum on the undisturbed spectrum yields a 'knee' in the resulting spectrum. In the case of low turbulence intensity with stable stratification, a plateau with a constant energy content is observed in front of the knee. This effect is caused by the new production of turbulence energy from the mean flow as well as by an energy transfer from larger to smaller vortices. Power spectra in strongly stable conditions show a more rapid decrease of intensity in the region where the inertial subrange is expected. The relevant scales of wake turbulence are derived from the maximum of the disturbance spectrum. Locations of the high-frequency peak do not depend on atmospheric stability, but are controlled mainly by mean wind speed. Apart from the reduction of the mean wind speed, the spectra and cospectra exhibit a strong anisotropy for such cases. The results demonstrate the significant influence of a tower on turbulence spectra in the wake region.

"CHARACTERIZATION OF THE SUMO TURBULENCE MEASUREMENT SYSTEM FOR WIND TURBINE WAKE ASSESSMENT"

Energy Procedia, Vol. 51, 2014, pp. 173-183.

The remotely piloted aircraft system (RPAS) SUMO (Small Unmanned Meteorological Observer) has been equipped with a miniaturized 5-hole probe sensor system for measurement of the 3-dimensional flow vector with a temporal resolution of 100 Hz. Due to its weight and size this system is particularly well suited for operations in the vicinity of wind turbines. To qualify for full scale measurements in turbine wakes the system has been characterized by several laboratory and field tests described in this study. A wind tunnel test against a hot-wire anemometer shows the capability of the 5-hole probe to react to turbulence in the same manner as the hot-wire system. The resulting spectra from the two platforms show in general good agreement for both laminar and turbulent flows. The 5-hole probe system can resolve turbulence up to frequencies around 20-30 Hz when using a tubing length of 15 cm between the probe and the pressure transducers. In addition, an environmental parallel test against two sonic anemometers mounted on the roof-top of a car was performed at Bergen airport Flesland. Despite several issues with the self-made and low-cost experimental setup, important system characteristics could be tested and verified. In particular the velocity spectral components of the sonic anemometer system and the 5-hole probe are in close resemblance to each other. This is at least a strong indication that the 5-hole probe is suitable for atmospheric turbulence measurements onboard the RPAS SUMO platform.

Bastankhah, M. and Porte-Agel, F.

"WIND TUNNEL STUDY OF THE WIND TURBINE INTERACTION WITH A BOUNDARY-LAYER FLOW:
UPWIND REGION, TURBINE PERFORMANCE, AND WAKE REGION"

Physics of Fluids, Vol. 29, 2017, pp. 065105-1 to 065105-18.

Comprehensive wind tunnel experiments were carried out to study the interaction of a turbulent boundary layer with a wind turbine operating under different tip-speed ratios and yaw angles. Force and power measurements were performed to characterize the variation of thrust forces (both magnitude and direction) and generated power of the wind turbine under different operating conditions. Moreover, flow measurements, collected using high-resolution particle-image velocimetry as well as hot-wire anemometry, were employed to systematically study the flow in the upwind, near-wake, and far-wake regions. These measurements provide new insights into the effect of turbine operating conditions on flow characteristics in these regions. For the upwind region, the results show a strong lateral asymmetry under yawed conditions. For the near-wake region, the evolution of tip and root vortices was studied with the use of both instantaneous and phase-averaged vorticity fields. The results suggest that the vortex breakdown position cannot be determined based on phase-averaged statistics, particularly for tip vortices under turbulent inflow conditions. Moreover, the measurements in the near-wake region indicate a complex velocity distribution with a speed-up region in the wake center, especially for higher tip-speed ratios. To elucidate the meandering tendency of far wakes, particular focus was placed on studying the characteristics of large turbulent structures in the boundary layer and their interaction with wind turbines. Although these structures are elongated in the streamwise direction, their cross sections are found to have a size comparable to the rotor area, so that they can be affected by the presence of the turbine. In addition, the study of spatial coherence in turbine wakes reveals that any statistics based on streamwise velocity fluctuations cannot provide reliable information about the size of large turbulent structures in turbine wakes because of wake meandering. The results also suggest that the magnitude of wake meandering does not depend on turbine-operating conditions. Finally, the suitability of the proper orthogonal decomposition for studying wake meandering is examined.

Batchelor, G. K.

"AXIAL FLOW IN TRAILING LINE VORTICES"

J. Fluid Mech., Vol. 20, Part 4, April 1964, pp. 645-658

A characteristic feature of a steady trailing line vortex from one side of a wing, and of other types of line vortices, is the existence of strong axial currents near the axis of symmetry. The purpose of this paper is to account in general terms for this axial flow in trailing line vortices. The link between the azimuthal and axial components of motion in a steady line vortex is provided by the pressure; the radial pressure gradient balances the centrifugal force, and any change in the azimuthal motion with distance X downstream produces an axial pressure gradient and consequently an axial acceleration. The concept of drag associated with the core of a trailing vortex is introduced, and the drag is expressed as an integral over a transverse plane which is independent of X .

Bate, Jr., E. R.

"AIRCRAFT WAKE MODELING: PRELIMINARY DESIGN ASPECTS"

AV-FR-445, August 1974, AeroVironment Inc., Pasadena, CA

The design of a scale model with a 6 ft wingspan which simulates the wake flow of a full-size airplane (B-747) is described. The wake is modeled to a full-scale downstream distance of 5 miles. The situation with respect to the simulation of wake instabilities is discussed. Only by the actual experiment that is planned for the model can the relationship between core bursting and vortex linking be established. If core bursting terminates the wake of the model too abruptly, the experimental situation might not adequately represent the full-scale case, where it is anticipated that linking due to the sinuous wake instability predominates.

Bate, Jr., E. R.

"A STUDY TO DETERMINE THE STRUCTURE OF TRAILING VORTICES FROM FULL SCALE FLIGHT TEST DATA"

AV-FR-441, July 1974, AeroVironment Inc., Pasadena, CA

Computerized data reduction techniques were applied to high resolution velocity measurements obtained during full-scale aircraft wake probing experiments. The desired results were the determination of vortex circulation and core size as a function of wake age. Data scatter prevented the desired results from being fully achieved; it is suggested that the data scatter represents real effects and that these effects are produced by turbulence.

"AIRCRAFT WEATHER INFORMATION SYSTEM"

US Patent 6,043,756, March 2000.

A system and method for downlinking weather data, generated by existing weather and data sensors, to a ground station. The ground station utilizes data from multiple aircraft to form refined weather information, and uplinks the refined weather information to the aircraft. The refined weather information is stored at the aircraft and picture generating equipment, such as an existing onboard ground proximity terrain picture and symbol generator, generates pictorial information depicting weather. The pictorial information is displayed, for example, by an existing EFIS or weather radar display, in the form of polygons.

"SHOCK WAVE INTERACTION WITH A VISCOUS WAKE IN SUPERSONIC FLOW"

J. Fluid Mech., Vol. 504, 2004, pp. 301-341

A theoretical investigation of the breakdown of the viscous wake downstream of a flat plate in supersonic flow is performed in this paper based on the large Reynolds number asymptotic analysis of the Navier-Stokes equations. The breakdown is provoked by an oblique shock wave impinging on the wake a small distance downstream of the plate trailing edge. Two flow regimes are considered. In the first case, the shock impinges on the wake within the region of viscous-inviscid interaction that is known to occupy a vicinity of the trailing edge. Under these conditions the interaction process may be described by the equations of the triple-deck theory. To obtain a numerical solution of these equations we used a rapid matrix Thomas technique in conjunction with Newton iterations. The results of the calculations not only predict the wake breakdown near the shock location but also reveal a hysteresis behavior of the flow as the shock is moved downstream, giving rise to three solution branches. The second part of the paper is concerned with the flow regime when the shock interacts with the wake further downstream of the trailing edge triple-deck region. In this case the fluid motion proves to be inviscid to leading order not only in the upper deck of the interaction region but also everywhere inside the wake. Due to this simplification the interaction problem can be reduced to a single integro-differential equation governing the pressure distribution along the interaction region. With known pressure the Bernoulli equation may be used to find the velocity field. The Bernoulli equation also allows us to formulate a simple criterion which may be used to predict the onset of wake breakdown. We found that viscosity becomes important again in a smaller vicinity of the breakdown point where the flow reversal takes place. It is remarkable that the viscous-inviscid interaction problem governing the flow in this vicinity admits an analytical solution.

"ADVANCEMENTS IN THEORETICAL MODELS OF CONFINED VORTEX FLOWFIELDS"

2007 JANNAF Propulsion Meeting, May 2007, Denver, CO.

In this article, we review some of the theoretical solutions used to describe swirl dominated flows in both unidirectional and bidirectional flow orientations. This short survey starts with the Rankine vortex and culminates in the presentation of a compressible solution of the bidirectional vortex. After classifying representative swirl motions as external or internal depending on physical boundary conditions, their commonalities are identified along with their relevance to either geophysical or industrial applications. For example, all swirl dominated flows comprise a forced vortex core centered around their axis of rotation. The core is due to viscous forces and increases in size with successive

increases in viscosity. It is delineated by the point where the swirl velocity reaches its maximum. Within the forced vortex core, the tangential velocity is linearly proportional to the radius, a characteristic of rigid body rotation. Outside the forced vortex core, the tangential velocity gradually becomes inversely proportional to the radius, thus exhibiting a free vortex tail. In internal flows, this free, irrotational tail is clipped at the boundaries in fulfillment of the no slip requirement. In external flows, it extends out to infinity. Finally, all swirl dominated flows decay axially and their vorticity is confined to either the core vortex or wall boundary layers. These will be described in the context of the bidirectional vortex confined in a cylindrical chamber. What is most prevalent here, and perhaps, what sets the analysis of the bidirectional vortex apart lies in its true prediction of essential flow attributes directly from first principles. Unlike other studies that require conjecture or post-diction, for example, in estimating or adjusting the maximum swirl velocity and thickness of the core vortex to fit a given flow pattern (e.g., the Rankine vortex), these are obtained directly from the asymptotic solution of the tangential boundary layer equation for the bidirectional vortex. We also identify the key similarity parameters that control the problem, including the inflow parameter and the vortex Reynolds number. The latter combines the mean flow Reynolds number and the product of the swirl number and chamber aspect ratio. In this study, the core and sidewall boundary layers are quantified as function of the vortex Reynolds number. The compressible solution is also obtained assuming a Rayleigh-Janzen expansion in the inflow Mach number squared.

Bauer, L. A.

"THE RELATION BETWEEN POTENTIAL TEMPERATURE AND ENTROPY"

Physical Review (Series I), Vol. 26, Issue 2, February 1908, pp. 177-183

A historical account of the concept as well as the modern-day terminology of potential temperature is given. The relationship between potential temperature and entropy is then derived and illustrated in the context of a perfect gas. It is shown that as far as a perfect gas is concern, it is possible to express the entropy function in its simplest form as the potential temperature function. As such, if the entropy is increased, the potential temperature is likewise increased. If the entropy remains constant, then the potential temperature would remain constant. Owing to the intimate relationship between entropy and potential temperature the term 'entropic temperature' has been proposed by the author.

"WING TIP DRAG REDUCTION AT NOMINAL TAKE-OFF MACH NUMBER: AN APPROACH TO LOCAL ACTIVE FLOW CONTROL WITH A HIGHLY ROBUST ACTUATOR SYSTEM"

Aerospace, Vol. 3, 2016, pp. 36-1 to 36-18.

This paper discusses wind tunnel test results aimed at advancing active flow control technology to increase the aerodynamic efficiency of an aircraft during take-off. A model of the outer section of a representative civil airliner wing was equipped with two-stage fluidic actuators between the slat edge and wing tip, where mechanical high-lift devices fail to integrate. The experiments were conducted at a

nominal take-off Mach number of $M = 0.2$. At this incidence velocity, separation on the wing section, accompanied by increased drag, is triggered by the strong slat edge vortex at high angles of attack. Based on global force measurements and local static pressure data, the effect of pulsed blowing on the complex flow is evaluated, considering various momentum coefficients and spanwise distributions of the actuation effort. It is shown that through local intensification of forcing, a momentum coefficient of less than 0.6 percent suffices to offset the stall by 2.4 degrees, increase the maximum lift by more than 10 percent and reduce the drag by 37 percent compared to the uncontrolled flow.

"IN-FLIGHT WAKE ENCOUNTER PREDICTION WITH THE WAKE ENCOUNTER AVOIDANCE AND ADVISORY SYSTEM"

AIAA Paper 2014-2333, June 2014, Atlanta, GA.

DLR is working on a Wake Encounter Advisory & Avoidance (WEAA) system to allow pilots to avoid potentially dangerous wake vortex encounters by a tactical evasion maneuver. Such maneuver is of small scale i.e. it tries to adhere to the planned flight track as closely as possible and is not intended to require ATC permission. The paper introduces system design and core functions of the WEAA system (meteorological data fusion, wake vortex prediction, trajectory prediction and conflict detection, hazard evaluation, avoidance trajectory generation, alerting and guidance) and briefly describes DLR's technical solutions. Initial results will be presented for the system implementation including first results from recent flight tests for on-board conflict detection employing DLR's Falcon 20E and A320 Advanced Technology Research Aircraft (ATRA).

Bauknecht, A., Ewers, B., Wolf, C., Leopold, F., Yin, J. and Raffel, M.

"THREE-DIMENSIONAL RECONSTRUCTION OF HELICOPTER BLADE-TIP VORTICES USING A MULTI-CAMERA BOS SYSTEM"

Experiments in Fluids, Vol. 56, 2015, pp. 1866-1 to 1866-13.

Noise and structural vibrations in rotorcraft are strongly influenced by interactions between blade-tip vortices and the structural components of a helicopter. As a result, knowing the three-dimensional location of vortices is highly desirable, especially for the case of full-scale helicopters under realistic flight conditions. In the current study, we present results from a flight test with a full-scale BO 105 in an open-pit mine. A background-oriented schlieren measurement system consisting of ten cameras with a natural background was used to visualize the vortices of the helicopter during maneuvering flight. Vortex filaments could be visualized and extracted up to a vortex age of 360 degrees. Vortex instability effects were found for several flight conditions. For the camera calibration, an iterative approach using points on the helicopter fuselage was applied. Point correspondence between vortex curves in the evaluated images was established by means of epipolar geometry. A three-dimensional reconstruction of the main part of the vortex system was carried out for the first time using stereophotogrammetry. The reconstructed vortex system had good qualitative agreement with the

result of an unsteady free-wake panel method simulation. A quantitative evaluation of the 3D vortex system was carried out, demonstrating the potential of the multi-camera background-oriented schlieren measurement technique for the analysis of blade-vortex effects on rotorcraft.

Bauknecht, A., Merz, C. B. and Raffel, M.

"AIRBORNE APPLICATION OF THE BACKGROUND ORIENTED SCHLIEREN TECHNIQUE TO A HELICOPTER IN FORWARD FLIGHT"

17th International Symposium on Application of Laser Techniques to Fluid Mechanics, July 2014, Lisbon, Portugal.

Blade-tip vortices and their interaction with the helicopter blades play an important role in the generation of noise on rotorcrafts. Full-scale vortex visualization is essential for the understanding of these effects and the validation of sub-scale experiments and numerical simulations. In the present work, the reference-free Background Oriented Schlieren (BOS) method was used to visualize blade-tip vortices of a full-scale BO 105 helicopter. Two flight tests were conducted with a dual-camera BOS system. In the first experiment, the ground-based camera was tested on the helicopter in hovering flight with an artificial background pattern. The main and tail rotor tip vortices and the exhaust gases from the helicopter engines were visualized during take-off and hovering flight. Main rotor tip vortices up to a vortex age of 450 degrees, vortex instability effects and interactions with the tail boom were detected. In the second flight test, a modified version of the dual-camera BOS was used to visualize the main rotor blade-tip vortices of the BO 105 during forward, curve and accelerating forward flight with velocities over the ground of 60-80 knots. The camera system was deployed aboard a microlight airplane flying above and to the side of the helicopter with fields and meadows serving as natural backgrounds. It was shown that, during curve flight, vortices up to a maximum vortex age of 630 degrees at distances of up to one rotor diameter behind the rotor plane could be visualized in some parts of the rotor wake. For accelerating forward flight, blade-vortex interaction effects and deformations of the vortex system were observed. In general, vortex visibility varied greatly between different parts of the rotor wake and different measurement images. This mainly resulted from the background noise level, which can vary based on the suitability of the natural background for the BOS method. A variety of natural backgrounds was analyzed and compared to the artificial dot pattern used for the hover test. Image contrast, homogeneity and structure size were found to vary between different natural backgrounds and to be significantly lower than for the artificial background pattern, but still within a useable range. The visualization results obtained during the inflight measurements show that the reference-free BOS method is highly suitable for the detection of helicopter blade-tip vortices during full-speed forward and maneuvering flight, therefore removing the restrictions imposed by ground-based measurements.

Bauknecht, A., Merz, C. B., Raffel, M., Landolt, A. and Meier, A. H.

"BLADE-TIP VORTEX DETECTION IN MANEUVERING FLIGHT USING THE BACKGROUND-ORIENTED SCHLIEREN TECHNIQUE"

Journal of Aircraft, Vol. 51, No. 6, November-December 2014, pp. 2005-2014.

The background-oriented schlieren technique was used to visualize the blade-tip vortices of a Eurocopter AS532UL Cougar helicopter in maneuvering flight. The test program covered a large part of the flight envelope, including maneuvers such as hover flight, fast forward flight, flare maneuvers, and high-speed turns. For selected flight conditions, the aerodynamic results are presented here. It is shown that, with the reference-free background-oriented schlieren method, the detection of vortex filaments up to vortex ages of 540 deg is possible. The visualization of the vortex system is used to detect aerodynamic phenomena such as blade-vortex interactions, vortex-airframe interactions, and the occurrence of smooth sinuous disturbances. A detailed description of the applied reference-free background-oriented schlieren setup is given, and the suitability of different natural backgrounds for the background-oriented schlieren method is analyzed.

Bauknecht, A., Raffel, M. and Grebing, B.

"AIRBORNE ACQUISITION OF BLADE TIP DISPLACEMENTS AND VORTICES ON A COAXIAL ULTRALIGHT HELICOPTER"

AIAA Paper 2017-3552, June 2017, Denver, CO.

A series of comprehensive flight tests investigated the flight dynamics and explored the flight envelope of a newly developed ultralight, coaxial, counter-rotating helicopter from the company EDM Aerotec. The present paper focuses on optical measurement techniques that were applied to study the minimum blade tip clearance and convection of blade tip vortices around the dual-rotor system. A calibrated single-camera system was used to quantify the movement and distances of the blade tip at a critical rotor azimuth for multiple steady and unsteady flight maneuvers. The measurements allowed critical flight conditions to be identified and provided flight data for the validation of comprehensive rotor codes. In an additional flight test, an airborne background-oriented schlieren (BOS) system was operated aboard a second helicopter to visualize the blade tip vortices of the ultralight helicopter in forward flight. The BOS measurements resulted in the first visualization of blade-vortex and vortex-structure interaction effects on a full-scale coaxial helicopter. The application of optical measurement systems in the present flight tests gives valuable insight into the aerodynamics and blade dynamics of a free-flying counter-rotating helicopter and demonstrates how these methods can effectively support the development process of new rotorcraft.

"LARGE-EDDY SIMULATIONS OF TWO DISTURBED COUNTER-ROTATING VORTEX PAIRS"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

Our simulations corroborate the idea that a system of two counter-rotating vortex pairs provides a desirable vorticity distribution behind an aircraft since such a system can be triggered to lose vortex coherence and circulation quickly. Properly 'injected' disturbances lead to the evolution of azimuthal and vertical structures of secondary vorticity which interacts with the primary vortices, resulting in a

quick decay of all coherent vortices into incoherent turbulence in the late mid to early far field. This, in turn, effectively diminishes the induced rolling moment experienced by a wake-encountering aircraft. The problem, though, remains to find robust and controllable disturbance mechanisms which yield the desired effects. Especially the differences between high turbulence forcing and low turbulence forcing cases underline the importance of a correct 'timing'.

"AN EVALUATION OF THE TEMPERATURE, WATER VAPOR, AND VERTICAL VELOCITY STRUCTURE OF AIRCRAFT CONTRAILS"

Journal of Geophysical Research, Vol. 103, No. D8, April 1998, pp. 8727-873.

Measurements made in contrails formed in the wake of a Lear 35 have been analyzed with respect to their temperature, water vapor, and vertical velocity structure. The National Center for Atmospheric Research (NCAR) Sabreliner traversed the Lear's wake at distances varying from 150 m to 5 km and penetrated the contrails 243 times over the course of seven flights. The width of the plume is documented as a function of the distance between the leading and chase aircraft and the temperature, humidity and vertical motion components inside the plume have been analyzed and compared with a three-dimensional wake vortex model. The analysis shows that the width increases very little within the first 5 km, in agreement with the vortex model. The increases in temperature and water vapor in the contrail 500 m from the exhaust were nearly equal to 0.6 degrees and 8 ppmv, respectively. The vertical velocity change across the contrail was nearly equal to 4 m/s. The agreement between observations and model predictions is quite good in comparisons of temperature. The model predicts larger water vapor mixing ratios, but the differences can be explained within the expected measurement uncertainties and lack of particle condensation in the vortex model. The model predicts larger excursions in vertical velocity but the trends are in excellent agreement between model and observations.

"OPERATIONAL CONCEPT FOR FLIGHT CREWS TO PARTICIPATE IN MERGING AND SPACING OF AIRCRAFT"

AIAA Paper No. 2006-7722, Wichita, KS, Sept. 2006

The predicted tripling of air traffic within the next 15 years is expected to cause significant aircraft delays and create a major financial burden for the airline industry unless the capacity of the National Airspace System can be increased. One approach to improve throughput and reduce delay is to develop new ground tools, airborne tools, and procedures to reduce the variance of aircraft delivery to the airport, thereby providing an increase in runway throughput capacity and a reduction in arrival aircraft delay. The first phase of the Merging and Spacing Concept employs a ground-based tool used by Air Traffic Control that creates an arrival time to the runway threshold based on the aircraft's current position and speed, then makes minor adjustments to that schedule to accommodate runway

throughput constraints such as weather and wake vortex separation criteria. The Merging and Spacing Concept also employs arrival routing that begins at an en route metering fix at altitude and continues to the runway threshold with defined lateral, vertical, and velocity criteria. This allows the desired spacing interval between aircraft at the runway to be translated back in time and space to the metering fix. The tool then calculates a specific speed for each aircraft to fly while enroute to the metering fix based on the adjusted land timing for that aircraft. This speed is data-linked to the crew who fly this speed, causing the aircraft to arrive at the metering fix with the assigned spacing interval behind the previous aircraft in the landing sequence.

Baxter, R. A.

"A SIMPLE STEP BY STEP METHOD FOR THE ALIGNMENT OF WIND SENSORS TO TRUE NORTH"

11th Symposium on Meteorological Observations and Instrumentation, Paper 1.2, January 2001, Albuquerque, NM.

The alignment of wind sensors to a known direction has traditionally presented a challenge to even the most experienced user. The common thread for most alignment methods is to use the reference to true north. Once this reference direction is accurately determined, the alignment of the wind sensor is adjusted either in software programming or with the hardware to read north or 0 degrees. It is the determination of that true north direction that has been the subject of discussions and development of various methodologies. This paper discusses some of the problems associated with the determination of true north using magnetic methods and traces the history of the presented methodology development. While not intended as a ground breaking technology, the presented method serves to establish a consistent set of procedures that will provide individuals responsible for the setup and verification of wind measurement equipment with a clear, unambiguous and repeatable method for sensor alignment.

Bazin, M. F.

"TRAJECTORY OF A PARTICLE RELEASED IN THE WAKE OF AN AIRCRAFT"

M.S. Thesis, May 1982, Mass. Institute of Technology, Cambridge, MA

In aerial spraying the trajectory of the spray droplets is affected by the aerodynamic wake of the aircraft. Analytical studies were carried out to assess the effect of the trailing vortices on the trajectory of a particle. The particles that are initially released in the wing-tip vortices are entrained by the wake until either the particles escape from its influence or the vortices weaken sufficiently to allow gravity to dominate the dispersion of the particles. The effect of the ground boundary layer on the vortex center trajectory is investigated and is shown to cause an upward displacement of the trajectory. However, this is too small an effect to explain the vortex rebound phenomenon. The equations of motion for a particle in a line vortex are derived. A dimensional analysis of these equations is carried out and computational models are given in specific domains. Particularly, in the Stokes' flow regime a mathematical description of great computational simplicity is derived.

"(UN)CONTROLLED FLIGHT INTO TERRAIN: A HISTORY OF OBSTACLE CLEARANCE REGULATIONS"

AIAA Paper 2018-1614, January 2018, Kissimmee, FL.

Because aviation is comprehensively regulated, commercial flying is safer than it ever was before. This was not the case during the early years of aviation. Back in the early 1930's, only limited regulations governed takeoff distance (land-based aircraft were expected to takeoff in less under 1000-ft) and all-engines-operating climb (the 'Rule of Eight' which required aircraft to have an all-engines operative climb rate (in ft/min) of eight times its stall speed (in knots)). In this paper, we make a historical inquiry into the evolution of regulations governing the takeoff obstacle clearance problem. We show that the FAA, and its predecessor agencies, typically establish and amend Federal Aviation Regulations on a reactionary -- not proactive -- basis after high profile crashes. We trace amendments to key regulations governing the obstacle clearance problem to specific air accidents where insufficient climb performance was deemed as the probable cause of death.

"EXPERIMENTS ON WAKE VORTEX CONTROL"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

This presentation is concerned with a laboratory investigation of trailing vortices and use is made of a water tank to visualize flow structure. Measurements of velocity and vorticity fields, at a series of downstream stations, are being made in a wind tunnel using PIV. The initial experiments have been performed using a delta wing with a 75-degree leading edge sweep, i.e. 30-degree apex angle. It is planned to move to a typical transport aircraft wing configuration soon. Disturbances are introduced in two ways: by adding a harmonic variation to the relative flow speed and by adding a sinusoidal perturbation to the wing incidence. Flow visualization is carried out in the water tank using fluorescent dye and a light beam from an argon ion laser. The beam passes through a set of optics to produce a near constant thickness sheet running the length of the tank. After the wing has traversed the tank the trailing vortices continue to interact and the flow is studied until the vortex structure has apparently broken down. Some caution has to be observed because dye is being viewed and not vorticity. In some experiments one trailing vortex was visualized with green dye and the other with red dye to obtain a clearer picture of the interaction process. Some video sequences of the flow visualization will be shown. Initially the short wavelength instability is clearly visible but as the flow evolves the well-known Crow, or long wavelength, instability develops. The time to the point where one vortex appears to wrap around the other is termed the breakdown point. This time is then transformed into an equivalent distance behind the wing, which in the present case is about 110 wing spans downstream. For a 75-degree delta wing the wavelength of the Crow instability, as shown in previous studies, is around $4.6b$, where b is the initial distance between the trailing vortices. If the flow speed is perturbed at this wavelength then the trailing vortices are found to breakdown closer to the wing. However, if the wavelength is smaller or larger than the Crow value by some critical amount the breakdown point

moves further downstream and the imposed disturbance decays before the Crow instability develops. It is clear, therefore, that if artificial disturbances are to be introduced it is important that the wavelength is carefully controlled. Further results using incidence variation will be shown, together with PIV measurements.

"NATURAL AND FORCED EVOLUTION OF A COUNTER ROTATING VORTEX PAIR"

Experiments in Fluids, Vol. 40, 2006, pp. 98-105

Naturally occurring instabilities such as the long wave Crow instability are one of the mechanisms that can bring about the break-up of aircraft wake vortex pairs. Encouraging the early onset of such instabilities by active or passive means offers the possibility of accelerating wake break-up of aircraft wake vortex pairs. Encouraging the early onset of such instabilities by active or passive means offers the possibility of accelerating wake break-up and dissipation with favorable consequences in terms of safe aircraft separation and airport capacity. This paper describes an experimental investigation of the evolution of the Crow instability in a counter rotating vortex pair perturbed by a pulsed air sheet. Flow measurements were made using two-dimensional particle image velocimetry and two methods devised to detect wake break-up from the two-dimensional data. Pulsed excitation at a wavelength within the range amplified by the Crow instability resulted in wake break-up and the formation of vortex rings at a downstream distance reduced by up to 37% compared to the baseline case. For excitation at a wavelength outside the excited range early break-up was also observed but the extent of the accelerated break-up was reduced as the amplitude of the excitation was increased.

Bearman, P., Heyes, A., Lear, C. and Smith, D.

"EVOLUTION OF A FORCED COUNTER ROTATING VORTEX PAIR FOR TWO SELECTED FORCING FREQUENCIES"

Experiments in Fluids, Vol. 43, 2007, pp. 501-507

In this paper, results from an experimental study of the natural and forced evolution of a pair of counter rotating wing-tip vortices are reported. The vortices were generated using a pair of opposed wing-tips in a wind tunnel and measurements made up to 77 tip-spacings downstream of the models at a chord Reynolds number of $1.3 \times 100,000$. The wake was interrogated using 2D particle image velocimetry and the long-wave Crow instability observed. Velocity data were recorded throughout the lifetime of the instability from initial growth through linking, formation of vortex rings and their subsequent decay. Forcing was achieved using pulsed air jets blowing in the span-wise direction from the wing tip and imparting spatially periodic perturbations to the vortices. Forcing at a frequency within the range amplified by the Crow instability was found to enhance the instability growth rate whereas forcing at a frequency outside the amplified range was found to inhibit instability growth. In the latter case the imparted wavelength was observed to die out with a preferred wavelength growing in its place.

Beasley, G. D.

"SYSTEM AND METHOD FOR CREATING VISUAL IMAGES OF AIRCRAFT WAKE VORTICES"

US Patent 5,845,874, December 1998

A system and method for creating visual images of aircraft wake vortices allows a user, such as an aircraft controller, to increase several airport transactions while maintaining a predetermined level of safety. Wake vortices are simulated in a three-dimensional environment considering various aircraft, environmental, and atmospheric conditions. The simulated wake vortices are rendered from a perspective selectable by the user. The displayed image allows the user to direct aircraft around potentially harmful wake vortices.

"DESCRIPTION AND VALIDATION OF THE ONERA COMPUTATIONAL METHOD FOR THE PREDICTION OF BLADE-VORTEX INTERACTION NOISE"

Aerospace Science and Tech., Vol. 9, 2005, pp. 31-43

The computational method used at ONERA for the prediction of Blade-Vortex Interaction noise is presented in this paper. The five steps of the computational chain are first described. The calculations are then validated by comparison with two different databases. The first one was obtained in the HART program; in this case, it is shown that the influence of Higher Harmonic Control on wake geometry and radiated noise is well captured. The second one was obtained in the ERATO program, where a passive blade shape optimization was done: in this case, the calculations succeed in predicting the relative difference in noise levels between the ERATO optimized blade compared to a reference blade, although the wake geometry of the ERATO rotor is not well captured. Finally, strategies to reduce the BVI noise for blades equipped with trailing-edge flaps are proposed.

"EVOLUTION OF CONFIGURATIONS OF VORTICES WITH THE SAME GLOBAL INTEGRAL INVARIANTS"

Comptes Rendus Mecanique, Vol. 332, Issue 10, October 2004, pp. 835-840

In this Note, we address the question of the evolution of a distribution of N identical localized vortices. Using direct numerical simulation, (here the Runge-Kutta scheme of order 4), together with the localized vortices model, we show that different initial distributions of vorticity with identical integral invariants may exist. We show that the initial configurations with the same invariants may evolve to totally different quasi-final states.

"LOW-FREQUENCY ATMOSPHERIC ACOUSTIC ENERGY ASSOCIATED WITH VORTICES PRODUCED BY THUNDERSTORMS"

Monthly Weather Review, Vol. 133, No. 1, January 2005, pp. 241-263.

An infrasonic observatory collocated with the Colorado State University CHILL radar during the summer of 1995 permitted unique comparisons between severe storm kinematics and detected acoustic energy at subaudible frequencies near 1 Hz. Radar observations of a velocity couplet aloft (evolving into a tornado) showed a circulation maximum descending for about 30 min while moving to the east. The detected infrasound followed the trend of these observations. A model of sound radiated from vortex systems predicts frequencies in the range observed. These data are interpreted in the context of past infrasonic observations. An ongoing study comparing regional tornado and funnel sightings with archived infrasonic data has identified over 100 cases to date where the infrasonic signals occurred at the time of, and from the direction of, the vortices. For some of these cases, the distances were greater than 100 km. The author and his associates continue to collect datasets to permit further evaluation of infrasonic detection methods.

Bedard, Jr., A. J.

"THE DYNAMICS OF ATMOSPHERIC AND INDUSTRIAL VORTICES"

Ph.D. Thesis, 1982, University of Colorado, Boulder, CO

This thesis reviews observed properties of a wide range of atmospheric vortices on scales from aircraft wake vortices (meters) to hurricanes (100's of kilometers). Common properties for atmospheric and industrial vortices (such as the forms of distant tangential flow fields) are documented as well as differences (such as effective generation mechanisms and core sizes). Analytical and numerical calculations predict features (e.g., decay, motions, pressure fields, and instabilities) for a variety of situations (e.g., isolated vortices, multiple vortices, and vortex sheets). Two models representing a line vortex and a line swirl are contrasted in comparing features of rotating flows. A review of complicating factors such as 2-dimensional instabilities, boundary layer effects, axial flows, 3-dimensional instabilities, and turbulence indicates the difficult problems posed for the execution and interpretation of full-scale atmospheric measurements. Experimental data taken for aircraft vortices are used to underline these problems and also demonstrate areas where analytical results are clearly applicable. A flexible apparatus designed for the generation and study of vortices in the laboratory is described. This water tank system utilizing the starting vortices behind airfoils of known characteristics offers wide possibilities for studying vortices under controlled conditions, overcoming many of the limitations of past techniques.

"MEASUREMENTS OF AN AIRCRAFT WAKE VORTEX SYSTEM USING A METEOROLOGICAL TOWER"

Proceedings 9th Conf. on Aerospace and Aeronautical Meteorology, American Meteorological Society, Omaha, NE, June 1983, pp. 252-256

The experiment for the data presented here involved flybys near the Boulder Atmospheric Observatory (BAO), which provided real-time outputs of various parameters, including wind speed, wind direction, and temperature. These data are used to predict the motion of the vortex system and to guide the aircraft height, bearing, and position in relation to the tower and the radar. The results of the experiment, which focused chiefly on the evaluation of an FM/CW radar for wake vortex detection, are seen as providing an interesting case study of vortex impingement upon a well-instrumented meteorological tower. The horizontal and vertical wind speed measurements are compared with those expected from the passage of a wake vortex system. The temperature perturbation obtained gives a data set indicating the temperature distribution in a wake vortex system.

Bedard, Jr., A. J.

"THE USE OF REMOTE SENSORS AND LABORATORY SCALE MODELS IN WAKE VORTEX ADVISORY SYSTEMS"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 50-1 - 50-22

Wake vortex advisory systems require improved definition of wind, temperature and turbulence profiles at airports. For example, in light wind situations a vortex can remain in the vicinity of a runway, not moving under ground-effect to a safe location. Also, the wake vortex vertical position and decay is influenced by vertical profiles of temperature and turbulence, as well as the presence of organized atmospheric structures (such as thermal plumes and gravity/shear waves). More knowledge is required about the three-dimensional structure of the atmosphere for operational use. As closer aircraft spacings become practical, interactions between wakes of different aircraft will become more likely with the result that a variety of unusual propagation paths could result. Such potential interactions, as well as the important effects of vertical atmospheric structure changes on individual wakes, make real-time monitoring of the airport lower atmospheric boundary layer a critical need. This paper addresses two main topics. Initial sections describe newly available remote profiling technologies capable of fulfilling these measurement needs with potential for contributing to other airport requirements, such as microburst and icing forecasting, low-level wind measurement, and enhancing wind shear monitoring capabilities. The second topic reviews ways that laboratory scale model experiments can help improve our knowledge of wake vortex instabilities, transport, and decay. Finally, potential applications of integrated remote sensing systems are reviewed in the context of verifying laboratory experiments for test bed experiments as well as operational environments.

Bedard, Jr., A. J. and Cook, R. K.

"PRESSURE FIELDS FROM AIRCRAFT AND LOCALIZED SEVERE WEATHER AS BUILDING DESIGN PARAMETERS"

Journal of Wind Engineering and Industrial Aerodynamics, Vol. 25, 1987, pp. 355-363

We observe that aircraft produce pressure increases at the surface proportional to the aircraft weight. Measured values are in general agreement with predictions. The time scales are longer for aircraft weight transfer pressure changes (typically 2-4 s, than for acoustic shock waves related to supersonic flight (typically 0.1-0.3 s). However, the amplitudes (typically from 0.1-1 mbar) are comparable. Summaries of observed aircraft pressure transients together with pressure measurements for thunderstorm gust fronts, downflows, and tornadoes should serve as a resource for investigating structure designs under a variety of conditions of atmospheric loading.

Beeler, D. E. and Gerard, G.

"WAKE MEASUREMENTS BEHIND A WING SECTION OF A FIGHTER AIRPLANE IN FAST DIVES"

NACA TN-1190, March 1947, Langley Aeronautical Lab., Langley Field, VA

Wake measurements made in a vertical plane behind a wing section of a fighter airplane are presented for a range of Mach number up to 0.78. Since evidences of reverse flow were found in a large part of the surveys - possibly because of interference of the rake support - the computed profile-drag coefficients are considered to be only qualitative. The results showed that the large increase in drag coefficient beyond the critical Mach number indicated by wind-tunnel tests was also obtained under flight conditions and that the wake width was extended sharply when shock was encountered. The wake extension occurred first at the upper surface since the highest local velocity was obtained on that surface. The large increase in drag coefficient for the wing section tested did not occur until after the critical Mach number had been exceeded by approximately 0.05. Comparison of the profile-drag measurements with total airplane drag measurements showed that the large increases in drag in both cases started to occur at the same value of Mach number. The results further indicated that wake measurements made in three-dimensional flow after shock had occurred cannot, in general, be interpreted in terms of section profile-drag coefficient because of the existence of the strong lateral flow indicated by tuft behavior in the dead-air region behind the shock.

Belano, J. C.

"C-17/PARATROOPER RISK ASSESSMENT ANALYSIS"

M.S. Thesis, March 1997, Air Force Inst. of Tech., Wright-Patterson AFB, OH

The C-17 test and evaluation community has been testing different aircraft formation geometries in search of a configuration which minimizes paratrooper encounter with the wake vortices of upstream aircraft. This thesis develops a simulation tool that the C-17 test and evaluation community can utilize as an advanced risk assessment model to use on proposed formation geometries prior to live testing. The model is developed under the architecture of object-oriented simulation using MODSIM III and parallels similar efforts by the Aerodynamic Decelerator Technology community in creating object-oriented counterparts to already developed trajectory models of various degrees of freedom. This thesis develops the paratrooper object portion of the simulation model while the Petry thesis (1997) develops the C-17 aircraft and vortex objects. Once integrated with the Petry C-17 aircraft and vortex

objects, and after verification and validation, the simulation model is applied to a simplified airborne operation scenario using the mean distance of paratrooper impact location to assembly areas and DZ dispersal distribution as MOEs for different aircraft formation geometries. Lateral separation is shown to have the most influence on both MOEs, while trail distance has minimal effects. For the airborne commander, this translates into operational parameters applicable to the choice of assembly areas and formation geometries. Further operational parameters of any significance are gained when coupled with the results from Petry on encounter rates between paratroopers and wake vortices where trail distance has a significant impact.

"AIRCRAFT LOSS-OF-CONTROL ACCIDENT ANALYSIS"

AIAA Paper 2010-8004, August 2010, Toronto, Ontario, Canada.

Loss of control remains one of the largest contributors to fatal aircraft accidents worldwide. Aircraft loss-of-control accidents are complex in that they can result from numerous causal and contributing factors acting alone or (more often) in combination. Hence, there is no single intervention strategy to prevent these accidents. To gain a better understanding into aircraft loss-of-control events and possible intervention strategies, this paper presents a detailed analysis of loss-of-control accident data (predominantly from Part 121), including worst case combinations of causal and contributing factors and their sequencing. Future potential risks are also considered.

"THE MEASUREMENT OF GUSTINESS AT ROUTINE WIND STATIONS - A REVIEW"

World Meteorological Organization Report No. 31, 1987, Royal Netherlands Meteorological Institute, De Bilt, The Netherlands.

Many meteorological stations observe wind gusts on a routine basis. The measuring procedures, however, are far from uniform. Some stations measure 'instantaneous gusts' with fast response equipment, whereas other stations report the fastest mile. In this report it is tried to unify the observation practice by formulating specifications for the measurement of wind gustiness. The user requirements are reviewed and the consequences for the measuring system are discussed. Two aspects play an important role in this problem. First of all, it is important to observe wind extremes in a uniform way and such that the results can be used directly in wind load studies. Secondly, gustiness measurements, can be used to characterize the exposure error of wind stations. The gustiness of the wind is a measure of the turbulence intensity which is directly related to the roughness of the upstream terrain. This information enables the correction of mean wind observations for local perturbations. Application of such procedures would greatly enhance the quality of surface wind observations over land. The best gustiness parameters for this application are the standard deviation of wind speed and wind direction. It is therefore recommended to measure these parameters on a routine basis with the new generation of wind measuring systems.

"INTERACTION OF A STREAMWISE VORTEX WITH A MIXING LAYER"

Phys. Fluids A, Vol. 2, No. 11, November 1990, pp. 2011-2023

An experimental study has been conducted on the interaction of a single streamwise vortex with a plane turbulent mixing layer. The vortex was generated by a half-delta wing mounted in the settling chamber of a blower-driven wind tunnel. The single-stream mixing layer originated from the top lip of the extended contraction exit, with a tripped initial boundary layer. Initially, the vortex rode below the mixing layer and its effect was to locally distort the mean velocity and Reynolds stress distributions in the lower (high-speed) side of the mixing layer. Once the vortex became embedded within the mixing layer, the distortion, which took the form of a wrinkle, spread through the whole width of the layer. The induced extra strain rates in the mixing layer resulted in the generation of additional, relatively large, Reynolds stresses in the regions around the vortex. In particular, the secondary shear stress reached a maximum absolute value equivalent to about 40% of the maximum primary shear stress, thus indicating significantly increased three-dimensionality in the mixing layer. The vortex appeared to decay rapidly once it was embedded in the mixing layer; the maximum mean streamwise vorticity was observed to decay as approximately $1/(X^2)$ in this region. By the last measurement station, almost all the effects in the mixing layer resulting from the vortex, and the identity of the vortex itself, had subsided.

Bell, W. A.

"SPECTRAL ANALYSIS ALGORITHMS FOR THE LASER VELOCIMETER: A COMPARATIVE STUDY"

AIAA Journal, Vol. 21, No. 5, May 1982, pp. 714-719.

Conventional methods of computing spectra require constant sampling rates and therefore must be modified to accommodate the randomly sampled data from the laser velocimeter. Four approaches that provide estimates of the power spectra from randomly sampled data are evaluated with respect to accuracy and computational speed. Simulated data of varying spectral content are used as input. An estimate of the correlation function that resolves the random time distribution into equidistant time intervals provides the best compromise between computational speed and accuracy for laser velocimeter data.

Bellamy-Knights, P. G.

"AN UNSTEADY TWO-CELL VORTEX SOLUTION OF THE NAVIER-STOKES EQUATIONS"

Journal of Fluid Mechanics, Vol. 41, Part 3, 1970, pp. 673-687.

The steady two-cell viscous vortex solution of Sullivan is extended to yield unsteady two-cell viscous vortex solutions which behave asymptotically as certain analogous unsteady one-cell solutions of Rott.

The radial flux is a parameter of the solution, and the effect of the radial flow on the circumferential velocity, is analyzed. The work suggests an explanation for the eventual dissipation of meteorological flow systems such as tornadoes.

Bellamy-Knights, P. G. and Saci, R.

"VISCOUS VORTEX CORE GENERATION"

Acta Mechanica, Vol. 67, 1987, pp. 121-127.

The unsteady flow of a viscous incompressible fluid between two porous co-axial circular cylinders is analyzed when the outer cylinder is impulsively set into rotation. When there is radial inflow, vorticity is transferred from an unsteady boundary layer initially over the outer cylinder to a steady boundary layer over the inner cylinder.

Bellastrada, C. and Breitsamter, C.

"LARGE TRANSPORT AIRCRAFT WAKE VORTEX AFFECTED BY VORTEX DEVICES"

Notes on Numerical Fluid Mechanics and Multidisciplinary Design, Vol. 87, 2004, pp. 1-9.

The results of a wind tunnel investigation on the wake vortex evolution behind a half-model of a four-engine large transport aircraft in high-lift configuration, with and without vortex devices, are presented. The wake is measured by means of advanced hot-wire anemometry up to 5.6 span distances downstream of the model. Results obtained include velocity, vorticity and turbulence intensity fields. The measured data are evaluated in order to establish and test possible wake vortex strength alleviation strategies.

Bellastrada, C. and Breitsamter, C.

"EFFECT OF DIFFERENTIAL FLAP SETTINGS ON THE WAKE VORTEX EVOLUTION OF LARGE TRANSPORT AIRCRAFT"

Notes on Numerical Fluid Mechanics and Multidisciplinary Design, Vol. 92, 2006, pp. 25-32.

Wind tunnel investigations have been performed to study the effect of different span loadings, obtained by means of differential flap settings, on the structure of the wake vortex behind a half-model of a four-engine large transport aircraft. Advanced hot-wire anemometry technique has been used to measure the wake vortex velocities at five cross stations up to 4.5 span distances downstream of the model. Results obtained are analyzed to identify possible benefits in terms of alleviation of the wake vortex hazard.

Bellastrada, C., Breitsamter, C. and Laschka, B.

"HOT-WIRE MEASUREMENTS OF WAKE VORTICES SHED FROM A TRANSPORT AIRCRAFT IN LANDING CONFIGURATION"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

The task of the Institute for Fluid Mechanics (FLM - Lehrstuhl fuer Fluidmechanik) of TU Muenchen is the investigation of the turbulent flow field of wake vortex originating from a four-engine large transport aircraft (LTA-E4) half-model in landing configuration. Using advanced hot-wire measurement technique the three velocity components of the wake flow field are measured over rectangular planes located at six different stations downstream of the model, up to six wing span distances downstream of the wing. Typical averaged quantities show the development of the wake: the initial vortex sheet at $x=0.37$, the merging of the vortices coming from the outboard flap edge and from the outboard nacelle giving the main vortical structure, which acts as the roll-up center of the whole wake. The vortices coming from the inboard nacelle, the wing-fuselage junction and from the horizontal stabilizer decrease very soon in strength. At $x=5.56$ the two most important vortical structures, the wing-tip vortex and the outboard flap vortex, merge together into a single strong vortex. Turbulence intensities and Reynolds stresses components reach their maximum peaks inside the core region of the vortices indicating the high stress level which the flow undergoes in the vortex core regions.

Belotserkovskii, Al. S. and Ginevskii, A. S.

"NUMERICAL SIMULATION OF A FAR VORTEX WAKE FOR AN AIRCRAFT IN THE TAKEOFF AND LANDING REGIMES"

Doklady Physics, Vol. 46, No. 10, 2001, pp. 747-750

The results of numerically simulating the two-dimensional problem on the interaction of a vortex pair with a screen make it possible to describe basic features of this interaction. We imply the flow separation from the screen, the interaction of the primary and secondary vorticity, and the creation of the loop-shaped trajectory for the motion of primary vortices. We consider the quasi-three-dimensional schematization of the flow. In other words, we analyze the behavior of the vortex system in a number of cross sections corresponding to different time moments. We list characteristic features of this method used for numerically simulating the airplane vortex system near the Earth.

Belotserkovskii, O. M., Belotserkovskaya, M. S., Denisenko, V. V., Eriklintsev, I. V., Kozlov, S. A., Oparina, E. I., Troshkin, O. V. and Fortova, S. V.

"ON THE DEVELOPMENT OF A WAKE VORTEX IN INVISCID FLOW"

Computational Mathematics and Mathematical Physics, Vol. 54, No. 1, 2014, pp. 172-176.

The evolution of an initial perturbation in an axisymmetric subsonic normal inviscid gas flow through a pipe is directly simulated. The basic (unperturbed) flow has a zero radial velocity component, while its axial velocity component (along the axis of symmetry) increases or decreases linearly with the radius. The perturbation is specified as a swirl (rotation about the axis) with a positive or negative

velocity vanishing on the central axis and the lateral surface. Irrespective of its direction, the swirl gives rise to a steady-state vortex carried by the flow. Its shape is spherical (contiguous to the rotation axis) or circular (sliding along the impermeable lateral surface).

Belotserkovsky, A.

"MATHEMATICAL MODEL OF FAR WAKES: TESTING AND SENSITIVITY"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 59-61

The lecture is devoted to computer integration of the near wake database (array of aerodynamic derivatives of free vortex circulations at aircraft trailing edges) and the other data with the mathematical model (MM) of far wakes. Wake evolution past aircraft is considered. The influence of the ground is included by the mirror vortices (vertical velocities are zero) and the ground boundary layer (horizontal velocities are zero). We consider generation of additional free vortices due to the boundary layer separation, as well as viscous effects yielding vortex diffusion. The numerical integration of differential equations is performed according to the Adams-Bashforth scheme. The lecture contains analysis of the test results of the far wake MM based on flight experiments (Idaho Falls and Memphis, about 150 flights). The test results demonstrate acceptable accuracy of the MM and a possibility of its use in the VFS.

Belotserkovsky, A.

"EVALUATION OF DANGER AREAS AND VFS PERFORMANCE"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 55-57

The VFS must predict vortex conditions at airports and eliminate the possibility of danger situations that could yield accidents due to the action of wake vortices. To this end we determine danger areas behind aircraft near vortex cores. It is necessary to calculate the danger areas for different distances from the aircraft. The method of efficient evaluation of aerodynamic disturbances acting on aircraft in wake vortices of a leader is described. The criterion of safety is chosen. The next step is calculation of a database of danger areas for different pairs of leader-follower. For evaluation of the VFS performance we consider a standard glidepath. A control section is a rectangle along the glidepath where the presence of any of the two vortex cores makes it impossible for the follower to enter it. The dimensions are determined by the accuracy in maintaining the glidepath by the pilot of the leader, by the dimensions of the danger areas for the corresponding pair, and errors in prediction of the leader far wake by the far wake model. The time separation acceptable for the follower is determined by the time period when all sections will be free of the wake vortices. The main factor which determines this time period is the wind velocity.

Belotserkovsky, A., Baranov, N. and Kanevsky, M.

"NEW PRINCIPLES IN THE AREA OF WAKE VORTEX SAFETY FOR AIR TRAFFIC CONTROL"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

Serious efforts being made recently for wake vortex safety all over the world require, in our opinion, thorough investigation of the ways of design, construction and implementation of air traffic control systems intended to alleviate wake vortex risks, increase airport capacity, and lighten the work of pilots. The main problem is that the increase in the airport capacity (using the reduced separations between aircraft) results in the inevitable decrease of the wake vortex safety. The only way to overcome this trouble is to provide the pilots with visual information on possible locations of dangerous wake vortices invisible to the eye. In view of the fact that instrumental methods of wake vortex detection are not valid, we suggest to use the numerical methods adapted to this aim. The airborne system to prevent the aircraft entering into wake vortices of a vortex generator (typically, another aircraft - the leader) consists of: the unit tracking parameters of the generator and the aircraft provided with the system (below - the aircraft); the unit calculating the wake vortices of the generator; the unit simulating the control plane situated at some distance ahead of the aircraft perpendicular to the aircraft velocity vector; the unit indicating a dangerous situation when the wake vortices lie within the prescribed zone (the zone of the aircraft possible positions at the time of the flight through the control plane) in the control plane; and some other auxiliary units. The system functions as follows: When the generator wake vortices are away from the prescribed zone, the vortices are not visible on the indicator screen. As soon as they are close enough to the zone, they become visible and the sound alarm notifies the pilot about the situation. Then the pilot decides which actions could prevent the vortex entering into the zone.

Belotserkovsky, A., Baranov, N., Kanevsky, M., Pasekunov, I. and Morozov, V.

"SIMULATION OF AMBIENT TURBULENCE EFFECTS ON CAPACITY OF A SINGLE RUNWAY AIRPORT EQUIPPED WITH THE VORTEX FORECASTING SYSTEM"

Second Workshop WakeNet2-Europe, 'Capacity Gains as Function of Weather and Weather Prediction Capabilities', Langen, November 2004.

A model of a single runway airport equipped with the Vortex Forecasting System (VFS) is developed. According to this model, all aircraft flying to the terminal area are aligned in the approach sequence on the first-come, first served basis. It is supposed that all the aircraft in the terminal area have the same flight speed. The aircraft are divided into 3 classes: heavy, large, and light aircraft. Each of the classes has its own landing speed. The safe separations in the approach sequence depend on the classes of aircraft in the leader-follower pair and evaluated through calculation of the wake vortex release times for 5 windows located along the glidepath (these windows are like the corresponding windows in the AVOSS). The aircraft flight through a window is safe if the window is free of the danger areas related to the leader wake vortices (including the case when the vortices are inside the window but very weak). The danger criterion for evaluation of danger areas is the following: the rolling moment due to the

wake vortices is more than one half the available aileron rolling moment of the follower or, otherwise, the follower maximum angle of roll is more than 15 degrees. The position and intensity of the wake vortices are calculated using the VFS algorithms (taking account of in-ground effects). The calculation errors are included into the model through the corresponding increase of the danger areas. The airport is simulated as a queuing system. The wind values are random with the known probability distribution. The length of the aircraft sequence in the airport terminal area is limited by the terminal area dimension, so some arriving aircraft could not be included into the sequence under unfavorable conditions and should wait some time (the service failure). The calculation results for the capacity gains as functions of the ambient turbulence index are submitted. The results demonstrate losses in airport capacity gains when the accuracy of ambient turbulence forecasting is low. The results could support the elaboration of requirements for the turbulence forecasting accuracy at different levels of the system performance.

Belotserkovsky, S. M.

"COMPUTERIZED STUDY OF VORTEX AEROHYDRODYNAMICS OF AIRCRAFT AND HELICOPTERS"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 20-1 - 20-33

The main research in the USSR is conducted by Central Aerohydrodynamics Institute (TsAGI) (calculations, computer simulations, wind-tunnel tests) and by Flight Research Institute (LII) (in-flight experiments) with participation of some other institutions. The principal objective is to ensure flight safety and to make better use of the potential of aircraft, helicopters, and airfields. To meet these demands it is necessary to study: wake vortices behind aircraft and helicopters; their effects on other aircraft and bodies; and dynamics of disturbed motion of the bodies. The most operative and cheap approach was selected, i.e., systematic computer simulation with selective experimental wind-tunnel and in-flight tests.

"STRUCTURE AND PRINCIPLES OF THE VFS FUNCTIONING"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 51-54

The solution to the problem of forecasting vortex danger at airports is addressed through the use of up-to-date computer technologies, modern methods of data acquisition on meteorological conditions surrounding an airport, and exhibition of the vortex danger prediction for flight control services. This lecture summarizes the 4-year activity of SABIGO together with Canadian researchers.

Belotserkovsky, S. M.

"COMPUTER VORTEX FORECAST SYSTEM"

TP-13373E, March 1999, Science-Engineering Centre SABIGO Ltd., Moscow, Russia.

This report describes phase 4 wake vortex prediction investigations conducted by SABIGO from April 1997 to March 1998. The report presents an enhancement of the far wake model of the vortex forecast system (VFS) that incorporates the ground boundary layer. Also provided are the results of a VFS evaluation using aircraft wake data collected at the Memphis International Airport in December 1994 and August 1995. The report also covers the following: extension of the near wake database to include more aircraft types; investigation of danger areas considering ground effects; and development of an approach to evaluate VFS performance during aircraft takeoff field trials.

Belyaev, I. V. and Kopiev, V. F.

"ON SOUND SCATTERING BY A RANKINE VORTEX"

AIAA Paper No. 2007-3421, Rome, Italy, May 2006

In the paper, the well-known problem of sound scattering by a Rankine vortex is considered. Despite almost semi-centennial history of the problem, it has not yet been solved satisfactorily. The main difficulty is the fact that the slow decrease of the mean velocity at the infinity hinders the correct formulation of the problem. It results in arising of multiple solutions, each of which pretends to be correct, including the solutions with singularities behind the vortex. A new formulation of the problem is proposed that allows to regularize the problem and to find the solution corresponding to the physical essence of the problem. It is shown that instead of plane wave condition it is necessary to pose the condition of the point source far from the vortex. The analysis made in the paper clarifies the cause of the multiplicity of answers and allows to compare the existing approaches. In the new formulation, the exact solution of the problem of non-resonant sound scattering by the Rankine vortex in the weakly compressible approximation is found. The different results for the resonant scattering are analyzed and the result unifying the previous ones is found. This approach demonstrates the benefit of partial harmonic expansion method in comparison with the Born approximation approach in Lighthill's equation due to unified consideration of non-resonance and resonance scattering.

"OPTIMAL DISTURBANCES IN SWIRLING FLOWS"

AIAA Journal, Vol. 42, No. 9, Sept. 2004, pp. 1841-1848

The mechanism of optimal disturbances, which are composed of growing and decaying modes, in swirling flows (with an axial velocity component) is explored. Two characterizing cases are considered; stationary disturbances in rotating pipe flow and temporal disturbances in a trailing vortex. It is found that in both cases the optimal transient growth amplification in short times or distances is much larger than the known exponential mode amplification. Unlike the flow in a nonrotating pipe, in which the amplification is based on the existence of a least stable pair of modes and the cancellation of their associated initial axial velocity components, when a rotation is added to the flow the optimal amplification mechanism is based on the cancellation, at the initial state, of the most unstable mode

velocity components by many decaying modes. For the trailing vortex, the transient growth mechanism seems to be based on the contribution of the continuous spectrum, and the optimal transient growth is not significantly affected by the existence of swirl in the flow.

"THREE-DIMENSIONAL ROTOR FLOW CALCULATION"

FME Transactions, Vol. 33, 2005, pp. 33-39.

This paper presents the numerical model developed for rotor blade aerodynamics loads calculations. The model is unsteady and fully three-dimensional. Helicopter blade is assumed to be rigid, and its motion during rotation is modeled in the manner that rotor presents a model of rotor of helicopter Aerospatiale SA 341 'Gazelle' (the blade is attached to the hub by flap, pitch and pseudo lead-lag hinges). Flow field around the blade is observed in succession of several azimuth locations. Flow field around helicopter rotor is modeled as fully three-dimensional, unsteady and potential. Blade aerodynamics is modeled using a lifting surface model. Rotor wake is generated from the straight elements of constant vorticity, released from the trailing edge, at fixed azimuth angles. These vortices represent both trailed and shed wake components, and are allowed to freely convect along local velocity vectors. Wake is modeled as free one, and its shape at certain moment can be calculated from simple kinematics laws applied on collocation points of the wake. Wake distortion is calculated only in the rotor near-field, i.e. in finite number of rotor revolutions. Vortex elements are modeled with vortex core. The radius of the vortex core is assumed independent of time, and it depends on circulation gradient at the point of vortex element released from the blade.

"AN EXPERIMENTAL STUDY OF THE EFFECT OF FREE-STREAM TURBULENCE ON A TRAILING VORTEX"

Experiments in Fluids, Vol. 38, 2005, pp. 244-257.

A study of turbulence evolution and spectra within and just outside the core of a trailing vortex is performed. The vortex is generated by a vortex generator consisting of four blades positioned orthogonally to each other with the same angle of attack and placed in a low-speed wind tunnel. A grid is placed upstream of the vortex generator to produce free-stream turbulence, which wraps around and interacts with the columnar vortex. Instantaneous measurements of the three velocity components are obtained using a miniature four-sensor hot-wire probe. The study focuses on the distribution of turbulence energy and Reynolds stress among the different spectral components of the flow at different positions across the vortex core and different axial positions along the tunnel. The effect of background grid turbulence on the spectral energy distribution of the vortex is examined in comparison to the vortex alone.

"EFFECT OF A GROUND PLANE ON A TURBULENT VORTEX RING TRAJECTORY"

63rd Annual Meeting of the APS Division of Fluid Dynamics, November 2010, Long Beach, CA.

Experiments were conducted to assess how a turbulent ($Re=20000$) vortex ring's trajectory is affected by a ground plane parallel to its initial trajectory. This study, part of a larger effort in vortex-particle interaction, aims to characterize the vortex ring flow disturbance that interacts with a particle. Vortex ring motion was characterized for four distances between the initial vortex ring axis and the ground plane. Characterization included vortex centroid motion and diameter from high-speed video, vortex ring circulation from DPIV, and the wall pressure disturbance time traces. It was observed that in all cases the vortex ring trajectory is deflected toward the plane, ending in a collision. As plate height is decreased, the collision occurs closer to the ring generator, the wall pressure is also more intense, and the symmetry of the ring is affected more strongly.

"ACCURACY OF ACARS WIND AND TEMPERATURE OBSERVATIONS DETERMINED BY COLLOCATION"

Weather and Forecasting, Vol. 14, No. 6, 1999, pp. 1032-1038.

A collocation study of meteorological reports from commercial aircraft relayed through the Aircraft Communications, Addressing, and Reporting System (ACARS) has been performed to estimate standard deviations of observation errors for wind and temperature. ACARS observations were collected over an

area in the western and central United States for a 13-month period, and this dataset was examined for pairs of reports within small spatial (less than or equal to 10 km) and temporal (less than or equal to 10 min) windows. The results showed an observation error of a single horizontal component of wind of 1.1 m/s and 0.5 K for temperature above the boundary layer. Within the boundary layer, the rms difference of wind and temperature between aircraft was larger, presumably due to larger small-scale variations in the atmosphere and, in the case of wind, from aircraft maneuvers. These observation error estimates are valuable for use in data assimilation and for determination of forecast error from ACARS observation-minus-forecast differences. By comparing standard deviations at different levels, estimates of mesoscale variability at a 10-km scale in the lower atmosphere were also calculated. These values (rms vector error of 1.8 m/s for wind, rms error of 0.5 K for temperature) can be interpreted as estimates of the 10-km lower-tropospheric error of representativeness, also useful for data assimilation.

Benjamin, T. B.

"THEORY OF THE VORTEX BREAKDOWN PHENOMENON"

J. Fluid Mech., Vol. 14, June 1962, pp. 38-44

The phenomenon examined is the abrupt structural change which can occur at some station along the axis of a swirling flow, notably the leading-edge vortex formed above a delta wing at incidence. Contrary to previous attempts at an explanation, the belief demonstrated herein is that vortex breakdown is not a manifestation of instability or of any other effect indicated by study of infinitesimal disturbances alone. It is instead a finite transition between two dynamically conjugate states of axisymmetric flow, analogous to the hydraulic jump in open-channel flow. A set of properties essential to such a transition, corresponding to a set shown to provide a complete explanation for the hydraulic jump, is demonstrated with wide generality for axisymmetric vortex flows; and the interpretation covers both the case of mild transitions, where an undular structure is developed without the need arising for significant energy dissipation, and the case of strong ones where a region of vigorous turbulence is generated.

Benjamin, T. B.

"SIGNIFICANCE OF THE VORTEX BREAKDOWN PHENOMENON"

J. Basic Engineering, Vol. 87, June 1965, pp. 518-522

The essential points in the author's published theory of the vortex breakdown phenomenon are summarized, and their implications regarding longitudinal vortex flows in general are reviewed. It is proposed that the physical principles serve to rationalize a wide variety of possible behavior in swirling flows.

Benjamin, T. B.

"SOME DEVELOPMENTS IN THE THEORY OF VORTEX BREAKDOWN"

J. Fluid Mech., Vol. 28, Part 1, April 1967, pp. 65-84

This analysis consolidates the ideas of the 'conjugate-flow' theory, which proposes that vortex breakdown is fundamentally a transition from a uniform state of swirling flow to one featuring stationary waves of finite amplitude. The original flow is assumed to be supercritical (i.e., incapable of bearing infinitesimal stationary waves), and the mechanism of the transition is explained based on physical principles that are well established in relation to the analogous supercritical flow phenomenon of the hydraulic jump or bore.

"PATCHED GRID AND ADAPTIVE MESH REFINEMENT STRATEGIES FOR THE CALCULATION OF THE TRANSPORT OF VORTICES"

International Journal for Numerical Methods in Fluids, Vol. 40, Issue 7, pp. 855-873

This paper presented two techniques allowing local grid refinement to calculate the transport of vortices, one is the patched grid (PG) method which allows non-coincident interfaces between blocks. Treatment of the non-coincident interfaces is given in detail. The second one is the adaptive mesh refinement (AMR) method which has been developed to create embedded sub-grids. The efficiency of these two methods is demonstrated by some validating tests. Then the PG and AMR strategies are applied in the computation of the transport of vortices. We start with a simple vortex flow in a cubic box. Then, the flowfield around a complex aircraft configuration is calculated using the two refinement techniques. Results are compared with a fine, referenced grid calculation.

Benkenida, A., Bohbot, J. and Jouhaud, J.-C.

"PATCHED GRID AND ADAPTIVE MESH REFINEMENT STRATEGIES FOR WAKE VORTEX TRANSPORT CALCULATION"

AIAA Paper No. 2001-2416, Anaheim, CA, June 2001

Applying mesh refinement strategies to the study of wake vortices is the principal subject of this study. We simulate the inviscid flow around a generic aircraft model using Patched grid and Adaptive Mesh Refinement techniques. The analysis of numerical results shows that the application of these strategies to wake vortices problems is promising, especially when we study complex cases in which it is necessary to use very fine grids and consequently enormous CPU times.

Benkenida, A., Jonville, G. and Darracq, D.

"NUMERICAL STUDY OF WAKE VORTICES OF A GENERIC AIRCRAFT MODEL"

AIAA Paper No. 2001-2428, Anaheim, CA, June 2001

This paper presents the numerical simulation of the wake vortices induced by the high lift system of an aircraft model up to the extended near field (6.5 and 13 wingspans) by the means of high-quality meshes and high-order schemes. Numerical simulations are done by the NSMB code which solves the three-dimensional Navier-Stokes equations (Euler equations here) on multi-block structured grids. The most important point discussed in this paper is the effect of the angle of attack on the behavior of wake vortices and their mutual interaction.

"EXPLORATORY STUDY OF C-130 AND C-47 AIRCRAFT TRAILING VORTICES IN GROUND EFFECT"

LWP-1040, March 1972, NASA Langley Research Center, Hampton, VA

In the development and checkout of an instrumented tower which is to be used to measure the velocity characteristics of aircraft trailing vortices, some measurements were made of trailing vortices shed by a NASA C-47 airplane and an Air Force C-130 airplane. The report describes the instrumentation and testing technique used and presents some preliminary results on the vortex characteristics of the C-47 and C-130 aircraft shed in close proximity to the ground.

Bennett, D. J., Covert, E. E. and Oliver, T.

"THE WING GRID: A NEW APPROACH TO REDUCING INDUCED DRAG"

Final Report, 16.622, December 2001, MIT, Cambridge, MA.

A new design of wing tip, called a wing grid, has been shown to provide a dramatic reduction in the induced drag a wing produces. This experimental project was performed to quantify that reduction and to better understand the wing grid effect. A model wing including three modular wing tips two different designs of wing grids and a control tip were constructed and tested at various wind speed and angles of attack in a wind tunnel. The performance of the wing grids relative to the control and to each other was investigated. The experiment showed that at low speeds, the wing grid does not reduce drag, but suggested that it might do so at higher speeds.

Bennett, W. J.

"ANALYTICAL DETERMINATION OF THE VELOCITY FIELDS IN THE WAKES OF SPECIFIED AIRCRAFT"

FAA-RD-64-55, May 1964, Boeing Co., Renton, WA

This report documents a study for the prediction of the velocity fields in the wakes of fixed-wing and rotary-wing aircraft. Thirty-three aircraft currently operating within the Air Traffic Control system are analyzed. Numerical data are presented for eleven of the aircraft, defining their respective wake velocity fields. A discussion of the assumptions and limitations of the analytical models used is included along with a discussion of possible correlation of the calculated values with test results.

Bennett, W. J.

"STATE-OF-THE-ART SURVEY FOR MINIMUM APPROACH, LANDING, AND TAKE-OFF INTERVALS AS DICTATED BY WAKES, VORTICES, AND WEATHER PHENOMENA"

FAA-RD-64-4, January 1964, Boeing Co., Renton, W.

This report is a study of the generation and decay of the wake behind an aircraft, both in free air and ground effect, and its effect on following aircraft. An analysis is presented for both fixed and rotary-wing aircraft which defines the wake movement with time and the wake-induced velocities. The influence of atmospheric parameters such as wind, temperature, and turbulence is discussed as it applies to the generation and decay of the wake.

Benton, S. I.

"CAPITALIZING ON CONVECTIVE INSTABILITIES IN A STREAMWISE VORTEX-WALL INTERACTION"

PhD Thesis, 2015, The Ohio State University, Columbus, OH.

Secondary flows in turbomachinery and similar engineering applications are often dominated by a single streamwise vortex structure. Investigations into the control of these flows using periodic forcing have shown a discrete range of forcing frequency where the vortex is particularly receptive. Forcing in this frequency range results in increased movement of the vortex and decreased total pressure losses. Based on the hypothesis that this occurs due to a linear instability associated with the Crow instability, a fundamental study of instabilities in streamwise vortex-wall interactions is performed. In the first part of this study a three-dimensional vortex-wall interaction is computed and analyzed for the presence of convective instabilities. It is shown that the Crow instability and a range of elliptic instabilities exist in a similar form as to what has been studied in counter-rotating vortex pairs. The Crow instability is particularly affected by the presence of a solid no-slip wall. Differences in the amplification rate, oscillation angle, Reynolds number sensitivity, and transient growth are each discussed. The spatial development of the vortex-wall interaction is shown to have a further stabilizing effect on the Crow instability due to a 'lift-off' behavior. Despite these discoveries, it is still shown that amplitude growth on the order of 20 percent is possible and transient growth mechanisms might result in an order-of-magnitude of further growth if properly initiated. With these results in mind, an experiment is developed to isolate the streamwise vortex-wall interaction. Using a vortex generating wing section and a suspended splitter plate, a stable interaction is created that agrees favorably in structure to the three-dimensional computations. A small synthetic jet actuator is mounted on the splitter plate below the vortex. Phase-locked stereo-PIV velocity data and surface pressure taps both show spatial amplification of the disturbance in a frequency range which agrees well with the prediction for the Crow instability. An analysis of the vortex response shows a primarily horizontal oscillation of the vortex column which strongly interacts with the secondary vortex structure that develops in the boundary layer.

Benton, S. I. and Bons, J. P.

"RESPONSE OF A STREAMWISE VORTEX-WALL INTERACTION TO UNSTEADY FORCING"

AIAA Paper 2016-1605, January 2016, San Diego, CA.

Streamwise vortices exist in several engineering flows in both external and internal aerodynamics, often with undesirable effects. An experimental investigation of a streamwise vortex-wall interaction is performed using a vortex generating wing section and a suspended splitter plate. The unsteady development of the interaction is documented using surface pressure taps and stereo particle image velocimetry. A synthetic jet actuator is implemented below the vortex and the response of the vortex to unsteady forcing is evaluated with a focus on spatial amplification through convective instabilities. At low forcing frequencies large displacement of the vortex is recorded, but with almost no spatial amplification. This behavior is expected to be linked to transient growth mechanisms. Within a specific frequency range, it is shown that spatial amplification of the vortex displacement occurs. This mechanism is related to the Crow instability and has recently been investigated using computational linear stability theory. The results here are in qualitative agreement with those studies. The vortex-wall interaction generates a secondary vortex structure which rolls-up from the boundary layer. This feature is involved in the dynamics of the instability and its behavior is described.

Bera, R. K.

"WING TIP VORTICES OF CYCLONIC PROPORTIONS"

Current Science, Vol. 64, No. 3, February 1993, pp. 138-139

The wing tip trailing vortices that are continuously shed by jumbo jets constitute a hazard to following aircraft if there is not enough lag time allowed between the aircraft. The hazard exists because of the sheer size of these vortices, and the high swirl velocities, which are directly related to vortex strength, contained in them. As an example, swirl velocities on the order of 18.3 m/sec may be found in the vortices shed by a C5-A Galaxy one and a half miles astern, or 30 sec. after the aircraft's passage. The type of hazards include: an aircraft experiencing imposed rolling moments upon penetrating the core of a vortex; loss in rate of climb or an increase in the rate of descent of an aircraft subject to the downwash; and the imposition of structural loads for the case of a penetrating aircraft approaching perpendicular to the vortex system. The use of a crossed blade turbine fixed immediately behind the wing tip, and fences placed near the wing tip above and below the wing, producing a swirl counter to vortex swirl has shown some promise in alleviating this danger. In addition, predominantly aerodynamical solutions to this problem have been proposed. One attempt is to alter the wing spanwise lift distribution by deflected flaps to produce centers of high shed vorticity, so that the wing wake attempts to roll up into several vortex cores, producing weaker individual vortices compared to the present tip vortices, and vortices whose mutual interaction will cause the vortices to destroy themselves in a Crow type instability or by vortex bursting. In the second approach, aerodynamic control surfaces are to be programmed to automatically generate an unsteady pressure distribution on the wing while maintaining constant lift to produce an unsteady wake. Attention is also given to

experimental data regarding aircraft wake behavior, considering the development of vortical and viscous wakes, and characteristic flow regions.

Bera, R. K.

"ACCURATE METHOD FOR CALCULATING INITIAL DEVELOPMENT OF VORTEX SHEETS"

J. Aircraft, Vol. 27, No. 10, October 1990, pp. 910-912

A fast and accurate numerical method for calculating the early evolutionary stages of an initially planar, finite-span vortex sheet has been found. The method may be used to determine wing downwash behind a wing, e.g., in the vicinity of the tail plane.

Bera, R. K.

"CALCULATION OF INITIAL VORTEX ROLL-UP IN AIRCRAFT WAKES"

Journal of Aircraft, Vol. 13, No. 1, January 1976, pp. 58-59

The intention of this note is to rederive the results of Yates by using a Fourier sine series for the lift distribution instead of the Chebyshev polynomials he has used, and to complete the analysis by also considering nonsymmetric flight conditions. These results may be used as the first step in the use of the extended Betz theory for rollup calculations.

Beran, D. W.

"REMOTE SENSING WIND AND WIND SHEAR SYSTEM"

FAA-RD-74-3, January 1974, NOAA Wave Propagation Laboratory, Boulder, CO.

The background for, and developmental history of acoustic Doppler is followed by a detailed study of winds that effect landing operations. A climatology of critical boundary layer wind shear and a study of optimum averaging times for reported winds show that the occurrence of severe wind shear is regional and not to be expected more than a small percentage of the time. Analysis of several ground based remote wind sensing devices suggests that the acoustic Doppler system is presently optimum. Weaknesses in any given device may, however, dictate that a joint sensor approach must be used to insure continual real time operation. The selection of an optimum configuration and details of the hardware used during experimental tests at Stapleton International Airport are discussed. Calibration of the Acoustic Doppler Wind System was accomplished by comparison with winds taken by anemometers suspended beneath balloons, tower mounted anemometers and slow ascent radiosondes. Agreement with all of these wind measurements was very good. Results from the operational tests at Stapleton indicate the Acoustic Doppler System can perform in the high noise environment of an airport. The effect of the high noise in terms of percentage of lost record has not yet been determined.

Beran, D. W.

"ACOUSTICS: A NEW APPROACH FOR MONITORING THE ENVIRONMENT NEAR AIRPORTS"

Journal of Aircraft, Vol. 8, No. 11, November 1971, pp. 934-936

The note describes a relatively new device, an acoustic echo sounder, which has the potential to not only indicate the presence or absence of wake vortices, but to act as a continuous monitor of other important meteorological parameters (wind, wind shear, and thermally generated turbulence). A fixed, vertically pointing antenna, in conjunction with two orthogonally positioned scanning antennas could provide a continual real time record of the inversion height, the turbulent intensity, an indication of the presence of wing tip vortices, and the vertical profile of the total wind vector.

Beran, D. W.

"ACOUSTIC RADAR DETECTION TECHNIQUES"

FAA Symposium on Turbulence, 1971, Federal Aviation Administration, Washington, DC, p. 27

Acoustic radar or echo sounding has the potential of providing a solution to both the wake vortex and low-level wind shear monitoring problems, at a cost which is realistic in terms of equipping most large airports with an operational system. Such a system would be based on the demonstrated ability to make Doppler wind measurements with an acoustic sounder (for monitoring strong shear layers) and the amplitude and phase scintillation of an acoustic wave when it is transmitted through a turbulent medium (for detecting wake vortices).

Berenger, T., Faier, D., Maresca, C. and Berton, E.

"EXPERIMENTAL AND NUMERICAL INVESTIGATION OF ROTOR AERODYNAMICS IN FORWARD FLIGHT"

Journal of Aircraft, Vol. 34, No. 3, May-June 1997, pp. 394-399.

This paper concerns an experimental and numerical investigation of the aerodynamic field of a model rotor in forward flight. The study emphasizes the characterization of the flow field in the immediate vicinity of the blade and in its near wake. The analysis of the blade aerodynamics is supported by measurements performed on the overall air loads, the three-dimensional velocity field around the blade and in the wake (determined by means of laser Doppler anemometry measurements), and the geometry of the tip vortex path. The corresponding data results allow the correlation of typical velocity profiles to the vortex characteristics parameters. From the computational approach, the prediction efficiency of a prescribed wake analysis code and its improvement are checked by direct comparisons with experiments performed either on the tip vortex path, or on the three-dimensional velocity field and the circulation distribution along the blade span.

Berens, M.

"POTENTIAL OF MULTI-WINGLET SYSTEMS TO IMPROVE AIRCRAFT PERFORMANCE"

Ph.D. Thesis, Technical University of Berlin, Berlin, Germany, March 2008

The potential of multi-winglet configurations to increase aircraft performance is the subject of the present thesis. A multidisciplinary tool, termed VLM++, has been developed based on an implementation of the 3D vortex lattice method. Apart from consideration of profile and interference drag, the method also considers effects that need to be regarded particularly in the case of multi-winglet configurations. The effect of mutual interference among the winglets on the individual surfaces maximum load abilities is considered, producing values which normally differ from those of the basic airfoil sections. Another module permits to explicitly model the nonlinear lift characteristics based on generalized lift polars. A comparison of the numerical results with published low speed measurement data of multi-winglet configurations having symmetrical NACA 0015 airfoil sections proves that the extended analysis model correctly predicts the lift and drag behavior even in the case of partly separated flow. The computational model correctly identifies the root sections of the foremost winglets as the locations where the flow separations first occur when the angle of attack is increased.

Beresh, S. J., Henfling, J. F. and Spillers, R. W.

"PLANAR VELOCIMETRY OF A FIN TRAILING VORTEX IN SUBSONIC COMPRESSIBLE FLOW"

AIAA Paper 2008-4179, June 2008, Seattle, WA.

A sub-scale experiment has been conducted to study the trailing vortex shed from a tapered fin installed on a wind tunnel wall to represent missile configurations. Stereoscopic particle image velocimetry measurements have been acquired in the near-field for several locations downstream of the fin tip and at different fin angles of attack. The vortex's tangential velocity is found to decay with downstream distance while its radius increases, but the vortex core circulation remains constant. Circulation and tangential velocity rise greatly for increased fin angle of attack, but the radius is approximately constant or slightly decreasing. The vortex axial velocity is always a deficit, whose magnitude diminishes with downstream distance and smaller angle of attack. No variation with Mach number can be discerned in the normalized velocity data. Vortex roll-up is observed to be largely complete by about four root chord lengths downstream of the fin trailing edge. Prior to this point, the vortex is asymmetric in the tangential velocity but the core radius stays nearly constant. Vortical rotation draws low-speed turbulent fluid from the wind tunnel wall boundary layer into the vortex core, which appears to hasten vortex decay and produce a larger axial velocity deficit than might be expected. Self-similarity of the vortex is established even while it is still rolling up. Attempts to normalize vortex properties by the fin's lift coefficient proved unsuccessful.

Beresh, S. J., Henfling, J. F. and Spillers, R. W.

"MEANDER OF A FIN TRAILING VORTEX AND THE ORIGIN OF ITS TURBULENCE"

Experimental Fluids, Vol. 49, 2010, pp. 599-611.

The low-frequency meander of a trailing vortex shed from a tapered fin installed on a wind tunnel wall has been studied using stereoscopic particle image velocimetry in the near-wake at Mach 0.8. Distributions of the instantaneous vortex position reveal that the meander amplitude increases with downstream distance and decreases with vortex strength, indicating meander is induced external to the vortex. Trends with downstream distance suggest meander begins on the fin surface, prior to vortex shedding. Mean vortex properties are unaltered when considered in the meandering reference frame, apparently because turbulent fluctuations in the vortex shape and strength dominate positional variations. Conversely, a large peak of artificial turbulent kinetic energy is found centered in the vortex core, which almost entirely disappears when corrected for meander, though some turbulence remains near the core radius. Turbulence originating at the wind tunnel wall was shown to contribute to vortex meander by energizing the incoming boundary layer using low-profile vortex generators and observing a substantial increase in the meander amplitude, while greater turbulent kinetic energy penetrates the vortex core. An explanatory mechanism has been hypothesized, in which the vortex initially forms at the apex of the swept leading edge of the fin where it is exposed to turbulent fluctuations within the wind tunnel wall boundary layer, introducing an instability into the incipient vortex core.

Beresh, S. J., Smith, J. A., Henfling, J. F., Grasser, T. W. and Spillers, R. W.

"INTERACTION OF A FIN TRAILING VORTEX WITH A DOWNSTREAM CONTROL SURFACE"

AIAA Paper No. 2008-342, Reno, NV, Jan. 2008

A sub-scale experiment has been constructed using fins mounted on one wall of a transonic wind tunnel to investigate the influence of fin trailing vortices upon downstream control surfaces. Data are collected using a fin balance instrumenting the downstream fin to measure the aerodynamic forces of the interaction, combined with stereoscopic Particle Image Velocimetry to determine vortex properties. The fin balance data show that the response of the downstream fin essentially is shifted from the baseline single-fin data dependent upon the angle of attack of the upstream fin. Freestream Mach number and the spacing between fins have secondary effects. The velocimetry shows that the vortex strength increases markedly with upstream fin angle of attack, though even an uncanted fin generates a noticeable wake. No variation with Mach number can be discerned in the normalized velocity data. Correlations between the force data and the velocimetry suggest that the interaction is fundamentally a result of an angle of attack superposed upon the downstream fin by the vortex shed from the upstream fin tip. The Mach number influence arises from differing vortex lift on the leading edge of the downstream fin even when the impinging vortex is Mach invariant.

Beresh, S. J., Smith, J. A., Henfling, J. F., Grasser, T. W. and Spillers, R. W.

"INTERACTION OF A FIN TRAILING VORTEX WITH A DOWNSTREAM CONTROL SURFACE"

Journal of Spacecraft and Rockets, Vol. 46, No. 2, March-April 2009, pp. 318-328.

A subscale experiment has been constructed using fins mounted on one wall of a transonic wind tunnel to investigate the influence of fin trailing vortices upon downstream control surfaces. Data were collected using a fin balance instrumenting the downstream fin to measure the aerodynamic forces of the interaction, combined with stereoscopic particle image velocimetry to determine vortex properties. The fin balance data show that the response of the downstream fin essentially is shifted from the baseline single-fin data dependent upon the angle of attack of the upstream fin. Freestream Mach number and the spacing between fins have secondary effects. The velocimetry shows the increase in vortex strength with upstream fin angle of attack, but no variation with Mach number can be discerned in the normalized velocity data. Correlations between the force data and the velocimetry indicate that the interaction is fundamentally a result of an angle of attack superposed upon the downstream fin by the vortex shed from the upstream fin tip. The Mach number influence arises from differing vortex lift on the leading edge of the downstream fin even when the impinging vortex is Mach invariant.

"DIRECT NUMERICAL SIMULATIONS OF VORTEX RINGS AT REYNOLDS NUMBER OF 7500"

J. Fluid Mech., Vol. 581, 2007, pp. 495-505

We present direct numerical simulations of the turbulent decay of vortex rings with Reynolds Number of 7500. We analyze the vortex dynamics during the nonlinear stage of the instability along with the structure of the vortex wake during the turbulent stage. These simulations enable the quantification of vorticity dynamics and their correlation with structures from dye visualization and the observations of circulation decay that have been reported in related experimental works.

"VORTEX BREAKDOWN INCIPIENCE: THEORETICAL CONSIDERATIONS"

Phys. Fluids, Vol. 7, No. 5, May 1995, pp. 972-982 (Also ICASE-92-63, November 1992, Inst. for Computer Applications in Science and Engineering, Hampton, VA)

The sensitivity of the onset and the location of vortex breakdowns in concentrated vortex cores, and the pronounced tendency of the breakdowns to migrate upstream have been characteristic observations of experimental investigations; they have also been features of numerical simulations and led to questions about the validity of these simulations. This behavior seems to be inconsistent with the strong time-like axial evolution of the flow, as expressed explicitly, for example, by the quasi-cylindrical approximate equations for this flow. An order-of-magnitude analysis of the equations of motion near breakdown leads to a modified set of governing equations, analysis of which demonstrates that the interplay between radial inertial, pressure, and viscous forces gives an elliptic character to these concentrated swirling flows. Analytical, asymptotic, and numerical solutions of a simplified non-linear equation are presented; these qualitatively exhibit the features of vortex onset and location noted above.

"SIMULATION OF C-130 H/J TROOP DOORS AND CARGO RAMP FLOW FIELDS"

AIAA Paper 2017-0967, January 2017, Grapevine, TX.

This paper presents the results of a continuing computational effort to understand the flow field characteristics of a C-130 Hercules aircraft configured for personnel airdrop operations. Flight operations with either the troop door or cargo door open lead to vortical structures and unsteady flows which can adversely affect airdrop operations. Open cargo ramp simulation results using the CFD solver Kestrel, developed within the High Performance Computing Modernization Program CREATE-AV program, show vorticity generated behind the open cargo door and with the flaps extended, a relatively strong vortex forms along the fuselage which traverses above the troop door into the upsweep section of the aircraft tail. Open troop door simulations capture large velocity gradients and unsteadiness for configurations with and without actuator disk propeller models and with and without sideslip. Simulations are computed on both converged hybrid meshes on the order of $100 \times 1,000,000$ cells and near-body/cartesian off-body grids, and these results reconfirm that vortex modeling is dependent on mesh refinement.

Bergh, H. and Tijdeman, H.

"THEORETICAL AND EXPERIMENTAL RESULTS FOR THE DYNAMIC RESPONSE OF PRESSURE MEASURING SYSTEMS"

NLR-TR F.238, January 1965, National Aero- and Astronautical Research Institute, Amsterdam, The Netherlands.

For a series-connection of N thin tubes and N volumes a general recursion formula has been derived that relates the sinusoidal pressure disturbance in volume j to the pressure disturbances in the preceding volume $j-1$ and the next volume $j+1$. From this recursion formula the expressions for the complex ratio of the pressure fluctuation of each volume j to the sinusoidal input pressure $p_{sub 0}$ can be derived by successively putting $j = N, N-1, \dots, 2, 1$. For a single pressure measuring system ($N = 1$) and a double pressure measuring system ($N = 2$) these dynamic response formulae are given explicitly. Theoretical results for single pressure measuring systems are presented that demonstrate the influence of the different parameters. As an illustrative example of the double pressure measuring system some calculations have been performed for a system with a discontinuity in tube radius. Comparison of theoretical and experimental results shows that the response characteristics of the pressure measuring systems considered can be predicted theoretically to a high degree of accuracy.

"PREDICTING NEAR-GROUND VORTEX LIFETIMES USING WEIBULL DENSITY FUNCTIONS"

AIAA Paper No. 2007-1057, Reno, NV, January 2007

To mitigate safety hazards posed by near-ground vortex lateral transport, under instrument flight rules (IFR), parallel runway operations must adopt aircraft spacing standards that often reduce capacity. Once the phenomenon of lateral transport is understood, it is conceivable that, under IFR, new separation standards could restore some runway capacity. In this context, it is of interest to establish the probability that a wake vortex is still surviving in lateral transport time seconds after it began migrating. This paper applies survival data analysis methods to demonstrate how to generate predictions of survival probability that are specific to aircraft type. Modeling assumptions lead to a family of Weibull probability densities, a form that is useful for modeling wind phenomenon.

Berkman, M. E.

"AN INTEGRATED NAVIER-STOKES -- FULL POTENTIAL -- FREE WAKE METHOD FOR ROTOR FLOWS"

PhD Thesis, December 1998, Georgia Institute of Technology, Atlanta, GA.

The strong wake shed from rotary wings interacts with almost all components of the aircraft, and alters the flow field thus causing performance and noise problems. Understanding and modeling the behavior of this wake, and its effect on the aerodynamics and acoustics of helicopters have remained as challenges. This vortex wake and its effect should be accurately accounted for in any technique that aims to predict rotor flow field and performance. In this study, an advanced and efficient computational technique for predicting three-dimensional unsteady viscous flows over isolated helicopter rotors in hover and in forward flight is developed. In this hybrid technique, the advantages of various existing methods have been combined to accurately and efficiently study rotor flows with a single numerical method. The flow field is viewed in three parts: (i) an inner zone surrounding each blade where the wake and viscous effects are numerically captured, (ii) an outer zone away from the blades where wake is modeled, and (iii) a Lagrangian wake which induces wake effects in the outer zone. This technique was coded in a flow solver and compared with experimental data for hovering and advancing rotors including a two-bladed rotor, the UH-60A rotor and a tapered tip rotor. Detailed surface pressure, integrated thrust and torque, sectional thrust, and tip vortex position predictions compared favorably against experimental data. Results indicated that the hybrid solver provided accurate flow details and performance information typically in one-half to one-eighth cost of complete Navier-Stokes methods.

Bernstein, S.

"ANALOG COMPUTER SIMULATION OF TRAILING VORTEX EFFECTS ON FOLLOWING AIRCRAFT"

M.S. Thesis, May 1971, Iowa State University, Ames, IA

The vortex effects on a penetrating aircraft are simulated using an analog computer. The mode of penetration considered is in an along-track fashion in which the following aircraft flies parallel to the trail of the vortices. A C-130 aircraft probing the vortex wake of another C-130 and the wake of a C-5A was investigated. It was found that the encounter aircraft experienced the largest violent response when the initial positioning of the aircraft was at approximately 0.4 wing span to the right or to the left

of the vortex center. A sharp decrease in the response was experienced when the aircraft was initially displaced above or below the vortex trail.

"ON THE GLOBAL EVOLUTION OF VORTEX FILAMENTS, BLOBS, AND SMALL LOOPS IN 3D IDEAL FLOWS"

Communications in Mathematical Physics, Vol. 269, 2007, pp. 693-71.

We consider a wide class of approximate models of evolution of singular distributions of vorticity in three dimensional incompressible fluids and we show that they have global smooth solutions. The proof exploits the existence of suitable Hamiltonian functions. The approximate models we analyze (essentially discrete and continuous vortex filaments and vortex loops) are related to some problems of classical physics concerning turbulence and to the numerical approximation of flows with very high Reynolds number. Finally, we apply our strategy to discrete models for filaments used in numerical models.

Bertenyi, T.

"MERGER OF AIRCRAFT WAKE VORTICES"

Thesis, November 2001, University of Cambridge, Cambridge, UK, p. 180

In the current study, vortex merger is investigated experimentally using a wake survey to provide quantitative measurements. Two lift-producing wings are used to generate the vortices and time to vortex merger is parameterized as a function of initial separation and circulation ratio. The evolution of the two vortices throughout the initial interaction, merger, and post-merger phases is quantified. During the initial interaction, the vortices bloom and draw together until a critical separation is reached at which point merger occurs rapidly. The resulting merged vortex has an altered structure but no significant amounts of circulation are destroyed. Characteristics of the merging process are identified and it is observed that the merging mechanism of nominally equal vortices is different than that of unequal strength vortices. In the case of two unequal strength vortices, the weaker vortex is strongly distorted during the initial interaction phase. Furthermore, unequal strength vortices reach the merger phase earlier and thus present a reduced time to merger compared to equal strength vortices.

Increased freestream turbulence is seen to enhance the rate of blooming thus also reducing the time to merger. Two-dimensional Euler and Navier Stokes computational simulations served as investigative tools and allowed for a direct comparison between the experimental data and two-dimensional vortex merger. It was shown that the assumption of two-dimensionality is inadequate for modelling the correct rate of vortex blooming and the drawing together of the vortices. It was concluded that the initial interaction between merging vortices is three-dimensional.

Bertenyi, T. and Graham, W.

"AN EXPERIMENTAL STUDY OF THE MERGING OF AIRCRAFT WAKE VORTICES"

AIAA Paper No. 2000-4129, Denver, CO, August 2000

This report presents the results of an experimental study of the merger of co-rotating aircraft wake vortices. Two lifting wings were used to generate a pair of co-rotating vortices in a wind tunnel and a single-tube yawmeter was traversed in planes behind the wing to provide both qualitative and quantitative observations. In the case of vortices of nominally equal circulation, they were seen to co-orbit, draw closer together and then very quickly merge. If the two vortices were of different strengths, the merger process took longer, as the smaller vortex was first distorted and wrapped around the larger. During this process, vorticity was bled from the smaller to the larger vortex. The actual distance to merger for a given initial separation of two nominally equal vortices was seen to collapse onto a single curve once the variables were properly non-dimensionalized. For similarly non-dimensionalized but distinctly non-equal vortices, merger was complete at an earlier point. A simple vortex blob numerical simulation method is able to provide a good description of the merger process, suggesting that the flow is essentially two-dimensional and inviscid.

Bertenyi, T. and Graham, W. R.

"EXPERIMENTAL OBSERVATIONS OF THE MERGER OF CO-ROTATING WAKE VORTICES"

J. Fluid Mech., Vol. 586, 2007, pp. 397-422

The interaction and merger of a pair of co-rotating vortices has been studied experimentally in a wind tunnel. The vortices are generated using two separate wings, allowing both initial circulation ratio and initial separation to be varied. At the nominal test speed of 30 m/s, the circulation-based Reynolds number is typically 64,000. Mean crossflow velocities at stations downstream are obtained with a traverse-mounted yaw meter. The vortex interaction is characterized by fitting Lamb-Oseen profiles to the measured, azimuthally averaged, tangential velocity profiles. It is found that the merger process differs in several important respects from lower-Reynolds-number studies. First, the separation of the vortices decreases continually throughout the initial, 'viscous growth', phase, instead of remaining constant. Second, the vortex core growth in this phase appears to be greater than can be accounted for by turbulent diffusivity, even after correcting for the effects of wandering. Finally, the time to merger lies well below that predicted by expressions based on the lower-Reynolds-number observations, and is further reduced when the circulation ratio departs from unity. We conclude that

the enhanced core growth is probably due to the short-wavelength 'elliptic' instability that has already been observed in some high-Reynolds-number experiments. The mechanism behind the decrease in separation, which is a crucial factor in the reduced merger time, is three-dimensional, but, beyond this, remains unknown.

Berthet, R., Fauve, S. and Labbe, R.

"STUDY OF THE SOUND-VORTEX INTERACTION: DIRECT NUMERICAL SIMULATIONS AND EXPERIMENTAL RESULTS"

Eur. Physical J., Vol. B32, 2003, pp. 237-242

We present a study of sound propagation through a single vortex by direct numerical simulations (DNS) compared to experimental measurements. We analyze the amplitude and the phase shift of the sound wave when it interacts with the vortical flow and we display the focusing effects produced by the vortex. We show that the turbulent fluctuations have a little effect on the sound phase shift whereas they induce a strong defocusing effect on the sound amplitude.

"SCALE-MODEL STUDIES OF BLAST-DEFLECTION FENCES FOR HIGH THRUST ENGINES"

Journal of Aircraft, Vol. 9, No. 6, June 1972, pp. 445-446.

A 0.02 scale model was constructed to represent a twin-engine aircraft, the proposed fence geometries, and the adjacent service roads requiring traffic protection. Data were obtained to define the flowfield immediately upstream of the fence and downstream to the roads. In addition to a single, long primary fence, flow field data were obtained for double fences in which a smaller, auxiliary fence was located upstream of the primary fence to provide a sheltered area for ground service equipment. Results of the experimental investigation are presented.

Bertrand, X.

"PARAMETRIC EFFECTS ON SPOILER GEOMETRY ASSESSMENT WITH CHIMERA TECHNIQUE"

1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-199, September 2007, pp. 3153-3161.

This paper presents the use of CFD methods based on RANS equations and Chimera technique to simulate the flow on a transport aircraft with deployed spoilers to improve the physical understanding of these control surfaces. The first part of the paper explains spoiler aerodynamics and their interactions with the wings, HTP and VTP. Then, spoiler geometry is modified as a function of various parameters (position on wing span and chord, hinge line sweep, spoiler chord size) and the impact of these geometrical effects on handling qualities coefficients is detailed.

"DOPPLER LIDAR DEVELOPMENTS FOR AERONAUTICS"

ONERA Aerospace Lab Journal, Issue 12, December 2016, pp. 1-16.

Detecting atmospheric hazards such as wake vortices, turbulences, wind shear or wind gusts would improve flight and airport traffic safety. Moreover, to face the current and future challenges of air traffic growth in terms of environment, safety, and costs, one of the major challenges is to increase runway throughput by optimizing the distance separation between aircraft. These are some of the issues, among others, addressed by Doppler LIDARs. This powerful technique can provide remote air speed data and is being deployed on the ground or in flight. The paper presents some of the recent Doppler LIDAR developments at ONERA. Some insight into state-of-the-art technology is provided, as well as perspectives for future applications in aeronautics.

"PULSED 1.5-MICRON LIDAR FOR AXIAL AIRCRAFT WAKE VORTEX DETECTION"

15th Coherent Laser Radar Conf., Toulouse, France, June 2009.

We present the development of an axial aircraft wake vortex Lidar sensor working in Mie scattering regime and based on a pulsed 1.5-micron fiber laser. An end-to-end Doppler heterodyne Lidar simulator is used for the Lidar design. The simulation includes the observation geometry, the wake vortex velocity image, the scanning pattern, the Lidar instrument, the wind turbulence outside the vortex, and the signal processing. A Doppler heterodyne Lidar is developed with an innovative high brightness pulsed 1.5 micron laser source, based on a MOPFA architecture with a special large core fiber amplifier. The Lidar includes a real time display of the wind field. Wind dispersion is post-processed. Field tests carried out at Orly airport in April 2008 are reported. Axial aircraft wake vortex signatures have been successfully observed and acquired at a range of 1.2 km with an axial resolution of 75 m for the first time with a fiber laser source.

"RESUSPENSION ONSET AND CRATER EROSION BY A VORTEX RING INTERACTING WITH A PARTICLE LAYER"

Physics of Fluids, Vol. 24, 2012, pp. 063301-1 - 063301-31.

This paper presents results from an experimental investigation of the interaction of a vortex ring with a particle layer. The flow dynamics during the onset of particle resuspension are analyzed using particle image velocimetry, while a light attenuation method provides accurate measurements of the final

eroded crater shape. This work is a continuation of the research described by Munro, Bethke and Dalziel, 'Sediment resuspension and erosion by vortex rings' which focused on the general resuspension onset dynamics and initial crater formation. Here, we analyze the velocity induced by the vortex ring on the particle layer surface during the resuspension of particles for different particle sizes, and the shape and size of the final craters that are formed by the impact of the vortex ring. We find that the boundary condition is characterized by a quasi-slip velocity at the particle layer surface, independent of the particle size. The particle diameter, and thus bed permeability, is found to have a significant effect on the final crater characteristics.

Betyaev, S. K.

"NONLINEAR THEORIES OF THE LAMINAR COLUMNAR VORTEX"

In: Investigation of Vortex Wake Evolution and Flight Safety - Collection of Papers, Trudy TsAGI, Vol. 2622, Publishing Dept. of TsAGI, Moscow, Russia, 1996, pp. 100-108

Exact and approximate solutions are proposed to the problem of the temporal and spatial evolution of the columnar vortex based on the Euler and Navier-Stokes equations. Unlike the linear theory of the thin columnar vortex, the nonlinear theory proposed has the main terms of the expansion (in terms of a small parameter characterizing the vortex width) that already take into consideration longitudinal gradients. It has been shown that the bilinear Euler equation allows both exponential and sinusoidal expansion of variables. Separation of variables in the Navier-Stokes equation is possible for the flow with constant velocity gradient. In this case a singularity of the solution was revealed along with its non-continuability into the domain adjacent to the vortex axis. [In Russian.

"MATHEMATICAL MODELING IN TRAILING VORTEX DYNAMICS"

In: Investigation of Vortex Wake Evolution and Flight Safety - Collection of Papers, Trudy TsAGI, Vol. 2622, Publishing Dept. of TsAGI, Moscow, Russia, 1996, pp. 22-40

The paper is intended to be a fast introduction to trailing-vortex dynamics. Problems associated and hierarchy levels of their description are categorized, the principles of constructing mathematical models and physical prerequisites underlying the theory are discussed. Preference is given to correlating dissimilar phenomena and establishing new relations between seemingly remote and isolated facts with primarily emphasizing the methodology rather than the 'formulism'. [In Russian.

Betyaev, S. K.

"MATHEMATICAL MODELS OF THE FAR VORTEX WAKE"

In: Flight Safety, Aircraft Vortex and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 125-147

The asymptotical analysis has enabled us to develop a model for the transverse structure of an axisymmetric columnar vortex in an incompressible fluid including the wall sublayer with dominating viscous and turbulent stresses, buffer zone with dominating turbulent stresses, buffer zone with dominating turbulent stresses and inertia, and the region of velocity and circulation defects, where the inertial terms prevail. For each of these regions, equations are obtained for averaged quantities, which remain nonclosed since the type of Reynolds stresses is unknown. Thicknesses of these regions depend on characteristic values of velocity fluctuations. A turbulence model in the Trefftz plane has been considered, where the nonlinearity is degenerated into a recurrently solvable one. A method of averaging over the circumferential coordinate was developed to solve a problem on asymmetric vortex evolution. Flow topology was investigated in the problem of diffraction of a thin vortical flow by a plate and its solution was obtained in an extremely simplified approximation.

Betyaev, S. K.

"ON THE EFFECT OF LAMINAR BOUNDARY LAYER SUCTION ON THE WING VORTEX SYSTEM"

In: Investigation of Vortex Wake Evolution and Flight Safety Problems - Collection of Papers, Trudy TsAGI, Vol. 2627, Publishing Dept. of TsAGI, Moscow, Russia, 1997, pp. 68-78

The classification of the mathematical models of suction is given, its concepts and influence on the aircraft wake are discussed. The conditions of appearing a secondary flow separation are considered and the optimum suction speed distribution required for preventing the separation is determined. The suction of inviscid fluid is shown to be capable of eliminating the original cause of the secondary separation - the pressure gradient singularity, and the suction speed distribution optimum for this purpose is determined.

Betyaev, S. K.

"HOW TO CUT A VORTEX FILAMENT?"

Fluid Dynamics, Vol. 36, No. 2, 2001, pp. 262-26.

The conditions of linear theory applicability, as well as the conditions under which the contact discontinuity effect can be neglected, are derived. The topology of the trajectories in the problem of thin vortex-jet diffraction on a plate is studied and the analytical solution of a maximally simplified version of the problem is obtained. An asymptotically rigorous model of an equivalent vortex in the form of a narrow high-velocity jet is proposed.

Betyaev, S. K.

"MATHEMATICAL MODELING OF THE COLUMNAR VORTEX"

Theoretical Foundations of Chemical Engineering, Vol. 34, No. 5, 2000, pp. 423-427

The columnar laminar vortex has a two-zone structure in the case of a highly swirling flow. Various asymptotics for the laminar, wave, and turbulent flows in the Trefftz plane are discussed.

Betz, A.

"VORTICES AND THE RELATED PRINCIPLES OF HYDRODYNAMICS"

NACA TN-68, November 1921, NACA Langley Aero. Lab., Langley Field, VA. (Also, Zeitschrift fur Flugtechnik und Motorluftschiffahrt, July 15, 1921.)

Here, conceptions concerning vortices are illustrated by the simplest possible examples. Mathematical formulas and similar means of presentation, which, for the most part, do not help the understanding of persons not versed therein, have been avoided as much as possible. Instead, the author has endeavored to demonstrate the phenomena by means of simple geometrical and mechanical illustrations. For the sake of clarity, the author chiefly considers currents in one plane only, a situation that can be readily represented by diagrams. Some of the peculiarities of vortices in three-dimensional flow are briefly discussed.

Betz, A.

"BEHAVIOR OF VORTEX SYSTEMS"

Zeit. fur angewandte Math. und Mech., Vol. 12, No. 3, June 1932, pp. 164-174. (Also, NACA TM-713, June 1933.)

Progressive application of the Kutta-Joukowski theorem to the relationship between airfoil lift and circulation affords a number of formulas concerning the conduct of vortex systems. The application of this line of reasoning to several problems of airfoil theory yields an insight into many hitherto little observed relations. The report is confined to plane flow, hence all vortex filaments are straight and mutually parallel.

Bevan, J. J. and Willis, D. J.

"A HIGH-ORDER CONSERVATIVE EULERIAN SIMULATION METHOD FOR VORTEX DOMINATED FLOWS"

AIAA Paper 2016-3349, June 2016, Washington, DC.

A high-order, conservative Eulerian method is presented for the simulation of vortex dominated inviscid fluid flows. The primitive variable incompressible Euler equations are recast in the velocity-vorticity form to explicitly enforce conservation of vorticity. The advection of the vorticity is then calculated via a two-step process: the velocity field is determined by evaluation of the Biot-Savart integral, and then a line-based discontinuous Galerkin (DG) Eulerian spatial discretization scheme is applied to accurately advect the vorticity field. The accuracy and convergence of this method was examined for test cases where an analytical solution exists, as well as more challenging test cases which lack an analytical solution. The convergence rate behavior is chiefly controlled by the error in the

calculated velocity field. Velocity errors are due to two factors: the approximation of the Biot-Savart integral with a desingularized form, and reduced quadrature convergence for the nearly singular integral. Solver parameters were chosen to balance these two effects resulting in nearly optimal convergence of the overall method in the analytical test, and high-order convergence in the qualitative test case.

Beves, C. C. and Barber, T. J.

"THE WINGTIP VORTEX OF A DIMPLED WING WITH AN ENDPLATE"

Journal of Fluids Engineering, Vol. 139, February 2017, pp. 021202-1 - 021202-9.

Dimples used as sub-boundary layer vortex generators have been shown to reduce wake size at large angles of incidence. The effect these dimples have on wingtip vortices with an endplate is measured via laser Doppler anemometry (LDA) on an inverted Tyrrel11026 airfoil ($Re = 5000$ and chord = 0.075 m) in ground effect to determine the flow characteristics for this configuration and to see if previous measurements were performed in a thinner part of the wake due to any potential wake waviness. The strength of the wingtip vortex for the dimpled wing is 10 percent higher than the 'clean' wing immediately downstream. The clean wing has large region of high turbulence throughout the wake, and the dimples reduce this by 50 percent. The net result is that dimples drastically improve the flow in the wake of the wing and endplate.

"INVESTIGATIONS INTO THE WAKE VORTEX EVOLUTION DOWNSTREAM THE A300 AIRCRAFT MODEL"

In: Flight Safety, Aircraft Vortex Wake and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 84-94

Experimental flow field data processing was made to obtain the vortex wake characteristics, such as vortex core radius, vortex core circulation and vortex position. Two programs (ZONWAKE and ENGWAKE) for wake parameters calculation were validated through this experimental data processing.

Bezrodnov, A. V., Koshcheyev, A. V., Markachev, Y. Y., Plekhanov, Y. A. and Yegorov, B. V.

"DIAGNOSTICS OF EXHAUST JETS AND AIRCRAFT VORTICES WITHIN THE MILLIMETER- AND SUBMILLIMETER-WAVE BANDS"

In: Flight Safety, Aircraft Vortex Wake and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 346-365

The updated theoretical expression for an absorption coefficient of radiation by dimers considering the modern data on their structure and experimental results has allowed one to conclude, that in the window of transparency of the atmosphere in the range of reciprocal wavelength of 7 to 8 reciprocal

cm in the vortex wake behind an airplane the controlling factor is the dimer mechanism of an absorption of millimetric and submillimetric radio waves.

Bezrodnov, A. V., Markachev, Y. Y. and Yegorov, B. V.

"FORMATION OF WATER VAPOR MOLECULAR CLUSTERS IN AIRCRAFT VORTEX WAKE"

In: Flight Safety, Aircraft Vortex Wake and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 340-345

The paper deals with the formation of water vapor molecular clusters in the aircraft wakes. Distributions of temperature and molar fraction of water dimers over a wake section are determined for two fluid-mechanical models: the Lamb-Rankine vortex and three-zone vortex model (Gaifullin et al. 1996). The dependence of water dimer molar fraction on flow humidity and temperature is obtained. Distribution of maximum water dimer molar fraction along the wake center line is determined for various atmospheric conditions. Studied separately is the dependence of clusters concentration on humidity, which may be employed to account for the condensation effect in the wake.

Bhagwat, M. and Leishman, J. G.

"TIME-ACCURATE FREE-VORTEX WAKE MODEL FOR DYNAMIC ROTOR RESPONSE"

Aeromechanics 2000, American Helicopter Society, November 2000, Atlanta, GA.

A time-accurate free-vortex method was developed to accurately predict the time evolution of rotor inflow during various transient, maneuvering flight conditions. Because of the highly non-linear nature of the problem, free-vortex wake solutions are often susceptible to numerical instabilities. Therefore, the new algorithm was examined for stability, accuracy and convergence. The rotor wake in near hovering wake is known to be inherently unstable and, therefore, the stability of the numerical algorithm is the most important criteria to ensure convergence. Solution convergence of the algorithm was demonstrated in steady-state conditions, with a verified second-order accuracy for both hovering and forward flight. This algorithm was then applied to help understand the rotor response during a step or a ramp increase in collective pitch. A slow build-up of inflow (a time lag) was found from the dynamic evolution of the trailed wake structure. The methodology was also successfully applied to transient axial and inclined descending flight through the highly unsteady vortex ring state.

Bhagwat, M. and Leishman, J. G.

"ON THE AERODYNAMIC STABILITY OF HELICOPTER ROTOR WAKES"

56th Annual Forum, American Helicopter Society, Virginia Beach, VA, May 2000

An eigenvalue analysis has been developed to study the stability of helicopter rotor wakes in hover and axial flight. The results are supported with observed trends from hovering rotor wake experiments. The rotor wake is shown to be intrinsically unstable, with the tip vortices exhibiting several possible

unstable deformation modes. The wake divergence (instability) rate associated with each deformation mode depends on the relative phase of the perturbations produced on tip vortex filaments generated by different blades. Wake divergence rates increase sharply after the initial radial contraction of the wake below the rotor, and is confirmed by experimental observations. The divergence rates are governed by the vortex-induced velocities; the divergence rate for any deformation mode decreases with increasing rotor thrust, and with increasing climb rate. The so-called tip vortex 'pairing' phenomenon, sometimes empirically observed in hovering flight conditions, is shown to be a particular unstable long-wave deformation mode of the rotor wake. It is further shown that in numerical solutions of the wake using free-vortex wake methods this deformation mode can be artificially excited by numerical errors. A proper choice of numerical time integration algorithm is necessary to prevent non-physical growth of these numerical errors.

Bhagwat, M. J. and Leishman, J. G.

"CORRELATION OF HELICOPTER ROTOR TIP VORTEX MEASUREMENTS"

AIAA Journal, Vol. 38, No. 2, February 2000, pp. 301-308.

The roll-up and development of the tip vortices generated by subscale helicopter rotors were measured and analyzed. The measurements were performed on one- and two-bladed hovering rotors using three-component laser Doppler velocimetry. A trip strip was used to simulate boundary-layer transition at the higher Reynolds numbers typical of the full-scale rotor. The detailed velocity field of the tip vortex was investigated, a strong self-similarity of the swirl velocity profile being found. The measurements suggest a general logarithmic growth of the viscous core, which for older vortex ages is proportional to the square root of time (vortex age). Measurements from other helicopter rotor and fixed-wing experiments are used to support the observations.

Bhagwat, M. J. and Leishman, J. G.

"MEASUREMENTS OF BOUND AND WAKE CIRCULATION ON A HELICOPTER ROTOR"

Journal of Aircraft, Vol. 37, No. 2, March-April 2000, pp. 227-234

High-resolution measurements of the three-dimensional velocity field around the blade and in the wake of a small-scale hovering rotor were made using three-component laser Doppler velocimetry. The tip-vortex circulation strength was determined from velocity field measurements in the rotor wake. The spanwise circulation distribution was estimated from the velocity field measurements around each spanwise blade section. It is shown that for helicopter rotors it is difficult to exclude the effects of the returning wake vorticity from contours that enclose the blade section, making unique, grid-independent, bound circulation measurements possible only under very specific conditions. The connection between blade circulation loading and the tip-vortex circulation was also examined. For the configurations studied the initial circulation strength of the tip vortices was found to be approximately 70% of the estimated peak circulation on the blades.

"NUMERICALLY EFFICIENT FREE VORTEX WAKE SOLUTIONS USING HIGHER-ORDER EXTRAPOLATION"

J. American Helicopter Society, Vol. 47, No. 4, October 2002, pp. 297-302

The increasing predictive success of free vortex wake models for rotor analyses has sparked an interest in improving their computational efficiency and decreasing computing costs to facilitate more routine applications. In this article, techniques to improve the numerical efficiency of discrete free vortex wake models are discussed. The impact of reduced computational costs on the accuracy and convergence characteristics of the wake solution is examined. The numerical efficiency is estimated based on reducing numerical errors corresponding to the associated computational costs. A new technique, based on Richardson's extrapolation, is shown to reduce the computational costs by improving the order of accuracy of the solution. This technique can be applied to obtain a more accurate prediction of the wake induced velocities, as well as to obtain a higher-order wake geometry solution. The higher order solution is shown to be numerically more efficient, with an improved ratio of numerical errors to computational cost.

"SELF-INDUCED VELOCITY OF A VORTEX RING USING STRAIGHT-LINE SEGMENTATION"

Journal of the American Helicopter Society, Vol. 59, 2014, pp. 012004-1 to 012004-7.

The accuracy of discretized induced velocity calculations that can be obtained using straight-line vortex elements has been reexamined, primarily using the velocity field induced by a vortex ring as a reference. The induced velocity of a potential (inviscid) vortex ring is singular at the vortex ring itself. Analytical results were found by using a small azimuthal cutoff in the Biot-Savart integral over the vortex ring and showed that the singularity is logarithmic in the cutoff. Discrete numerical calculation showed the same behavior, with the self-induced velocity exhibiting a logarithmic singularity with respect to the discretization, which introduces an inherent cutoff in the Biot-Savart integral. Core regularization or desingularization can also eliminate the singularity by using an assumed 'viscous' core model. Analytical approximations to the self-induced velocity of a thin-cored vortex ring have shown that the self-induced velocity has a logarithmic singularity in the core radius. It is further shown that the numerical calculations require special treatment of the self-induced velocity caused by the curvature, which is lost by the inherent cutoff in the straight-line discretization, to correctly recover this logarithmic singularity in the core radius. Numerical solution using straight-line vortex segmentation, augmented with curved vortex elements only for the self-induced velocity calculation, is shown to be second-order accurate in the discretization.

"GENERALIZED VISCOUS VORTEX MODEL FOR APPLICATION TO FREE-VORTEX WAKE AND AEROACOUSTIC CALCULATIONS"

The development of a generalized viscous vortex model is described for application in rotor aero-acoustic analyses. A summary is given of previous models for the viscous core growth and induced velocity field of a trailing tip vortex. The assumptions made for the vortex core growth are shown to influence the predictions of the rotor wake geometry, as well as the induced velocities, air loads, and performance, thereby emphasizing the need for a more universal and physically representative vortex model. In the present approach, the viscous core growth was modeled using an extension of the classic Lamb-Oseen model for the diffusion of laminar vortices. Turbulence in the tip vortex affects the diffusion of vorticity, and these effects were incorporated using an empirically validated correction for the average apparent or 'eddy' viscosity. The vortex induced velocity profiles measured in experiments were found to exhibit strong self-similarity when using the vortex core radius as a length-scale, suggesting that a generalized model is possible. A family of algebraic models for the swirl, axial, and radial components of the velocity induced by a viscous trailing tip vortex is proposed. These velocity components were found from a solution to a simplified form of the incompressible Navier-Stokes equations. The velocity profiles are written in terms of a single integer exponent with the viscous core growth being given by a semi-empirical relation for the turbulent viscosity that scales as a function of the vortex Reynolds number. The model is compared with velocity field measurements for both fixed-wing and rotating-wing tip vortices, with good agreement.

"EFFECT OF TIP VORTEX APERIODICITY ON MEASUREMENT UNCERTAINTY"

Experimental Fluids, Vol. 53, 2012, pp. 1191-1202.

Vortex aperiodicity introduces random uncertainty in the measured vortex center location. Unless corrected, this may lead to systematic uncertainty in the vortex properties derived from the measured velocity field. For example, the vortex core size derived from averaged or mean flow field appears larger because of aperiodicity. Several methodologies for aperiodicity correction have been developed over the past two decades to alleviate this systematic uncertainty. However, these do not always reduce the accompanying random uncertainty. The current work shows that the analysis methods used to derive the vortex properties from the measured velocity field play an important role in the resultant random uncertainty in these properties; perhaps, even more important role than the aperiodicity correction methodology itself. It is hypothesized that a class of methods called global methods, which use a large extent of measured data, yield a smaller measurement uncertainty compared to local methods. This hypothesis is verified using a newly proposed global method based on a planar least-squares fit. The general applicability of the method is demonstrated using previous particle image velocimetry measurements of rotor tip vortices. The results clearly demonstrate a reduced random uncertainty in the vortex core properties, even in the presence of secondary vortical structures. Furthermore, the results are independent of the choice of aperiodicity correction methodology.

"TRANSIENT ROTOR INFLOW USING A TIME-ACCURATE FREE-VORTEX WAKE MODEL"

AIAA Paper No. 2001-0993, Reno, NV, January 2001

A time-marching free-vortex wake analysis was developed for application to the prediction of the aerodynamics of a helicopter rotor under transient or maneuvering flight conditions. The stability, accuracy and convergence of the time-marching algorithms was rigorously examined. A linearized analysis was used to determine the basic stability characteristics of the algorithms. A new time-marching algorithm is proposed to ensure numerical stability and convergence of the wake solution. The second-order accuracy and grid independent nature of the wake geometry solution is demonstrated. This algorithm is applied to the problem of transient rotor response resulting from time-varying changes in the rotor collective pitch inputs. Good agreement is shown between the predictions and experimental measurements.

"FUNDAMENTAL CHARACTERIZATION OF SPANWISE LOADING AND TRAILED WAKE VORTICES"

SR-RDMR-AD-16-02, July 2016, US Army Research, Development, and Engineering Command, Redstone Arsenal, AL.

This report focuses on one of the most prominent flow features of the hovering rotor wake, the close interaction of the tip vortex with a following blade. Such vortex interactions are fundamental determinants of rotor performance, loads, and noise. Yet, they are not completely understood, largely due to the lack of sufficiently comprehensive experimental data. The present study aims to perform such comprehensive measurements, not on hovering helicopter rotors (which hugely magnifies test complexity) but using fixed-wing models in controlled wind tunnel tests. The experiments were designed to measure, in considerable detail, the aerodynamic loading resulting from a vortex interacting with a semi-span wing, as well as the wake resulting from that interaction. The goal of the present study is to answer fundamental questions such as (a) the influence of a vortex passing below a wing on the lift, drag, tip vortex and the wake of that wing, and (b) the strength of the forming tip vortex and its relation to the wing loading and/or the tip loading.

"AIRCRAFT VORTEX CHARACTERIZATION BY ESTIMATING THE DOMINANT MODES FROM THE RETURN POWER SPECTRUM OF A DOPPLER LIDAR"

AIAA Paper 2017-4240, June 2017, Denver, CO.

A new exploratory approach for aircraft vortex tracking is presented in this paper. The 'Dominant Modes Estimation' technique is a promising motivation to improve the accuracy with which we locate the vortex core position. Using the lidar simulator in tandem with the analytical vortex model defined in section II, we can simulate the Doppler spectrum estimate for different lidar system parameter settings, like the lidar signal to noise ratio and also vortex characteristics like the core radius and

circulation strength, depending on the aircraft type. The algorithm is a step towards accurate vortex parameter estimation. When compared with other techniques like the method of velocity envelope the new approach estimates the spectral width by choosing an appropriate model instead of the traditional unimodal Gaussian spectrum. The choice of a bi-model Gaussian spectra was justified based on the spectrum estimate simulated using the Doppler lidar simulator. The new model is a first step towards more efficient and accurate estimation of vortex parameters. A more detailed analysis on real data collected using a Doppler lidar is necessary to compare its performance with other existing methods.

Bhattacharya, S.

"EXACT ANALYTICAL SOLUTIONS FOR STEADY THREE-DIMENSIONAL INVISCID VORTICAL FLOWS"

Journal of Fluid Mechanics, Vol. 544, 2007, pp. 147-162.

Vortical flows with an axial swirl and a toroidal circulation can be observed in a wide range of fluid mechanical phenomena such as flow around rotary machines or natural vortices like tornadoes and hurricanes. In this paper, we obtain exact analytical solutions for a general class of steady systems with such three-dimensional circulating structures. Assuming incompressible ideal fluid, a general single-variable equation, known as the Squire-Long equation, can be constructed which can uniquely describe the velocity fields with steady axial and toroidal circulations. In this paper, we consider the case where this type of flow can be analyzed by solving a linear homogeneous partial differential equation. The derived equation resembles the governing equation of the hydrogen problem. As a result, we obtain a quantization relation which is similar to the expression for the quantized energy states in a hydrogen atom. For circulating flows, this formalism provides a complete set of orthogonal basis functions which are regular and localized. Hence, each of the basis solutions can be used as a simplified model for a realistic phenomenon. Moreover, an arbitrary circulating field can be expanded in terms of these orthogonal functions. Such an expansion can be potentially useful in the study of more general vortices.

Bhattacharyya, S. and Conlisk, A. T.

"THE STRUCTURE OF THE ROTOR WAKE IN GROUND EFFECT"

AIAA Paper No. 2003-1255, Reno, NV, January 2003

The form of the rotor wake in presence of a ground has been investigated through a simplified approach. Both hover and forward speed of the rotor have been considered. The presence of the ground is modeled using the method of images. A lifting-line theory is used to model each rotor blade and a time-stepping vortex method has been used to obtain the evolution of tip-vortex. The agreement of our computed results with the experimental data due to Light in hover with IGE is encouraging. The wake geometry for both single and two bladed rotors has been calculated for different ground to rotor separation distance and for several forward flight speeds. The form of the ground vortex in proximity of ground in the low speed forward flight of the rotor has been studied. Our

results show that the size of the ground vortex reduces and the vortex core shifts downstream as the forward speed of the rotor increases.

"ASSESSMENT OF THE VORTICITY CONFINEMENT TECHNIQUE APPLIED TO ROTORCRAFT FLOWS"

AIAA Paper No. 2003-3524, Orlando, FL, June 2003

The application of the vorticity confinement technique to single-blade rotorcraft simulations, both in hovering and forward flight conditions, allows to improve the representation of certain features of the flow field but has a very limited influence on the predicted thrust. Comparison with experimental sectional blade loads shows localized improvements, mainly in the central region of the retreating blade.

Biblarz, O.

"THINGS YOUR BAB (BASIC AERODYNAMICS BOOK) NEVER TOLD YOU"

AIAA Paper 1994-0849, January 1994, Reno, NV.

Standard coverage in basic aerodynamic books tends to be deficient in detail. The author picks 4 topics where missing detail can be counter-productive. Dimensional analysis as used to derive the force coefficient must begin with a three-dimensional wing; this has the added advantage of bringing out the aspect ratio (AR) directly. Inviscid flow equations can be used to calculate lift but lift originates from the circulation which is produced by viscous interactions. At angles of attack above 15 degrees, this airfoil theory requires modifications which still yield the very useful, closed form solutions of this theory as indicated in the paper. Finally, the aerodynamic center is shown to be at the quarter-chord location via a direct manipulation of thin-airfoil theory results.

Biehl, K. J., Teager, S. A. and Tymczyszyn, J. J.

"FLIGHT TEST INVESTIGATION OF THE WAKE VORTICES GENERATED BY HELICOPTERS"

Cockpit, October-December 1991, pp. 5-22

Helicopter wake vortices were probed by small airplanes to acquire direct assessment of vortex danger as a function of distance behind the generating helicopter. The flight tests were planned to provide data for establishing ATC separation criteria and for comparison with theoretical calculations. Ground based tests indicate a very high vortex hazard from helicopters and therefore imply very large separation distances for safe IFR flight behind rotorcraft. These tests are deemed valid and useful as they represent an accurate duplication and analysis of real-world wake vortex hazards of helicopters in forward flight.

"SUMMARY OF FLIGHT TESTING AND RESULTS FOR THE FORMATION FLIGHT FOR AERODYNAMIC BENEFIT PROGRAM"

AIAA Paper 2014-1457, January 2014, National Harbor, MD.

The Air Force Research Lab and DARPA have been investigating the challenges and opportunities associated with flying aircraft in formation for aerodynamic benefit. Under the Surfing Aircraft Vortices for Energy (SAVE) concept, aircraft are flown autonomously at longitudinal separations of 3000-8000 ft at offsets from the wake sufficient to obtain significant aerodynamic benefit. Flight test of the enhanced auto-pilot to accomplish this was demonstrated in Oct. 2012, obtaining a savings of 5-10 percent fuel burn and capturing data on the effects on the airframe, engines, and aircrew for a representative transport aircraft, the C-17. Additional flight tests more representative of complete missions were performed in July 2013. For extended durations greater than 90 minutes, fuel burn savings exceeded 10 percent and were accomplished fully automated. This paper will provide an overview of the flight test efforts and summarize key results.

"SENSITIVITY ANALYSIS OF AIRCRAFT ENCOUNTERS WITH DEFORMED WAKE VORTICES"

AIAA Paper 2015-3175, June 2015, Dallas, TX.

Aging wake vortices deform due to the characteristic long-wave Crow instability. This can lead to vortex linking, breakup and the formation of vortex rings. It is generally believed that encounters of following aircraft with deformed vortices are less severe than encounters with straight vortices. However, it is not clear if this effect results directly from vortex deformation, the simultaneous reduction of vortex circulation or both. This study analyzes the sensitivity of such encounters with respect to i) the encounter scenario, ii) the level of deformation, iii) the encounter angles and iv) the location of the aircraft-vortex intersection point. The encounter severity is assessed in terms of the maximum bank angle upsets induced by the vortex flow field. Vortex shapes are based on Large-Eddy Simulations of wake vortex decay under atmospheric conditions that promote the formation of vortex rings. The reduction of encounter severity before vortex breakup is found to be less pronounced than what was concluded from previous studies. Most importantly, the location of the aircraft-vortex intersection has a strong impact on the aircraft upsets and must be accounted for in future investigations, especially when risk assessments are based on dynamic encounter simulations. When only encounters with a targeted penetration of the vortex core are analyzed, wavy vortices may even yield an increased severity prior to vortex breakup, which contradicts the assumption of continuous severity reduction with growing deformation level. After vortex breakup, aircraft upsets for most encounter parameter combinations are significantly lower than those generated by a straight vortex pair of equal strength.

"SIMULATION OF AIRCRAFT ENCOUNTERS WITH PERTURBED VORTICES CONSIDERING UNSTEADY AERODYNAMIC EFFECTS"

AIAA Paper No. 2012-4657, August 2012, Minneapolis, Minnesota.

Today, wake turbulence related aircraft separations are a limiting factor for the capacity of airports worldwide. Detailed knowledge about the severity of potential wake encounters is necessary for a safe revision of the current ICAO separation requirements. Vortex encounter simulation is an important part in building an understanding how the encountering aircraft is adversely affected by the vortex-induced disturbances. Whereas most research has focused on aircraft encounters with a pair of straight vortices, this paper describes the simulation of encounters with perturbed vortices as they are observed under various atmospheric conditions. A method to account for unsteady aerodynamic effects during computation of vortex-induced forces and moments is presented. These effects are becoming especially important for vortex-induced disturbances of higher frequency as they appear during encounters with perturbed vortices. In combination with existing models for vortex deformation due to long-wave Crow instability, the realism of encounter simulations is increased. The simulation models are suitable for real-time and fast-time applications such as piloted simulator experiments and fast-time Monte Carlo simulations. First results of a simulator study with airline pilots are discussed.

Bieniek, D. and Luckner, R.

"INVESTIGATION OF ENCOUNTERS WITH DEFORMED WAKE VORTICES USING A MONTE-CARLO SIMULATION METHODOLOGY"

AIAA Paper 2014-2334, June 2014, Atlanta, GA.

Flight simulation is an important tool for investigating the impact of a wake-vortex flow field on aircraft response and on the severity of wake vortex encounters as it allows to evaluate a large variety of encounter parameters under controlled conditions without risk, at low costs and time-efficient. Most simulation studies have used a pair of counter-rotating straight vortices to represent the vortex wakes. However, as part of the decay process, the vortices develop a periodic long-wave deformation due to Crow instability that may lead to a breakup into vortex rings. The paper describes a methodology to perform Monte-Carlo simulations of aircraft encounters with such perturbed vortices. A high-fidelity six degree-of-freedom aircraft simulation is coupled with a wake encounter simulation that includes models of wavy vortices and vortex rings, that are fitted to wake shapes from pre-computed large-eddy simulations. Application of the methodology is demonstrated by assessing aircraft bank angle upsets from encounters with straight and deformed vortices for different test setups. First results indicate that the impact of wake deformation is strongly affected by the simulated encounter scenario. For a full-scale Monte-Carlo simulation with uniform parameter distributions and assuming the same and constant vortex strength, vortex rings exhibit a lower probability of experiencing bank angle upsets above a specific threshold, whereas only small differences between straight and wavy vortices are observed.

Bieniek, D. and Luckner, R.

"SIMULATION OF AIRCRAFT ENCOUNTERS WITH PERTURBED VORTICES CONSIDERING UNSTEADY AERODYNAMIC EFFECTS"

Journal of Aircraft, Vol. 51, No. 3, May-June 2014, pp. 705-718.

Today, wake-turbulence-related aircraft separations are a limiting factor for the capacity of airports worldwide. A detailed knowledge about the severity of potential wake encounters is necessary for a safe revision of the current International Civil Aviation Organization separation requirements. Vortex encounter simulation is an important part in building an understanding how the encountering aircraft is adversely affected by the vortex-induced disturbances. Whereas most research has focused on aircraft encounters with a pair of straight vortices, this work focuses on the simulation of encounters with perturbed vortices as they are observed under various atmospheric conditions. In addition, a method to account for unsteady aerodynamic effects during the computation of vortex-induced forces and moments is presented. These effects are becoming especially important for vortex-induced disturbances of a higher-frequency range as they may appear during encounters with perturbed vortices. This combination of models for vortex deformation due to long-wave Crow instability and unsteady aerodynamic models increases the realism of encounter simulations. The simulation models are suited for real-time and fast-time applications, such as piloted-flight-simulator experiments and fast-time Monte Carlo simulations. The results of a simulator study with airline pilots are discussed concerning the differences between encounters with straight and perturbed vortices.

"PARAMETRIC STUDY AND SIMPLIFIED APPROACH TO WAKE VORTEX ENCOUNTER OFFLINE SIMULATION"

1st CEAS European Air and Space Conference, Berlin, Germany, September 2007, pp. 3403-3412

This paper describes the application of an existing Wake Vortex Encounter (WVE) Model in a parameter sensitivity study and in a simplified simulation. Within this model an encounter scenario is defined by a list of different parameters. The effects of a variation of these parameters on the reaction of various encountering aircraft types are being investigated and results are presented and discussed. Furthermore, a simplified approach to an offline WVE simulation is presented. Since the primary effect of a near parallel WVE is a bank angle disturbance, only roll motion is taken into consideration. The possibility of combining results from the parametric study with the simplified offline-simulation model to investigate worst case encounter scenarios is discussed.

"SIMULATION METHODS FOR AIRCRAFT ENCOUNTERS WITH DEFORMED WAKE VORTICES"

Journal of Aircraft, Vol. 53, No. 6, November-December 2016, pp. 1581-1596.

Simulation of aircraft wake-vortex encounters is regularly applied in the research toward revised aircraft separation minima. Most encounter flight simulation studies have used a pair of straight counter-rotating vortices. However, after being shed by the generating aircraft, the wake vortices begin to develop a growing deformation due to the long-wave Crow instability, especially under low-turbulent atmospheric conditions when vortices decay slowly. In this study, two methods for simulation of aircraft encounters with such perturbed wake vortices are described and compared. The first method uses a vortex simulation model, which is based on analytical models of the deformation that consider the large-scale vortex shapes. The second method applies vortex-velocity fields from high-fidelity large-eddy simulations. It offers the highest possible level of realism and is used as the reference. The resulting aircraft responses induced by wavy vortices and vortex rings are reproduced with good quality by the vortex simulation model. The comparison of both methods shows that the vortex simulation model captures the overall impact of vortex deformation on the aircraft upsets. It can be used for future safety assessments that require a large number of encounter simulations.

Bierach, K. F.

"WAKE VORTEX SENSING, PROCESSING AND DISPLAY"

Proceedings of 19th International Aerospace Instrumentation Symposium, Instrument Society of America, Vol. 19, 1973, pp. 153-16.

The FAA has embarked on a program to develop a wake vortex avoidance system to permit airport operations to function at optimum capacity commensurate with safety requirements. Computer modeling has identified a system concept based upon vortex prediction and detection in a closed-loop configuration. In concept, the vortex position, in defined arrival and departure corridors, is predicted from existing and projected meteorological conditions. The vortex movement is sensed within specified vertical scan planes to update this prediction. Aircraft arrivals or departures are then scheduled according to the prevailing vortex predictions and knowledge of the aircraft involved. The paper describes the system concept and potential techniques that are available to satisfy the sensor, data processing, and display subsystems requirements.

"LASER VELOCIMETER MEASUREMENTS OF THE HELICOPTER ROTOR-INDUCED FLOW FIELD"

J. American Helicopter Society, Vol. 20, No. 1, January 1975, pp. 2-10

The use of a two-color laser velocimeter to measure the flow velocities in the wake of a helicopter rotor is discussed, including methods for obtaining two components of both instantaneous and time-averaged velocities. Results are presented from an experiment using a 2.13 m (7 ft) diameter model helicopter rotor operating at a tip speed ratio 0.18 in a wind tunnel. The location of the tip vortex from the preceding blade was determined on the advancing side, and the diameter of the vortex core was found to be 15 percent of the blade chord (1.5% of the radius). The effects of the airfoil's bound

vorticity were observed in the velocity distributions very near the blade. The structure and boundary of the time-averaged wake were investigated.

Biggers, H. C., Chu, S., and Orloff, K. L.

"LASER VELOCIMETER MEASUREMENTS OF ROTOR BLADE LOADS AND TIP VORTEX ROLLUP"

31st Annual National V/STOL Forum, American Helicopter Society, Washington, DC, May 1975.

A method for obtaining and analyzing the instantaneous velocities of helicopter rotor flow fields through use of a laser velocimeter capable of simultaneously sensing two components of velocity is described. Rotor blade aerodynamic loads may be computed from the velocity distributions near the blades. The experiment was conducted with a 2.13 m (7 ft) diameter model helicopter rotor operating in a wind tunnel. Velocity distributions are presented which document the flow field near the advancing blade, circulation is calculated from the velocity measurements, and the radial distribution of circulation is discussed. The influence of the tip vortex from the preceding blade is apparent in this distribution. Tip vortex rollup on the advancing blade was documented by making a series of measurements at various distances behind the blade. Effects of blade drag are evident in the velocities behind the blade trailing edge. Methods are also discussed for determining blade section drag from these velocity measurements.

Bilanin, A. J.

"WAKE MECHANICS OF LINE VORTICES"

Ph.D. Thesis, June 1973, Mass. Institute of Technology, Cambridge, MA

Wave propagation on a vortex with a uniform axial vorticity core and a top-hat axial velocity distribution is studied and the results are a dispersion relation from which group velocities of the various modes can be calculated. A new definition of sub- and supercritical vortices based on group velocity is developed. This definition eliminates the difficulties encountered by others in determining sub- and supercritical states for asymmetric waves. Wave propagation along a vortex with slight axial inhomogeneity is developed for axisymmetric waves to introduce kinematic wave theory to vortices. Critical conditions exist along the slowly varying vortex which block the upstream propagation of waves.

Bilanin, A. J.

"COMPUTER TECHNOLOGY TO EVALUATE AIRCRAFT VORTEX WAKE INTENSITY"

SBIR-198, May 1985, Continuum Dynamics, Princeton, NJ

Existing analytical models of aircraft vortex wake dynamics have been assembled to predict the evolution and decay of two commercial jet liner wakes. The calculations undertaken demonstrate that aircraft configurational characteristics, such as engine placement and wing load distribution, can significantly influence the early stages of wake decay. This study concludes that it is currently possible

and practical to develop a computer design tool capable of assessing wake intensity for existing and future jet liners. This tool could be utilized by FAA regulators in an evaluation of separation standards for current and future aircraft, and allows airframe manufacturers to factor wake intensity into their aircraft design.

Bilanin, A. J. and Donaldson, C. duP.

"ESTIMATION OF VELOCITIES AND ROLL-UP IN AIRCRAFT VORTEX WAKES"

Journal of Aircraft, Vol. 12, No. 7, July 1975, pp. 578-585

A nonlinear model is developed which determines the swirling and axial velocities in an aircraft vortex wake, given wing lift and drag distributions. The model is shown to reduce to that given by Betz when the axial velocity is the freestream value. The nonlinear interaction of swirling and axial velocities may lead to velocity distributions which are different from those previously calculated. Qualitatively, drag reduces the axial velocity in the vortex and results in an enlarged vortex radius and, therefore, a reduction in swirl velocity. The inviscid model that predicts that significant changes in the structure of the vortex wake, brought about solely by modification of the drag distribution, may require prohibitively large drag penalties. Theoretical results compare favorably with measurements made by Orloff and Grant. A model is developed to estimate the time to roll up a two-dimensional vortex sheet. Results are presented for the cases of linear, parabolic, and elliptic wing loading.

"SYSTEM AND METHOD OF VORTEX WAKE CONTROL USING VORTEX LEVERAGING"

Patent 6,042,059, 28 March 2000, Continuum Dynamics, Inc., Princeton, N. J.

This invention relates to a system and method for reducing the primary vortex wake structure generated by a lifting body mounted on an object moving through a fluid. This is achieved by first altering the generated initial vortex wake to make it vulnerable to rapid breakup; and, second, producing disturbances to this wake with secondary vortices from auxiliary lifting surfaces called vortex leveraging tabs to instigate this breakup. This invention relates to various fields of uses to include vortices generated by any type of lifting body moving through a fluid to include aircraft and watercraft such as surface vessels and submarines.

Bilanin, A. J. and Teske, M. E.

"NUMERICAL STUDIES OF THE DEPOSITION OF MATERIAL RELEASED FROM FIXED AND ROTARY WING AIRCRAFT"

NASA CR-3780, March 1984, Continuum Dynamics, Princeton, NJ

The computer code AGDISP (Agricultural Dispersal) has been developed to predict the deposition of material released from fixed and rotary wing aircraft in a single-pass, computationally efficient manner.

The formulation of the code is novel in that the mean particle trajectory and the variance about the mean resulting from turbulent fluid fluctuations are simultaneously predicted. The code presently includes the capability of assessing the influence of neutral atmospheric conditions, inviscid wake vortices, particle evaporation, plant canopy and terrain on the deposition pattern. In this report, the equations governing the motion of aerially released particles are developed, including a description of the evaporation model used. A series of case studies, using AGDISP, are included.

Bilanin, A. J. and Widnall, S. E.

"AIRCRAFT WAKE DISSIPATION BY SINUSOIDAL INSTABILITY AND VORTEX BREAKDOWN"

AIAA Paper No. 1973-0107, Washington, DC, 1973

Sinusoidal instability of aircraft trailing vortices was induced by differentially oscillating inboard and outboard flaps on a model wing in a ship towing tank. Measured amplification rates qualitatively agree with theoretical predictions. Axial velocities in the vortex core were directed toward the wing and measured to be approximately 25% of the tow speed. Vortex breakdown was observed to occur along trailers undergoing sinusoidal instability near but ahead (toward the wind) of positions of maximum trailer separation. It is shown that axisymmetric pressure gradients are imposed along the vortex core by the other sinusoidally deformed trailer and are responsible for the observed changes in core diameter. A theoretical model predicts the short-time behavior of the vortex core and shows that the response of the vortex depends crucially on the axial velocity in the vortex.

Bilanin, A. J., Donaldson, C. duP. and Snedeker, R. S.

"CALCULATION OF THE INVISCID WAKE OF A BOEING 747 AIRCRAFT"

ARAP Rept. No. 224, August 1974, Aeronautical Research Assoc. of Princeton, Princeton, NJ

A wake model based on an extension of the inviscid method of Betz used to calculate the rolled-up wake structure behind a Boeing 747 aircraft. Two aircraft flight configurations, at a lift coefficient of 1.2, are analyzed and it is shown that the inviscid wake is markedly different in structure. Comparisons between calculated and measured rolling moment on a penetrating wing show that the inviscid model provides useful estimates. When the generating aircraft is in other than the clean configuration, accurate predictions of the rolling moment will require a wake model which includes turbulent transport.

Bilanin, A. J., Donaldson, C. duP. and Snedeker, R. S.

"AN ANALYTIC AND EXPERIMENTAL INVESTIGATION OF THE WAKES BEHIND FLAPPED AND UNFLAPPED WINGS"

AFFDL-TR-74-90, September 1974, Aeronautical Research Assoc. of Princeton, Princeton, NJ

An analytic and experimental program was undertaken to define the near wake structure behind flapped and unflapped wings. The vortex wake structure is determined, given the wing lift and drag distributions with models developed in the spirit of Betz. A procedure to estimate the turbulent kinetic energy distribution in the vortex is also given, as well as a method to determine discrete vortex positions in the downstream wake.

Bilanin, A. J., Hirsh, J. E., Teske, M. E. and Hecht, A.

"ATMOSPHERIC-WAKE VORTEX INTERACTIONS"

ARAP-331, April 1978, Aeronautical Research Associates of Princeton, Princeton, NJ

The interactions of a vortex wake with a turbulent stratified atmosphere are investigated with the computer code WAKE. It is shown that atmospheric shear, turbulence, and stratification can provide the dominant mechanisms by which vortex wakes decay. Computations included the interaction of a vortex wake with a viscous ground plane. The observed phenomenon of vortex bounce is explained in terms of secondary vorticity produced on the ground. This vorticity is swept off the ground and advected about the vortex pair, thereby altering the classic hyperbolic trajectory. The phenomenon of the solitary vortex is explained as an interaction of a vortex with crosswind shear. Here, the vortex having the sign opposite that of the sign of the vorticity in the shear is dispersed by a convective instability. This instability results in the rapid production of turbulence which in turn disperses the smoke marking the vortex.

"INTERACTIONS AND MERGING OF LINE VORTICES"

ARAP-276, February 1976, Aeronautical Research Assoc. of Princeton, Princeton, NJ

The results of a theoretical and experimental study of the interaction between adjacent line vortices are presented. Emphasis is given to the process of merging or pairing in which two vortices of like sign coalesce to form a single vortex. Merging is discussed in terms of its importance to the growth and aging of turbulent shear layers and aircraft wakes. Flow visualization experiments are described in which merging was observed by means of smoke injected into a wind tunnel flow. Vortex pairs of like sign and equal strength, varying sign and strength, and opposite sign and equal strength were studied. Good qualitative agreement is found between the observed flow patterns and those calculated by means of a computer code.

"EXPERIMENTAL AND THEORETICAL STUDY OF AIRCRAFT VORTICES"

AFOSR-TR-75-0664 and ARAP No. 238, February 1975, Aeronautical Research Assoc. of Princeton, Princeton, NJ

A review is given of development during the past five years in ARAP's study of the aircraft wake turbulence problem. Significant results are described including the successful application of the Betz roll-up method to inviscid wake calculations and its extension to multivortex wakes. Also discussed are effects due to viscous and induced drag, as well as the role of turbulence in the wake decay process. Recent results of an experimental study of a vortex flow in ARAP's vortex tube tunnel are presented including measurements of mean and turbulent velocity profiles and turbulent correlations.

"FEASIBILITY OF AN ONBOARD WAKE VORTEX AVOIDANCE SYSTEM"

NASA-CR-187521, April 1987, Continuum Dynamics, Inc., Princeton, NJ

It was determined that an onboard vortex wake detection system using existing, proven instrumentation is technically feasible. This system might be incorporated into existing onboard systems such as a wind shear detection system, and might provide the pilot with the location of a vortex wake, as well as an evasive maneuver so that the landing separations may be reduced. It is suggested that this system might be introduced into our nation's commuter aircraft fleet and major air carrier fleet and permit a reduction of current landing separation standards, thereby reducing takeoff and departure delays.

Bilanin, A. J., Teske, M. E. and Curtiss, Jr., H. C.

"ONBOARD WAKE VORTEX AVOIDANCE: INSTRUMENTATION TO QUANTIFY VORTEX WAKE HAZARD"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 55-1 - 55-27

An onboard vortex wake detection system using existing proven instrumentation such as a combination of accelerometers and angle of attack vanes may be technically feasible. This system might be incorporated into existing onboard systems (such as wind-shear detection systems) and might provide the pilot with the location of the vortex wake as well as a suggested evasive maneuver. This system, if implemented, might permit a reduction of current landing separation, thereby reducing takeoff and departure delays. This instrumentation may also have a short-term use in quantifying the magnitude of upset resulting from an aircraft encountering a vortex wake. Several onboard wake detection systems are discussed and limitations are identified. Their use as a wake hazard detector will also be discussed.

"THE ROLE OF ATMOSPHERIC SHEAR, TURBULENCE, AND A GROUND PLANE ON THE DISSIPATION OF AIRCRAFT VORTEX WAKES"

AIAA Paper 1978-0110, January 1978, Huntsville, AL.

Enhanced dispersion of two-dimensional trailed vortex pairs within simplified neutral atmospheric backgrounds is studied numerically for three conditions: when the pair is imbedded in a constant turbulent bath (constant dissipation); when the pair is subjected to a mean cross-wind shear; and when the pair is near the ground. Turbulent transport is modeled using second-order closure turbulent transport theory. The turbulent background fields are constructed using a super equilibrium approximation. The computed results allow several general conclusions to be drawn with regard to the reduction in circulation of the vortex pair and the rolling moment induced on a following aircraft: (1) the rate of decay of a vortex pair increases with increasing background dissipation rate; (2) cross-wind shear disperses the vortex whose vorticity is opposite to the background; and (3) the proximity of a ground plane reduces the hazard of the pair by scrubbing. The phenomenon of vortex bounce is explained in terms of secondary vorticity produced at the ground plane. Qualitative comparisons are made with available experimental data, and inferences of these results upon the persistence of aircraft trailing vortices are discussed.

"DEINTENSIFICATION AS A CONSEQUENCE OF VORTEX BREAKDOWN"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 283-296.

The physical mechanisms underlying the phenomenon of vortex breakdown have been the subject of speculation for nearly 20 years. What has become clear from numerous observations of the phenomenon on aircraft trailing vortices is that breakdown can be violently turbulent. This conclusion is drawn from the observation of smoke in the center of the vortex being dispersed with the passage of

breakdown along the vortex. The question that has been asked repeatedly by those concerned with the vortex wake hazard is: Does the vortex breakdown phenomenon provide a mechanism of sufficient magnitude to be of aid in lessening the hazard of an aircraft vortex wake? The work reported herein is an attempt to answer this question. Since the vortex breakdown phenomenon is decidedly nonlinear and from observation, violently turbulent, a numerical approach has been undertaken to define the breakdown flow field. Donaldson's second-order closure turbulent transport model has been coded in circular cylindrical coordinates. The result is an axisymmetric elliptic code in the radial and axial coordinates with time as the marching direction. The code has the capability of computing dispersal of a passive tracer.

"VORTEX INTERACTIONS AND DECAY IN AIRCRAFT WAKES"

AIAA Journal, Vol. 15, No. 2, February 1977, pp. 250-260

The dynamic interactions of aircraft wake vortices are investigated using both inviscid and viscous models. The phenomenon of vortex merging resulting in the rapid aging of a vortex wake is examined in detail. It is shown that the redistribution of vorticity from convection and diffusion during merging is a mechanism effective in reducing the hazard of a wake. Inviscid computations show that the merging phenomenon may be sensitive to small changes in spanwise load distribution and that the fuselage vortex shed from the wing-fuselage junction can play a significant role in promoting merging of wing tip and flap vortices. Vortex wake merging computations using a second-order closure model of turbulent transport indicate that a low hazard wake occurs when the generating aircraft trails flap and wing tip vortices of the same strength and sign. This optimum is achieved when the flap vortex is located outboard approximately 40% of the distance to the tip vortex.

"VISCOUS EFFECTS IN AIRCRAFT TRAILING VORTICES"

Proceedings Wake Vortex Minimization Symposium, NASA, SP-409, 1977, pp. 61-128

The mechanism of merging of like-signed aircraft vortices leads to a rapid redistribution of trailed vorticity in a wake through both convective and turbulent processes. Merging is investigated experimentally in a small wind tunnel and analytically using a code which computes turbulent transport using a second-order closure turbulent model. Computations are reported which demonstrate the merging phenomenon, and comparisons are made with experimental results. The usefulness of point vortex computations in predicting merging is explored. Limited computations have shown that jet exhaust does not appreciably alter the merging phenomenon. The effect of ambient atmospheric turbulence on the aging of an aircraft wake is investigated at constant turbulent dissipation rate. It is shown that under stable atmospheric conditions, when atmospheric macroscales are less than or equal to the vortex spacing, misleading results may be obtained. This conclusion cautions against using one parameter to characterize the ability of the atmosphere to dissipate aircraft wake vortices.

"VORTEX INTERACTIONS AND DECAY IN AIRCRAFT WAKES"

NASA CR-2870, September 1977, Aeronautical Research Assoc. of Princeton, Princeton, NJ

The dynamic interaction of aircraft wake vortices was investigated using both inviscid and viscous models. For the viscous model, a computer code was developed using a second-order closure model of turbulent transport. The phenomenon of vortex merging which results in the rapid aging of a vortex wake was examined in detail. It was shown that the redistribution of vorticity during merging results from both convective and diffusive mechanisms.

"LASER DOPPLER VORTEX MEASUREMENTS AT JOHN F. KENNEDY INTERNATIONAL AIRPORT"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 81-93

Marshall Space Flight Center in cooperation with the Federal Aviation Administration has developed a Scanning Laser-Doppler Velocimeter System which has been used to detect, track, and measure the velocity flow fields of wake vortices of aircraft landing at John F. Kennedy International Airport. The tests were performed with the cooperation of the Transportation Systems Center and the National Aviation Facilities Experiment Center, and resulted in detailed velocity and track data on the vortices generated by over 1600 landings of 13 different aircraft types. The paper describes the overall operation and performance of the system as well as the operation of the individual components. It discusses the data-handling capabilities of the system and the algorithms used in processing the laser-Doppler data, both in real time and in post analysis. Selected runs are examined for the spectral characteristics of vortices, their transport, velocity flow fields, and circulation. A summary of the results and a description of the Kennedy tests are also provided.

"LASER DOPPLER VELOCIMETER WAKE VORTEX TESTS"

FAA-RD-76-11, March 1976, NASA Marshall Space Flight Center, Huntsville, AL

A scanning laser Doppler velocimeter (SLDV) was installed at John F. Kennedy (JFK) International Airport and was operated for six months collecting data on vortices generated by landing aircraft. A description of the SLDV system, a summary of the JFK test operations, an analysis of selected portions of the data, and recommendations for improvements to the SLDV are presented. The vortex information, including track and velocity data, on over 1,600 aircraft landings is contained in the appendices.

"AIRBORNE DOPPLER LIDAR WIND FIELD MEASUREMENTS"

Bulletin American Meteorological Society, Vol. 65, No. 4, April 1984, pp. 348-359.

A coherent Doppler lidar has been used in an aircraft to measure the 2-dimensional wind field in several different atmospheric situations. The lidar, a pulsed CO₂ system, was installed in the NASA Convair 990, Galilao II, and flown in a summer field program that included flights in California, in Oklahoma at the National Severe Storms Laboratory, and in Montana at the Cooperative Convective Precipitation Experiment (CCOPE). This paper provides a brief description of the instrumentation and summarizes the research flights. Examples of some of the results are given along with plans for future use of the lidar.

"EXPERIMENTAL EVIDENCE FOR A NEW INSTABILITY OF A VERTICAL COLUMNAR VORTEX PAIR IN A STRONGLY STRATIFIED FIELD"

J. Fluid Mech., Vol. 418, 2000, pp. 167-188

This paper shows that a long vertical columnar vortex pair created by a double flap apparatus in a strongly stratified fluid is subjected to an instability distinct from the Crow and short-wavelength instabilities known to occur in homogeneous fluid. This new instability, which we name zigzag instability, is antisymmetric with respect to the plane separating the vortices. It is characterized by a vertically modulated twisting and bending of the whole vortex pair with almost no change of the dipole's cross-sectional structure. No saturation is observed and, ultimately, the vortex pair is sliced into thin horizontal layers of independent pancake dipoles. It is tentatively argued that this new type of instability may explain the layering widely observed in stratified turbulent flows.

Billant, P., Brancher, P. and Chomaz, J.-M.

"THREE-DIMENSIONAL STABILITY OF A VORTEX PAIR"

Physics of Fluids, Vol. 11, No. 8, August 1999, pp. 2069-2077

This paper investigates the three-dimensional stability of the Lamb-Chaplygin vortex pair. Short-wavelength instabilities, both symmetric and antisymmetric, are found. The antisymmetric mode possesses the largest growth rate and is indeed the one reported in a recent experimental study [J. Fluid Mech. 360, 85 (1998)]. The growth rates, wave numbers of maximum amplification, and spatial eigenmodes of these short-wavelength instabilities are in good agreement with the predictions from elliptic instability theory. A long-wavelength symmetric instability similar to the Crow instability of a pair of vortex filaments is also recovered. Oscillatory bulging instabilities, both symmetric and antisymmetric, are identified albeit their growth rates are lower than for the short-wavelength

instabilities. Their behavior and eigenmodes resemble those of the oscillatory bulging instability occurring in the mixing layer.

"INSTABILITIES AND VORTEX BREAKDOWN IN SWIRLING JETS AND WAKES"

Proceedings IUTAM Symposium on Dynamics of Slender Vortices, September 1997, Aachen, Germany.

The objective of the presentation is two-fold: First, we report on recent results in the theoretical and numerical study of instabilities in swirling jets and wakes, particular attention being given to the determination of the absolute/convective nature of the instability. Secondly, we present a detailed experimental investigation of the onset of vortex breakdown in swirling jets.

Billant, P., Dritschel, D. G. and Chomaz, J.-M.

"BENDING AND TWISTING INSTABILITIES OF COLUMNAR ELLIPTICAL VORTICES IN A ROTATING STRONGLY STRATIFIED FLUID"

J. Fluid Mech., Vol. 561, 2006, pp. 73-102

In this paper, we investigate the three-dimensional stability of the Moore-Saffman elliptical vortex in a rotating stratified fluid. By means of an asymptotic analysis for long vertical wavelength perturbations and small Froude number, we study the effects of Rossby number, external strain, and ellipticity of the vortex on the stability of azimuthal modes $m = 1$ (corresponding to a bending instability) and $m = 2$ (corresponding to a twisting instability). In the case of a quasi-geostrophic fluid (small Rossby number), the asymptotic results are in striking agreement with previous numerical stability analyses even for vertical wavelengths of order one. For arbitrary Rossby number, the key finding is that the Rossby number has no effect on the domains of long-wavelength instability of these two modes: the two-dimensional or three-dimensional nature of the instabilities is controlled only by the background strain rate and by the rotation rate of the principal axes of the elliptical vortex relative to the rotating frame of reference. The present results for the azimuthal mode $m = 1$ suggest that the vortex-bending instabilities observed previously in quasi-geostrophic fluids (tall-column instability) and in strongly stratified fluids (zigzag instability) are fundamentally related.

"CONTROL OF FORMATION FLIGHT VIA EXTREMUM SEEKING"

Proceedings of the American Control Conference, May 2002, Anchorage, AK, pp. 2848-2853.

We present a comprehensive design procedure based on extremum seeking for minimum power demand formation flight, the first with performance guarantees. The procedure involves the design of a new wake robust formation hold autopilot, and transformation of the closed loop aircraft dynamics to a form in which a newly available rigorous design procedure for extremum seeking is applicable. We

apply the design procedure on a formation of Lockheed C-5s, extending the use of maximum performance formation flight to large transports. Using available experimental wake data of the C-5, we develop a model of the aircraft in the wake that models aerodynamic interference as feedback nonlinearities. Thus, our work is also the first to attain stable extremum seeking for a plant with nonlinear feedback. Optimal formation flight is attained by online minimization of an easily measurable objective, the pitch angle of the wingman.

Bingol, F.

"ADAPTING A DOPPLER LASER ANEMOMETER TO WIND ENERGY"

MS Thesis, March 2005, Technical University of Denmark, Riso, Denmark.

The Kyoto Protocol which proposes to cut greenhouse gas emissions has been developed by many countries in the world and finally signed in 2005. EU countries in particular are already being urged to raise the proportion of renewable energy, including wind energy, in their total energy production. The EU Directive on Renewable Energy, which took effect in October 2001, sets goals that the renewal energy share of electricity generation from 11 percent in 2001 to 22 percent by 2010. Most of the challenges in the wind turbine technology have been passed and turbines have become one of the leading technologies in the renewable energy business. There was a lot to do, but it did change the way of looking to the energy for mankind and this is a breakthrough in our energy history. Everybody is interested in even better designed and more efficient wind turbines. Customers want wind turbines, which work with the same performance in different surroundings and working conditions. This is a big challenge and there is a long way to go, but the development process has been started. New concepts need new tools to analyze the wind, the effect of the wind on the wind turbine and the effect of the wind turbine on the wind. Currently there are trusted tools like cup and vane anemometers measuring the wind speed and direction for the cases listed, but there are also new ideas. This thesis project is based on one of them, a remote wind-sensing tool, ZephIR. It is a Laser Doppler Anemometer prototype by QinetiQ from United Kingdom. The main goal of the project is to adapt the ZephIR to further uses within wind energy. Adaptation process includes speed up in the measurement software and a new way of using ZephIR for measuring the wake behind a wind turbine. Project is an experimental study. Results show that a six-fold speed up in the software is possible, and wake effect can be examined. This project has opened many new ways of investigating, suitable for a PhD project. For example, testing of a wake model with real data.

Bir, G. S., Chopra, I. and Kim, K.-C.

"HELICOPTER RESPONSE TO AN AIRPLANE'S VORTEX WAKE"

12th DGLR, European Rotorcraft Forum, Garmisch-Partenkirchen, West Germany, September 1986

An analytical formulation is developed for studying the rotor-fuselage system response to an airplane's trailing vortex field. The blades are modeled as elastic beams undergoing flap bending, lag bending and torsional deflections. The fuselage is modelled as a rigid body with five degrees of

freedom: longitudinal, lateral, vertical, roll and pitch. Quasi-steady strip theory is used to obtain aerodynamic forces, and a dynamic inflow model is used to include the wake-induced unsteady effect. Dynamic stall and reverse flow effects are also included. The coupled rotor-fuselage equations are linearized about the vehicle trim state and the blade steady-state deflected position, and then solved by a numerical time-integration technique. Dynamic response results are determined in terms of blade deflections, blade stresses, rotor disk tilts, and hub loads and moments. Results are calculated for four cases of vortex encounters: hovering helicopter with vortex axis aligned with hub center; hovering helicopter with descending vortex at 16 ft/sec; helicopter flies along vortex axis; and helicopter flies across a two-vortex system. For the vortex model, a fresh wake of a B-747 airplane is used and the response is calculated for typical helicopters including hingeless, articulated and teetering rotors.

Birch, D. and Lee, T.

"INVESTIGATION OF THE NEAR-FIELD TIP VORTEX BEHIND AN OSCILLATING WING"

Journal of Fluid Mechanics, Vol. 544, 2005, pp. 201-241.

The near-field tip-vortex flow structure behind an oscillating NACA 0015 wing was investigated at $Re = 186000$. For attached-flow and light-stall oscillations, a small hysteretic property existed between the pitch-up and pitch-down motion, and many of the vortex flow features were found to be qualitatively like those of a static wing. For deep-stall oscillations, the wing oscillations imposed a strong discrepancy in contour shapes and magnitudes between the pitch-up and pitch-down phases of the oscillation cycle. The vortex was less organized during pitch-down (because of leading-edge-vortex-induced massive flow separation) than during pitch-up. The tangential velocity, circulation and lift-induced drag increased progressively with the airfoil incidence, and had higher magnitudes during pitch-up than during pitch-down, while varying slightly with the downstream distance. The vortex size, however, was larger during pitch-down than during pitch-up. The axial flow was always wake-like during the deep-stall oscillation cycle. The normalized circulation within the inner region of the tip vortex also exhibited a self-similar structure, like that of a static wing, and was insensitive to the reduced frequency.

Birch, D. and Lee, T.

"EFFECT OF TRAILING-EDGE FLAP ON A TIP VORTEX"

Journal of Aircraft, Vol. 42, No. 2, March-April 2005, pp. 442-447

The near-wake tip vortex flow structure behind a NACA 0015 airfoil with a trailing-edge flap was investigated. Lift-induced drag was computed based on vorticity and was compared with force-balance data. The vortex strength reached a maximum immediately behind the trailing edge and remained nearly constant up to two chord lengths downstream ($x/c = 3$). The displaced flap produced a more concentrated vortex of similar diameter and a higher induced drag compared to that of a baseline airfoil and had a larger radial gradient in circulation strength for flap angle, less than or equal to 15 deg; the vortex radius increased significantly for flap angle = 20 deg. For flap angles less than or equal to 15 deg, the axial flow velocity was jetlike with the peak values increased with the flap angle. The nearly

symmetric vortex was observed at $x/c = 2.25$ for a displaced flap while at $x/c = 1.5$ for a baseline airfoil. The strength and interaction of the secondary and main vortices along the tip were also found to increase with the flap angle, and the vortex flow (immediately downstream of the deflected flap) was dominated by the presence of multiple vortices. The normalized circulation in the inner part of the symmetric vortex exhibited a self-similar structure, insensitive to the flap angle.

Birch, D. and Lee, T.

"TIP VORTEX BEHIND A WING OSCILLATED WITH SMALL AMPLITUDE"

J. of Aircraft, Vol. 42, No. 5, September-October 2005, pp. 1200-1208.

The effect of reduced frequency on the tip vortex in the near field behind a NACA 0015 wing oscillated sinusoidally within the static-stall angle ($= 14$ deg) was investigated at $Re = 1.86 \times 10,000$. The nearly symmetric vortex was observed at 0.5 to 1.5 chords downstream of the trailing edge similar to the case of a stationary wing. The oscillating wing produced a less concentrated vortex of similar diameter and had a larger radial gradient in circulation strength, compared to that of a stationary wing, for reduced frequency less than about 0.1. The axial-flow velocity was always wake-like, with its minimum value increasing with the reduced frequency. The peak value of the vorticity and the vortex strength and the lift-induced drag were higher during pitch-down than during pitch-up. The normalized circulation in the inner part of the axisymmetric vortex also exhibited a self-similar structure, which was insensitive to the reduced frequency. The induced drag increased with the reduced frequency.

Birch, D. and Lee, T.

"TIP VORTEX BEHIND A WING UNDERGOING DEEP-STALL OSCILLATION"

AIAA Journal, Vol. 43, No. 10, October 2005, pp. 2081-2092

The flow structure of a tip vortex in the near field of a NACA 0015 wing with an effective aspect ratio of 5.04 undergoing a deep-stall oscillation with $\alpha(t) = 18 \text{ deg} + 6 \text{ deg} \sin \omega t$ at $Re = 1.86 \times 10,000$ was investigated. The wing oscillation imposed a strong discrepancy in contour shapes and magnitudes between the pitch-up and pitch-down phases of the oscillation cycle. The vortex was more organized and nearly axisymmetric for $x/c > 0.5$ during pitch-up than during pitch-down. The peak tangential velocity and vorticity and the strength and size of the vortex increased with $\alpha(t)$, except in the vicinity of a max, and had higher values during pitch-up than during pitch-down. The axial flow was always wake like and the velocity deficit decreased with $\alpha(t)$, while exhibiting a sharp increase and decrease on the upstroke and downstroke in the vicinity of a max, respectively. The tangential velocity decreased slightly with the downstream distance. The vortex size increased rather significantly with x/c during pitch-down while remaining virtually unchanged during pitch-up. The inner region of the vortex exhibited a self-similar structure, similar to that of a stationary wing. The induced drag increased with $\alpha(t)$ and had a local maximum at 20 deg during pitch-up.

Birch, D. M.

"SELF-SIMILARITY OF TRAILING VORTICES"

Physics of Fluids, Vol. 24, 2012, pp. 025105-1 - 025105-11.

Trailing vortices have been repeatedly shown to exhibit a remarkably robust self-similarity independent of the Reynolds number and upstream boundary conditions. The collapse of the inner-scaled circulation profiles of a trailing vortex has even been previously demonstrated for the cases of highly unsteady and turbulent vortex systems, as well as for vortices which were incompletely developed. A number of factors which contribute to and may artificially promote this self-similarity are discussed. It is shown that the amplitude of vortex 'wandering' (or the random modulations in the vortex trajectory) observed in some experimental measurements are of sufficient amplitude to cause any arbitrary finite and axisymmetric flow structure to collapse with an idealized trailing vortex when scaled on inner parameters. It is further shown that, for the case of an incompletely developed wing-tip vortex, similarity in the outer core region may be an artifact of the rate of roll-up of the vortex sheet. Great care must, therefore, be taken when interpreting experimental measurements of vortex flows.

Birch, D. M. and Martin, N.

"TRACER PARTICLE MOMENTUM EFFECTS IN VORTEX FLOWS"

Journal of Fluid Mechanics, Vol. 723, 2013, pp. 665-691.

The measurement of vortex flows with particle-image velocimetry (PIV) is particularly susceptible to error arising from the finite mass of the tracer particles, owing to the high velocities and accelerations typically experienced. A classical model of Stokes-flow particle transport is adopted, and an approximate solution for the case of particle transport within an axisymmetric, quasi-two-dimensional Batchelor q-vortex is presented. A generalized expression for the maximum particle tracking error is proposed for each of the velocity components, and the importance of finite particle size distributions is discussed. The results indicate that the tangential velocity component is significantly less sensitive to tracking error than the radial component, and that the conventional particle selection criterion (based on the particle Stokes number) may result in either over- or under-sized particles for a specific allowable error bound. Results were demonstrated by means of PIV measurements carried out in air and water using particles with very different properties.

Birch, D., Lee, T., Mokhtarian, F. and Kafyeke, F.

"STRUCTURE AND INDUCED DRAG OF A TIP VORTEX"

Journal of Aircraft, Vol. 41, No. 5, September-October 2004, pp. 1138-1145

The three-dimensional flow structure of a tip vortex in the near wake of both a rectangular, square-tipped NACA 0015 airfoil and a high-lift cambered airfoil was investigated by using a seven-hole pressure probe at $Re = 2.01 \times 100,000$. Lift-induced drag was computed based on vorticity and was compared with force-balance data. For both the airfoils tested, the vortex strength reached a

maximum immediately behind the trailing edge and remained nearly constant up to two chord lengths downstream. As the airfoil incidence increased, the increase in the lift force resulted in a basically linear increase in the vortex strength and the peak values of the tangential velocity and vorticity, whereas the vortex radius did not appear to have a clear dependence on the vortex strength. Depending on the airfoil incidence, the core axial velocity could be wake-like or jet-like. The normalized circulation within the inner region of the nearly axisymmetric tip vortex exhibited a universal, or self-similar, structure. The NACA 0015 airfoil, however, possessed smaller tangential velocities but similar vortex core diameters compared to those of a cambered airfoil.

Birch, D., Lee, T., Mokhtarian, F. and Kafyeke, F.

"ROLLUP AND NEAR-FIELD BEHAVIOR OF A TIP VORTEX"

Journal of Aircraft, Vol. 40, No. 3, 2003, pp. 603-607

The formation and growth of a tip vortex in the tip and near-field regions of a single-element rectangular high-lift wing were investigated for Reynolds numbers up to 325000. The tip region was dominated by multiple secondary vortex structures. The rollup was almost complete at the trailing edge. The strength of the vortex remained nearly constant up to 1.5 chords downstream of the trailing edge. The core radius and strength and the maximum tangential and core axial velocities of the tip vortex significantly increased with the angle of attack. Also, depending on the angle of attack, the axial velocity in the core could be directed either toward the wing or away from it, that is, of wakelike or jetlike patterns.

Bird, J. D.

"TUFT-GRID SURVEYS AT LOW SPEEDS FOR DELTA WINGS"

NASA TN D-5045, February 1969, Langley Research Center, Hampton, VA.

Tuft-grid surveys were made along the chord and in the near wake of 60-degree, 75-degree, 82.5-degree, and 86.5-degree delta wings at low speeds in the Langley stability tunnel to show the nature of the flow in the vicinity of such wing planforms. The results are presented without a detailed discussion in that the photographs of the flow patterns are felt to be largely self-explanatory. An unusual wake pattern which gave evidence of three asymmetrically arranged trailing vortices was obtained for the 86.5-degree delta wing at an angle of attack of 25 degrees and zero sideslip.

Bird, J. D.

"VISUALIZATION OF FLOW FIELDS BY USE OF A TUFT GRID TECHNIQUE"

Journal of the Aeronautical Sciences, July 1952, New York, NY, pp.481-485.

A technique for obtaining a physical picture of the flow field behind a wing, combination of wings, or other airplane components is described wherein the action of a great number of tufts of uniform

length, attached to a wire grid, are photographed from far downstream. The procedure yields, with a minimum of labor, an approximate vector plot of the flow field in a plane normal to the air stream. An examination of the data obtained from an application of this tuft grid technique to the study of the flow fields behind several low aspect ratio rectangular and delta wing arrangements indicates that analyses of such factors as trailing vortex strength and location and approximate downwash and sidewash angles over a large area around lifting surfaces and other aerodynamic forms may be satisfactorily conducted by this technique.

Bird, J. D. and Riley, D. R.

"SOME EXPERIMENTS ON VISUALIZATION OF FLOW FIELDS BEHIND LOW ASPECT RATIO WINGS BY MEANS OF A TUFT GRID"

NACA TN-2674, May 1952, Langley Aeronautical Lab., Langley Field, VA

A technique for obtaining a physical picture of the flow behind lifting surfaces is described wherein the action of a large number of tufts of uniform length attached to a wire grid are photographed from far downstream. The procedure yields, with a minimum of labor, an approximate vector plot of the flow field in a plane normal to the air stream. The flow fields behind a rectangular wing and several triangular wings were investigated through the angle-of-attack range. The effects of tip-control deflection, sideslip, and oscillation in sideslip on the flow field behind a 60-degree triangular wing were also determined.

"IN-FLIGHT STUDIES OF VORTEX WAKES, 1970-73"

TM AERO-1554, November 1973, Royal Aircraft Establishment, Farnborough, England.

In-flight studies of vortex wakes made in the UK during 1970-73 are described together with some discussion of the results, so far as the latter are available.

Bisgood, P. L., Maltby, R. L. and Dee, F. W.

"SOME WORK AT THE ROYAL AIRCRAFT ESTABLISHMENT ON THE BEHAVIOR OF VORTEX WAKES"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 171-206

The paper reviews the work done at the Royal Aircraft Establishment on the behavior of vortex wakes. Measurements of the development of wakes behind straight and swept wings are described. The results of observations on the formation of loops in a vortex wake, on the behavior of the wakes close to the ground, and on the development of the wake from a slender wing are given in some detail.

Bizinos, N. and Redelinghuys, C.

"TENTATIVE STUDY OF PASSENGER COMFORT DURING FORMATION FLIGHT WITHIN ATMOSPHERIC TURBULENCE"

Journal of Aircraft, Vol. 50, No. 3, May-June 2013, pp. 886-900.

Formation flight is currently being investigated to reduce drag and improve fuel efficiency in commercial aviation. To approximate passenger impact in formation flight, a simple aerodynamic model for two aircraft in formation was developed. The wing trailing vortices were assumed to shift in an ideal fashion within atmospheric turbulence resulting in aerodynamic disturbance loads acting on the trailing aircraft. As the sensitivity of the human body to vibration is frequency dependent, a spectral representation of atmospheric turbulence was incorporated. Monte Carlo simulations were done for various levels of turbulence intensity. The predicted acceleration responses of the trailing aircraft were used to determine the passenger comfort levels by applying the criteria of standard 2631-1 from the International Organization for Standardization and comparing with comfort levels experienced in an aircraft flying in isolation in the same turbulent atmosphere. A significant increase in discomfort was predicted for the lateral separations corresponding to the location for optimum drag benefit. Seating locations forward and inboard (closer to the lead aircraft) of the mass center showed the greatest increase in discomfort..

"PERIODIC AND QUASIPERIODIC MOTION OF POINT VORTICES"

In Vortex Dominated Flows, edited by D. Blackmore, E. Krause and C. Tung, 2005, World Scientific, New Jersey, Chapter 2, pp. 21-42.

Several generalizations and recent extensions of the Poincare-Birkhoff fixed point theorems are presented, along with applications to some problems in vortex dynamics. The problem of four-or-more point vortices in a plane is analyzed in considerable detail for the case where all the vortex strengths have the same sign. This is accomplished using a combination of KAM theory and a recent version of the Poincare-Birkhoff fixed point theorem. For example, it is proved that if the diameter of the initial system of vortices is sufficiently small, there exists an ample set of starting configurations that produce dynamics exhibiting quasiperiodic flows on invariant KAM tori, and periodic orbits of arbitrarily large period near these tori. It is also shown that analogous dynamical behavior occurs for configurations of any finite number of point vortices in a half-plane.

"A HAMILTONIAN APPROACH TO VORTEX BREAKDOWN"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

The flow of fluid particles in an ideal fluid induced by the motion of a pair of coaxial vortex rings in a swirling flow is studied in the context of Hamiltonian dynamics. By assuming that the axisymmetric

flow induced by the pair of coaxial vortex rings (kinematics) is modeled by a desingularized version of the Biot-Savart law, one obtains a stream function for the velocity field that is tantamount to a time-varying Hamiltonian function for the equations of motion. A new coordinate system moving with the center of vorticity of the rings is introduced and the Hamiltonian function is determined by solving the completely (Liouville-Arnold) integrable Hamiltonian equations for the ring motion (dynamics). This leads to a decomposition of the Hamiltonian for the fluid kinematics into a completely integrable term plus a nonintegrable part whose size can be controlled by making the initial distance between the rings sufficiently small, depending on the ambient swirl. Whence we obtain a Poincare map for the flow with respect to any fixed meridional half-plane that is a twist map. As the initial separation of the rings is increased, the invariant tori tend to break up and the fluid trajectories become more irregular until a point is reached where transverse homoclinic periodic points appear and Smale horseshoe chaos ensues. Thus, the two-ring model enables one to prove the existence of a wide range of regular and chaotic dynamical structures, depending on natural system parameters, that are remarkably consistent with those found in several experimental and numerical studies of axisymmetric bubble-type (B-type) vortex breakdown.

"THE EFFECTS OF AIRCRAFT TRAILING VORTICES ON HOUSE ROOFS"

Journal of Wind Engineering and Industrial Aerodynamics, Vol. 52, No. 4, 1994, pp. 155-170

This paper describes work carried out by the Building Research Establishment to investigate the phenomenon of aircraft trailing vortices and their effect on the roofs of domestic dwellings. As part of this investigation the roof of a house close to runway 27R at Heathrow Airport was instrumented to detect vortices. Measurements of pressure and velocity were carried out for nearly 3000 h during a 12-month period in 1991/92. During this period 399 vortex strikes were detected on the test house giving an average strike rate of 1.5/day. Most of these strikes produced pressures within the range plus or minus 150 Pa. On 6 occasions suctions exceeded - 500 Pa with a maximum suction of - 1190 Pa. Over 70% of all vortex strikes occurred when the ambient mean wind speed was below 5 m/s. Peak instantaneous tangential velocities of up to 40 m/s were recorded at the anemometer location.

Blackmore, P. A. and Redfearn, D.

"AIRCRAFT TRAILING VORTICES AND THEIR EFFECT ON ROOFS"

Journal of Meteorology, Vol. 18, No. 181, September 1993, pp. 229-237

This paper describes work carried out by the Building Research Establishment to investigate the phenomenon of aircraft trailing vortices and their effects on roofs. Measurements of vortex pressure and velocity on the roof of a house close to the end of runway 27R at Heathrow Airport were made during a 12-month period in 1991/92. During this period 399 vortex strikes were detected giving an approximate strike rate of 1.5/day. The minimum vortex pressure measured on the roof was -1190 Pa and the maximum vortex tangential velocity measured at the anemometer was 40 m/s.

"INFLUENCE OF TURBULENCE ON THE DRAG OF SOLID DISCS AND TURBINE SIMULATORS IN A WATER CURRENT"

Experimental Fluids, Vol. 55, 2014, pp. 1637-1 to 1637-10.

Laboratory experiments have been used to investigate the effects of turbulence on the drag of both solid discs and porous disc turbine simulators. These discs were introduced to turbulent flows, in a gravity-fed water flume, with various levels of turbulence intensity and integral length scales. The turbulence was generated using three different grid configurations, which produced intensities and scales comparable with previous wind tunnel studies. The drag measurements were taken with discs of two different diameters and porosities with and without the upstream grids. The experimental results have demonstrated that the drag coefficients, of all discs tested, are significantly dependent on both the turbulence intensity and integral length scale. For small integral length scales, relative to the disc, the drag coefficients converged for turbulence intensities greater than 13 percent, with an increase of around 20 percent in drag coefficient over the low-intensity case. Experiments with turbulence intensities of 10 percent demonstrated minimum drag coefficients when the integral length scale-to-disc diameter ratio was around 50 percent. Significant variations in the drag coefficient of circular bluff bodies are therefore expected when operating in turbulent flows with different characteristics.

"STREAMWISE VORTICES ASSOCIATED WITH THE BURSTING PHENOMENON"

Journal of Fluid Mechanics, Vol. 94, part 3, 1979, pp. 577-594.

The streamwise and spanwise velocity components and the gradients of these components normal to the wall were examined by using hot-film sensors and flush-mounted wall elements to study the vortex structures associated with the bursting phenomenon. Quadrant probability analysis and conditional sampling techniques indicated that pairs of counter-rotating streamwise vortices occur frequently in the wall region of a bounded turbulent shear flow. A streamwise momentum defect occurred between the vortices as low-speed fluid was 'pumped' away from the wall by the vortex pair. The defect region was long and narrow and possibly forms the low-speed streak as observed in visualization studies. The velocity defect was terminated by a strong acceleration followed by a high-speed region.

"METHOD AND APPARATUS FOR CONTROLLING BOUND VORTICES IN THE VICINITY OF LIFTING SURFACES"

US Patent 4,697,769, October 1987

The lift generated by delta wings is due primarily to large vortices associated with the flow separation near the leading edge. The invention includes a perturbation device to control the separation shedding of those vortices and manipulate their frequency and pairing. This results in different growth rates of the vortices downstream of the device and thus the lift produced by the large bound vortices may be controlled. If the invention is applied to both leading edges, the total lift of the wing will be altered; if the perturbation is preferentially applied on only one side of the wing, the moment around the roll axis of the aircraft is controlled. A first embodiment uses a piston coupled to a cavity and slot to produce the desired perturbation. Alternative embodiments are described which achieve the results without moving parts.

"DNS AND LES OF A STRAINED TURBULENT AXIAL VORTEX"

Third AFOSR International Conference on Direct Numerical Simulation and Large Eddy Simulation (TAICDL), Arlington, TX, August 2001

The work presented includes direct numerical simulations (DNS) and large eddy simulations (LES) of a strained turbulent axial vortex. This effort is part of an on-going project on the DNS and LES of turbulent axial vortices with and without the effect of an external strain field. The overall project is motivated by the wake hazard problem for commercial aircraft where the wing-tip vortices behind large aircraft present a serious safety concern for the following aircraft. For progress to be made in the prediction and control of these vortices, it will be helpful to have a better understanding of how turbulence within these vortices behaves and how the turbulence affects the distribution of vorticity. Also, current turbulence models do not perform well for strongly rotating flows and the current study provides needed data for the improvement of turbulence models for such flows.

Blake, W.

"PREDICTION OF PARATROOP/WAKE VORTEX ENCOUNTERS DURING FORMATION AIRDROP"

AIAA Paper No. 1996-3387, Reston, VA, 1996

A modeling technique is described for predicting the relative locations of paratroops and trailing vortices for a formation of transport aircraft. The wake behind each vehicle is treated as a fully rolled up vortex pair with empirical relations used for the vortex decay. The technique is applied to two and six aircraft formations, with the objective being to maximize the distance between the vortices and paratroops, subject to numerous operational constraints. Nineteen sorties were flown using the formations developed. A total of 286 mannequins and 299 live troops were dropped with no paratroop/wake vortex interactions observed.

Blake, W. B.

"AN AERODYNAMIC MODEL FOR SIMULATION OF CLOSE FORMATION FLIGHT"

AIAA Paper No. 2000-4304, Denver, CO, August 2000.

A mathematical representation of the aerodynamics for simulation of many vehicles in close formation flight is presented. Aerodynamic coupling effects between the aircraft due to wake interference are included. A combination of wind tunnel results and vortex lattice analysis is used to significantly reduce the number of state variables included in the aerodynamic coupling terms. Computational results are presented for two tailless aircraft at a wide variety of relative locations.

Blake, W. B.

"DEVELOPMENT OF THE C-17 FORMATION AIRDROP ELEMENT GEOMETRY"

Journal of Aircraft, Vol. 35, No. 2, March-April 1998, pp. 175-182

The analysis and tests that established a three-ship C-17 element geometry suitable for formation airdrop operations at night are discussed. The objective is to avoid jumpers encountering vortices generated by aircraft upstream. Candidate formation geometries were judged using a vortex tracking code that estimated the closest lateral proximity between a vortex and a jumper for a given wind condition. The initial formation geometry underwent two changes during the test because of the introduction of tolerance boxes for aircraft position and vortex encounters that occurred during mannequin trials. An echelon geometry 6000 ft long and 1500 ft wide was ultimately adopted. In 101 passes over the drop zone, 1349 mannequins and 1251 personnel were dropped from this formation geometry without a vortex encounter.

Blake, W. B. and Gingras, D. R.

"COMPARISON OF PREDICTED AND MEASURED FORMATION FLIGHT INTERFERENCE EFFECTS"

Journal of Aircraft, Vol. 41, No. 2, March-April 2004, pp. 201-207

Results from a wind-tunnel test of two delta-wing aircraft in close proximity are presented and compared with predictions from a vortex lattice method. Large changes in lift, pitching moment, and rolling moment are found on the trail aircraft as it moves laterally relative to the lead aircraft. The magnitude of these changes is reduced as the trail aircraft moves vertically with respect to the lead aircraft. Lift-to-drag ratio of the trail aircraft is increased when the wing tips are slightly overlapped. Wake-induced lift is overpredicted slightly when the aircraft overlap in the spanwise direction. Wake-induced pitching and rolling moments are well predicted. A maximum induced drag reduction of 25% is measured on the trail aircraft, compared with a 40% predicted reduction. Three positional stability derivatives, change in lift and pitching moment with vertical position and change in rolling moment with lateral position, are studied. Predicted boundaries between stable and unstable regions were generally in good agreement with experimentally derived boundaries.

"UAV AERIAL REFUELING -- WIND TUNNEL RESULTS AND COMPARISON WITH ANALYTICAL PREDICTIONS"

AIAA Paper 2004-4820, August 2004, Providence, RI.

Results from a wind tunnel test of a delta wing UAV behind a KC-135R are presented and compared with predictions from a planar vortex lattice code. Both the predictions and data show wake interference effects on the UAV that vary significantly with relative lateral and vertical position, and weakly with relative longitudinal position. Predicted trends are excellent for all force and moments except for drag, and magnitudes are reasonably well predicted. The distribution of lift between the tanker wing and tail is shown to have a strong effect on the receiver aerodynamics.

"OPTIMAL RESPONSE OF BATCHELOR VORTEX"

Physics of Fluids, Vol. 29, 2017, pp. 064108-1 to 064108-14.

The optimal response of the Batchlor vortex is studied by considering the time-harmonically forced problem with frequency w . High variance levels are sustained in this system under periodic forcing. The optimal response is largest when the input frequency is null in the axisymmetric case ($m=0$). In addition, the axial flow does not play a relevant part in determining the optimal response. When considering helical modes.

Bleviss, Z. O.

"THEORETICAL ANALYSIS OF LIGHT PLANE LANDING AND TAKE-OFF ACCIDENTS DUE TO ENCOUNTERING THE WAKES OF LARGE AIRPLANES"

Report SM-18647, December 1954, Douglas Aircraft Co., Santa Monica, CA

Many accidents and near accidents have been caused by light planes encountering the wakes of large airplanes during landing and take-off even though normal separation times were observed. The two typical difficulties generally reported by the pilots of the light plane were: a sudden violent roll accompanied or unaccompanied by a sudden large 'apparent' loss of lift characterized by rapid loss of altitude. A theoretical analysis of the cause of these accidents is presented in this report. It is shown that the accidents are caused by the rotational field of air associated with the rolled-up trailing vortex system from the wing of the large airplane. The suddenness of the onset of the difficulties is due to the unexpected entry of the light plane into this vortex system.

Bliss, D. B.

"NEW VORTEX DYNAMICS METHODS FOR ROTOR FREE WAKE ANALYSIS"

ARO 25747.1-EG, May 1993, Duke University, Durham, NC.

This report summarizes recent work on rotorcraft aerodynamics involving novel methods for rotor free wake calculations. A new method called Analytical/Numerical Matching (ANM) was developed. ANM is a hybrid analytical and numerical method that achieves accurate results by combining a low-resolution numerical solution with a high-resolution analytical solution. Although originally developed for vortex dynamics, ANM has proven to be of a general nature. The application of ANM to the rotor wake problem provides accurate answers with a significant reduction in computation time. The use of ANM introduces the opportunity to develop new solution strategies, including Far-Field Linearization and Periodic Inversion. These methods afford the means to obtain accurate solutions over the entire flight regime. Work involving applications of ANM has also led to a scheme that represents vortex filament dynamics by a hierarchy of nested problems of varying resolution joined by matching solutions. This approach, called ANM with Pyramiding, has reduced calculation times by more than a factor of twenty in some sample problems.

Bliss, D. B.

"THE DYNAMICS OF FLOW WITH HIGH CONCENTRATIONS OF VORTICITY"

Ph.D. Thesis, June 1973, Mass. Institute of Technology, Cambridge, MA

A general method is developed for predicting the dynamics of curved rotational vortex lines with axial flow. The vortex core size must be much smaller than both the local radius of curvature and the length scale for axial variation. The self-induced motion is characterized by the size and energy content of the rotational core, as well as the filament geometry. The presence of axial flow diminishes the self-induced motion. The Biot-Savart law can be used to find the motion of a vortex filament, if the proper cut-off distance is used. A general formula for cut-off distance, depending only on local core structure, is derived. Results for a sinusoidally perturbed vortex line are compared with the solution of the dispersion relation for a hollow core vortex to ascertain the limits of validity of the solution. The prospect of finding higher order solutions is investigated and the additional effects that can arise are identified.

Bliss, D. B.

"EFFECT OF UNSTEADY FORCING ON THE SINUSOIDAL INSTABILITY OF VORTEX WAKES"

Journal of Aircraft, Vol. 19, No. 9, September 1982, pp. 713-721

An analytical model of the vortex wake instability subject to forcing by unsteady lift fluctuations has been developed. These lift fluctuations can be caused either by variations in angle of attack or by flying through atmospheric turbulence. The effect of turbulence in the fluid itself, already studied by Crow and Bate, has been reviewed and incorporated into the analysis. A simple procedure is provided to estimate the time at which contact occurs between the two wake vortices as a function of certain characteristics of the forcing inputs. The behavior of the instability is somewhat altered by these forcing terms. In particular, it was found that contact between vortices can occur at much shorter wavelengths than predicted for the unforced case. Furthermore, in the presence of forcing, the

minimum completion time for the instability does not correspond to the wavenumber for which the amplification rate is a maximum because the length of the vortex trajectories is also an important factor. Finally, the stability boundary is extended to larger wavenumbers by the presence of forcing, and the boundary location depends on the forcing level.

Bliss, D. B. and Epstein, R. J.

"NOVEL APPROACH TO AERODYNAMIC ANALYSIS USING ANALYTICAL/NUMERICAL MATCHING"

AIAA Journal, Vol. 34, No. 11, November 1996, pp. 2225-2232.

Analytical/numerical matching (ANM) is a hybrid scheme combining a low-resolution global numerical solution with a high-resolution local solution to form a composite solution. ANM is applied to lifting surfaces in steady potential flow to calculate the aerodynamic loading and associated circulation distribution. The solution methodology utilizes overlapping smoothed doublets and local corrections to calculate the doublet strength distribution along the airfoil chord. The global low-resolution solution is calculated numerically using smoothed doublet solutions to the linear potential equation, and converges quickly. Simultaneous local corrections are done with high-resolution local analytical solutions. The global numerical solution is asymptotically matched to the local analytical solutions via a matching solution. The matching solution cancels the global solution in the near field, and cancels the local solution in the far field. The method is very robust, offering insensitivity to control-point location. ANM provides high-resolution calculations from low resolution numerics with analytical corrections, while avoiding the subtlety involving singular integral equations, and their numerical implementation. The approach provides a novel alternative treatment to lifting-surface aerodynamics.

Bliss, D. B., Teske, M. E. and Quackenbush, T. R.

"A NEW METHODOLOGY FOR FREE WAKE ANALYSIS USING CURVED VORTEX ELEMENTS"

NASA CR-3958, December 1987, Continuum Dynamics, Inc., Princeton, NJ

The Basic Curved Vortex Element (BCVE) was developed to do rotor free wake calculations. The element is based on the approximate Biot-Savart integration for a parabolic arc filament shape. A scheme called the interpolated point method was also developed to determine the curvature and orientation of these elements when placed between collocation points along the wake contour. The computer time and accuracy of the BCVE were studied extensively in relation to the performance of the simpler straight-line elements which have traditionally been used. In numerical simulations, curved elements were found to be far more accurate in predicting vortex filament flow fields, even when much larger elements were used. Although the curved element is more complex analytically, the fact that the elements can be larger leads to a net reduction in computer time while maintaining a strong accuracy advantage. As part of the accuracy study, the errors made by straight-line elements were evaluated. These errors were found to be related to deviations in position relative to the filament contour and to a failure to simulate the local curvature of the arc. Based on a local analysis, universal formulas were developed for predicting straight-line element errors. Within one element length of a vortex filament,

straight-line elements induce velocity errors of the same order as the self-induced velocity due to local curvature, an effect included in free wake analyses. The curved element method was implemented into a forward flight free wake analysis using a time stepping approach. A new far wake model was also developed which utilizes free wake information to prescribe and update the far wake shape downstream of the free wake region. Sample calculations were performed for different element sizes and advance ratios for single and multi-blade rotors. The highly distorted free wake shapes showed several common features, the most distinctive being a strong tendency toward rapid roll-up of the sides of the wake immediately downstream of the rotor. A preliminary assessment was made of the effect of element size on the downwash size at a rotor blade, with there being only small differences between elements generated by 15 deg, 30 deg, and 45 deg increments of blade rotation. In general, the curved element approach exhibited rapid convergence. As a final demonstration of capability, the free wake routine was implemented into the Boeing Vertol B-65 rotor aerodynamics program. Sample calculations were performed for a four-bladed rotor with a prescribed wake and with free wakes using different element sizes.

"ROLL-UP OF AIRCRAFT TRAILING VORTICES USING ARTIFICIAL VISCOSITY"

Journal of Aircraft, Vol. 11, No. 11, November 1974, pp. 714-716

A study was made of the roll-up characteristics of aircraft trailing vortices applying the artificial viscosity method of Kuwahara and Takami to a number of practical aerodynamic configurations and comparing the results for the core location with existing experimental data where possible.

Bloy, A. W. and Jouma'a, M.

"TRAILING VORTEX EFFECTS ON LARGE RECEIVER AIRCRAFT"

Journal of Aircraft, Vol. 32, No. 6, November-December 1995, pp. 1198-1204

The aerodynamic forces and moments on the Hercules receiver aircraft, due to its horizontal and vertical position and bank, yaw, and pitch attitudes in the wake of the KC10 tanker aircraft, are assessed relative to the receiver's aerodynamic characteristics in free air. Large changes in lift, drag, and pitching moment are predicted near the tanker wake centerline. As the receiver is displaced sideways towards the tanker wingtip vortices it experiences large side force and yawing moment and particularly high rolling moment. The most significant term due to the receiver attitude is the rolling moment due to bank.

Bloy, A. W. and Lea, K. A.

"DIRECTIONAL STABILITY OF A LARGE RECEIVER AIRCRAFT IN AIR-TO-AIR REFUELING"

J. Aircraft, Vol. 32, No. 2, March-April 1995, pp. 453-455

Wind-tunnel data have been obtained from a receiver aircraft model tested in yaw behind a tanker aircraft model. Because of the sidewash acting on the fin below the tanker wake, the receiver aircraft experienced a significant loss of directional stability. The effect of the sidewash on the receiver fuselage was found to be relatively small. Tests with and without a fuselage on the tanker differed slightly. Similar results were obtained for the side force derivative. The theoretical results obtained using a roll-up model of the tanker wing wake and excluding fuselage effects compare favorably with the experimental data.

Bloy, A. W. and West, M. G.

"INTERFERENCE BETWEEN TANKER WING WAKE WITH ROLL-UP AND RECEIVER AIRCRAFT"

Journal of Aircraft, Vol. 31, No. 5, September-October 1994, pp. 1214-1216

A model of wing wake roll-up has been developed and applied to the problem of the lateral aerodynamic interference between tanker and receiver aircraft during air-to-air refueling. For the configuration considered, the wake roll-up gives a tip vortex strength at the receiver wing position that is 42.5% of the circulation at the tanker wing centerline. From the downwash and sidewash distributions the receiver rolling moments due to sideways and bank displacements have been calculated. Compared with the predictions from a flat vortex sheet model of the wing wake, the predictions from the wake roll-up model indicate significantly higher values of the receiver rolling moment due to sideways displacement derivative. For the configuration considered, the effect of roll-up on the receiver rolling moment due to bank derivative is negligible.

Bloy, A. W., West, M. G., Lea, K. A. and Jouma'a, M.

"LATERAL AERODYNAMIC INTERFERENCE BETWEEN TANKER AND RECEIVER IN AIR-TO-AIR REFUELING"

J. Aircraft, Vol. 30, No. 5, Sept.-Oct. 1993, pp. 705-710

Wind-tunnel data have been obtained from a tapered tanker wing and receiver aircraft model at varying vertical separation. The data are presented in derivative form and compared with theory using a flat vortex sheet model of the tanker wing wake to determine the induced angle-of-attack variation on the receiver wing, fin, and tailplane due to the tanker wing. Aerodynamic loads on the receiver are obtained by the vortex lattice method, with an allowance made for the vertical displacement of the tanker wake in the estimation of the fin side force. In the experiments, the lateral aerodynamic interference between tanker and receiver was determined by banking the tanker wing and displacing it sideways, and by yawing the receiver aircraft model. Data were obtained from open and closed test sections to assess the significant boundary interference effect and corrections estimated from the image vortex system of the tanker and receiver wings in the test section. In general, the theory compares favorably with the experimental data. The most significant terms are the rolling moments due to sideways and bank displacements. Significant side forces are produced due to sidewash on the fin from the tanker and receiver wings and, when displaced in yaw, the receiver experienced a loss in directional stability.

Bluemink, J. J., Lohse, D., Prosperetti, A. and van Wijngaarden, L.

"DRAG AND LIFT FORCES ON PARTICLES IN A ROTATING FLOW"

Journal of Fluid Mechanics, Vol. 643, 2010, pp. 1-31.

A freely rotating sphere in a solid-body rotating flow is experimentally investigated. When the sphere is buoyant, it reaches an equilibrium position from which drag and lift coefficients are determined over a wide range of particle Reynolds numbers (Re greater than or equal to 2 and less than or equal to 1060). The wake behind the sphere is visualized and appears to deflect strongly when the sphere is close to the cylinder axis. The spin rate of the sphere is recorded. In fluids with low viscosity, spin rates more than twice as large as the angular velocity of the cylinder can be observed. By comparing numerical results for a fixed but freely spinning sphere with a fixed non-spinning sphere for Re less than or equal to 200, the effect of the sphere spin on the lift coefficient is determined. The experimentally and numerically determined lift and drag coefficients and particle spin rates all show excellent agreement for Re less than or equal to 200. The combination of the experimental and numerical results allows for a parameterization of the lift and drag coefficients of a freely rotating sphere as function of the Reynolds number, the particle spin and the location of the particle with respect to the cylinder axis. Although the effect of the flow rotation on the particle spin is different in shear flow and solid-body rotating flow, the effect of spin on lift is found to be comparable for both types of flow.

Bly, E.

"EFFECTS OF REDUCED IFR ARRIVAL-ARRIVAL WAKE VORTEX SEPARATION MINIMA AND IMPROVED RUNWAY OPERATIONS SEQUENCING ON FLIGHT DELAY"

M.S. Thesis, February 2005, Mass. Institute of Technology, Cambridge, MA

Two methods to improve runway throughput are evaluated in this thesis. The first, increasing runway capacity during periods of bad weather by reducing IFR arrival-arrival wake vortex separations. The second, increasing runway efficiency in all weather conditions using event sequencing algorithms. Two algorithms were studied: a Serve-the-Longest-Queue algorithm for flight sequencing coupled with a greedy heuristic algorithm for runway assignment and a mixed integer programming optimization algorithm for simultaneous flight sequencing and runway assignment. The MIT Extensible Air Network Simulation (MEANS) was used to simulate NAS operations to determine the potential benefits in terms of delay reduction for both methods. For the case where reduced IFR arrival-arrival wake vortex separations was studied, the Airport Runway Capacity Calculator (ARCC), developed in support of this work, was used to determine the increased capacity at eleven congested US airports. Results indicate that the total delay in the National Airspace System (NAS) could have been reduced by 31.8% over the month of January, 1999 (a reduction of 243,672 minutes) representing a benefit of 116 minutes per IFR hour. For the cases where the event sequencing algorithms were studied, the algorithms were only implemented at Newark Airport (EWR) and the resulting delay values were compared to the

performance of a FIFO algorithm that is representative of existing operations. The flight delay for the Serve-the-Longest-Queue algorithm and the FIFO algorithm were similar, though relative performance depended on the airline schedule. The integer programming optimization algorithm outperformed the other two algorithms significantly reducing the average delay at EWR by 65.6% and 67.0% and the average NAS delay by 24.3% and 24.7% relative to the FIFO and Serve-the-Longest-Queue algorithms respectively.

Boatright, W. B.

"AN ANALYSIS OF PRESSURE STUDIES AND EXPERIMENTAL AND THEORETICAL DOWNWASH AND SIDEWASH BEHIND FIVE POINTED-TIP WINGS AT SUPERSONIC SPEEDS"

NACA-TR-1380, 1958, NACA Langley Aeronautical Lab., Langley Field, VA.

Flow-angle and pressure surveys behind five, thin, pointed-tip wings of varying plan form have been made at Mach numbers 1.62 and 2.41. Schlieren studies at a Mach number 1.93 for the same five plan-form wings were made to illustrate the behavior of the vortex sheet. The surveys were conducted at 1.5, 3, and 4 root chords behind three triangular wings of 50-degree, 63-degree, and 72-degree leading-edge sweep angle, and behind the 50-degree, triangular wing reversed. The flow behind a pointed-tip wing having a sweptback leading edge and a swept forward trailing edge (both 50 degrees) was also surveyed. Experiment and one of the theoretical methods are compared for the reversed triangular wing and the pointed-tip wing with the 50-degree sweptback leading edge and sweptforward trailing edge.

"A STUDY OF THE INFLUENCE OF WING-TIP VORTICES ON THE TRAJECTORIES OF PARTICLES RELEASED FROM AIRCRAFT"

Journal No. 1702A, December 1968, Mississippi State Univ. Agriculture Experiment Station, State College, MS.

This report describes results of tests conducted to determine if radar reflective chaff injected at the wing tip of an aircraft would be ingested into the vortex structure and sufficiently distributed to allow velocity profiles to be measured by a Doppler radar. The results are presented in the form of flow field visualization results and an analysis of radar returns.

"MEASUREMENTS OF VELOCITY COMPONENTS IN THE WAKE OF A FULL-SCALE HELICOPTER ROTOR IN HOVER"

U.S. AAMRDL TR-72033, 1972, Mississippi State Univ., State College, MS

This report presents three-component wake velocity measurements made with a split-film total vector anemometer. The measurements were made in the wake of a full-scale OH-13E helicopter rotor. The results indicated that maximum values of the induced velocity in the mean wake exceeded twice the magnitude of momentum values, and that instantaneous values of the vertical velocity component in the vicinity of the vortex trails could be as large as ten times the momentum value of induced velocity at high thrust coefficients. Velocity distributions across tip vortices revealed longitudinal components of velocity of the same order of magnitude as the rotational components. Also, tip vortex structure and dissipation characteristics were found to be like the vortices shed from fixed-wing aircraft.

"MATHEMATICAL MODEL OF INTERACTION WITH THE VORTEX WAKE FOR A SET OF GEOMETRICALLY SIMILAR AIRCRAFT"

In: Flight Safety, Aircraft Vortex Wake and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 239-246

The paper considers interaction of five medium-class aircraft (UK classification) with a non-curved vortex generated by a B-747-type 'heavy' aircraft at its landing approach. The aerodynamic and inertia and mass characteristics of the set of aircraft were obtained from those of the Tu-154 aircraft by resizing method and similarity relations. The landing approach is executed in the automatic mode, the automatic control algorithms being simulated on the basis of the AFCS-154.

"AN ANALYSIS OF STOCHASTIC EFFECTS OF THE VORTEX WAKE ON AIRCRAFT MOTION AT AUTOMATED LANDING"

In: Investigation of Vortex Wake Evolution and Flight Safety - Collection of Papers, Trudy TsAGI, Vol. 2622, Publishing Dept. of TsAGI, Moscow, Russia, 1996, pp. 197-208

The problem of the development of a stochastic model of the vortex wake behind an aircraft is considered together with the assessment of the probability of unfavorable influence on another aircraft performing an automated landing. The stochastic character of some atmospheric factors (gradient wind, atmospheric turbulence, and stratification) is taken into consideration. The stochastic model determines the influence of these factors on the motion of the vortices, changes in their circulation and random time of vortex breakdown due to the Crow instability. [In Russian.]

"MATHEMATICAL SIMULATION OF THE WAKE VORTICES EFFECT ON AIRCRAFT MOTION DURING AUTOMATIC LANDING"

In: Investigation of Vortex Wake Evolution and Flight Safety Problems - Collection of Papers, Trudy TsAGI, Vol. 2627, Publishing Dept. of TsAGI, Moscow, Russia, 1997, pp. 198-208

This paper considers the process of automatic landing of the Tu-204 medium weight class aircraft in the vortex wake behind a B-747-type heavy aircraft. The computations were aimed at determining the structure of the wake vortices mathematical model and the influence of this model elements upon the computational results overall. Besides it describes a methodology of statistical modeling for obtaining the probability of large deviations of trajectory kinematics parameters of an encountering aircraft at the touch-down moment. The methodology is based on the method of essential sample, which allows singling out realizations with one of the vortices near the landing trajectory.

"AIRCRAFT VORTEX WAKE AND FLIGHT SAFETY PROBLEMS"

Journal of Aircraft, Vol. 47, No. 2, March-April 2010, pp. 663-674.

This paper presents a mathematical model of the aircraft vortex wake for evaluating the safe separation considering the wake-generating and following aircraft types and weather conditions. The solution of four major problems is contained in the model concerned, namely, the wake generator, the interaction of the following aircraft with the preceding aircraft vortex, the description of the turbulent atmosphere, and the vortex destruction. Verification of the model was made based on experimental results of wind-tunnel and flight tests. Given are calculations of the wake characteristics aft of aircraft and safe distance values in landing with various turbulent atmosphere states.

"THREE-DIMENSIONAL STRUCTURE OF WIND TURBINE WAKES AS MEASURED BY SCANNING LIDAR"

Atmospheric Measurement Techniques, Vol. 10, 2017, pp. 2881-2896.

The lower wind speeds and increased turbulence that are characteristic of turbine wakes have considerable consequences on large wind farms: turbines located downwind generate low power and experience increased turbulent loads. The structures of wakes and their downwind impacts are sensitive to wind speed and atmospheric variability. Wake characterization can provide important insights for turbine layout optimization in view of decreasing the cost of wind energy. The CWEX-13 field campaign, which took place between June and September 2013 in a wind farm in Iowa, was designed to explore the interaction of multiple wakes in a range of atmospheric stability conditions. Based on lidar wind measurements, we extend, present, and apply a quantitative algorithm to assess wake parameters such as the velocity deficits, the size of the wake boundaries, and the location of the wake centerlines. We focus on wakes from a row of four turbines at the leading edge of the wind farm to explore variations between wakes from the edge of the row (outer wakes) and those from turbines in the center of the row (inner wakes). Using multiple horizontal scans at different elevations, a three-dimensional structure of wakes from the row of turbines can be created. Wakes erode very quickly during unstable conditions and can in fact be detected primarily in stable conditions in the conditions

measured here. During stable conditions, important differences emerge between the wakes of inner turbines and the wakes of outer turbines. Further, the strong wind veer associated with stable conditions results in a stretching of the wake structures, and this stretching manifests differently for inner and outer wakes. These insights can be incorporated into low-order wake models for wind farm layout optimization or for wind power forecasting.

"ACCURATE AND EFFICIENT VORTEX-CAPTURING FOR ROTOR BLADE VORTEX INTERACTION; FINAL REPORT"

NLR TP-2000-051, February 2000, National Aerospace Lab., Amsterdam, The Netherlands

The objective of this paper is to present an innovative computational fluid dynamics (CFD) algorithm for the simulation of wake vortices generated by helicopter rotors. Special emphasis is placed on the CFD technology in terms of: basic requirements for these CFD algorithms, general CFD development stages, important CFD issues such as accuracy, efficiency and parallelization, and demonstration of a prototype CFD system on test cases relevant for vortex wake simulation.

Boelens, O. J., van der Ven, H., Oskam, B. and Hassan, A. A.

"BOUNDARY CONFORMING DISCONTINUOUS GALERKIN FINITE ELEMENT APPROACH FOR ROTORCRAFT SIMULATIONS"

Journal of Aircraft, Vol. 39, No. 5, September-October 2002, pp. 776-785

A numerical method has been developed for predicting the complex vortex wake for a helicopter rotor in hover and in forward flight. The method is based on the solution of the three-dimensional, compressible Euler equations expressed in an arbitrary Lagrangian Eulerian reference frame. A second-order accurate discontinuous Galerkin finite element method is used to discretize the governing equations on a hexahedral mesh. Unstructured, local mesh refinement is performed to enable prediction of the structure of the vortex wake. The capabilities of this computational fluid dynamics method are demonstrated by simulations of the flow around the Caradonna-Tung helicopter rotor in hover and simulations of the flow around the Operational Loads Survey helicopter rotor in forward flight. Accuracy of the method is assessed through comparison with wind-tunnel data, if available. Special attention is given to a rotor trimming procedure developed at the National Aerospace Laboratory/NLR and to the grid adaptation algorithm.

Boer, J. F., Hermans, C. and Pengel, K.

"EXPERIMENTAL AND THEORETICAL ASSESSMENT OF THE HELICOPTER GROUND VORTEX PHENOMENON"

NLR-TP-2002-305, June 2002, National Aerospace Laboratory, Amsterdam, The Netherlands

During recent wind tunnel tests, performed in the European 4th Framework program HELIFLOW, the position and flow characteristics of the rotorwash induced ground vortex were measured. These results were used for the verification and improvement of the NLR helicopter ground vortex calculation model, which is part of the rotorwash induced horizontal airflow calculation tool OUTWASH, currently under development for the Ministry of Defence of the Netherlands. The wind tunnel tests were performed in the Large Low-speed Facility of the German-Dutch Wind Tunnels. The use of state-of-the-art test techniques, such as Laser Light Sheet and Particle Image Velocimetry, and DLR's powered main rotor BO 105 wind tunnel model made it possible to measure the ground vortex induced velocities. The NLR ground vortex mathematical model is a tool for the prediction of the helicopter ground vortex position, shape and strength. It consists of an empirical radial wall-jet model and a set of airflow equilibrium equations. The vortex is represented by discrete filaments, while the induced velocities are calculated using Biot-Savart Law. The improved ground vortex model calculation results show a good match with the experimental ground vortex core positions and strengths data for all HELIFLOW test conditions.

Boer, J. F., Hermans, C. and Pengel, K.

"HELICOPTER GROUND VORTEX: COMPARISON OF NUMERICAL PREDICTIONS WITH WIND TUNNEL MEASUREMENTS"

NLR TP-2001-569, December 2001, National Aerospace Lab., Amsterdam, The Netherlands

In the framework of the Brite Euram project HELIFLOW, research activities were conducted aimed at knowledge acquisition in interactional aerodynamics, validation of wind tunnel test technologies and verification of related theoretical tools. This paper describes the ground vortex activities performed in Task 3 of the project, which addressed the low-speed phenomena of quartering flight. During sideward flight in ground proximity, the helicopter main rotor induced ground vortex influences the main and tail rotor inflow conditions and thus its performance. Wind tunnel tests were performed with a powered BO 105 model in the Large Low-speed Facility (LLF) of the German-Dutch Wind Tunnels (DNW). State of the art airflow test techniques were applied to measure the ground vortex flow phenomena. The in-house developed OUTWASH code was extended with several features for application within HELIFLOW. It was applied for pre-test calculations to refine the wind tunnel test matrix and to define the experimental set-up for the flow measurements by calculating the ground vortex locations. Based on the test results obtained, an OUTWASH analysis activity was performed. Specific attention was given to the numerical and experimental assessment of the ground vortex core position and velocity distribution.

"METHOD FOR REDUCING IN FLIGHT WAKE VORTICES AND AN AIRCRAFT WINGTIP ARRANGEMENT USED IN SUCH METHOD"

US Patent 8,894,018 B2, November 2014.

This invention discloses a method to break down, destabilize, or destroy an in-flight wake vortex shed from an aircraft's wing. The wingtip has a winglet mounted to an extremity of the wing, and means for actuating displacement of the winglet relative to the wing. The winglet is displaced from a stationary position, in which the in-flight wake vortex is stable, to a continuous moving condition, in which the winglet is displaced to a secondary temporary stationary position, remote from the initial stationary position, and having any angle relative to a plane extending through a vertical, longitudinal, or lateral axis of the aircraft to alter the winglet's angle of attack, and persisting in the moving condition as long as required to break down, destabilize or destroy the in-flight wake vortex. The invention includes a wingtip arrangement for use in the method and an aircraft including the wingtip arrangement.

Bofah, K. K.

"SOME REMARKS ON AIRCRAFT WAKE VORTEX ANALYSIS"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 31-46

Analysis techniques for aircraft trailing vortices are presented. Employing vortex theories by Saffman and Moore, predictive methods for vortex-induced rolling moments and coalescence time for a vortex pair are obtained. The predictions compare favorably with published data in the far field.

Bofah, K. K.

"A STUDY OF THE TRAILING VORTICES BEHIND A RING WING"

Ph.D. Thesis, 1975, California Institute of Technology, Pasadena, CA

Experiments were conducted in the Graduate Aeronautical Laboratories, California Institute of Technology Low Speed Water Channel, using laser Doppler velocimetry techniques to measure vertical and axial velocity components in the trailing vortex wake. A thin cylindrical ring wing model was tested at various axial angles of attack and free stream velocities. Velocity profiles were measured at several downstream stations from the trailing edge to 45 wing diameters downstream. The inviscid roll-up of the trailing vortex sheet shed by a ring wing was numerically examined. A line vortex representation was used to calculate the evolution of the initially cylindrical vortex sheet. The vortex sheet was found to distort in shape and then smoothly roll up into a pair of doubly connected spirals whose centers originate from approximately the center of gravity of vorticity in the upper quadrants of the ring wing's circular trailing edge. The experimental and flow visualization results are consistent with the numerical data and show that a pair of counter-rotating vortices do develop from the rolling up of the vortex sheet shed by a ring wing in an nonaxial flow. The vortices trail, downstream of the wing, with their vorticity centroids spaced by $\pi/4$ wing diameters.

"COMPUTATION OF FLOW NOISE USING SOURCE TERMS IN LINEARIZED EULER'S EQUATIONS"

AIAA Journal, Vol. 40, No. 2, February 2002, pp. 235-243

An acoustic analogy using linearized Eulers equations (LEE) forced with aerodynamic source terms is investigated to compute the acoustic far field. This hybrid method is applied to three model problems simulated by solving Navier-Stokes equations. In this way, its validity is estimated by comparing the predicted acoustic field with the reference solution given directly by the Navier-Stokes equations. The noise radiated by two corotating vortices is studied: first, in a medium at rest and, second, in a mean sheared flow with no convection velocity. Then the sound field generated by vortex pairings in a subsonic mixing layer is investigated. In this case, a simplified formulation of LEE is proposed to prevent the exponential growth of instability waves. The acoustic fields obtained by solving LEE are in good agreement with the reference solution. This study shows that the source terms introduced into the LEE are appropriate for free sheared flows and that acoustic-mean flow interactions are properly taken into account in the wave operator.

"OPTICAL AIR FLOW MEASUREMENTS IN FLIGHT"

RTO AGARDograph 160, Vol. 20, December 2003

The goal of this AGARDograph is to provide an introductory practical overview of in-flight optical flow measurement techniques. This document is written to aid an instrumentation engineer or research scientist in making non-intrusive flow measurements on an aircraft. It is hoped that this document will be particularly useful for the technologist with a limited background in optical theory and limited experience in applying optical technology. The experience of the authors and numerous other contributors has been infused here to provide guidance in avoiding expensive non-productive diversions that can occur when applying optical technology for the first time in the flight environment. This AGARDograph provides basic knowledge and techniques necessary for assessing the applicability of optical measurements and addressing effective optical measurement techniques in flight. Key aspects of optical measurements are discussed and the tradeoffs are identified, as they are currently understood. Basic components of optical measurement systems are discussed and key requirements are identified. Specific systems designed for a variety of applications are discussed to provide insight for the reader.

"LES PREDICTIONS OF ROUND ISOTHERMAL AND HEATED JETS"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

The main aim of the work presented was to perform the LES calculations of the isothermal and heated air jet to study the mechanism of the jet instability and the influence of some governing parameters like density ratio of the jet to ambient fluid, shear layer thickness and turbulence level at the nozzle outlet. The LES results were verified with experimental data. The experimental set-up was

designed in such a way that the shear layer at the nozzle outlet was laminar to not disturb formation of the coherent vortices resulting from the jet instability and to generate conditions for absolute instability in the case of hot jet. Very low turbulence level at the nozzle exit was obtained by application of cubic equation nozzle with very high contraction ratio and careful design of the settling chamber. Within the experiment the shear layer thickness at the nozzle exit was controlled by using the extension tubes variable lengths attached to the main nozzle. The LES calculations were aimed mainly at the prediction of the absolutely unstable mode of hot jet hence the effort was concentrated on the case of relatively thick shear layer. The LES calculations were performed with the use of in-house LES code SAILOR - Spectral And compact Differences High Order Code for Low Mach Number LES). The code uses the Fourier spectral approximation in the lateral directions and compact differences in the longitudinal one. To study variable density flow for low Mach number an extension of Navier-Stokes and energy equations was applied. For integration of the system of equation with respect to time low-storage three stage Runge-Kutta method was used and within each time step the projection method was applied for pressure.

Bohbot, J., Grondin, G., Corjon, A. and Darracq, D.

"A PARALLEL MULTIGRID CONSERVATIVE PATCHED/SLIDING MESH ALGORITHM FOR TURBULENT FLOW COMPUTATION OF 3D COMPLEX AIRCRAFT CONFIGURATIONS"

AIAA Paper No. 2001-1006, Reno, NV, January 2001

Body fitted structured grid generation is a crucial step in the computation of flow around complex aircraft configurations. The structured body fitted mesh inevitably leads to dense meshes even in zones where gradients are expected to be low. The challenge is to develop an efficient way to simplify the grid generation for complex configurations in transonic flow without wasting points. In this paper, a 3D patched/sliding mesh algorithm is described. The patched grid algorithm is associated with the LU-SGS scheme for implicit time integration and a multigrid technique. The turbulence terms are approximated by the Baldwin-Lomax algebraic model or by the one equation Spalart-Allmaras model. The efficiency of the patched grid algorithm is demonstrated with several referenced test cases. Finally, computations over the AS28G aircraft (fuselage, wing, pylon, nacelle) using the patched grid algorithm are presented. An unsteady calculation of pitching NACA0012 airfoil is analyzed to assess the performance of moving grid using the sliding mesh algorithm.

Bohl, D. and Koochesfahani, M. M.

"MOLECULAR TAGGING VELOCIMETRY MEASUREMENTS OF AXIAL FLOW IN A CONCENTRATED VORTEX CORE"

Physics of Fluids, Vol. 16, No. 11, November 2004, pp. 4185-4191

The characteristics of the axial flow within the core of a concentrated line vortex are investigated using molecular tagging velocimetry (MTV). A well-defined array of isolated vortices of alternating sign is generated in the wake of a NACA-0012 airfoil pitching sinusoidally at small amplitude and high

reduced frequencies. The circulation and peak vorticity of the vortices are varied by the choice of oscillation frequency. Interaction of these two-dimensional vortices with the walls of the test section generates an axial flow within the vortex cores. The magnitude of the axial flow and its spatial/temporal characteristics are quantified using the MTV technique. Results show that the peak axial flow speeds can be very high, of the order maximum swirl speed of the vortices. The maximum axial speed ratio (maximum axial speed normalized by maximum swirl speed) is found to vary in the range 0.6-1.0 for the parameters investigated here. Initially, the axial flow is spatially confined in isolated structures corresponding to the core of vortices. As the vortex convects downstream, however, the spatial structure of axial flow changes from isolated regions to a continuous region for the highest reduced frequency investigated here. This change in structure is correlated with a significant decrease in the peak axial flow speed.

Bohl, D. G. and Koochesfahani, M. M.

"MTV MEASUREMENTS OF AXIAL FLOW IN CONCENTRATED VORTEX CORES"

Physics of Fluids, Vol. 16, No. 11, Nov. 2004, pp. 4185-4191

The characteristics of the axial flow within a concentrated vortex core are investigated using Molecular Tagging Velocimetry (MTV). A well-defined array of isolated vortices of alternating sign is generated in the wake of a NACA-0012 airfoil pitching sinusoidally at small amplitude and high reduced frequencies. The circulation and peak vorticity of the vortices are varied by the choice of oscillation frequency. Interaction of these 2-D vortices with the walls of the test section generates an axial flow within the vortex cores. The magnitude of the axial flow and its spatial/temporal characteristics are quantified using the MTV technique. Results show that the peak axial flow speeds can be very high, of order maximum swirl speed of the vortices. It is found that maximum swirl ratio (axial speed normalized by swirl speed) was between 0.6 and 1.0 of the swirl velocity for the range of parameters investigated. The axial flow is initially confined in isolated structures corresponding to the vortices created by the airfoil oscillation. If the reduced frequency is high enough, the structure of the axial flow changes from isolated structures to a continuous region of axial flow. The change in structure is correlated with a decrease in the peak axial flow speed.

Bohne, A. R.

"COMPARISON OF IN-SITU AIRCRAFT AND GROUND-BASED DOPPLER RADAR TURBULENCE MEASUREMENTS"

AIAA Paper 1989-0790, January 2019, January 1989, Reno, NV.

Spatially and temporally collocated Doppler radar and instrumented aircraft data acquired during the Joint Agency Turbulence Experiment are analyzed. The radar Doppler spectrum velocity and variance are utilized in structure function and variance-based methods to develop a methodology for remotely detecting hazardous turbulence. Aircraft gust data from 34 thunderstorm penetrations serve as 'ground truth'. The analyses show that the large-scale quasi-stationary storm winds can significantly influence

the measurements and much care must be utilized to separate their effects from the smaller-scale turbulence field. Use of radar Doppler velocity in structure function analysis usually results in severe underestimation of the turbulence intensity. Use of a Doppler spectrum variance-based methods employing a modeled turbulence field with a maximum effective outer scale of .5-2 km is found quite effective in delineating weak to severe turbulence regimes.

Bohne, A. R.

Bohning, P.

"AKUSTISCHE LOKALISIERUNG VON WIRBELSCHLEPPEN"

Ph.D. Thesis, April 2006, Technical University of Berlin, Berlin, Germany

Wake vortices are generated behind aircraft because of the lift and a finite aircraft wing span. They consist of two strong counter-rotating vortices which pose potential hazards on following aircraft. The aircraft separation rules introduced to ensure safety during landing and take-off is one of the most important constraints limiting the capacity of highly frequented airports. To cope with the expected increase in air-traffic and aircraft size, current research activities concentrate on aircraft design modifications and the development of wake vortex detection systems. Experience shows that wake vortices of landing aircraft are audible. In the framework of this thesis the sound emission of wake vortices and their detection and characterization by means of microphone arrays were studied. A potential sound generating mechanism, the interaction of primary and secondary vortex structures, and the resulting spectral properties were investigated in a numerical study using LES and Acoustic Analogy methods. It was demonstrated that the secondary structures are accelerated as they move closer to the vortex cores of the primary structures. Since accelerated vorticity is a known source of sound, strongest sources are expected in the vicinity of the cores of the primary vortex structures. A correlation of the spectral properties of the sound emission and the vortex characteristics revealed a

relation between the rotation frequency f_r of the primary vortex cores and the frequency f_a of maximal sound pressure level, $f_a \sim 0.8 f_r$. To experimentally validate the results of the numerical study, the sound of wake vortices of landing aircraft was measured in three fly-over tests applying microphone arrays. The expectation that the dominant sound sources are in the vicinity of the vortex cores was proven by the experimental results. A comparison of the sound pressure spectra revealed the existence of two classes of spectra. The aircraft types of Airbus and Boeing belong to different classes. Two maxima were found in the vortex noise spectra, at $f_1 \sim 12\text{Hz}$ and $f_2 \sim 100\text{Hz}$. The origin of the first maxima was not identified since the microphone array was too small to resolve the sound sources at frequencies below 40Hz . The second maxima could be clearly related to the vortex cores. The results demonstrated that wake vortices can be detected and characterized by its generated and radiated sound. [In German.]

Bohning, P. and Michel, U.

"ACOUSTIC PROPERTIES OF AIRCRAFT WAKE VORTICES"

1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-001, September 2007, pp. 1039-1048

The noise generation by aircraft wake vortices has been studied numerically and experimentally. The numerical study revealed a relation between the circulation, the vortex core size, and the frequency of the peak level in the vortex noise spectra. The experimental data were obtained in measurements at airports by applying phased microphone arrays. It has been found that sound sources are closely located to the vortex cores. The focused noise spectra of the wake vortices of all measured aircraft types are dominated by two maxima. The second maximum at $f = 100\text{ Hz}$ is clearly caused by wake vortices. The origin of the first at f of about 10 Hz has not been identified. Wake vortices were acoustically detected in 80 percent of the flyovers. Lowest detection rates were observed for the newer aircraft types Airbus A319, A320 and Boeing 737-800. A comparison of the wake trajectories measured by phased microphone arrays and LIDAR revealed that the detection capability of the latter is superior.

Bohning, P., Baumann, R., Michel, U and Gerz, T.

"NUMERICAL STUDY OF WAKE VORTEX NOISE USING LES AND AN ACOUSTIC ANALOGY METHOD"

EUROMECH Colloquium No. 467, Turbulent Flow and Noise Generation, Marseille, France, July 2005

Wake vortices of landing aircraft emit a faint noise that is audible when the wind speed is low. The noise is most likely related to aerodynamic parameters of the vortices. In recent years, it has been demonstrated that wake vortices can be localized and their noise spectra can be determined by means of microphone arrays. Noise sources are found to be located close to the vortex cores. To improve the understanding of the sound generating mechanism and the relation between aerodynamic wake parameters and noise emission, wake vortex noise was studied numerically. In the present work, the flow field of a system of four vortex filaments was calculated by 3D LES. Its noise emission was

calculated by making use of an acoustic analogy method. The results show that the peak frequency in a wake noise spectrum is likely related to the core size of the wake vortices.

"LIFT AND DRAG BEHAVIOR OF A LOW REYNOLDS WING SECTION SUBMITTED TO A NEARBY STREAM WISE VORTEX"

AIAA Paper No. 2008-340, Reno, NV, January 2008

The purpose of this work is to determine the influence of spiral vortical structures upon low Reynolds number airfoils. Our main goal is to find out how such vortical structures, generated by a delta wing, modify the aerodynamic coefficients and the overall behavior of those airfoils. The tip vortex wake produced by one aircraft could affect other aircrafts in different ways over other airplanes depending on whether it flows under, over or across its wing. In all cases the fluid pattern will influence the local circulation affecting the overall lift. The purpose of this work is to study this influence. The instantaneous flow velocities inside and outside the vortices will be measured by means of a hot wire anemometry (HWA). The tested airfoil is a modified Eppler 387. The experiments were carried out in a low turbulence flow (1.8%) at a Reynolds number of 350.000 (based on the airfoil chord and on the free stream velocity).

Bollman, J. R.

"WAKE VORTEX ADVISORY SYSTEM OPERATIONAL TEST AND EVALUATION"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 335-341

The objectives of the operational test and evaluation of the Vortex Advisory System (VAS) are described. The critical issues on the operational test and evaluation of VAS may be simplified as: what are the procedural implications of the system and how will operating efficiency of the airport facilities be affected?

Boluriaan, S. and Morris, P. J.

"TWO-DIMENSIONAL SIMULATIONS OF WAKE VORTEX DETECTION USING RASS"

AIAA Paper 2001-0984, January 2001, Reno, NV.

A parallel code is developed to numerically simulate wake vortex detection using a Radio Acoustic Sounding System (RASS). The code is written in Fortran 90 with the Message Passing Interface (MPI) for parallel implementation. The numerical simulation solves simultaneously the linearized Euler equations for a non-uniform mean flow and the Maxwell equations for a non-homogeneous medium. The radar transmitter and receiver antennas are modeled using an array of point sources and a beamforming technique, respectively. Many features of the RASS are explored using the numerical simulation. First, a

uniform mean flow is considered and the RASS simulation is performed for two different types of incident acoustic field: a short single frequency acoustic pulse and a continuous broadband acoustic source. Both monostatic and bistatic configurations are examined and their results are compared. Taylor and Oseen vortex velocity profiles are used as a vortex model, and the mean flow fields are reconstructed from the backscattered electromagnetic signal using the Abel transform. The effect of radar beam width is also shown.

Boluriaan, S. and Morris, P. J.

"TWO-DIMENSIONAL SIMULATIONS OF WAKE VORTEX DETECTION USING RADIO ACOUSTIC SOUNDING SYSTEMS"

AIAA Journal, Vol. 40, No. 11, November 2002, pp. 2247-2256

A parallel code is developed to simulate numerically wake vortex detection using a radio acoustic sounding system (RASS). The code is written in FORTRAN 90 with the message passing interface for parallel implementation. The numerical simulation solves simultaneously the linearized Euler equations for a nonuniform mean flow and the Maxwell equations for a nonhomogeneous medium. The radar transmitter and receiver antennas are modeled using an array of point sources and a beam-forming technique, respectively. Many features of the RASS are explored using the numerical simulation. First, a uniform mean flow is considered, and the RASS simulation is performed for two different types of incident acoustic field: a short single-frequency acoustic pulse and a continuous broadband acoustic source. Both monostatic and bistatic configurations are examined, and their results are compared. Taylor and Oseen vortex velocity profiles are used as sample models, and their mean flowfields are reconstructed from the backscattered electromagnetic signal using the Abel transform. The effect of radar beam width is also considered, as are the issues of non-axisymmetric and interacting vortices.

"NUMERICAL SIMULATION OF WAKE VORTEX DETECTION USING A RADIO ACOUSTIC SOUNDING SYSTEM"

AIAA Journal, Vol. 39, No. 6, June 2001, pp. 1097-1105

A parallel, two-dimensional Euler, one-dimensional, Maxwell code is developed to numerically simulate wake vortex detection using a radio acoustic sounding system. The code is written in Fortran 90 with the message passing interface for parallel implementation. The main difficulty with a time-accurate simulation is the number of samples required to resolve the Doppler shift in the scattered electromagnetic signal. Even for a one-dimensional simulation with typical scatterer size, the CPU time required to run the code is far beyond currently available computer resources. Two alternatives that overcome this problem are described. In the first, the code is run for a fictitious speed of light. Second, the governing differential equations are recast to remove the carrier frequency and solve only for the frequency shift using an implicit scheme with large time steps. The numerical stability characteristics of

the resulting discretized equation with complex coefficients are shown. The code is run for both the approaches with Taylor and Oseen vortex velocity profiles. Finally, the Abel transform is applied to the outputs of both explicit and implicit schemes, and the wake vortex velocity field is retrieved with very good accuracy.

"TWO-DIMENSIONAL SIMULATIONS OF WAKE VORTEX DETECTION USING RASS"

AIAA Journal, Vol. 39, No. 6, 2001, pp. 1097-1105

A parallel code is developed to numerically simulate wake vortex detection using a Radio Acoustic Sounding System (RASS). The code is written in Fortran 90 with the Message Passing Interface (MPI) for parallel implementation. The numerical simulation solves simultaneously the linearized Euler equations for a non-uniform mean flow and the Maxwell equations for a non-homogeneous medium. The radar transmitter and receiver antennas are modeled using an array of point sources and a beamforming technique, respectively. Many features of the RASS are explored using the numerical simulation. First, a uniform mean flow is considered and the RASS simulation is performed for two different types of incident acoustic field: a short single frequency acoustic pulse and a continuous broadband acoustic source. Both monostatic and bistatic configurations are examined and their results are compared. Taylor and Oseen vortex velocity profiles are used as a vortex model, and the mean flow fields are reconstructed from the backscattered electromagnetic signal using the Abel transform. The effect of radar beam width is also shown.

"IMPACT OF BUOYANCY ON VORTEX RING DEVELOPMENT IN THE NEAR FIELD"

Exp. Fluids, Vol. 48, 2010, pp. 737-745.

The development of a buoyant vortex ring in the near field was examined experimentally, and the findings were compared with those of a non-buoyant ring with a similar Reynolds number. The experiments were performed in a water tank, and the vortices were produced by a cylindrical tube of aspect ratio 2. Laser sheet flow visualization and PIV measurements were carried out. In the near field, the initial column of the buoyant fluid breaks down due to the presence of Rayleigh-Taylor instability at the buoyant fluid interface. Subsequently, a large diameter vortex ring with a large spreading rate, compared with the non-buoyant ring, emerges. The celerity of buoyant vortex continued to decrease throughout the range examined, in contrast to the constant celerity of the non-buoyant ring. The vorticity in the core of buoyant and non-buoyant vortex rings is symmetric and has a Gaussian distribution. However, the buoyant vortex ring evolves into a thin core ring, whereas the non-buoyant ring becomes a thick core ring shortly after the ring formation. This difference is brought on by the rapid entrainment and the significant growth of the buoyant ring following the breakup of the initial formation.

"PAIRED APPROACH OPERATIONAL CONCEPT"

IEEE Digital Avionics Systems Conference, Vol. 1, October 2001, pp. 5B3-1-5B3-14

The paired approach procedure is intended to facilitate IFR approaches to closely spaced parallel runways i.e., runways separated by less than 2500 feet. Parallel ILS approaches cannot currently be conducted under instrument meteorological conditions to such runways. The paired approach procedure requires aircraft to maintain longitudinal separations within a specific band on approach to the runways such that protection is provided against collision as well as wake vortex hazards. The procedure requires air traffic control to pair eligible aircraft and deliver them to the final approach courses within certain longitudinal tolerances. The flight crew of the trailing aircraft then conducts the paired approach procedure with a set of cockpit-based spacing tools. These spacing tools help the flight crew to achieve and maintain a defined longitudinal spacing prior to the final approach fix. Real time simulations were conducted with line pilots and full performance level controllers in a medium fidelity simulation. The simulation capability included a commercial twin jet flight deck and an ATC platform, which in turn, were used to define flight deck tasks, develop cockpit display and spacing tool requirements, and define ATC procedures and controller tasks. This paper describes these ATC procedures, pilot and controller tasks and cockpit display requirements. It also discusses ways in which the spacing concept and tools so developed are being applied and developed further for other approach spacing applications.

"TRACKING AND CHARACTERIZATION OF AIRCRAFT WAKES USING ACOUSTIC AND LIDAR MEASUREMENTS"

AIAA-2005-2964, Monterey, CA, May 2005

Data from the 2003 Denver International Airport Wake Acoustics Test are further examined to discern spectral content of aircraft wake signatures, and to compare three-dimensional wake tracking from acoustic data to wake tracking data obtained through use of continuous wave and pulsed lidar. Wake tracking data derived from acoustic array data agree well with both continuous wave and pulsed lidar in the horizontal plane, but less well with pulsed lidar in the vertical direction. Results from this study show that the spectral distribution of acoustic energy in a wake signature varies greatly with aircraft type.

"ANALYSIS AND OPTIMISATION OF PULSED DOPPLER LIDAR WIND PROFILE MEASUREMENT PROCESS IN COMPLEX TERRAIN"

Proceedings 15th Coherent Laser Radar Conference, June 2009, Toulouse, France, pp. 117-120.

Accuracy of Lidar remote sensors for wind energy has been previously reported. Coherent Doppler lidars have shown very high correlation with calibrated cup anemometers in flat terrain, both onshore and offshore. However, in more complex terrain, not only more turbulent air flow but also loss of flow homogeneity happens, and remote sensors measurement process need to be closely examined. We compare and simulate cup's point and lidar's volume measurements to understand and explain for the two sensor's response. We put in evidence the main error term in the horizontal and vertical wind speed retrieval. Geometrical optimizations of the WINDCUBE (TM) measurement process are also investigated to get more reliable wind speed estimate. We show our conclusions and the results of the CFD simulation performed on a Spanish complex terrain case.

"SAFETY ASSESSMENT OF IMPLEMENTED NEXTGEN OPERATIONAL IMPROVEMENTS"

Transportation Research Procedia, Vol. 14, 2016, pp. 3731-3740.

Since most NextGen Operational Improvements (OIs) have been implemented recently, there is no traditional safety statistics, such as the number of accidents and/or incidents available to perform their formal safety evaluations. In this paper we present a process of safety assessment using precursors that may lead to unsafe outcomes. We use the radar track data to estimate traffic separations before and after NextGen OI implementation at Memphis International Airport (MEM). The FAA implemented Phase I of wake re-categorization (RECAT) separation standards at MEM in November 2012. We examine the counts of wake, proximity, and anomalous events for two 30-day samples of pre- and post-RECAT periods. While the paper focuses on the methodology and is not intended to provide a detailed

safety evaluation of RECAT, the findings suggest that RECAT implementation did not adversely affect the air traffic safety.

"FORMATION AIRDROP SCALING EFFECTS ON AIRCRAFT WAKE VORTEX FORMATION AND INTERACTION"

AIAA Paper 2013-0361, January 2013, Grapevine, TX.

A parametric model for location and strength of aircraft wake vortices is used to determine the potential for hazardous wake vortex/personnel interaction for different operational, environmental, and formation geometry parameters across two scaling studies. In the first study, 729 variations of a four-aircraft formation resulted in 39 geometries with potential for adverse jumper-wake vortex interactions. A second six-aircraft study, with finer variations in element-to-element spacing, indicated adverse interactions in 575 of the 1,224 variations considered. In both experiments, the formations with adverse interactions included nontrivial yet predictable combinations of lateral and longitudinal spacing, airspeed, and crosswind, with a noticeable lack of sensitivity to aircraft weight. These results can lead to more flexible formation airdrop planning guidelines by identifying the combinations of conditions that lead to adverse wake vortex encounters.

Borough, C. K.

"ELECTRO-OPTICAL VORTEX STUDIES FOR LARGE AIRCRAFT"

TR 1976, January 1976, Naval Electronics Lab. Center, San Diego, CA

Several promising approaches to the wake vortex problem have been recommended by electro-optical industries. Most of them recommend taking advantage of the concentration of CO₂ in the 14-to-16-micron region.

Borovoy, V. Y.

"FLOW PATTERNS AND HEAT EXCHANGE IN SUPERSONIC VORTEX"

SPC-93-4045, 1994, Central Aerohydrodynamics Institute, Moscow, Russia.

In many cases vortices are being generated on the aircraft surface: on the upper wing and body surfaces, in the vicinity of the deflected fins. They can essentially influence pressure distribution and heat transfer. The vortex generated on the upper surface of a body or a wing can encounter the shock wave in front of the fin, located downstream. Another example is: interaction of the vortex, generated by a canard, a strake or a nose flap intended for aircraft trimming with the wing or fin shock wave. A case important for practical purposes is described in: interaction between the vortex and inlet shock waves qualitatively changes the inlet entry flow pattern. A similar phenomenon can be observed in the case of interaction of the vortex generated in the inlet with the pylon of the air-breathing jet

combustion chamber. In this context, it is worthwhile to investigate the vortex structure and its interaction with the streamlined body.

"NONLINEAR MODELS FOR REPRESENTING AERODYNAMIC COEFFICIENTS OF A WING IN GROUND EFFECT"

AIAA Paper 2018-1759, January 2018, Kissimmee, FL.

The aim of the present work is to develop a model for representing lift, drag, and pitching moment coefficients of a wing and/or flight vehicle in ground effect when the height is a function of time. By assuming that the airplane is a rigid-body, the altitude variations are sufficiently small that the flow density, the kinematic viscosity, and the dynamic pressure remain constant, and by including the non-dimensional height into the aircraft states, it was possible to obtain a general longitudinal aerodynamic model of an airplane in ground effect. In this model, the non-dimensional stability derivatives are functions of the non-dimensional height, and the nonlinear effects in ground effect are represented by a group of terms, which are equal to zero in steady flight close to ground. Three cases are considered to represent the nonlinear effects that occur in a dynamic ground effect phenomenon: 1) They can be represented by the h derivative, 2) the h derivatives are also functions of the angle of attack, and 3) there is an additional term to represent the unsteady flow effects. It is concluded that the non-dimensional h derivatives are linked to a specific history of the flight path or trajectory due to the flow downstream.

"DYNAMIC GROUND EFFECT ON THE AERODYNAMIC COEFFICIENTS USING A PANEL METHOD"

Journal of Aircraft, Vol. 54, No. 2, March-April 2017, pp. 835-841.

The ground proximity of a wing in flight produces changes in its aerodynamics characteristics; the induced drag is reduced and the lift is increased. The most significant findings of this study can be summarized as follows: (1) The sink rate produces significant variations in lift, induced drag, and

pitching moment coefficients of a wing and this must be considered in flight simulation and flight control system design in ground effect. (2) Nonlinear models of a wing in dynamic ground effect were developed to model flare and descent at constant sink rate, meaning that each maneuver needs a specific model.

"FEATURES OF AIRPLANE VORTEX WAKE DECAY IN CRUISE FLIGHT AND IN LAND PROXIMITY"

International Conference on the Methods of Aerophysical Research (ICMAR 2016), AIP Conference Proceedings, Vol. 1770, 2016, pp. 030122-1 to 030122-9.

The cases of the vortex wake decay after the large aircraft are considered for the case of cruise flight and near the ground. It is shown that the scenarios of destruction process are principally different from each other. The physical features of the phenomenon are described and the two models for description of such phenomenon are compared.

Bossel, H. H.

"VORTEX EQUATIONS: SINGULARITIES, NUMERICAL SOLUTION, AND AXISYMMETRIC VORTEX BREAKDOWN"

NASA CR-2090, July 1972, University of California, Santa Barbara.

A method of weighted residuals for the computation of rotationally symmetric quasi-cylindrical viscous incompressible vortex flow is presented and used to compute a wide variety of vortex flows. The method approximates the axial velocity and circulation profiles by series of exponentials having $(N + 1)$ and N free parameters, respectively. Formal integration results in a set of $(2N + 1)$ ordinary differential equations for the free parameters. The governing equations are shown to have an infinite number of discrete singularities corresponding to critical values of the swirl parameter. The computations point to the controlling influence of the inner core flow on vortex behavior. They also confirm the existence of two critical swirl parameter values: one separates vortex flow which decays smoothly from vortex flow which eventually breaks down, and the second is the first singularity of the quasi-cylindrical system, at which point physical vortex breakdown is thought to occur.

Bossel, H. H.

"INVISCID AND VISCOUS MODELS OF THE VORTEX BREAKDOWN PHENOMENON"

Ph.D. Thesis, Report No. A.S. 67-14, August 1967, University of California, Berkeley, CA

In the case of high swirl and large Reynolds number, the Navier-Stokes equations for rotationally symmetric incompressible flow are shown to reduce to (1) a viscous parabolic system for slender (quasi-cylindrical) flows and (2) an inviscid elliptic system for expanding (or contracting) flows. The inviscid system is solved for the case of flow with initial rigid rotation in a cylindrical stream surface.

Assuming different downstream boundary conditions, Fourier-Bessel series solutions are computed for the supercritical (non-oscillatory) case and plotted. For very high swirl values, closed and open bubbles of recirculating fluid are obtained for certain cases, where the closed bubbles resemble those observed in vortex tube experiments. The viscous slender problem is formulated in an integral method using approximating functions for axial velocity and circulation which satisfy boundary and asymptotic requirements. Weighting functions are used to generate a linearly independent set of equations of sufficient number to determine the coefficients in the velocity and circulation approximations as functions of one (the axial) coordinate. The formulation is for any order of approximation. Computational difficulties appear near the suspected breakdown point. Flows resembling breaking flows are obtained.

Bossel, H. H.

"VORTEX BREAKDOWN FLOWFIELD"

Phys. Fluids, Vol. 12, No. 3, March 1969, pp. 498-507

The Navier-Stokes equations for incompressible rotationally symmetric vortex flow at high swirl and large core Reynolds number are shown to approximate to the equation of inviscid rotating flow in regions where rigid rotation results from viscous action. Series solutions at high supercritical swirl values near the critical one under the condition of flow retardation near the axis are found to exhibit the experimentally observed features of vortex breakdown flows: bulges of decelerated flow, or bubbles of recirculating fluid, with reversed axial and swirl velocities near the axis. It is concluded that the vortex breakdown in vortex tubes and on delta wings is neither due to hydrodynamic instability, nor is it a phenomenon akin to the hydraulic jump. Rather it is a regular feature of the solution of the equations of motion under the given conditions.

Boswinkle, Jr., R. W.

"AIRCRAFT VORTEX WAKES"

Proceedings of Annual Corporate Aircraft Safety Seminar, Flight Safety Foundation, May 1970

An aircraft which is producing lift leaves a rotating flow field behind each wing as it flies forward. There is usually one pair of oppositely rotating flow fields, or vortices, extending downstream from each wing tip and moving downward. Each vortex has a core region in which the rotational velocities build up from zero in the center to some maximum velocity at the edge of the core. If another aircraft crosses laterally through the core of each vortex, it will be subjected to an up-flow, a down-flow, and then another up-flow. Hazards connected with these air motions for a light aircraft are discussed.

Boswinkle, Jr., R. W.

"VORTEX WAKE TURBULENCE"

Flight Safety Foundation 23rd International Air Safety Seminar, Washington, DC, 1970

The talk highlighted the status of the vortex wake problem from the aircraft operator's standpoint. The vortex wake is described, accident statistics discussed, status of knowledge of vortex wake turbulence indicated, and example results of some measurements presented.

Bottausci, F. and Petitjeans, P.

"VISUALIZATIONS OF STRETCHED VORTICES"

Lecture Notes in Physics, Vol. 555, 2000, pp. 124-134

We study the structure, dynamics, and the instabilities of a stretched vortex in two different experiments: The first experiment generates a vortex by stretching the vorticity of a laminar boundary layer on a plane wall in a water channel. The second experiment generates a vortex between two co-rotating discs with a suction through a hole in the center of each disc. These vortices model the filaments of vorticity of turbulent flow. Visualizations are presented which show the structure and the instabilities of these stretched vortices.

"EFFECT OF AN EXTERNAL VORTEX ON THE UAV AERODYNAMIC PERFORMANCES"

EPJ Web of Conferences, Vol. 25, 2012, pp. 01104-1 to 01104-6.

In this present work, the CFD and wind tunnel are used to investigate the effect of an external vortex around an UAV to obtain initial estimates of lift and drag coefficients with flow velocity of 30 meters per second for various angles of attack. The model of Spalart-Allmaras turbulence is used for the investigation of the complex flow around the UAV. The wind tunnel and CFD results are compared and appropriate error bands placed on the data.

Boulanger, N., Meunier, P. and Le Dizes, S.

"TILT-INDUCED INSTABILITY OF A STRATIFIED VORTEX"

J. Fluid Mech., Vol. 596, 2008, pp. 1-20

This experimental and theoretical study considers the dynamics and the instability of a Lamb-Oseen vortex in a stably stratified fluid. In a companion paper, it was shown that tilting the vortex axis with respect to the direction of stratification induces the formation of a rim of strong axial flow near a critical radius when the Froude number of the vortex is larger than one. Here, we demonstrate that this tilt-induced flow is responsible for a three-dimensional instability. We show that the instability results from a shear instability of the basic axial flow in the critical-layer region. The theoretical predictions for the wavelength and the growth rate obtained by a local stability analysis of the theoretical critical-layer profile are compared to experimental measurements and a good agreement is

observed. The late stages of the instability are also analyzed experimentally. In particular, we show that the tilt-induced instability does not lead to the destruction of the vortex, but to a sudden decrease of its Froude number, through the turbulent diffusion of its core size, when the initial Froude number is close to 1. A movie is available with the online version of the paper.

Boulanger, N., Meunier, P. and Le Dizes, S.

"STRUCTURE OF A STRATIFIED TILTED VORTEX"

J. Fluid Mech., Vol. 583, 2007, pp. 443-458

The structure of a columnar vortex in a stably stratified fluid is studied experimentally and theoretically when the vortex axis is slightly tilted with respect to the direction of stratification. When the Froude number of the vortex is larger than 1, we show that tilting induces strong density variations and an intense axial flow in a rim around the vortex. We demonstrate that these characteristics can be associated with a critical-point singularity of the correction of azimuthal wavenumber $m=1$ generated by tilting where the angular velocity of the vortex equals the Brunt-Vaisala frequency of the stratified fluid. The theoretical structure obtained by smoothing this singularity using viscous effects (in a viscous critical-layer analysis) is compared to particle image velocimetry measurements of the axial velocity field and visualizations of the density field and a good agreement is demonstrated.

Bourdin, P., Gatto, A. and Friswell, M. I.

"AIRCRAFT CONTROL VIA VARIABLE CANT-ANGLE WINGLETS"

J. Aircraft, Vol. 45, No. 2, March-April 2008, pp. 414-423

This paper investigates a novel method for the control of 'morphing' aircraft. The concept consists of a pair of winglets with adjustable cant angle, independently actuated and mounted at the tips of a baseline flying wing. The general philosophy behind the concept was that for specific flight conditions such as a coordinated turn, the use of two control devices would be sufficient for adequate control. Computations with a vortex lattice model and subsequent wind-tunnel tests demonstrate the viability of the concept, with individual and/or dual winglet deflection producing multi-axis coupled control moments. Comparisons between the experimental and computational results showed reasonable to good agreement, with the major discrepancies thought to be due to wind-tunnel model aeroelastic effects.

"VORTICITY AND STRAIN DYNAMICS FOR VORTEX RING MIXING PROCESS"

14th International Symposium on Applications of Laser Techniques to Fluid Mechanics, Lisbon, Portugal, July 2008

Mixing is of paramount importance in the chemical, petrochemical, and pharmaceutical industries, as almost half of their production lines involve mixing in stirred vessels, but further optimization of related processes is hampered by incomplete understanding of the fluid mechanics of mixing. Consequently, further investigations are necessary to obtain a better understanding of the different mixing mechanisms taking place at different spatial length scales to optimize chemical processes and reactor design. Due to the complexity of mixing reactor design, a fundamental flow, such as that associated with a vortex ring, has been selected to develop a reliable procedure to gain some improved understanding of mixing mechanisms by assessing the competitive actions of the strain rate tensor and vorticity vector.

Bourgeois, N., Choroba, P. and Winckelmans, G.

"CONDITIONAL REDUCTION OF ICAO WAKE TURBULENCE SEPARATION MINIMA ON FINAL APPROACH"

5th International Conference on Research in Air Transportation, May 2012, Berkeley, CA.

An intensive LIDAR measurement campaign of aircraft wake vortices (WV) in the landing phase has been carried out at London Heathrow Airport. The WV trajectory and circulation as well as wind intensities have been collected. The possibility of reducing current ICAO wake turbulence minimum separations in case of favorable wind conditions is assessed by comparing the wake vortex encounter (WVE) risk associated to calm conditions to the WVE risk in these propitious conditions. An original approach used to quantify the frequency and the severity of the potential WVE is presented. As some of the WV are stopped being tracked before they effectively become insignificant, it is also decided to fit and extrapolate each WV circulation evolution using a two-phase decay model. First, the computed severity-frequency curves provide generic results, and indicate that a 0.5 NM reduction is possible in case of 'pure' headwind equal to 9-10 knots and 'pure' crosswind equal to 7-8 knots. The potential local application of these conditional reductions is also evaluated at two European hubs, London Heathrow and Paris Charles de Gaulle. The resulting headwind and crosswind thresholds are very similar to those obtained for the generic analysis. Yet, in addition to this theoretical study, a complete safety assessment must be performed before such thresholds can be used operationally to reduce separation.

"EXPERIMENTAL EVALUATION OF THE EFFECT OF FLOW DEFLECTORS ON HELICOPTER ROTOR WAKE VORTICES"

18th Australasian Fluid Mechanics Conference, December 2012, Launceston, Australia.

Understanding the rotor wake flow characteristics of a helicopter is fundamental to the investigation of its aerodynamic characteristics. When operating close to the ground the rotor wake can reflect to create large, doughnut-shaped vortices around the helicopter. In certain environments these vortices can cause the formation of dust clouds, resulting in a phenomenon commonly referred to as brownout. This study seeks to assess the interactional aerodynamics between a small-scale rotor wake and a range of active and passive flow deflectors. Two sets of experimental results will be presented, the first a

smoke flow visualization which qualitatively assessed the potential of both passive and active deflectors to modify major wake structures. The second experiment used Particle Image Velocimetry to assess the effect of the active deflectors.

Bourne, K., Wahono, S. and Ooi, A.

"NUMERICAL INVESTIGATION OF VORTEX RING GROUND PLANE INTERACTIONS"

Journal of Fluids Engineering, Vol. 139, July 2017, pp. 071105-1 - 071105-10.

The interaction between multiple laminar thin vortex rings and solid surfaces was studied numerically to investigate flow patterns associated with near-wall flow structures. In this study, the vortex-wall interaction was used to investigate the tendency of the flow toward recirculatory behavior and to assess the near-wall flow conditions. The numerical model shows very good agreement with previous studies of single vortex rings for the case of orthogonal impact (angle of incidence, 0 deg) and oblique impact (20 deg). The study was conducted at Reynolds numbers 585 and 1170, based on the vortex ring radius and convection velocity. The case of two vortex rings was also investigated, with particular focus on the interaction of vortex structures post impact. Compared to the impact of a single ring with the wall, the interaction between two vortex rings and a solid surface resulted in a more highly energized boundary layer at the wall and merging of vortex structures. The azimuthal variation in the vortical structures yielded flow conditions at the wall likely to promote agitation of ground-based particles.

Boutier, A., Lefevre, F. and Micheli, F.

"ANALYSIS OF HELICOPTER BLADE VORTEX STRUCTURE BY LASER VELOCIMETRY"

Experiments in Fluids, Vol. 21, 1996, pp. 33-42

In descent flight, helicopter external noise is mainly generated by the Blade Vortex Interaction (BVI). To understand the dynamics of this phenomenon, the vortex must be characterized before its interaction with the blade, which means that its viscous core radius, its strength, and its distance to the blade have to be determined by non-intrusive measurement techniques. As part of the HART program (Higher Harmonic Control Aeroacoustic Rotor Test, jointly conducted by US Army, NASA, DLR, DNW and ONERA), a series of tests have been made in the German Dutch Wind Tunnel (DNW) on a helicopter rotor with 2 m long blades, rotating at 1040 rpm; several flight configurations, with an advance ratio of 0.15 and a shaft angle of 5.3 degrees, have been studied with different higher harmonic blade pitch angles superposed on the conventional one (corresponding to the baseline case). The flow on the retreating side has been analyzed with a specially designed 3D laser velocimeter, and, simultaneously, the blade tip attitude has been determined to get the blade-vortex miss distance, which is a crucial parameter in the noise reduction. A 3D laser velocimeter, in backscatter mode with a working distance of 5 m, was installed on a platform 9 m high, and flow seeding with submicron incense smoke was achieved in the settling chamber using a remotely controlled displacement device. Acquisition of instantaneous velocity vectors by an IFA 750 yielded mean velocity and turbulence maps across the

vortex as well as the vortex position, intensity, and viscous radius. The blade tip attitude (altitude, jitter, angle of incidence) was recorded by the TART method (Target Attitude in Real Time) which makes use of a CCD camera on which is formed the image of two retroreflecting targets attached to the blade tip and lighted by a flash lamp. In addition to the mean values of the aforementioned quantities, spectra of their fluctuations have been established up to 8 Hz.

Boutier, A., Lefevre, J. and Micheli, F.

"VORTEX INVESTIGATION ON A RETREATING HELICOPTER BLADE WITH 3D LASER VELOCIMETRY IN DNW"

8th International Symposium on Applications of Laser Techniques to Fluid Mechanics, Lisbon, Portugal, July 1996

As part of the HART program (Higher Harmonic Control Aeroacoustic Rotor Test), a series of tests have been made in the German Dutch Wind Tunnel on a helicopter rotor with 2 m long blades, rotating at 1040 rpm; several flight configurations, with an advance ratio of 0.15 and a shaft angle of 5.3 deg, have been studied with different higher harmonic blade pitch angles superposed on the conventional one. Helicopter external noise is mainly generated by the blade vortex interaction; therefore, the vortex must be characterized as to viscous core radius, strength, and distance to the blade by nonintrusive measurement techniques. The flow on the retreating side has been analyzed with a 3D laser velocimeter, and, simultaneously, the blade tip attitude has been determined to get the blade-vortex miss distance, which is a crucial parameter in noise reduction. The blade tip attitude (altitude, jitter, angle of incidence) was recorded via Target Attitude in Real Time, which makes use of a CCD camera on which is formed the image of two retroreflecting targets attached to the blade tip and lighted by a flash lamp. In addition to the mean values of the aforementioned quantities, spectra of their fluctuations have been established up to 8 Hz.

"UTILIZATION OF CFD IN THE AMERICAN AIRLINES FLIGHT 587 ACCIDENT INVESTIGATION"

AIAA Paper No. 2008-6905, Honolulu, HI, August 2008

On November 12, 2001, American Airlines flight 587, an Airbus Industrie A300-600, was destroyed when it crashed into the residential area of Belle Harbor, New York, shortly after takeoff from runway 31L at John F. Kennedy International Airport. The NTSB determined that the probable cause of the accident was the in-flight separation of the vertical stabilizer because of the loads beyond ultimate design that were created by the first officer's unnecessary and excessive rudder pedal inputs. During the investigation, it was determined that the airplane had encountered wake turbulence from a Boeing 747 at the time the first officer made his rudder pedal inputs. This paper describes an overview of how the airplane motion and aerodynamic loads on the vertical tail during the accident sequence were determined from the Flight Data Recorder and the aerodynamic properties of the vertical stabilizer and rudder were computed using Computational Fluid Dynamics.

Boyd, E. A. and Kusmarwanto, I.

"GROUND EFFECT ON A ROTOR WAKE"

Report 8323, August 1983, Cranfield Institute of Technology, Cranfield, Bedford, UK.

This paper reports an experimental study of the ground effect on a rotor wake when the rotor is operating at a height of less than one rotor diameter above the ground. Particular attention was paid to how the rotor slipstream reacts to the oncoming wind and to the ground vortex generated when the wake eventually strikes the ground. The rotor wake was visualized by smoke, the ground vortex by a tuft grid and smoke and the ground interaction boundary by a surface flow visualization. An attempt was made to measure the strength of the ground vortex using pitot and static tubes fine enough to cause little disturbance to the vortex field. Details are given of a new rig planned to extend the reported measurements.

Bradley, R. G. and Wray, W. O.

"A CONCEPTUAL STUDY OF LEADING-EDGE-VORTEX ENHANCEMENT BY BLOWING"

Journal of Aircraft, Vol. 11, No. 1, January 1974, pp. 33-38

A conceptual wind-tunnel-test program has been conducted to verify that blowing a stream of high-pressure air over a swept-wing surface in a direction roughly parallel to the leading edge enhances the vortex system. The blowing is shown to intensify the leading-edge vortex and thus delay the deleterious effects of vortex breakdown to higher angle of attack. As a result, the vortex-lift is significantly increased and, as the blowing rate is increased, appears to approach the value predicted by the Polhamus suction-analogy for thin wings.

Bradley, S.

"A SIMPLE MODEL FOR CORRECTING SODAR AND LIDAR ERRORS IN COMPLEX TERRAIN"

Journal of Atmospheric and Oceanic Technology, Vol. 29, December 2012, pp. 1717-1722.

Ground-based sensing of wind profiles by sodars and lidars is becoming the standard for wind energy and other applications. However, there remain difficulties in complex terrain since the instruments sense wind components in spatially separated volumes, and systematic spatial variations of the wind components can lead to systematic bias in wind estimates. The errors are typically less than 6 percent, so corrections do not need to be very sophisticated. Analytic potential flow models are developed for the flow over a bell-shaped hill and over an escarpment. These models are then used to find the radial Doppler shift from sampling volumes in typical sodar and lidar beam geometries, thereby allowing spatial variation bias to be removed. Since the models are straightforward, bias removal is readily achieved, and lends itself to an understanding of the significant parameters affecting wind errors. The bell model is tested against field data from sodars and lidars in both moderately complex and in very

complex terrain. It is found that corrected winds are to within approximately 1 percent of those measured by mast instruments. Much more complex models do not correct wind errors better than these simple models.

Bradley, S. and Mikkelsen, T.

"A REVIEW OF SODAR ACCURACY"

16th International Symposium for the Advancement of Boundary-Layer Remote Sensing, ISARS 2012, June 2012, Boulder, CO.

What accuracy and reliability can today be expected from SODAR wind measurements? Is there traceable evidence for performance? Environmental factors, turbulent fluctuations, and non-uniform terrain all affect the wind speed uncertainty. So, site-to-site variations for SODAR-mast comparisons can be large. On a uniform terrain site, differences between a SODAR and a mast-mounted cup anemometer will arise due to turbulent fluctuations and wind components being measured in different spaces, as well as to variable background noise. We develop theories for turbulence-related random fluctuations due to finite sampling rates and to sampling from spatially distributed volumes. Effects can be minimized by selecting the environment and selectively filtering the data for periods of low fluctuations. But there is still real difficulty in answering the question: How good is a SODAR? Most field use, away from an idealized test environment, appears to produce SODAR-mast rms differences greater than the 0.1 m/s or less typically quoted by SODAR manufacturers. However, in these real environments it is likely that much of the difference arises from the mast sensors and the SODAR measuring in different spaces. We show some field results which reinforce this view. Both the turbulence-related random fluctuations and systematic errors in complex terrain (where systematic wind shears arise) can potentially be removed by use of a vertical column geometry. Field results from a new bistatic receiver shed some light on the differences between such 'common volume' sampling and the usual monostatic sampling.

Bradley, S. G.

"VALIDATION OF SODAR REAL-TIME SENSING AND VISUALISATION OF WAKE VORTICES"

Proceedings of the Twelfth Conference on Aviation Range and Aerospace Meteorology, American Meteorological Society, Atlanta, Georgia, Feb. 2006

We have described the main sources of noise leading to uncertainties in SODAR wind speed estimates. The most common and persistent of these is background acoustic noise. Based on a robust method for estimation of the position of the spectral peak in the SODAR Doppler spectrum, we simulate noisy spectra typical of SODAR data which might arise from observations of aircraft vortices. This field of noisy vertical velocity estimates is used as the input to the inversion method described by Bradley et al. (2006a). The resulting error estimates for the vortex position and strength are shown to depend systematically on SODAR SNR, and on the SODAR array configuration (spacing and number of

SODARs as well as range-gate size). The outcome provides recommendations as to optimized design of a SODAR array for characterization of aircraft vortices.

Bradley, S. G., von Hunerbein, S. and Underwood, K.

"OPERATIONAL RELIABILITY AND ACCURACY OF SODARS IN WING VORTEX CHARACTERIZATION"

Proceedings of the Twelfth Conference on Aviation Range and Aerospace Meteorology, American Meteorological Society, Atlanta, Georgia, Feb. 2006

We have evaluated the common causes of data loss in SODARs: low back-scatter; rainfall; and high background acoustic noise. Contrary to intuition, high background acoustic noise is not expected to be particularly problematic at airports. This finding is supported by measurement experience at many airports. Low back-scatter, due to low thermal or refractive index contrast, has been found to be a major cause of data loss in other field experiments, particularly at elevated heights. However, the vortex situation is rather different in three aspects: 1) most interest is in heights from 0-100 m, 2) airports are high thermal contrast sites, and 3) vortices provide mechanical mixing. These factors are expected to strongly increase data availability. Acoustic back-scatter from rainfall is expected to be the main cause of data loss.

"SODAR MEASUREMENTS OF WING VORTEX STRENGTH AND POSITION"

Journal of Atmospheric and Oceanic Technology, Vol. 24, Feb. 2007, pp. 141-155

A method is developed for robust real-time visualization of aircraft vortex spatial and temporal development based on measurement data from a line array of sodars. The method relies on using a potential-flow vortex model, with spatial averaging according to the along-beam and transverse spatial resolution of the sodar. The model comprises the wing vortex pair, together with two image vortices below ground such that there is no flow through the ground surface. An analytic solution for the temporal-spatial evolution of this four-vortex system is obtained as an aid to establishing relevant scales and performance criteria for any sodar. Field results from an array of four sodars are used on an individual profile basis (every 2 s of real time) to fit the model parameters of vortex circulation, position, and spacing. This method gives vortex trajectories and strength as a function of real time without dependence on assumptions regarding interactions with the atmosphere. Estimates of parameter uncertainties are also produced in real time, and it is found that estimates of position and spacing can be obtained to around plus or minus 4 m and of vortex circulation to plus or minus 50 meters squared per second. Recommendations are given for optimizing sodars for vortex measurement using practical technology.

Brailovskaia, I. I.

"FLOW IN THE NEAR WAKE"

Soviet Physics - Doklady, Vol. 16, Sept. 1971, pp. 197-199.

A numerical solution of Navier-Stokes equations for a compressible viscous gas is obtained in the near-wake region behind the perpendicular (to the flow surface) trailing face of a plate in supersonic flow. The velocity, density, temperature, and boundary layer parameters for the oncoming flow are known. The Navier-Stokes equations for the region of interest consist of two equations of motion, an energy equation, and a continuity equation. Pressure, density, and temperature are related by the equation of state. The viscosity and thermal conductivity coefficients are power functions of temperature. The boundary value problem for the region with specified boundary conditions was solved numerically by the finite difference method. The results for nine different cases of specified initial parameters are given graphically in the form of characteristic streamlines and pressure profiles.

Bramesfeld, G.

"A HIGHER ORDER VORTEX-LATTICE METHOD WITH A FORCE-FREE WAKE"

PhD Thesis, August 2006, The Pennsylvania State University, University Park, PA.

A higher-order, lifting surface method is presented that uses elements with distributed vorticity. Consequently, the newly developed method is highly accurate in force prediction and numerically extremely robust, even when using a relaxed wake model. The accurate prediction is accomplished using lower panel densities than other methods require. The numerical robustness is achieved without compromising the irrotationality assumption, unlike other potential flow methods do that use discrete vortices with solid core models in the wake. The distributed vorticity element of the newly developed method consists of a vortex sheet that holds streamwise vorticity that varies linearly over the element span. Transverse vorticity is concentrated in two vortex filaments that are located along the leading and trailing edge of the element. Their spanwise circulation distributions vary in a parabolic fashion. The circulations of the leading and trailing edge filaments are equal in magnitude, but opposite in orientations. By introducing additional singularities along the edges of the distributed vorticity elements, any extreme velocities associated with the edge singularities of the vortex sheets are removed. The velocity induced by a distributed vorticity element is determined with an analytical expression. One of several spanwise systems of distributed vorticity elements are used to model the lifting surface and the wake that is relaxed using a time-stepping method. There, the shed vorticity forms an essentially continuous vortex sheet. Thus, because of the elimination of point or line singularities, many of the numerical problems are avoided that are encountered with conventional vortex-lattice and panel methods. In addition, the continuous vorticity distribution across the lifting surface yields an accurate load prediction that is relatively insensitive to panel density changes on the lifting surface and in the wake. Consequently, significantly fewer singularity elements are needed to achieve accuracies comparable to other potential flow methods. The subsequent method is a relatively fast tool for determining the location of the free wake and its interaction with complex wing geometries, especially when accurate load predictions are required. The potential of the method is demonstrated with two sample applications. Especially in the case of the formation flight of two aircraft, the relaxed wake model yields performance results that differ to those that are obtained with a fixed wake model.

Bramesfeld, G. and Maughmer, M. D.

"EFFECTS OF WAKE ROLLUP ON FORMATION-FLIGHT AERODYNAMICS"

J. Aircraft, Vol. 45, No. 4, July-August 2008, pp. 1167-1173

The aerodynamic performance of two high aspect-ratio wings flying in formation is investigated with particular interest in the importance of considering wake rollup in making aerodynamic predictions. For this purpose, formations of various separations were investigated using a drag-free, fixed-wake model as well as a force-free, relaxed one. In all cases the aircraft were trimmed for roll and the follower aircraft pitch attitude was adjusted to match the lift coefficient of the lead aircraft. Both wake representations result in similar induced-drag minima for the follower aircraft which result when the lateral overlaps of the two aircraft are around 10 percent of a wingspan. Computations with the fixed-wake model, however, predict a wider region of lateral separations having the lowest induced drag than do the simulations with wake rollup. A small performance difference due to the model also exists when one aircraft follows directly behind the other. Independent of the wake model used, trimming the aircraft in roll and pitch can have a significant influence on their performance, although the required control-input solutions for trim are essentially not affected by the choice of wake representation.

Bramesfeld, G. and Maughmer, M. D.

"RELAXED-WAKE VORTEX-LATTICE METHOD USING DISTRIBUTED VORTICITY ELEMENTS"

J. Aircraft, Vol. 45, No. 2, March-April 2008, pp. 560-568

A lifting-surface method is presented that uses elements having distributed vorticity to model lifting surfaces and their shed wakes. Using such distributed vorticity elements allows the representation of a force-free continuous wake-vortex sheet that is free of numerical singularities and is thus robust in its numerical rollup behavior. Unlike other potential-flow methods that use discrete vortex filaments having solid-core models at their centers to avoid problems with the singularities, the numerical robustness of the new method is achieved without the subsequent solution being dependent on the choice of a cutoff distance or core size. The computed loads compare well with the results of classical theory and other potential-flow methods. Its numerical robustness, computational speed, and ability to predict loads depend strongly on the influence of the wake and its shape, as is the case for the two application examples presented: formation flight and rotating-wing systems.

Bramesfeld, G. and Maughmer, M. D.

"THE EFFECTS ON FORMATION-FLIGHT AERODYNAMICS DUE TO WAKE ROLLUP"

AIAA Paper No. 2007-729, Reno, NV, January 2007

A lifting-surface method is used to investigate the aerodynamic performance of two high aspect-ratio wings flying in formation. In particular, the influence of wake rollup is investigated. The relaxed-wake

cases have performance results that differ from those obtained with a fixed-wake model. In particular, the fixed-wake model predicts more optimistic results for the follower aircraft for formations having a lateral separation of 70- to 90-percent span, which are also the lateral formation spacings with the greatest performance gains for the trailing aircraft. For formations with streamwise separations of a half-span or more, the choice of wake model has very little influence on the changes resulting from the formation moving further apart in the streamwise direction. This reflects the fact that, in the case of the relaxed wake, most of the rollup of the lead-aircraft wake occurs within a short distance aft of its trailing edge and any further wake-roll-up has little effect. In contrast, the fixed wake model experiences no changes at all after being shed. Increasing lateral and vertical separations reduce the differences due to a fixed versus relaxed wake. For the investigation of the performance of the formation, both aircraft are trimmed in pitch and roll. To a limited degree, the control inputs required to trim the formation depend on whether the relaxed- or fixed wake model is used, especially when the performance of the trailing aircraft is at an optimum.

"RESULTS FROM LASER SHEET VISUALIZATION OF A PERIODIC ROTOR WAKE"

J. Aircraft, Vol. 26, No. 5, May 1989, pp. 438-443

A laser sheet has been applied to the visualization of a periodic rotor wake produced by a model rotorcraft in forward flight. A stiff, two-bladed teetering rotor is mounted independently of an idealized airframe consisting of an instrumented circular cylinder with a hemispherical nose. The model was installed in a wind tunnel, and tests were carried out at three different advance ratios (forward flight speeds) at one value of rotor collective pitch angle. The laser sheet technique enables detailed flow visualization to be carried out. Quantitative data regarding the location of the rotor tip vortex can be obtained. Results from the flow visualization confirm that the rotor wake is a complex flow field not amenable to simple analysis. However, the details of the tip vortex geometry are both periodic and repeatable. The motion of the rotor wake near the airframe is examined. The behavior of the tip vortex is strongly affected by the presence of the airframe. In particular, the interaction of the rotor tip vortex with the airframe results in the destruction of the vortex core; apparently the vorticity is diffused, and the vortex loses its definition. No vortex filaments appear below the airframe as identifiable flow features. Examples of airframe surface pressure data are presented and are seen to correlate well with the results from the flow visualization.

"APPLICATION OF WIND TUNNEL FREE-FLIGHT TECHNIQUE FOR WAKE VORTEX ENCOUNTERS"

NASA TP-3672, November 1997, Langley Research Center, Hampton, VA

A wind tunnel investigation was conducted in the Langley 30- by 60-Foot Tunnel to access the free-flight test technique as a tool in research on wake vortex encounters. A typical 17.5-percent scale business-class jet airplane model was flown behind a stationary wing mounted in the forward portion

of the wind tunnel test section. The span ratio (model span-generating wingspan) was 0.75. The wing angle of attack could be adjusted to produce a vortex of desired strength. The test airplane model was successfully flown in the vortex and through the vortex for a range of vortex strengths. Data obtained included the model airplane body axis accelerations, angular rates, attitudes, and control positions as a function of vortex strength and relative position. Pilot comments and video records were also recorded during the vortex encounters.

"THE PHYSICS OF VORTEX MERGER AND THE EFFECTS OF AMBIENT STABLE STRATIFICATION"

J. Fluid Mech., Vol. 592, 2007, pp. 413-446

The merging of a pair of symmetric, horizontally oriented vortices in unstratified and stably stratified viscous fluid is investigated. Two-dimensional numerical simulations are performed for a range of flow conditions. The merging process is resolved into four phases of development and key underlying physics are identified. In particular, the deformation of the vortices, explained in terms of the interaction of vorticity gradient, and rate of strain leads to a tilt in vorticity contours in the vicinity of the center of rotation (a hyperbolic point). In the diffusive/deformation phase, diffusion of the vortices establishes the interaction between the vorticity gradient and mutually induced rate of strain. During the convective/deformation phase, induced flow by filaments and, in stratified flow, baroclinically generated vorticity (BV), advects the vortices thereby modifying rate of strain, which, in general, may enhance or hinder the development of the tilt. The tilting and diffusion of vorticity near the center hyperbolic point causes vorticity from the core region to enter the exchange band where it is entrained. In the convective/entrainment phase, the vortex cores are thereby eroded and ultimately entrained into the exchange band, whose induced flow becomes dominant and transforms the flow into a single vortex. The critical aspect ratio, associated with the start of the convective/entrainment phase, is found to be the same for both the unstratified and stratified flows. In the final diffusive/axisymmetrization phase, the flow evolves towards axisymmetry by diffusion. In general, the effects of stratification depend on the ratio of the diffusive time scale (growth of cores) to the turnover time (establishment of BV), i.e. the Reynolds number. A crossover Reynolds number is found, above which convective merging is accelerated with respect to unstratified flow and below which it is delayed.

Brandt, L. K.

"NUMERICAL AND ANALYTICAL STUDIES OF TWO-DIMENSIONAL VORTEX PAIR DYNAMICS IN UNSTRATIFIED AND STRATIFIED ENVIRONMENTS"

PhD Thesis, 2009, University of California, San Diego, CA.

This work investigates fundamental two-dimensional vortex pair dynamics in unstratified and stably stratified environments through numerical and analytical techniques. The study focuses on two main topics: (i) vortex interaction and merging of co-rotating vortex pairs and (ii) internal wave generation by co-rotating and counter-rotating vortex pairs. Two-dimensional vortex merging in a viscous fluid is

studied using numerical simulations. Analysis of the ideal case of two equal co-rotating vortices (symmetric pair) identifies the basic underlying physics of vortex merger. Through the interaction of the vorticity gradient and the mutually induced strain rate near the central hyperbolic point, a tilt in vorticity contours is established. This leads to core detrainment and the entrainment of core fluid into the exchange band, which transforms the flow into a single vortex. In the case of the asymmetric (unequal strength) vortex pair, the disparity in the deformation rates between the vortices alters the interaction. A critical value for a strain rate parameter characterizing the establishment of core detrainment is determined. The onset of merging is associated with the achievement of the critical strain by both vortices and a generalized merging criterion is formulated. The generation of internal waves by horizontally oriented co-rotating and counter-rotating vortex pairs is studied. Linearized inviscid equations are derived that describe the internal wave, vorticity, and energy fields. These solutions are compared with nonlinear numerical viscous simulations in moderately and strongly stratified environments. Through evaluation of the energy field, the time at which the flow reaches a steady state for strongly stratified flows is found, along with a characterization of the regimes of strongly and moderately stratified environments.

Brandt, L. K. and Nomura, K. K.

"CHARACTERIZATION OF THE INTERACTION OF TWO UNEQUAL CO-ROTATING VORTICES"

Journal of Fluid Mechanics, Vol. 646, 2010, pp. 233-253.

The interactions and merging of two unequal co-rotating vortices in a viscous fluid are investigated. Two-dimensional numerical simulations of initially equal-sized vortices with differing relative strengths are performed. In the case of equal-strength vortices, i.e. symmetric vortex pairs, the mutually induced strain deforms and tilts the vortices, which leads to a core detrainment process. The weakened vortices are mutually entrained and rapidly move towards each other as they intertwine and destruct. The flow thereby develops into a single compound vortex. With unequal strengths, i.e. asymmetric pairs, the disparity of the vortices alters the interaction. Merger may result from reciprocal but unequal entrainment, which yields a compound vortex; however other outcomes are possible. The various interactions are classified based on the relative timing of core detrainment and core destruction of the vortices. Through scaling analysis and simulation results, a critical strain rate parameter which characterizes the establishment of core detrainment is identified and determined. The onset of merging is associated with the achievement of the critical strain rate by 'both' vortices, and a merging criterion is thereby developed. In the case of symmetric pairs, the critical strain rate parameter is shown to be related to the critical aspect ratio. In contrast with symmetric merger, which is in essence a flow transformation, asymmetric merger may result in the domination of the stronger vortex because of the unequal deformation rates. If the disparity of the vortex strengths is sufficiently large, the critical strain rate is not attained by the stronger vortex before destruction of the weaker vortex, and the vortices do not merge.

Brandt, L. K., Cichocki, T. K. and Nomura, K. K.

"ASYMMETRIC VORTEX MERGER: MECHANISM AND CRITERION"

Theoretical Computational Fluid Dynamics, Vol. 24, 2010, pp. 163-167.

The merging of two unequal co-rotating vortices in a viscous fluid is investigated. Two-dimensional numerical simulations of initially equal sized Lamb-Oseen vortices with differing relative strengths are performed. Results show how the disparity in deformation rates between the vortices alters the interaction. Key physical mechanisms associated with vortex merging are identified. A merging criterion is formulated in terms of the relative timing of core detrainment and destruction. A critical strain parameter is defined to characterize the establishment of core detrainment. This parameter is shown to be directly related to the critical aspect ratio in the case of symmetric merger.

Brandt, R.

"DRAG EVALUATION BY WAKE SURVEY"

Stagiaire Report 1988-31, September 1988, von Karman Institute for Fluid Dynamics, Waterloo, Belgium.

A computer program that calculates the drag of a body placed in a wind-tunnel is modified so the drag can be calculated by a single traverse plane downstream of the body. The results are compared with direct measurement of the forces by using an aerodynamic balance.

Brandt, S. A.

"VORTEX BURST MODEL FOR THE VORTEX LATTICE METHOD"

Journal of Aircraft, Vol. 32, No. 6, November-December 1995, pp. 1394-1396.

A model for leading-edge vortex bursting has been developed and used with the vortex lattice method to predict vortex bursting on highly swept wings. The model was derived from the steady, incompressible Navier-Stokes equations for the vortex core. The method was tested on four highly swept wing models. In all cases vortex burst predictions agreed well with the vortex burst locations observed in wind- and water-tunnel tests.

Brandt, S. A. and Iversen, J. D.

"MERGING OF AIRCRAFT TRAILING VORTICES"

Journal of Aircraft, Vol. 14, No. 12, December 1977, pp. 1212-1220

A merging distance criterion for equal-strength corotational vortices is derived from low-turbulence wind tunnel flow visualization data. The vortex separation distance is normalized by defining a vortex core diameter based on circulation defect and angular momentum defect. Merging may take place for larger separation distances than predicted from earlier two-dimensional inviscid calculations, which

indicates that viscosity and possibly three-dimensional effects are important factors in the merging phenomenon. Hot-wire velocity distributions and rolling moment measurements show that attenuation of the vortex hazard is associated with vortex merging.

"FLIGHT TEST TO DETERMINE FEASIBILITY OF A PROPOSED AIRBORNE WAKE VORTEX DETECTION CONCEPT"

NASA-TM-102672, DOT/FAA/CT-TN-90/25, April 1991, NASA Langley Research Center, Hampton, VA

An investigation was conducted jointly by the FAA and NASA to determine the radial extent of the circulatory flow field around the lift-induced vortex system of an aircraft in flight. This flow field, if found to be of sufficient strength and span to activate instrumentation onboard a following aircraft, may provide the basis for designing a feasible airborne wake detection and avoidance system. A small probe aircraft was flown behind a larger wake generator aircraft to measure the lateral separation distance at which the vortex could be detected using conventional instrumentation. This report discusses the results and mechanics of the flight test and proposes recommendations for future tests.

Brasefield, C. J.

"WINDS AND TEMPERATURES IN THE LOWER STRATOSPHERE"

Journal of Meteorology, Vol. 7, February 1950, pp. 66-69.

About twenty radiosonde flights to altitudes above 100,000 ft have been made from Belmar, New Jersey (latitude 40.2 degrees N) during the period July 1948 to April 1949, using a balloon whose nominal weight was 10,000 grams. The radiosonde and associated equipment were specially designed to accurately measure pressure, temperature, and winds to an altitude of 150,000 ft. It was found that the mean daytime temperature of the stratosphere is about -60C from 50,000 ft to 60,000 ft, above which the mean temperature rises at a rate of about 0.5C per 1000 ft to a temperature of about -30C at 120,000 ft. No abnormally high temperatures at high altitudes resulting, for example, from a solar flare, were detected in any of these flights.

Brashears, M. R. and Eberle, W. R.

"VERIFICATION OF WIND MEASUREMENT TO 450-METER ALTITUDE WITH MOBILE LASER DOPPLER SYSTEM"

FAA-RD-77-181, December 1977, Lockheed Missiles & Space Co., Huntsville, AL.

The Lockheed mobile atmospheric unit is a laser Doppler velocimeter system designed for the remote sensing of winds. The capability of the laser Doppler velocimeter accurately to measure winds to 150-meter altitude has been previously demonstrated. To assess the capability of the laser Doppler velocimeter to measure winds at higher altitudes, the system was tested adjacent to the 481-meter

instrumented WKY-TV television transmission tower at the National Severe Storms Laboratory test site near Norman, Oklahoma. Comparisons between the laser-measured winds and the anemometer-measured winds are presented. The sources of discrepancies between laser-measured and anemometer-measured wind are discussed.

Brashears, M. R. and Hallock, J. N.

"AIRCRAFT WAKE VORTEX TRANSPORT MODEL"

Journal of Aircraft, Vol. 11, No. 5, May 1974, pp. 265-272

A wake vortex transport model has been developed which includes the effects of wind and wind shear, buoyancy, mutual and self-induction, ground plane interaction, viscous decay, finite core and Crow instability effects. Photographic and ground-wind vortex tracks obtained from DC-6, B-747, B-707, and CV-880 aircraft flybys are compared with predicted vortex tracks computed using meteorological and aircraft data as inputs to the transport model. A parametric analysis of the effects of the aircraft, fluid mechanic, and meteorological parameters shows the relative magnitude of each transport mechanism. The study constitutes the first detailed comparison of vortex transport theory with experimental data.

Brashears, M. R. and Hallock, J. N.

"ANALYSIS OF PREDICTED AIRCRAFT WAKE VORTEX TRANSPORT AND COMPARISON WITH EXPERIMENT"

Journal of Aircraft, Vol. 12, No. 7, July 1975, pp. 619-620

An aircraft wake vortex transport model has been developed which combines fluid mechanic representations of the various vortex-induced and atmospheric effects. A series of flight tests was conducted to verify the model using B-747, B-707, CV-880 and DC-6 aircraft in which both the motion of the vortices and the attendant meteorological conditions were recorded. The differences between predicted and measured vortex tracks consistently fell within the computed uncertainty in the transport due to random fluctuations in the wind field.

Brashears, M. R. and Hallock, J. N.

"PREDICTIVE MOTION OF WAKE VORTICES"

Proceedings Int. Conf. on Future of Aircraft All-Weather Operations, Inst. Electrical Engineers, London, November 1976, pp. 42-45

Predictive models for the motion of wake vortices are considered as a contribution to vortex avoidance strategy. Four stages are envisaged in the construction of a predictive model: a mathematical model of vortex behavior based on aerodynamics and fluid mechanics; verifying the model against controlled flight test data; refining the model to account for deviations; verification of

the model under operational conditions. Each stage is discussed separately. A geometrical approach to vortex detrainment in an approach zone with wind velocity considered is sketched.

Brashears, M. R. and Hallock, J. N.

"THE MEASUREMENT OF WIND SHEAR AND WAKE VORTICES BY LASER VELOCIMETRY"

Proceedings 7th Conf. on Aerospace and Aeronautical Meteorology, AIAA/AMS, Melbourne, FL, November 1976, pp. 175-181

The Laser Doppler Velocimeter (LDV) discussed was developed to measure three-dimensional wind and corresponding wind shear at heights below 500 m, and the location and persistence of aircraft wake vortices in the terminal environment. In particular, the Vertical Azimuth Display mode of operation is shown to be an extremely accurate technique. The measurement accuracy of + or -0.5 m/sec in wind speed and + or - 2.5 deg in wind direction has been further improved by using least-squares techniques in data processing.

Brashears, M. R. and Hallock, J. N.

"A PREDICTIVE MODEL OF WAKE VORTEX TRANSPORT"

Proceedings of the Sixth Conference on Aerospace and Aeronautical Meteorology, American Meteorological Society, 1974, pp. 387-392

An aircraft wake vortex transport model has been developed which includes meteorological and fluid mechanic mechanisms. It has been applied to the prediction of the location of aircraft vortices relative to an approach corridor; comparisons of predicted tracks with measured vortex tracks show excellent agreement. The effects of wind shear and the Ekman spiral on vortex transport are discussed, and it is shown that the combination of wind shear and ground effect may be possible mechanisms underlying the tilting of vortices. The application of Pasquill class criteria is shown to be an effective technique to describe the wind profile in the absence of detailed wind data.

Brashears, M. R. and Zalay, A. D.

"LASER DOPPLER VELOCIMETER MEASUREMENTS OF B-747 WAKE VORTEX CHARACTERISTICS"

FAA-RD-77-85, September 1977, Lockheed Missiles & Space Company, Huntsville, AL

To determine the behavior of the wake vortices of a B-747 at low altitudes and to measure the vortex-decay process behind the B-747 as a function of altitude above ground, flap and spoiler settings, and different flight configurations, a B-747 aircraft flew 54 passes at low level over a ground-based laser Doppler velocimeter (LDV) system. From the LDV measurements, the location and flow field of the wake vortices and the general vortex roll-up, transport, and decay trends were obtained. Results of the study indicated that the deployment of spoilers and flaps enhanced the decay of the vortex peak tangential velocity in the near wake while aircraft altitude, glide slope, and landing gear deployment

had little effect. The report discusses the LDV wake vortex measurements including the instrumentation used, the experimental test sequence, the results of the wake measurements in terms of the vortex roll-up, transport, and decay trends, and a comparison of the wake vortex characteristics for different configurations.

Brashears, M. R., Hallock, J. N. and Logan, N. A.

"ANALYSIS OF PREDICTED AIRCRAFT WAKE VORTEX TRANSPORT AND COMPARISON WITH EXPERIMENT"

AIAA Paper No. 1974-0506, Palo Alto, CA, June 1974.

Predicted vortex tracks from a wake vortex transport model previously developed (including the effects of wind and wind shear, buoyancy, mutual and self-induction, ground plane interaction, viscous decay, and finite core and Crow instability effects) have been compared with vortex tracks obtained from B-747, B-707, CV-880 and DC-6 aircraft flybys. Excellent agreement was found between prediction and measurement when sufficient wind data were available. A detailed explanation of vortex tilting is given along with observations concerning the mechanism itself.

"MOBILE LASER DOPPLER SYSTEM CHECKOUT AND CALIBRATION"

FAA-RD-77-48, June 1977, Lockheed Missiles & Space Co., Huntsville, AL

A program has been carried out to make modifications to the Lockheed-Huntsville Mobile Laser Doppler Velocimeter (LDV) system; to calibrate and operate the system at the John F. Kennedy (JFK) Airport; to obtain a data base of wind, wind shear, and wake vortex measurements; and to assess the basic operational capabilities of the system based on these measurements. The basic operational capabilities, resolution, and integrity of a scanning LDV for the remote sensing of winds, wind shear, and wake vortices at terminal areas has been established.

"THE EFFECT OF WIND SHEAR AND GROUND PLANE ON AIRCRAFT WAKE VORTICES"

Journal of Aircraft, Vol. 12, No. 10, October 1975, pp. 830-833

A previous comparison of predicted wake vortex transport with experiment revealed two consistent sources of discrepancy, namely, lower predicted sink rates of the vortex pair relative to observed and a lagging of the predicted upwind vortex transport compared with the measured values. It was hypothesized that either a wake tilting or a decrease in circulation was occurring to account for this lagging. Accordingly, an analysis was performed to determine the streamlines associated with the presence of a vortex pair in a shear near the ground and the movement of the stagnation points in such a region. It was found that the upper and lower stagnation points rise or sink relative to their shearless location, depending upon the magnitude of non-dimensional parameters defining ground proximity and wind shear to circulation.

"ANALYSIS OF PREDICTED AIRCRAFT WAKE VORTEX TRANSPORT AND COMPARISON WITH EXPERIMENT"

FAA-RD-74-74.I and 74.II, April 1974, Lockheed Missiles & Space Company, Huntsville, AL

A unifying wake vortex transport model is developed and applied to a wake vortex predictive system concept. The fundamentals of vortex motion underlying the predictive model are discussed including vortex decay, bursting, and instability phenomena. A parametric and sensitivity analysis is presented to establish baseline uncertainties in the algorithm to allow meaningful comparison of predicted and measured vortex tracks. A detailed comparison of predicted vortex tracks with photographic and ground-wind vortex data is presented. Excellent agreement between prediction and measurement is shown to exist when sufficient wind data are available. Application of the Pasquill class criteria is shown to be an effective technique to describe the wind profile in the absence of detailed wind data. The effects of wind shear and the Ekman spiral on vortex transport are discussed. It is shown that the combination of wind shear and ground plane may be possible mechanisms underlying vortex tilting and a theoretical explanation is advanced that is somewhat supported by comparison with the experimental data. Finally, recommendations for further vortex data collection in the vicinity of an airport are presented.

"WAKE VORTEX TRANSPORT CONSIDERATIONS AND METEOROLOGICAL DATA ANALYSIS"

LMSC-HREC TR D390424, November 1974, Lockheed Missiles & Space Company, Huntsville, AL

Comparisons were made between predicted wake vortex motions and vortex tracks measured by propeller anemometers arrayed in baselines oriented perpendicularly to the aircraft flight path. The

effect of buoyancy in ground plane on the predicted vortex transport was described. Meteorological data processing computer routines were developed to provide a detailed atmospheric characterization.

"ANALYSIS OF WAKE VORTEX MEASUREMENTS"

LMSC-HREC TR D496558, September 1975, Lockheed Missiles & Space Company, Huntsville, AL

Wake vortex measurements obtained by DOT-TSC at John F. Kennedy (JFK) International Airport have been reduced, analyzed, and correlated with a theoretical vortex transport model. The predictive wake vortex transport model has been updated so that detailed on-site meteorological measurements can be interpreted and utilized to predict more accurately the vortex transport and decay characteristics. A discussion of the wake vortex test data analysis and software development is presented including a description of the JFK wake vortex test program, the computer processing of wake vortex measurements, the analysis of ground wind sensor measurements, and the analysis of meteorological measurements.

Brashears, M. R., Shrider, K. R., Love, D. A., Robertson, S. J. and Zalay, A. D.

"WAKE VORTEX AND GROUNDWIND METEOROLOGICAL MEASUREMENTS"

FAA-RD-76-93, May 1976, Lockheed Missiles & Space Company, Huntsville, AL

Wake vortex ground-wind and meteorological measurements obtained by DOT-TSC at John F. Kennedy (JFK) International Airport have been reduced, analyzed, and correlated with a theoretical vortex transport model. The predictive Wake Vortex Transport Model has been updated so that detailed on-site meteorological measurements can be interpreted and utilized to predict more accurately the vortex transport and decay characteristics. A discussion of the wake vortex test data analysis and software development is presented, including a description of the JFK wake vortex test program, the computer processing of wake vortex measurements, the analysis of ground wind sensor measurements, and the analysis of meteorological measurements.

"PREDICTED AND MEASURED WAKE VORTEX MOTION NEAR THE GROUND"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 316-325

Vortex track and meteorological measurements obtained by the Transportation Systems Center at Kennedy International Airport have been processed and cataloged in a computerized data management system. A total of 1320 flybys have been cataloged. A calculated vortex track using meteorological data measured concurrently with the measured vortex track has been generated and placed in the data management system for each flyby. An analysis of measured vortex parameters and corresponding

vortex parameters generated from the analytic model was performed. A comparison of calculated vortex residence time and measured vortex residence time is presented. The reasons for deviations between the calculated residence time and measured residence time are discussed. Design considerations for a wake vortex avoidance system are also discussed.

Brashears, M. R., Zalay, A. D., Chou, L. C. and Shrider, K. R.

"DEVELOPMENT OF PREDICTIVE WAKE VORTEX TRANSPORT MODEL FOR TERMINAL AREA WAKE VORTEX AVOIDANCE"

FAA-RD-76-94, May 1976, Lockheed Missiles & Space Company, Huntsville, AL

The wake vortex transport program has been expanded to include viscous effects and the influence of initial roll-up, atmospheric turbulence, and wind shear on the persistence and motion of wake vortices in terminal areas. Analysis of wake characteristics has shown that changes in the spanwise loading due to flaps increase the initial sink rate, decrease the separation, and initiates the circulation decay process earlier. Buoyancy due to jet exhaust entrainment and ambient stratification retards vortex spreading and increases descent. Atmospheric turbulence and shear promote a more rapid decay reducing the late-time descent and spread rates of vortices. Vortex tilting has been related to an interaction involving the wind shear, ground plane, and the vorticity detrainment process. Recognition of the effects of tilting, spanwise loading, vorticity detrainment, burst/sink instabilities, and atmospheric conditions has resulted in an analytic wake transport and decay model with increased accuracy and improved predictive capabilities.

"LASER DOPPLER FLIGHT TEST MEASUREMENTS OF B-747 WAKE VORTEX CHARACTERISTICS"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 106-113

In order to determine the behavior of aircraft wake vortices at low altitudes and to measure the wake vortex decay process behind a wide-body transport aircraft as a function of altitude above ground, flap and spoiler settings, and different flight configurations; a B-747 aircraft flew 54 passes at low level over a ground-based laser-Doppler velocimeter (LDV) system. From the LDV measurements, the location and velocity distribution of the wake vortices and the general vortex roll-up, transport, and decay trends were obtained. Results of the study indicated that the deployment of spoilers and flaps enhanced the decay of the vortex peak tangential velocity in the near wake while aircraft altitude, flight path angle, and landing gear deployment had little effect. The paper discusses the LDV wake vortex measurements including the instrumentation used, the experimental test sequence, and the results of the wake measurements in terms of the vortex rollup, transport and decay trends. A comparison of the wake vortex characteristics for different aircraft configurations is also presented.

"PREDICTION OF THE VORTICITY FIELD PRODUCED BY AIR-JET VORTEX GENERATORS"

ICAS Paper 98-2.8.2, Sept. 1998, Melbourne, Australia.

A parametric study of the vorticity profiles of air-jet vortex generators has been carried out, and an empirical model which allows the prediction of the vorticity field downstream of the air-jet vortex generators has been derived. Measurements were carried out in two studies: a low speed and a high-speed test. The low-speed test was at a free-stream velocity of 20 m/s ($M = 0.588$), while the high-speed test was at Mach numbers of 0.5, 0.6, 0.75. Both tests used a miniature 5-hole pressure probe traversed in a plane normal to the free-stream, downstream of the vortex generators. The experimental data has been used to produce a series of relationships which allow the prediction of vorticity from vortex generators with the aim of simplifying numerical simulations of a flow field incorporating such devices.

"SPATIAL STABILITY ANALYSIS OF A FLAP SIDE EDGE VORTEX"

Computational Aeroacoustics: From Acoustic Sources Modeling to Far-Field Radiated Noise Prediction
Colloquium EUROMECH 449, December 9-12, 2003, Chamonix, France

The flap side edge vortex is suspected to contribute to aerodynamic noise generation. Using a temporal stability analysis, Khorrami has shown that unstable modes could exist in this vortex. Due to the convective nature of this instability, a spatial analysis is more suitable. This is the subject of the present work. The mean flow past a 2D wing with a half-span flap has been computed with a steady 3D Navier-Stokes code. Then, local linear stability calculations are performed in several planes perpendicular to the vortex axis. The vortex is assumed axisymmetric and modelled with Batchelor's analytical vortex. Using Gaster's relation, the spatial amplification rate is calculated, giving by integration the relative amplitude of the fluctuations. Some low-frequency fluctuations are seen to be preferentially amplified by the vortex, but the amplifications remain small.

Brazier, J.-P., Moens, F. and Bardoux, P.

"SPATIAL STABILITY ANALYSIS OF A FLAP SIDE EDGE VORTEX"

Aeroacoustics, Vol. 4, Nos. 1 and 2, 2005, pp. 37-47

The flap side edge vortex is suspected to contribute to aerodynamic noise generation. Using a temporal stability analysis, Khorrami and Singer have shown that unstable modes could exist in this vortex. Due to the convective nature of this instability, a spatial analysis is more suitable. This is the subject of the present work. The mean flow past a 2D wing with a half-span flap has been computed with a steady 3D Navier-Stokes code. Then, local linear stability calculations are performed in several planes perpendicular to the vortex axis. The vortex is assumed axisymmetric and modelled with Batchelor's analytical vortex. Using Gaster's relation, the spatial amplification rate is calculated, giving

by integration the relative amplitude of the fluctuations. Some low-frequency fluctuations are seen to be preferentially amplified by the vortex, but the amplifications remain small, so that this mechanism alone should not produce important noise in this particular configuration, where the flap deflection angle is moderate.

Breidenthal, R. E.

"A NEW PARAMETER FOR VORTICES NEAR INTERFACES -- THE VORTEX PERSISTENCE"

AIAA Paper No. 1997-0437, Reno, NV, January 1997

When a turbulent vortex is near an interface such as a solid wall, the fluxes at the interface depend on conventional parameters such as the Reynolds, Schmidt and Prandtl numbers. A new theory asserts that another parameter is equally important. The vortex persistence is a measure of the stationarity of the vortex with respect to the surface. It is defined as the number of rotations the vortex completes while in one place. The persistence is proportional to the ratio of rotational to translational speeds of the vortex, the eddy viscosity ratio. If it is small, then the smallest scale turbulence controls the wall fluxes, the Kolmogorov microscale. On the other hand, if the persistence is large, the largest scale vortices control the fluxes. The theory compares favorably with laboratory experiments of stratified entrainment, wall heat transfer, and starting vortices in the human heart.

"EXPERIMENTAL AERODYNAMICS APPLIED TO SEPARATED AND VORTICAL FLOWS"

NATO STO, AVT-307, Research Symposium on Separated Flow: Prediction, Measurement and Assessment for Air and Sea Vehicles, October 2019, Trondheim, Norway, paper 16.

An overview of measurement techniques and application scenarios is presented focusing on leading- and trailing-edge vortex flow development. Measurement data obtained for the Mach number range of interest are typically exploited for the analysis of global and local aerodynamic load characteristics as well as for the analysis of flow physics phenomena based on specific field quantities. Experimental data serve as reference data for numerical flow simulations. Today's high fidelity computational simulations require high quality experimental data of detailed flow field quantities to improve numerical schemes and, in particular, to set up and enhance numerical modeling related to transitional and turbulent flow. Similarity in Reynolds number may require cryogenic wind tunnel testing which substantially increases the effort on measurement equipment and test conduction. The present article briefly addresses standard measurement techniques to obtain aerodynamic forces and moments, surface pressures, flow field velocities and surface flow visualization. A special focus is on optical measurement systems including pressure sensitive paint, particle image velocimetry and photogrammetry for surface deformation analysis. Transition detection methods are addressed as well. Future directions concentrate on time-accurate and volumetric measurements enhancing continuously the capabilities of particle image velocimetry applications as well as on refinements of unsteady pressure sensitive paint.

Breitsamter, C.

"WAKE VORTEX CHARACTERISTICS OF TRANSPORT AIRCRAFT"

Progress in Aerospace Sciences, Vol. 47, 2011, pp. 89-134.

The flow and flight physics of wake vortex systems has been intensively investigated concentrating on a large variety of aspects. This paper gives a brief overview on past and present wake vortex research activities such as early studies, integrated programs, model and flight tests, numerical investigations, fundamental physical aspects and alleviation strategies. Then, detailed results of the properties of the wake near field and extended near field are presented addressing typical length and time scales and especially turbulence quantities. Progressing from the near field to the far field wake instability mechanisms are explained along with their relevance for wake vortex decay. Characteristic quantities are given for the short and long wave instabilities associated vortex merging and wakes consisting of two and four trailing vortices. A non-dimensional frequency parameter is introduced to classify the main instability types. Means for wake vortex alleviations are described aimed at influencing the wake vortex turbulence field or triggering and amplifying the inherent instabilities. The methods discussed include passive means such as the effects of spoilers, differential flap setting and four-vortex systems and active means using oscillating flaps or auxiliary devices.

"TRANSPORT AIRCRAFT WAKE INFLUENCED BY OSCILLATING WINGLET FLAPS"

J. Aircraft, Vol. 46, No. 1, Jan.-Feb. 2009, pp. 175-188

The wake vortex development in the near field and extended near field behind a four-engine large transport aircraft model fitted with an active winglet is presented. A detailed wind-tunnel investigation is conducted using a half-model focusing on the high-lift case of a typical approach configuration at a Reynolds number of 500000 based on the wing mean aerodynamic chord and an angle of attack of 6.5 deg. The flow field is observed using advanced hot-wire anemometry mainly focusing on the crossflow plane at 5.6 spans downstream of the model. Based on the time-dependent velocity components the wake flow field is analyzed by distributions of mean vorticity, turbulence intensities, and spectral densities. Seven main vortical structures dominating the near-field wing vortex sheet roll up and merge to form the remaining trailing vortex in the extended near field. Using oscillating winglet flaps, the velocity fluctuations at the core region of the remaining vortex are significantly influenced. Distinct narrowband concentrations of the turbulent kinetic energy can be found for the farthest downstream plane documenting the presence of the disturbances generated by the winglet flaps which result in an amplification of inherent far-field instabilities.

"VORTEX INTERACTIONS WITH WAKES: WING ELEMENTS, FUSELAGE, AND LANDING GEAR"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 200.

The presentation concentrates on the influence of wing elements, the fuselage and the landing gear on the wake vortex formation and evolution in the near field and extended near field of a typical four engine wide body transport aircraft configuration. To evaluate the influence of the main components, the fuselage alone and the configurations without and with horizontal tail plane, nacelles, winglet, and landing gear are investigated in comparison to a baseline configuration. The wind tunnel model used consists of a detailed half model studied in a typical high lift approach configuration. The flow fields are analyzed by velocity, vorticity, and turbulence intensity fields as well as by spectral densities. The associated time dependent velocities are measured based on advanced hot-wire anemometry using miniature triple-wire probes. The cross flow is inspected at several planes covering a downstream distance up to 5 spans. The wing elements studied affect the near field wake vortex formation with respect to position and strength of the main near field vortices during the roll-up process. The overall influence on the remaining rolled-up vortex is small, nevertheless some changes in velocity gradients and turbulence intensities can be observed. The fuselage alone case exhibits the presence of three vortices, namely a vortex linked to separation at the inclined fuselage, a vortex emanating from the belly fairing and a vortex shed at the tail cone. The sense of rotation of the latter is opposite to that of the other two vortices. The wake of the fuselage, particularly due to the thick turbulent boundary layer, creates a concentrated turbulent region stretched in vertical direction because of fuselage inclination and wing downwash. This turbulent region affects strongly the inboard wake vortices, especially the wing-fuselage vortex and the horizontal tail plane vortex. Thus, the latter becomes significantly weakened within the extended near field region.

Breitsamter, C. and Laschka, B.

"VORTICAL FLOWFIELD STRUCTURE AT FORWARD SWEEP-WING CONFIGURATIONS"

Journal of Aircraft, Vol. 38, No. 2, March-April 2001, pp. 193-207,

Extensive aerodynamic investigations have been carried out on forward swept-wing configurations with a wing sweep of -40 degrees. A generic wing-body model with removable aft swept canards is used to measure the instantaneous velocities in several crossflow planes applying advanced hot-wire anemometry. The tests were made at 10-, 20-, and 30-degree angle of attack at a Reynolds number of 460000. Detailed surveys of mean and rms velocities show that at moderate angles of attack strong wing leading-edge vortices are generated rotating opposite in a sense to the wing tip vortices. At higher incidences trailing-edge vortices are shed at the inner-wing part with the same sense of rotation as the wing tip vortices. The canard vortices pass the wing leading-edge relatively high, and after the onset of wing vortices they are moved upward and outboard. The interference between these vortices is studied in detail by analyzing the associated turbulent flow structure. Vortex bursting over the wing occurs already at moderate angles of attack. Downstream, the highest turbulence intensities are found in an annular region around the burst vortex core, where fluctuations are significantly channeled into a narrow band.

Breitsamter, C., Bellastrada, C. and Laschka, B.

"INVESTIGATIONS ON THE TURBULENT WAKE VORTEX FLOW OF LARGE TRANSPORT AIRCRAFT"

ICAS-2002-3.8.2, Toronto, Canada, September 2002

The wake vortex formation and development behind a four-engine large transport aircraft model is studied in detail. Wind tunnel experiments have been conducted on an 1:22.5 scaled half-model in landing configuration at angle of attack of 9.5 degrees. The wake flowfield is carefully surveyed at six cross-flow planes located over a distance of 6 wing spans using advanced hot-wire anemometry. The results obtained include velocity, vorticity and Reynolds stress fields and spectral densities. Specific wake vortex instability mechanisms were analyzed while vortex meandering acts as a broad-band turbulence phenomenon.

Brend, M. A. and Thomas, P. J.

"DECAY OF VORTEX RINGS IN A ROTATING FLUID"

Physics of Fluids, Vol. 21, 2009, pp. 044105-1 - 044105-5..

Vortex rings propagating through a rotating fluid, along the axis of rotation, are studied experimentally. The length, x , traveled by the rings until they have completely decayed is measured. In agreement with theoretical arguments based on the Taylor-Proudman theorem it is observed that the value of x decreases with decreasing Rossby number, Ro . For the parameter range investigated here we determine an overall, global trend for the scaling of the mean decay length that can be roughly summarized by the expression $(x/D) = 4.77$ times Ro to the 1.06 power, where D is the diameter of the generator nozzle used to produce the vortex rings.

Brendmoen, J. V. and Netzer, D. W.

"ATMOSPHERIC DISPERSION OF HIGH VELOCITY JETS"

NPS-67-79-012, November 1979, Naval Postgraduate School, Monterey, CA.

A neutrally stable atmospheric surface layer was simulated in a low-speed wind tunnel by tripping the boundary layer with a fence and letting the turbulent flow develop over a length of roughness elements. Turbojet exhaust dispersion characteristics, simulated by a burner/nozzle system, were investigated by measuring the horizontal and vertical temperature profiles at axial stations downwind from the nozzle exit. Dispersion sensitivity to different nozzle exit conditions, angles of incidence to the wind, and nozzle surface blockage were investigated. The results were compared to dispersion methods used in the Air Quality Assessment Model (AQAM). It was found that (1) the experimental jet penetration length was much shorter than that assumed in AQAM, (2) the horizontal jet exhibited plume rise, (3) the initial dispersion coefficients were a function of wind direction, and (4) the plume spreading rate was more rapid than for low velocity, elevated sources in neutrally stable atmospheric conditions.

Brennenstuhl, U. and Hummel, D.

"VORTEX FORMATION OVER DOUBLE-DELTA WINGS"

ICAS 1982, August 1982, Seattle, WA.

Low-speed wind-tunnel tests have been carried out on a series of double-delta wings. The effects of variations in leading-edge kink angle and in kink position have been investigated by means of three-component, pressure distribution and flow field measurements as well as by flow visualization at $Re = 1,300,000$. At small angles of attack two primary vortices exist on each side of the wing, originating from the apex and from the leading-edge kink. At moderate kink angles these two vortices join each other with increasing angle of attack. The junction process is analyzed in detail and is interpreted as a 'potential flow effect.' At very large angles of attack vortex breakdown occurs within the joined vortices, which leads to the limitations of the aerodynamic coefficients.

Brenner, F.

"AIR TRAFFIC CONTROL PROCEDURES FOR THE AVOIDANCE OF WAKE VORTEX ENCOUNTERS"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 4-1 to 4-14

DFS Deutsche Flugsicherung GmbH is the corporatized provider of air traffic control services in Germany. The German wake turbulence separation minima are following those prescribed by ICAO, yet it is possible to deviate from these values. How a vortex detection and warning system could be used to improve the situation is discussed.

Brewer, B. S. and Brewer, J. S.

"WAKE TURBULENCE AVOIDANCE LIGHTS"

US Patent 5,949,353, September 1999.

A wake turbulence light system is provided including an aircraft runway with a periphery including a pair of long parallel side edges and a pair of short end edges. Also included is a plurality of light assemblies mounted along at least one of the side edges of the runway in spaced relationship. A plurality of sensors is adapted for indicating a point on the runway at which a plane has departed. Finally, control circuitry is connected between the light assemblies and the sensors for indicating a location of the point by illuminating a light assembly adjacent thereto, as detected by the sensor.

Briassulis, G. and Andreopoulos, J.

"WAKE STRUCTURE OF A HELICOPTER ROTOR IN FORWARD FLIGHT"

The wake of an idealized two-bladed helicopter rotor in forward flight has been experimentally investigated using hot-wire anemometry techniques. A model was designed, constructed, installed, and tested in a wind tunnel. Time-dependent measurements of three-dimensional velocity vectors were obtained for two pitch angles corresponding to a Reynolds number based on the rotor tip rotational velocity and blade chord of 82,000 and 62,000, respectively, at an advance ratio of 0.15. The results include time- and phase-averaged data of mean velocity components and turbulence intensities, as well as spectral analysis. Profiles of the streamwise component of the velocity vector have shown the existence of a z component of the vorticity vector. Analysis of the vertical and the transverse component of the velocity vector also revealed the existence of a z component of the vorticity vector at both edges of the wake. Large levels of turbulent kinetic energy were found almost everywhere in the wake. Turbulence intensity due to the presence of the counterclockwise rotating vortex reached the maximum values of 22.4 and 19% for pitch angle 10 and 6 deg, respectively. Spectral analysis of the velocity components revealed peaks of power spectral densities at frequencies two or four times higher than the blade passage frequency. This suggests a possible breakup of the vortex sheets roll-up or tip vortices due to large scale instabilities.

Bricteux, L.

"SIMULATION OF TURBULENT AIRCRAFT WAKE VORTEX FLOWS AND THEIR IMPACT ON THE SIGNALS RETURNED BY A COHERENT DOPPLER LIDAR SYSTEM"

PhD Thesis, March 2008, University Catholique de Louvain, Louvain-la-Neuve, Belgium.

This thesis concerns the numerical simulation and the remote sensing of aircraft wake vortex flows. Due to its lift force, an aircraft releases large scale swirling flows (vortices) in its wake. As these vortices can impact significantly the trajectory of a following aircraft, their study is of great importance for practical applications concerning safety of air traffic management. The investigation carried here is twofold: it concerns, on one hand, the physics and the numerical simulation of aircraft wake vortices and, on the other hand, the technique to detect those vortices and measure their properties. The numerical simulation of aircraft wake vortices requires high order and energy conserving codes. Moreover, as aircraft wake vortex flows are turbulent, subgrid scale (SGS) models are required to perform Large Eddy Simulation (LES) of these flows. In the first part of this work, the numerical codes used (here spectral and high order finite differences) are presented and validated. Several SGS models are presented and their ability to perform LES of vortical flows, also in presence of a ground is assessed. In particular a new 'multiscale' model with a natural wall damping behavior has been developed and investigated: its performance is very good. In the second part, two flows relevant to the wake vortex problem are analyzed. The LES of a wake vortex system in a weakly turbulent atmosphere allowed highlighting the turbulent equilibrium state of such a flow. LES of wake vortices in ground effect, with and without wind, were also carried out. These simulations help to better understand the physics of wake vortices. In the last part, we simulate the remote sensing of aircraft wake vortices using a ground-based LIDAR (Light Detection And Ranging) system. The aim of this LIDAR is to sense aircraft wake vortices and turbulent winds. As the LIDAR signals are simulated using realistic parameters and realistic turbulent flows, this work serves as support in the design of an airport-based LIDAR system.

Bricteux, L., Duponcheel, M. and Winckelmans, G.

"A NEW MULTISCALE MODEL WITH PROPER BEHAVIOR IN BOTH VORTEX FLOWS AND WALL BOUNDED FLOWS"

In Direct and Large-Eddy Simulation, Vol. VII, Series 13, 2010, pp. 253-258.

A new subgrid-scale (SGS) model which has an adequate behavior in both vortical flows and wall-bounded flows is proposed. In wall-bounded flows computed using wall-resolved LES, the theory predicts that the SGS dissipation should vanish with a y to the +3-power behavior near the wall. In the case of vortex flows, one needs to have models which do not dissipate energy in the strongly vortical and essentially laminar part of the flow, e.g. in vortex core regions. The model presented here aims at combining the strengths of two models as it is a regularized variational multiscale model, thus acting on the high pass filtered LES field, and for which the sub-grid scale viscosity is evaluated using the wall adapting local eddy viscosity scaling of Nicoud and Ducros, itself computed using the high pass filtered LES field. Thus, this model is only active when there is a significant high wavenumber content in the flow and it has a natural near wall damping behavior. The ability of this model to simulate vortex and wall-bounded flows is demonstrated on three test cases. The first case is the turbulent channel flow. The second case concerns a four-vortex system. The third case concerns a two-vortex system in ground effect. It is shown that this new model allows to perform successfully LES of these flows with the proper dissipative behavior in both near wall and vortical regions. The LES are performed using a parallel fourth order code based on finite differences.

Bridges, D. H.

"FINITE WING LIFT-CURVE SLOPE CALCULATIONS USING LIFTING-LINE THEORY"

AIAA Paper 2005-4839, June 2005, Toronto, Canada.

Lifting-line theory is a valuable tool for preliminary evaluation of wing planform designs. It has been used to predict the induced drag of finite wings, and such results for untwisted wings have been tabulated in basic aerodynamics textbooks for use by students and others in evaluating finite wing designs. It is also possible to compute the lift-curve slope of a finite wing using the theory, and yet few such tabulated results exist for the effects of taper ratio and aspect ratio on lift-curve slopes of finite wings. This paper describes such calculations and contains the figures necessary to predict the effects of aspect ratio and taper ratio on the lift-curve slopes of linearly-tapered finite wings.

Bridges, D. H.

"ESTIMATE OF THE DISTURBANCE ENERGY IN AN ASYMMETRIC VORTEX WAKE"

AIAA Paper 2008-4180, June 2008, Seattle, WA.

Previous studies have suggested that the asymmetric vortex wake which developed behind an axisymmetric body at high angle of attack is the result of the amplification of a disturbance introduced at the tip of the body, implying that the asymmetric vortex wake problem is a stability problem. Measurements by previous researchers have shown the exponential growth of the so-called 'distortion energy' in the wake, supporting the stability problem hypothesis. The definition of distortion energy, more generally described as a disturbance energy, chosen by these investigators requires a large set of measurements for a single result, and so another less experimentally-expensive definition of disturbance energy is desired. This study uses the potential flow solution for two vortices behind a circular cylinder in cross flow as a 'virtual wind tunnel' to explore the validity of a particular definition of the disturbance energy. This definition, the product of the local section side force coefficient, the vortex separation distance, and the angle between the line connecting the vortices and the perpendicular to the incidence plane, is shown to exhibit the desired variations and is thus a plausible measure of the disturbance energy in the vortex wake.

"A SUMMARY OF TURBULENCE FORECASTING TECHNIQUES USED BY THE NATIONAL WEATHER SERVICE"

In *Aviation Turbulence*, edited by R. Sharman and T. Lane, Chapter 10, 2016, Springer International Publishing Switzerland, pp. 213-226.

A summary of turbulence forecasting by the US National Weather Service (NWS) is provided. This chapter begins with a historical perspective, beginning with the Wright brothers and ending with NextGen. Following the historical perspective, present-day aviation-based meteorological operations are described. This discussion covers the services provided by the NWS and its partners and includes a foundational summary of present-day (2015) forecasting techniques. This chapter closes with a narrative on current and future prediction, built around numerical models and ensemble systems. These systems will drive intelligent information extraction and decision support services provided by operational meteorologists, leading to a safer and weather-ready airspace.

Brillant, G., Chilla, F. and Pinton, J.-F.

"TRANSMISSION OF SOUND THROUGH A SINGLE VORTEX"

Eur. Physics J. Vol. B37, 2004, pp. 229-239

We investigate experimentally the deformation of acoustic wavefronts after crossing of a single, isolated vortex in free space. The incident sound wavelength can be varied in a large domain. We study the wavefronts at variable distance after transmission through the vortex, when the wavelength and the vortex strength are varied. For small wavelength our results are in very good agreement with predictions and simulations based on geometrical acoustics principles. However, as the sound wavelength increases to value comparable with the vortex diameter, the deformation of the wavefronts

shows the development of scattering contributions, with characteristics in agreement with recent theoretical and numerical studies.

Brion, V. and Jacquin, L.

"MEASUREMENTS OF A TURBULENT VORTEX PAIR USING TIME RESOLVED PIV"

AIAA Paper No. 2011-3892, June 2011, Honolulu, Hawaii.

Stereoscopic time resolved PIV is applied to study vortex pair instabilities. The two vortices are generated by a split wing apparatus that is designed to fasten the development of cooperative instabilities such as the Crow and Widnall modes thanks to a short vortex separation and a strong circulation. We use spectral analysis and vortex center detection to validate the presence of both instabilities. In addition, we characterize these instabilities in terms of wavelength, growth rate and of the direction of the oscillations of the vortices. Our results are found to be in good agreement with theoretical results taken from literature. The structure of the flow is found to be richer than the sole instabilities, with the presence of strong turbulence levels at the outskirts of the vortices, that results from the elongation of vorticity at the leading stagnation point of the vortex pair and wrapping of this vorticity around the vortex cores.

"ANALYSIS OF THE TIP LEAKAGE VORTEX DYNAMICS WITH A SLOTTED WING APPARATUS"

9th European Turbomachinery Conference, March 2011, Istanbul, Turkey.

In this paper we analyze the validity of replacing the casing wall in the tip leakage vortex flow by an image vortex. The study is based on an experimental set-up that allows two academic flow configurations. The first configuration is an idealized tip leakage vortex configuration with one wing set perpendicular to a flat plate playing the role of the casing wall. In the second configuration, the flat plate is replaced by an image wing to create the image vortex. The wing is rectangular and placed at 8 degrees angle of attack in a uniform flow. The distance between the flat plate and the wing tip can be adjusted between 1 and 10 percent of wing chord. The objective of the study is to examine the validity of the image vortex approach through the comparison of the vortex characteristics and evolution in the two flow configurations when the gap size is varied. The mean flow exhibits important differences, most notably concerning the vortex trajectory, size and circulation. The unsteady flow is analyzed with the objective of verifying the presence of the Crow instability in the tip leakage vortex, as indicated in the work of Bae. The Crow instability is however only observed in the image vortex flow. Comments on this result are given in the conclusion.

"OSCILLATIONS OF A VORTEX PAIR"

11th ONERA-DLR Aerospace Symposium, February 2011, Toulouse, France.

Aircraft trailing vortices may, under specific meteorological conditions, evolve into cirrus clouds and significantly impact the climate of a region where air traffic is dense. To understand the formation of these clouds, several authors have shown the importance of the secondary wake forming above the primary wake. An accepted mechanism for the generation of this secondary wake is the baroclinic production of vorticity at the separatrix between the atmosphere and the contrail. Here we present another mechanism that could add up to the latter. We describe it thanks to a viscous linear stability analysis of a realistic counter-rotating vortex pair modelling the trailing vortices. A family of unstable modes is found whose most unstable mode is two-dimensional and leads to the formation of a secondary wake in agreement with observations. The instability induces growing oscillations of the vortex pair when it descends with a Strouhal number equal to 0.2.

"INFLUENCE OF AXIAL FLOW AND ASPECT RATIO ON THE STABILITY OF VORTEX PAIRS"

Bulletin American Physical Society, Vol. 51, No. 9, 2006, p. 91.

A planar vortex pair with axial flow is simulated using DNS. The evolution of the flow is stopped when the aspect ratio of the dipole has reached a desired value. Values between 0.2 and 0.4 are investigated. A tail of vorticity forms downstream the dipole as it evolves toward higher aspect ratios. Using three-dimensional stability analyses, we study the sensibility of the Widnall modes of the dipole about the swirl number of the base flow and the aspect ratio. Those short-wave modes are recovered for two-dimensional vortex pairs. New modes appear as we progressively increase the axial flow. The increase in aspect ratio seems to widen the bands of instability. Long time instability modes are then compared to short time modes that are found by a code of optimal perturbation based on an adjoint method. We show that the perturbation that gives the highest increase in energy at short time is localized in the vicinity the center of each vortex whereas the perturbation that gives the highest increase in energy at long time is localized at the periphery of the vortices.

Brion, V., Sipp, D. and Jacquin, L.

"OPTIMAL AMPLIFICATION OF THE CROW INSTABILITY"

Physics of Fluids, Vol. 19, 2007, pp. 111703-1 to 111703-4

A mechanism for promoting the Crow instability in a counter-rotating vortex pair is presented within the framework of linear dynamics. It consists of (i) the creation of a periodic array of vortex rings along the length of the vortices by stretching of vorticity at the leading hyperbolic point of the dipole, and (ii)

the deformation of the vortices by the vortex rings leading to the Crow instability. A reduction of the characteristic time of the Crow instability by a factor of roughly 2 can be obtained by this mechanism.

Bristol, R.

"AN EXPERIMENTAL INVESTIGATION INTO THE WAKE VORTEX ROLL-UP OF A RECTANGULAR AIRFOIL"

MS Thesis, 1999, University of California, Berkeley, CA.

The roll-up process of trailing vortices from small rectangular airfoils was studied in a towing tank using a particle imaging velocimetry technique. The measurements were made in a Eulerian frame, that is, the measurement plane remained fixed while the wing swept by. Chord-based Reynolds numbers ranged from 13000 to 67000 and circulation-based Reynolds numbers from 2300 to 17000. The flow was interrogated at distances from 0.2 chord to 60 chords aft of the wing. Data were analyzed for both velocity and velocity-gradient fields perpendicular to the path of travel of the wing. Much of the roll-up process occurred on the airfoil itself; the vortices were completely rolled-up within one span. Unsteady strands of oppositely-signed vorticity were observed in the rolling-up vortex sheet immediately aft of the wing. Fluctuating structures such as these have rarely been seen before, as most studies have employed point measurements, therefore obtaining a time-averaged picture of the overall flow field. Using a PIV technique, this study made essentially instantaneous measurements in a plane, and thus was able to capture unsteady effects. The Lamb-Oseen distribution was found to be a fair fit to the vortices, although the reader is cautioned the actual vortices were not quite azimuthally symmetric.

Bristol, R. L., Ortega, J. M. and Savas, O.

"EXPERIMENTAL STUDY OF COROTATING WAKE-VORTEX MERGER AT REYNOLDS NUMBERS OF ORDER 100,000"

AIAA Journal, Vol. 41, No. 4, April 2003, pp. 741-744.

Corotating tip-flap vortex pairs are studied at Re of order 100,000. The evolution of the velocity field at a fixed cross section is recorded, yielding measures of the circulation ratio, separation, and vortex size. The pair is observed to merge within about one orbital period. Flow visualization clearly shows the three-dimensional nature of this process, with the appearance of strong sinuous disturbances on the weaker flap vortices, and to a lesser extent on the tip vortex. The wave number of this disturbance and its alignment with the extensional axis of the straining field from the partner vortex suggest it to be an example of an elliptical instability. For such an instability driven by the straining field of the partner vortex, the growth rate scales as the inverse of the square of the vortex separation, $1/(d^2)$. This growth rate matches the scaling of the orbit period, thus, yielding finite amplitudes within one orbit. This provides an explanation for the observed merger in about one orbit, even for vortices spaced too far apart to merge in two dimensions.

Bristol, R., Ortega, J. and Savas, O.

"A TOWING TANK STUDY OF AIRFOIL WAKE VORTICES AT CIRCULATION-BASED REYNOLDS NUMBER OF 10,000"

AIAA Paper No. 1999-3419, Norfolk, VA, June-July 1999.

An experimental study of airfoil wake vortices was carried out in a 70 m long towing tank. Circulation based Reynolds numbers ranged from 80,000 to 300,000. PIV images were recorded up to 120 spans downstream of the airfoil and processed with an adaptive Lagrangian Parcel Tracking algorithm, allowing velocity and velocity-gradient fields to be obtained. Airfoils with and without one symmetrical flap were used, generating either two or one pair of counter-rotating vortices, respectively. The structure of individual vortices is well described by a Gaussian vorticity distribution. The wakes from flapped airfoils show merger of the co-rotating vortices. For this study, merger was based on the time for the merged vortex to axisymmetrize itself and descend in a straight path, as marked by buoyant particles. The merger consistently reaches completion in one to two orbit periods over a wide range of Reynolds numbers and initial vortex separations. Fluctuating moments of vorticity indicate that the merger process is inherently three-dimensional. Isolated vortices do not exhibit measurable decay. The present study extends the maximum circulation-based Reynolds number over that of a recent paper by Chen, Jacob, and Savas by a factor of 5, yet the qualitative features of the flow remain the same.

Britt, C. L.

"ESTIMATION OF VORTEX CHARACTERISTICS FROM COHERENT LIDAR MEASUREMENTS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 280-291

This presentation outlines a technique for the estimation of aircraft wake vortex position and strength from Doppler measurements by a pulsed coherent lidar. A minimum variance method is used to estimate the vortex circulation from maximum velocities detected by the lidar at various range bins along the line of sight during a lidar scan. The circulation is calculated at each point in the scan, and the points of maximum circulation provide the positions of both positive and negative vortices in the scan volume. The methods are currently being used in the NASA/LaRC wake vortex lidar and are providing excellent results, with over 700 aircraft vortices successfully detected and tracked during field experiments.

Britt, C. L.

"ESTIMATION OF AIRCRAFT WAKE VORTEX SIZE AND STRENGTH FROM COHERENT PULSED LIDAR MEASUREMENTS"

9th Conference on Coherent Laser Radar, Paper Tu18, Linkoping, Sweden, June 1997

A mathematical framework has been developed to estimate wake vortex characteristics from lidar measurement data. The estimations are optimal in the sense that they minimize the variance of the errors between the measurement data and a model of the lidar measurement process. Calculations with simulated measurement data indicate that the estimation equations are valid and that the techniques work as expected.

Britt, C. L., Kelly, C. W. and Nguyen, D. P.

"ALGORITHMS FOR GENERATION OF WIND TURBULENCE PROFILES FROM PULSED LIDAR MEASUREMENTS"

RTI/8348/010-01F, RTI International, Hampton, VA, March 2003

Methodology and algorithms are suggested for a pulsed lidar system that will provide EDR and TKE altitude profiles in real time for future experimental or operational vortex detection programs. Archived raw lidar data have been used to develop and test the algorithms and to develop a practical set of algorithm parameters. Numerous cases from past AVOSS tests have been analyzed and results comparing the lidar estimates with tower measurements obtained during the 2000 DFW AVOSS experiments are presented.

Britt, C. L., Nguyen, D. P. C. and Koch, G.

"PULSED LIDAR MEASUREMENTS OF AIRCRAFT WAKE VORTICES AT DFW AND JFK"

AIAA Paper No. 1999-0982, Reno, NV, January 1999

During 1997, extensive measurements of wake vortices from landing aircraft were conducted using a state-of-the art pulsed coherent lidar system constructed at the National Aeronautics and Space Administration's Langley Research Center. The measurements were part of the NASA Aircraft Vortex Spacing System (AVOSS) program to quantify and predict the behavior of vortices generated by aircraft during landing approach and takeoff. Predicting reliable real-time vortex hazards and behavior may permit ATC spacing rules to be adjusted to more closely reflect the true vortex hazards, and could lead to higher airport capacity in the future. This paper presents examples of the results of vortex measurements under various conditions, along with a brief description of the NASA lidar system, the AVOSS concept, and the field deployments to John F. Kennedy and Dallas Fort-Worth International Airports.

Britton, J. W.

"SOME REMARKS ON EN-ROUTE VORTEX ENCOUNTERS"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 243-246

Encounters with vortex wakes can and have occurred during cruising flight on airways. Observations at RAE Bedford indicate that trailing vortices may persist for more than two minutes after the passage of an intercontinental airliner in cruising flight at high altitude.

Britton, J. W.

"SOME OBSERVATIONS OF THE BEHAVIOR OF THE VORTEX WAKE OF A VC 10 AIRCRAFT"

TM FS-105, February 1977, Royal Aircraft Establishment, Farnborough, England.

Some observations of the nature and persistence of the trailing vortices of a VC 10 aircraft are presented. Particular attention is drawn to the difference between the wakes for the aircraft in the cruise and approach/landing configurations. The effects of thermals and of the wakes of airfield buildings on the position and persistence of the wake are also described.

"A REVIEW OF HELICOPTER ROTOR BLADE TIP SHAPES"

Progress in Aerospace Sciences, Vol. 56, 2013, pp. 35-74.

A review of helicopter rotor blade tip design technology has been carried out with a view to understanding subsequent computations to evaluate the performance of new tip designs. The review starts by briefly looking at (fixed) wing tip design concepts and the underlying fluid mechanics on which they are based to see if there is any carry-over of ideas on which improved tip design concepts might be based. Then, rotor blade tip shapes that have been used, or suggested for use, on past and present rotorcraft are examined to obtain a better understanding of the helicopter tip design problem. In parallel, the review traces the development of analysis tools to evaluate the performance of the rotor and blade tip design. In the past, the designer relied heavily on classical aerodynamic knowledge, supplemented by experience and intuition, supported by wind tunnel and model rotor testing, and relatively low-order aerodynamic calculations. New rotor designs were, and still are the subject of intensive flight test verification. However, recent development of Computational Fluid Dynamics now offers an opportunity to accurately predict the viscous, compressible flow-field in the tip region, and thus predict the performance of new rotor and tip designs, provided that the solver has adequate resolution, is able to handle all aspects of the helicopter problem, and sufficient computational resources are available to complete the design in a practical time-scale.

"WAKE VORTEX LIDAR SYSTEM: OVERVIEW OF LARC PULSED LIDAR MEASUREMENTS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 247-260

The NASA Langley Research Center trailer-mounted Pulsed Lidar Facility is described including: lasers, transceivers, scanner, and data systems. Results from deployments at Langley Air Force Base and Norfolk Airport are given and future deployments to JFK and DFW airports are described. Results include data from two micrometer lasers, one a 20 pulse per second, 3 mi, 100 ns system developed by Lockheed Sanders for the Air Force and modified by NASA and a 100 pulse per second, 7 mi, 380 ns system developed by Coherent Technologies Inc. under a NASA SBIR. A 1.5 micrometer, 10 mi, 100 ns laser being developed by Lite Cycles Inc. is described. Results from two data systems, one developed by CTI under a NASA SBIR and the second by Research Triangle Institute and NASA are described.

"COHERENT PULSED LIDAR SENSING OF WAKE VORTEX POSITION AND STRENGTH, WINDS AND TURBULENCE IN THE TERMINAL AREA"

Tenth Biennial Coherent Laser Radar Technology and Applications Conference, Mount Hood, OR, November 1999.

NASA Langley Research Center has field tested a 2.0 gm, 100 Hertz, pulsed coherent lidar to detect and characterize wake vortices and to measure atmospheric winds and turbulence. The quantification of aircraft wake-vortex hazards is being addressed by the Wake Vortex Lidar Project as part of Aircraft Vortex Spacing System (AVOSS), which is under the Reduced Spacing Operations Element of the Terminal Area Productivity Program. These hazards currently set the minimum, fixed separation distance between two aircraft and affect the number of takeoff and landing operations on a single runway under Instrument Meteorological Conditions. The AVOSS concept seeks to safely reduce aircraft separation distances, when weather conditions permit, to increase the operational capacity of major airports. The current NASA wake-vortex research efforts focus on developing and validating wake vortex encounter models, wake decay and advection models, and wake sensing technologies. These technologies will be incorporated into an automated AVOSS that can properly select safe separation distances for different weather conditions, based on the aircraft pair and predicted/measured vortex behavior. The sensor subsystem efforts focus on developing and validating wake sensing technologies. The lidar system has been field-tested to provide real-time wake vortex trajectory and strength data to AVOSS for wake prediction verification. Wake vortices, atmospheric winds, and turbulence products have been generated from processing the lidar data collected during deployments to Norfolk, John F. Kennedy, and Dallas/Fort Worth International Airports.

"FORMATION FLIGHT CONTROL SYSTEM FOR IN-FLIGHT SWEET SPOT ESTIMATION"

AIAA Paper 2013-1037, January 2013, Grapevine, TX.

A formation flight control system has been designed that addresses the unique environment encountered by aircraft flying in formation and in the upwash of the leading aircraft. To test the control system a simulation environment has been created that adequately represents the aerodynamic

coupling effects between aircraft flying in formation and implements an INDI-based formation control system. Since the exact position of the sweet spot cannot be known the research presented in this paper used an advanced extremum seeking algorithm that utilizes an EKF to estimate the gradients. Simulations have shown the algorithm to be robust to errors induced by turbulence and having the ability to consistently find the sweet spot.

Broderick, A. J., Bevilaqua, P., Crouch, J., Gregory, F., Hussain, F., Jeffers, B. F., Newton, D. W., Nguyen, D. P., Powell, J. D., Spain, A. T., Stone, R. P. and Willcox, K.

"WAKE TURBULENCE -- AN OBSTACLE TO INCREASED AIR TRAFFIC CAPACITY"

National Research Council, The National Academies Press, Washington, DC, 2008.

The report is an independent assessment of the nation's wake turbulence research and development program to overcome wake turbulence challenges. The report identified the most important challenges to address and why; an assessment of the current relevant research being conducted by NASA, the FAA and other federal government agencies; and a review of research being conducted by nonfederal government organizations within the US and by foreign organizations in wake turbulence. The report presents a recommended priority and level of effort for the wake turbulence challenges.

"THE INFLUENCE OF IMPERFECTIONS ON THE FLOW STRUCTURE OF STEADY VORTEX BREAKDOWN BUBBLES"

Journal of Fluid Mechanics, Vol. 578, 2007, pp. 453-466.

Vortex breakdown bubbles in the flow in a closed cylinder with a rotating end-cover have previously been successfully simulated by axisymmetric codes in the steady range. However, high-resolution experiments indicate a complicated open bubble structure incompatible with axisymmetry. Numerical studies with generic imperfections in the flow have revealed that the axisymmetric bubble is highly sensitive to imperfections, and that this may resolve the apparent paradox. However, little is known about the influence of specific, physical perturbations on the flow structure. We perform fully three-dimensional simulations of the flow with two independent perturbations: an inclination of the fixed cover and a displacement of the rotating cover. We show that perturbations below a realistic experimental uncertainty may give rise to flow structures resembling those obtained in experiments, that the two perturbations may interact and annihilate their effects, and that the fractal dimension associated with the emptying of the bubble can quantitatively be linked to the visual bubble structure.

Brons, M., Thompson, M. C. and Hourigan, K.

"DYE VISUALIZATION NEAR A THREE-DIMENSIONAL STAGNATION POINT: APPLICATION TO THE VORTEX BREAKDOWN BUBBLE"

Journal of Fluid Mechanics, Vol. 622, 2009, pp. 177-194.

An analytical model, based on the Fokker-Planck equation, is constructed of the dye visualization expected near a three-dimensional stagnation point in a swirling fluid flow. The model is found to predict dye traces that oscillate in density and position in the meridional plane in which swirling flows are typically visualized. Predictions based on the model are made for the steady vortex breakdown bubble in a torsionally driven cylinder and compared with computational fluid dynamics predictions and experimental observations. Previous experimental observations using tracer visualization techniques have suggested that even for low-Reynolds-number flows, the steady vortex breakdown bubble in a torsionally driven cylinder is not axisymmetric and has an inflow/outflow asymmetry at its tail. Recent numerical and theoretical studies show that the asymmetry of the vortex breakdown bubble, and consequently its open nature, can be explained by the very small imperfections that are present in any experimental rig. Distinct from this, here it is shown that even for a perfectly axisymmetric flow and breakdown bubble, the combined effect of dye diffusion and the inevitable small errors in the dye injection position led to the false perception of an open bubble structure with folds near the lower stagnation point. Furthermore, the asymmetries in the predicted flow structures can be remarkably like those observed in flow observations and computational predictions with geometric asymmetries of the rig. Thus, when interpreting dye-visualization patterns in steady flow, even if axisymmetric flow can be achieved, it is important to consider the relative diffusivity of the dye and the accuracy of its injection..

Brookfield, J. M., Waitz, I. A. and Sell, J.

"WAKE DECAY: EFFECT OF FREESTREAM SWIRL"

International Gas Turbine and Aeroengine Congress and Exhibition, June 1997, Orlando, FL.

A study of the effects of freestream swirl on the decay characteristics of wakes shed from a rotating blade row is presented. The freestream swirl behind the rotor causes the wakes to skew tangentially, stretching the wakes as they are convected from the rotor to the stator. The effect of stretching on wake decay is illustrated using a simplified two-dimensional model. The model is described and the results are compared to 1) measurements from a two-dimensional cascade facility where no stretching or skewing of the wake occurs, 2) solutions obtained using a three-dimensional, Reynolds-averaged Navier-Stokes solver, and 3) experimental wake measurements taken behind a low hub-to-tip ratio fan. For typical fan geometries with hub-to-tip ratios of approximately 0.5 and rotor-stator spacings of one to two rotor chord lengths, the wake can be stretched by over 50 percent. The stretching increases the mixing rate which leads to a reduction in the mean wake velocity deficit of approximately 30 percent and a widening of the wake of about 15 percent. These effects account for much of the difference seen between cascade wake measurements and those taken behind rotating fan blade rows.

Brooks, T. F. and Marcolini, M. A.

"AIRFOIL TIP VORTEX FORMATION NOISE"

AIAA Journal, Vol. 24, No. 2, February 1986, pp. 246-252

Special data are presented for the noise produced due to turbulent three-dimensional vortex flow existing near the rounded tip of lifting airfoils. The results are obtained by the comparison of sets of two- and three-dimensional test data for different airfoil model sizes, angles of attack, and tunnel flow velocities. Microphone cross-correlation and cross-spectral methods are used to determine the radiated noise. Corrections are made for tunnel shear-layer and source directivity effects. Interpretation of the results is aided by a three-dimensional flow analysis developed for this study which determines open wind tunnel and finite aspect ratio corrections heretofore neglected in tip vortex studies. Hot-wire measurements are made in the tip vortex formation region for the specification of governing flow parameters. The spectral data are normalized in a format considered most useful for quantitative prediction of this noise mechanism for practical systems such as helicopter rotors. A recommended prediction method is given.

"PRINCIPLES AND APPLICATIONS OF PARTICLE IMAGE VELOCIMETRY"

Onera Journal, Issue 1, December 2009, pp. 1- 11.

In this paper, the principles of two-component Particle Image Velocimetry (PIV) and stereoscopic PIV are first recalled. Recent improvements in the camera calibration procedure for stereoscopic PIV are highlighted. The advantages of the PIV technique are illustrated through different studies performed in Onera laboratories for non-reacting flows, and various issues raised by the nature of fluid, flow dynamics, spatial and temporal resolutions, as well as data utilization, are examined. Finally, recent advances in the technique, time-resolved PIV and tomographic PIV, as well as potential gains from novel processing and post-processing algorithms, are presented.

Brousmitche, S.

"SIMULATION OF COHERENT DOPPLER LIDAR SIGNALS AND THEIR ANALYSIS WITH THE COHEN'S CLASS"

PhD Thesis, November 2010, Universite Catholique de Louvain, Louvain-la-Neuve, Belgium.

The problem of wind statistics measurements in the planetary boundary layer using a coherent Doppler LIDAR is addressed. More specifically, it focuses on the design of efficient algorithms in the time-frequency space dedicated to the detection and the characteristics of atmospheric hazards, such as aircraft wake vortices or wind shears. To support this study, a simulation program has been developed which combines the numerical simulation of LASER beam propagation in a turbulent medium with state-of-the-art Large Eddy Simulation (LES) of wake vortex in atmospheric turbulence or in ground effect. This tool constitutes a complete framework for optimizing the LASER source while developing and evaluating the performance of the whole estimation process. Moreover, an analytical formulation of the coherent LIDAR Wigner-Ville spectrum has been derived along with its associated Cohen's class of time-frequency estimators. This theoretical basis leads to explicit equations of the

wind statistics that are retrievable, depending on the measurement conditions and the LASER pulse parameters. It also yields to an adaptive spectral modeling algorithm which is used to detect the wake vortices and then estimate their wind speed probability density function as well as their maximum radial velocity profiles. Another major achievement of this thesis is the development and the validation of a fast inversion method dedicated to wake vortex characterization, e.g., the estimation of its position and intensity. In this method, a Burnham-Hallock model, transformed by a new measurement model integrating the effects of the estimation process, is directly matched to the retrieved radial velocity map. Monte Carlo simulations have been carried out on both analytical models and LES to confirm its good performance. Finally, the validation of the axial detection of vortices with a fiber-based LIDAR has been performed during a test campaign conducted by ONERA at Orly airport in April 2008 during the FIDELIO project. Wake vortex signatures have been successfully obtained with some of the algorithms developed in this thesis.

Brousmiche, S., Bricteux, L., Sobieski, P., Winckelmans, G., Macq, B. and Craeye, C.

"PARAMETERS ESTIMATION OF WAKE VORTICES IN GROUND EFFECT"

15th Coherent Laser Radar Conf., Toulouse, France, June 2009.

In this paper, we propose a method for evaluating the parameters, i.e. core positions and circulation, of wake vortices with a ground-based coherent Doppler Lidar assuming a scanning plane perpendicular to the runway. Its principle is to fit a modified Hallock-Burnham model on the velocity estimates given by the output of a LIDAR simulation module working directly on the velocity space. This simulation uses the results of a computational fluid dynamics simulation of wake vortices in presence of ground effect. The robustness of this method can therefore be assessed when secondary vortices are present in the sensing volume. This model allows us to evaluate how the pulse duration as well as the spatial resolution affects the estimates. The obtained vortex circulations are compared to the exact circulation, as well as to the Gamma 5-15 quantity evaluated on the fluid simulation field. It is shown that the estimation error can vary substantially depending on the position of the vortices and the pulse duration.

Brousmiche, S., Bricteux, L., Winckelmans, G., Macq, B. and Sobieski, P.

"MODELING OF WAKE-VORTEX DETECTION BY A GROUND-BASED FIBER LIDAR SYSTEM"

Advances in Geoscience and Remote Sensors, Chapter 11, Oct. 2009, Intech, pp. 249-268.

The aim of this chapter is twofold. On the one hand, it describes a complete simulation method to evaluate the performance of a Doppler LIDAR for aircraft wake vortices detection near the ground. The principal interest of the simulation presented here is to combine a LASER beam propagation method with fluid dynamics simulations. On the other hand, it proposes effective wind velocity map reconstruction algorithms. The performance of spectral and correlogram accumulation algorithms in the vicinity of wake vortices is analyzed. The effect of velocity gradients on the estimation error is thus addressed.

Brown, A. P.

"WAKE VORTEX CORE PROFILES AND STABILITY FROM ENROUTE FLIGHT DATA"

AIAA Paper No. 2011-3032, June 2011, Honolulu, Hawaii.

Wake vortex core profile and stability characteristics have been analyzed, based upon enroute flight data, gathered upon research flights using the NRC CT-133. The flow field analysis has centered upon the vortex-induced gust velocities measured in the immediate vicinity outside and inside of trailing-pair vortex cores, mildly perturbed in non-turbulent atmospheres, at very large Reynolds Numbers of 2-3 times 1,000,000,000,000, based upon induced windspeed and axial length of the trailing vortices. Vortex-induced core and outside-core profiles were determined by vector-differencing of air and inertial velocity vectors. Kinematic geometry was used to estimate vortex center and radial distance from the center. Core radius was defined by peak vortex-induced velocity. Generally, discrete gust vortex-induced velocity profiles were found to consist of primary, secondary, and tertiary vortex elements. Combinations of primary and secondary elements were prevalent, with peaks of 25 m/s and core radii of 2-6 m, and resulted in sharp-peaked velocity profiles, adequately described by the potential or Rankine vortex model. Occasionally, the profiles were rounded with no secondary or tertiary elements -- such profiles were adequately described by the Burnham-Hallock model. Tertiary vortex elements were small and intense, induced wind speeds and core radii to approximately 35-45 m/s and 0.3-0.6 m, respectively. When normalized, and considered statistically -- about 25% of profiles were of Burnham-Hallock shape with low turbulence levels. The remainder were full-shape profiles: 50% of profiles were between B-H and potential profiles, whilst 25% of profiles had induced velocities greater than potential, of which 5% were greater than twice potential peak velocity. Numerical differentiation of the profiles showed that many of profiles were characterized by a strong Rankine radial mode instability between 0.95 and 1.5 of the vortex core radius. The instability was harmonically mirrored at 2 and 4 times the vortex core radius. Radial analysis indicated that strong, unsteady radial velocities existed for the full-profiles (but not B-H profiles) near core edges and inside cores. The radial flows were both in-flows and outflows. Associated with the inflows was intensification of quasi-vorticity, wherefore spatial gradients of wind gusts were measured under the assumption of frozen-flow, at small scale level.

Brown, A. P.

"THE IMPACT UPON AIRCRAFT AIRWORTHINESS DESIGN FROM ENCOUNTERS WITH DISCRETE VORTICES"

AIAA Paper No. 2006-229, Reno, NV, January 2006

Through the course of the development of aviation, threats to the integrity of aircraft design, as posed by encounters with discrete free vortex flow field structures have generally been realized through bitter experience. Therefore, the engineering response has been, for the most part, reactionary. As an assembly of data, earlier and recent flight research data involving discrete vortex encounters, as conducted by the NRC Flight Research Laboratory, has been reviewed and is presented,

particularly in terms of the parametric variables of the core radius, and vortex strength-to-scale parameter. The flow field characteristics and the aerodynamic loading, flightpath stability and flightpath performance effects upon airplanes encountering the flow fields are categorized and summarized, particularly in relation to current airworthiness and operational requirements. In relation to strength, comparative calculations highlight the shortfall of the classical (1-cos) gust shape, and the complex nature of wake vortex instability scales, wherein substantial loadings, about 0.5g lateral and 2.5g normal, and flightpath disturbances, including roll accelerations of approximately 300 degrees/sec/sec, suggest the generation of smaller scale vortices.

Brown, A. P.

"WAKE VORTEX ENCOUNTER AIRCRAFT AND UNDERWING POD LOADS"

AIAA Paper No. 2012-2673, June 2012, New Orleans, LA.

The NRC CT-133 aircraft has been used for wake turbulence research, over a period of five years. More recently, underwing sensor pod development has been completed, for the conduct of jet aircraft emission flight research, with the intention of being able to fully measure various aspects of emissions holistically, over the whole aircraft wake regimes. Critical airworthiness issues included the loads that the aircraft and pods would be subjected to, in the wake turbulence regimes of wakes, and the trailing-pair wake vortex regime. NRC CT-133 wake turbulence data without the pods has been analyzed and transformed to the pod CG locations, and resulting reactions derived for the pod mounting rack attachment bolt locations, the critical loading points. The resulting pod mounting rack attachment bolt loads have been parametrically related for wake turbulence parameters. When installed, the pods were fitted with accelerometers and accelerations measured, from which loads have been derived. These loads have been compared with those estimated for wake vortex encounter data without the pods. The pods mounting bolts were within the airworthiness safety limit.

Brown, A. P.

"TRAILING VORTEX FORMATION BY LIFTING-LINE FIELD INDUCTION AND CENTRIFUGAL STABILITY ANALYSES"

AIAA Paper No. 2012-2671, June 2012, New Orleans, LA.

Analyses of Wake Vortex formation and downstream development have been conducted, using mutual field induction calculations of the shed vorticity sheet. To illustrate and compare the formation and downstream development of wingtip vortices, the analyses were conducted for two widely-different cases of spanwise distribution of bound-vorticity. Termed inboard and outboard distributions, the loadings were nearly triangular and rectangular, respectively. For development analysis, Biot-Savart field calculations were conducted for the induced velocity field, and hence displacement of the elements of the shed vorticity sheet. Although an induced field calculation does not represent all fluid-element forces (in particular, the expansion pressure field) and thus, might over-estimate core radius for example), the comparative calculations provided results of interest, regarding the properties of

developed wingtip vortices, such as core radius, span location, core asymmetry and peak velocity location. Following this and with reference to the NRC flight measurements of small, intense vortex elements with peaks greater than potential vortex peaks, centrifugal stability analysis is conducted, using a number of models: (1) the developed vortices for the outboard loading case were stimulated with, and released from, radial forcing; (2) a physical model of the centrifugal balance between inertia and pressure forces was examined by time-wise solution of the equations of elemental equations of motion, and (3) the Euler equations in axisymmetric, cylindrical coordinate form were numerically, spatiotemporally solved for excess-velocity vortex profiles. An example of resultant radial flow behavior is compared to flight data.

Brown, A. P.

"WAKE VORTEX CHARACTERISTICS FROM MEDIUM CATEGORY JET TRANSPORTS"

AIAA Paper 2018-2867, June 2018, Atlanta, GA.

In 2017, the NRC undertook biofuel contrail flight research, using Air Canada A320/A321 jet transport aircraft as the contrail generators. In measuring the full contrail cross-section, the NRC CT-133 research aircraft additionally measured the wake vortex characteristics of the aircraft types, Medium Category jet transports. The vortex cores tended to be large, compared to the wingspans, and thus more laterally proximate. Long-wave instability was relatively small wavelength. Short-wave mutual instabilities between vortices exhibited strong excitation of axial vortex velocity components. Cross-plane (orthogonal to the vortex axes) contour plots of vortex parameters, particularly quasi-vorticity, elucidated vortex structural detail. EDR contours were maxima at vortex core edges, some vortex cores were vented, core edges were warm, and core centers cool. Surprisingly perhaps the Brunt-Vaisala frequency contours exhibited stratified, rotating structures to the vortices, delineating Rossby-style spiral structures.

Brown, A. P.

"LINE VORTEX MODELLING OF FREE VORTICES ENCOUNTERED DURING LOW-LEVEL FLIGHT OPERATIONS OVER THE BOREAL FOREST"

AIAA Paper No. 2002-4808, Monterey, CA, August 2002

During BOREAS low-level flight operations, the NRC DHC-6 Twin Otter aircraft of the Institute of Aerospace Research Flight Research Laboratory encountered several discrete large-amplitude thermal gusts, which had an apparent vortical nature to the gust structure, that may be akin to that of other convectively-driven natural vortices, such as 'dust devils'. Assuming a free line vortex model, vertically-aligned, the vortices can be modeled and relevant vortex-aircraft interaction parameters of vortex strength, vortex core radius and vortex-center miss distance identified. This has been conducted for the most severe of the discrete gusts. The identified vortex parameters show the line vortex to be of strength 1315 (meters squared)/s, or that approximately equivalent to the strength of a trailing vortex shed from a wing lifting 10,500 kg mass per meter span at typical takeoff speed, roughly the same

order of magnitude as the effective span loading of the largest widebody design. The vortex core radius was identified as approximately 19 meters and the closest point of approach of the traversing aircraft, about half the core radius. The analysis indicates that the vortex core acted akin to a rotating and vertically-translating 'solid-body', in the upwards transport of high enthalpy momentum. By conducting a traveling 1/2 second sampling window analysis, the 'high frequency' unsteadiness in derived air velocity has been studied. So defined, turbulent velocity components show magnitudes which are proportional to the vortex-induced tangential velocity magnitude, and peak at the edge of the vortex core at values of 10-15%. Inside the core, the turbulence drops linearly. Approximate cross-plane vorticity, estimated by differencing along the flightpath within the core, displays an annular or doughnut distribution of magnitude, with a peak of about 6.7 s at about 80% core radius, thence reducing to about zero at 50% core radius. This might indicate that the vortex core was in a temporally-decaying state and that if so, temporally-maturing thermal vortices, by comparison with other line vortices, might have smaller relative core sizes with greater induced velocity magnitudes and greater hazards to low-flying aircraft.

Brown, A. P.

"AN ENGINEERING STUDY OF THE UNSTEADY RESPONSE OF A JET TRANSPORT DURING A WAKE ENCOUNTER IN A TRANSITIONAL STATE OF POTENTIAL CROW INSTABILITY"

AIAA Paper No. 2002-4715, Monterey, CA, August 2002

An engineering study has been conducted into the unsteady motion and loads response of a widebody jet transport encountering a vortex wake from a preceding 'heavy' aircraft, the wake undergoing a transitional change of flow-state from a trailing-pair through a Crow instability mechanism to a train of vortex rings. It is postulated that, having formed, the migratory Crow instability vortex rings have then rotated to the more stable upright position (coaxial with the downwash vector). The second aircraft is assumed to follow a flight path through the vortex cores of the right side of the vortex rings at 260 knots. On this flight path the estimated strength of the vortex rings is such that the induced velocity produces sideslip angle excursions to plus/minus 10 degrees, with extremely dynamic reversals, up to 200 degrees per second. Accounting for sideslip, lateral and yaw accelerations, the fin loads have been estimated using indicial functions. A yaw damper operating on a simple rate law is calculated to slightly reduce the responsive motion, albeit with a mild increase in fin loads. If reactive pilot rudder inputs are assumed, the analysis indicates that, depending upon sensory/system input-output lag, it could be possible to couple the rudder activity in-phase to each subsequent vortex ring encounter - in which case, significant magnification of fin loads is estimated to occur, of the order of 30-35% greater than that estimated without reactive, dynamic rudder input commands. For the subject transport aircraft, this would represent peak load values of the order of twice the estimated critical design maneuver limit load case.

Brown, A. P.

"THE ALLEVIATION OF WAKE VORTEX ENCOUNTER LOADS, A STUDY OF FLIGHT RESEARCH DATA"

AIAA Paper 2014-2337, June 2014, Atlanta, GA.

Wake vortex encounters, occurring in air transport operations, involve substantial loads, which can result in aggravated flight-path upsets. In order to explore flight control system design for alleviation, the alleviatory effects of conventional flight control surface deflections, upon wake vortex encounter loads has been examined. For this, data was gathered during NRC T33 wake turbulence flight research, of Heavy and Super Category jet transports engaged in enroute operations. Comparative data consists of stick-fixed wake vortex encounters and manually-applied alleviatory control inputs to conventional flight control surfaces. For the alleviatory control-input case, the inputs are experience-based, fully-learned, in other words categorized as instinctive. As such, they were of a high frequency-band, for manual control inputs. Thus, they represent a close-to-limit ability to alleviate wake vortex encounter loads, for the T33 with manual control inputs. The reduction in loads between the two cases, stick-fixed and stick-alleviatory was of the order of 50-60 percent. Given the greater bandwidth of digital flight control systems, it is reasonable to speculate that a wake vortex loads alleviation of significantly greater than 50 percent could be possible with a digital flight control system, based upon the appropriate flight control laws.

Brown, A. P.

"WAKE VORTEX CONSIDERATIONS IN THE ANALYSIS OF RECORDED DATA FROM THE UPSET TO FLIGHT AC190"

LTR-FR-289, Feb. 2008, National Research Council Canada, Ottawa, Canada

Analysis has been conducted of the recorded data of the flightpath upset experienced by Flight AC190, an A319 in scheduled service, in relation to the possibility of having encountered the wake vortex generated by a B747-400 aircraft, approximately ten nautical miles ahead of, and 650 feet above, Flight AC190. The data parameters recorded by the Flight Data Recorder were reviewed and assembled by the Transportation Safety Board, for NRC analysis. The NRC analysis consisted of estimation of incidence and sideslip angles, the derivation of the perturbed wind field, open path integral and circulation estimation, frequency domain analysis of the derived wind field and coherence analysis between pilot flight control commands and aircraft state. In addition, the derived wind field was compared with that experienced by the NRC Falcon 20 aircraft during a flightpath upset following entrainment into the wake vortex flow field generated by a B747-400 aircraft, during an NRC wake vortex research flight.

Brown, A. P.

"FLIGHT DATA OF AXIAL FLOWS IN WAKE VORTEX INSTABILITY"

AIAA Paper 2016-3435, June 2016, Washington, DC.

NRC wake vortex flight research using the CT-133 has included several hundred wake vortex core traverses from a wide range of contemporary Heavy Category wake-generating jet aircraft, measuring a variety of instability modal states of trailing vortices. The long-wave instability of a trailing vortex pair is

a clearly identified and relatively well understood mode, in isolation at least. However, an understanding of short period modes and potential interactions of such modes with the long-wave mode has remained elusive. Prevalent short period modes observed in flight have included forward-facing funnels of axially-varying core radius and vented cores, occasional rear-facing funnels, concentrations of vorticity into annular 'necklace' vortices, and 'sausage-type' axial stretching and contracting of vortex cores. Short period modes have been measured, to have high axial spatial gradients of flow velocity, core radius and vorticity concentration. During research flights measuring emissions from the NRC Falcon in 2015, very intense axial flows were measured at a wave length of approximately 25 wingspans. Axial velocity magnitudes were measured to be the same order as those of cross plane velocity components, with pressure expansions of -2.5 kPa and heating of +5 degrees C. The spatial scale of cross plane vortex-induced flow was much reduced from a nominal core radius of approximately one meter, implying a localized intensification of vorticity and axial inter-change of moments.

Brown, A. P.

"ON THE SPECIFICATION OF WAKE VORTEX ENCOUNTER GUST-FIELDS FROM FLIGHT DATA"

AIAA Paper No. 2010-7678, Toronto, Canada, August 2010.

Wake vortex encounter flow field data has been analyzed for vortices generated by Heavy and Super Category jet transports in enroute cruise, using research flight measurements. The NRC CT-133 was used for the purpose. The flow field analysis has been centered upon the vortex-induced gust velocities measured in the immediate vicinity outside and inside of trailing-pair vortex cores, mildly perturbed to varying degrees in non-turbulent atmospheres, at very large Reynolds Numbers. Analyses used consisted of rise-and-fall analysis of turbulent gusts, continuous turbulence power spectral analysis, and discrete gust analysis. Power spectral analysis indicated that the gust-field intensity did not exceed existing continuous turbulence design standards for a typical Medium Category transport mass and size. However, discrete gust size, shape and magnitude exceeded existing standards. Generally, discrete gust vortex-induced velocity profiles consisted of primary, secondary, and tertiary vortex elements. Combinations of primary and secondary elements were prevalent, with peaks of 25 m/s and core radii of 2-6 m, and resulted in sharp-peaked velocity profiles, adequately described by the potential or Rankine vortex model. Occasionally, the profiles were rounded with no secondary or tertiary elements - such profiles were adequately described by the Burnham-Hallock model. Tertiary vortex elements were intense, up to 32 m/s at core radii 0.3 m.

Brown, A. P.

"GUST LOAD-LINE ANALYSIS RESEARCH OF WAKE VORTEX ENCOUNTER FLIGHT DATA"

AIAA Paper No. 2010-0518, Orlando, FL, January 2010.

In a search for improvements in airport and air route operational capacity, an acceptable level of wake turbulence encounter could be considered -- perhaps by comparing wake vortex encounter (WVE)

upsets with discrete turbulent gust design requirements, for which transport aircraft are certificated, a priori. Such a study has been conducted. Analysis of wake vortex encounters from DAS, DFDR and QAR recorded flight data from research aircraft and commercial aircraft encountering inflight upsets from wake vortex encounters has been used successfully to estimate the detailed characteristics of the upset wind field normal, lateral and axial gust components, in body axes, experienced by the aircraft. The body axis gust components are correlated against the gross loads experienced by the WVE aircraft, in time-domain based Lissajous cross-plots. The cross-plots are compared with the design gust-loads estimated by the CAR 4b and early FAR 25 gust load-line design requirements, for 12.5c '1-cosine' discrete gusts. Comparisons are conducted for a range of WVE aircraft. Agreement with FAR 25 gust load-line estimations is generally quite good, although they disclose concurrent multi-axis gust experiences, with at least one-axis at exceedance magnitude, in the simultaneous presence of autopilot or human-pilot induced maneuver loads, nor in the presence of pilot-induced-maneuver loads. A digital FBW system airplane with gust alleviation is shown to effectively handle WVE loads.

Brown, A. P.

"ANALYTICAL APPROACH TO WAKE VORTEX AND JET WAKE FLOW INTERACTION IN CRUISING FLIGHT"

AIAA Paper No. 2010-0519, January 2010, Orlando, FL.

An analytical approach has been taken, to the cross-plane nature of wake vortex and jet wake flows from commercial heavy jet transports in cruise, with a view to providing insight into the condensation patterns observed visually and sensed by ground-based LIDAR during flight research campaigns by the NRC, DLR and others. For this study, the essential features of the engine-exhaust turbulent jet flow have been considered, amidst the roll-up of the shed vorticity sheet, from the spanwise lift distribution, into a pair of primary, wingtip vortices. Jet-flow entrainment analysis yielded a mass-balancing radial inflow of such a magnitude to be a second-order effect. The buoyant nature of the jet-core airflow from the gas-generator of turbofan engines, used on large jet transport airplanes constituted the principal effect. The degree of mixing between the hot core-flow and the cold bypass jet exhaust flow within the engine installation contributes to the magnitude of buoyancy. In particular, the mixing fraction will be greater in the case of podded-engine installation designs, which mix exhaust streams within the nacelle, compared to a nacelle which does not result in any hot and cold exhaust stream mixing until before discharge into the atmosphere. It is shown that for a hot-stream core-flow exhaust gas temperature of 650 degrees C, upon discharge to the atmosphere in the case of a non-pre-mixed jet-flow, the core-flow detrains from the surrounding cold-stream jet, to rise above and remain above the shed vorticity sheet, essentially non-entrained, whereas the cold flow jet is entrained by the wrapping vorticity sheet. On the other hand, for a 40 percent hot/cold stream pre-mixing in the engine pod, the warmer core-flow detrains initially, but subsequently is re-entrained downwards under wingtip vortex inducement. Both cases have been observed to occur in the contrails of flight observations.

Brown, A. P. and Bastian, M.

"FLIGHT MEASUREMENT OF ENROUTE CONFIGURATION WAKE VORTEX CHARACTERISTICS: A FEASIBILITY STUDY"

AIAA Paper No. 2005-0261, Reno, NV, January 2005

The Flight Research Laboratory has undertaken a feasibility study into obtaining inflight measurements of wake vortex flow fields generated by jet transport airplanes in enroute configuration. The objectives of the study included the establishment of air traffic procedures for the usage of jet transports in commercial service as wake generators, the usage of condensation wake conditions for delineation of wake vortex regions, and the usage of FRL-developed air data and inertial data instrumentation for the accurate identification of wake vortex state parameters from the relatively small wind perturbations induced by the trailing vortices, whilst sampling around the perimeter of the delineated condensation wake domain. Using the NRC Falcon 20 as the wake sampling airplane, the study was conducted in two phases. The first phase studied wakes of length 1-6nm. The second phase, presently reported, studied wakes from 5 to approximately 30 nm in length. The proof-of-concept of the techniques was satisfactorily demonstrated. Condensation wake domains enabled the visual identification of the characteristic upper and lower vortex structures and instability states, and wind perturbations enabled the identification of some vortex characteristics. Results are presented, including examples of vortex strength dissipation, wake descent rates, and the details of several flightpath disturbances induced by close encounters with the trailing vortices.

Brown, A. P. and Bastian, M.

"A FEASIBILITY STUDY ON THE INFLIGHT MEASUREMENT OF ENROUTE WAKE VORTEX CHARACTERISTICS"

AIAA Paper No. 2004-5366, Providence, RI, August 2004

The wider application of RVSM airspace and the emphasis upon the reduction in terminal airspace occupancy times by individual arriving and departing airplanes is tending towards a greater potential for experiencing wake turbulence encounters, where the wake generator is a jet transport in the enroute configuration, either within terminal airspace at an airspeed of 210-250 knots or greater, or whilst climbing/cruising at a Mach Number of 0.7 or greater. It is desirable to obtain controlled flight-measured wake vortex data on enroute configuration wake states and flow-field characteristics. To assess the feasibility of obtaining such data using a sampling airplane undertaking coordinated flights with commercial jet transport wake generators, an internally funded program of measurement has been conducted. The program is based upon: (1) usage of the NRC Falcon airplane as the wake vortex flow-field sampling airplane, with high fidelity air data and inertial data sampling, for the high fidelity resolution of wind components; (2) the prevalence of condensation wake conditions, for visualizing the wake flight-path and state condition; (3) the measurement of vortex-induced wind-flow components (around the vicinity of the trailing vortices, but not necessarily through the vortices) over wake lengths of 30 nautical miles and longer; and (4) usage of a commercial jet transport (B-727-100C) as a wake generator.

Brown, A. P. and Bastian, M.

"OBSERVATIONS OF WAKE VORTEX INSTABILITY FLOWFIELDS AND AIRCRAFT RESPONSE TO ENCOUNTERS"

AIAA Paper No. 2006-6002, Keystone, CO, August 2006

The Flight Research Laboratory (FRL) of NRC Aerospace has undertaken wake vortex flight measurements of wake vortex flow fields generated by jet transport airplanes in enroute configuration, initially aimed at proof-of-concept validation using the NRC Dassault Falcon 20 airplane, for which a two-phase approach was adopted. The first phase observed wakes of length 1 to 6 nm or a normalized time from 0.5 to 3. The second phase, studied wakes from 5 to approximately 30 nm in length or a normalized time from 1 to 6. Sampling was conducted at 32 Hz. More recently, the NRC CT-133 airplane, with 600 Hz sampling air and inertial data systems, has conducted an additional data gathering flight against enroute jet transports. Through the course of all flights, a variety of condensation wake conditions prevailed, with condensation intensity and longevity varying between the upper engine exhaust jet wake and the lower trailing pair vortex wake domains. The sampling airplane conducted helical flightpaths around, rather than through, the condensation flow regimes. However, following the onset of significant multi-wavelength long-period instability (at enroute speeds, generally beyond 6 nm wake lengths), several entrainments of the Falcon 20 into wake vortex cores occurred. The effects of wake vortex core entrainments upon aerodynamic loading, flightpath stability and systems operation have been of particular interest.

Brown, A. P. and Bastian, M.

"ENROUTE FLIGHT DATA OF WAKE VORTEX CORE PROFILES AND PROPERTIES FROM YAWED TRAVERSES"

AIAA Paper No. 2012-2670, June 2012, New Orleans, LA.

Over the period 2006 to 2012, the NRC enroute wake vortex flight research project has measured vortex core profiles and properties, during numerous traverses of the vortex cores generated by Heavy and Super Category jet transports, flying enroute in cruise. The vortex core traverses were conducted by the NRC T-33 and were all initiated in-trail, with the T-33 flight-path being parallel to the vortex core axis -- generally vortex core entries were made in the vortex core six o'clock position. Core traverses took 3/4 to 1 1/4 seconds, over which the T-33 flew along the vortex axis a distance of 200-300 meters, and 4-20 m across the cores, amounting to traverse angles of 2-4 degrees. The vortex core profile symmetry and/or constancy over such a small traverse angle was ascertained by comparing the advancing and retreating segments (to the closest point-of-approach, CPA) of the profiles. Often the implied symmetry/constancy was good, sometimes it was not. Small, very energetic secondary and tertiary vortex segments were encountered only to or from the CPA, on either the advancing or retreating segment. In particular, they made identification of vortex core funnel segments difficult. In 2011, yaw traverses of vortex cores were conducted, entering the cores at angles of yaw to the vortex axial direction, of 15-30 degrees, and/or angles of pitch of c.5 degrees, so that the cores were traversed

over much smaller axial distances than in-trail traverses. The analysis of the flight data from these yaw core-traverses is presented.

Brown, A. P. and Bastian, M.

"WAKE VORTEX FLIGHT MEASUREMENTS AND TACTICAL AIRCRAFT WVE DESIGN & FLIGHT TESTING REQUIREMENTS"

AIAA Paper 2008-1651, February 2008, Los Angeles, CA.

The NRC has undertaken re-instrumentation of the NRC CT-133 ruggedized research airplane, for high altitude atmospheric research. In the process, a new air data system has been designed, and optimized for high data acquisition rates, in particular matching the capability of the aircraft's FRL inertial reference and navigation system, to derive and acquire wind vector data at 600 Hz. The platform has been used to conduct transport aircraft wake vortex (WV) surveys, and acquire instability wake vortex flow field data, most recently in comparative straight flight and turning flight maneuvers, using a Falcon 20 wake generator, to 3 nm distance. Vortex core traverse analysis has highlighted a greater frequency of small-scale vortex segments with high (greater than 150 percent exceedance of the primary vortex) tangential velocities in turning flight. Also, there was a greater bandwidth in short-wave instability wavelengths, and higher amplitude in long-wave instability, and also multi-wavelength, but centered at 3 to 5 generator wingspans, whether in straight or turning flight. Such observations and general considerations of possible tactical jet aircraft wake vortex flow fields suggests the need to establish from flight data, wake vortex flow field environmental design requirements, in order that contemporary and new tactical aircraft types may be developed with robust flight control systems, able to handle the [frequency amplitude] environments experienced during wake vortex encounters.

Brown, A. P. and Bastian, M.

"WAKE VORTEX CORE FLOWFIELD DYNAMICS AND ENCOUNTER LOADS IN-SITU FLIGHT MEASUREMENTS"

AIAA Paper No. 2008-468, Reno, NV, January 2008

The NRC has undertaken re-instrumentation of the NRC CT-133 ruggedized research airplane, for high altitude atmospheric research. In the process, a new air data has been designed, and optimized for high data acquisition rates, in particular matching the capability of the aircraft's FRL inertial reference and navigation system, to derive and acquire wind vector data at 600 Hz. The platform has been used to conduct wake vortex surveys, and acquire WV flow-field data. Vortex core traverse analysis has highlighted a limited number of encounters with vortex elements of circulation to core radius relationships well in exceedance of the general reduction in vortex strength with smaller core radius, typically found in turbulent atmospheric vortex flow-fields. For these encounters, the relationships approached the characteristic relationship of a funnel vortex, in which core radius reduces at constant circulation, so that the circulation to core radius ratio is significantly greater. These observations support the condensation appearance of funneling segments within the WV cores. The core traverse

surveys have provided the opportunity to obtain WV encounter loads data for a small jet encountering vortex wakes in-trail, in cruise. The loads data did not show a consistent decay with wake length (age).

Brown, A. P. and Bastian, M.

"IN-SITU MEASUREMENTS OF ENROUTE CONFIGURATION WAKE VORTEX SCALAR FIELD CHARACTERISTICS"

AIAA Paper No. 2007-289, Reno, NV, January 2007

The scalar fields of vortex-pair-induced pressure, temperature and velocity magnitude from the NRC wake vortex inflight measurement proof-of-concept program are presented for an inbound B767-300 wake of vortex strength of approximately 350 meters squared per second (wake age 1/2 to 1 minute), an outbound B747-400 wake of vortex strength of approximately 600 meters squared per second (wake age 1 to 1.5 minutes), and the vortex core characteristics of an inbound A310 wake of vortex strength of approximately 430 meters squared per second. Correspondence between induced temperature and pressure fields indicated that the fields were representative of near-adiabatic compression or expansion. Between the two wakes the scalar fields exhibited similarities and differences in characteristics, possibly attributable to differences in wake ages/lengths. Similarities were the existence of generalized areas of temperature and pressure rises above the vortex pairs and temperature and pressure reductions in the immediate vicinity of vortex core edges, and between the vortex pair. Differences were notably the lack of distinction of vortex core delineation, in the case of the B747-400 wake and different asymmetries in the scalar fields. Possibly the former was attributable to the greater age, length, and state (near to vortex-linking) of the B747-400 wake. However, the differences in asymmetry were probably attributable to background atmospheric flow field differences. In particular, the B767-300 wake existed in a strong crosswind shear from the right, within which the vortex pair appeared to roll, with the downwind vortex displaced and stretched upwards. From a vortex core transect of the left vortex of the A310 at a wake length of 6 nm (wake age 0.77 min.), internal core-flow features of significance have been identified.

Brown, A. P. and Bastian, M.

"DERIVATION OF WAKE VORTEX CIRCULATION FROM FLIGHT DATA USING PATH INTEGRALS"

AIAA Paper No. 2007-286, Reno, NV, January 2007

In 2003/2004 NRC Aerospace conducted a wake vortex flight measurement proof of concept program, aimed at the demonstration of the cost-effective data gathering of wake vortex flow-field characteristics from jet transports in commercial service. Survey flying consisted of helical flight paths around condensation-delineated wake vortex flow fields. Instrumentation consisted of inertial and air data systems capable of the high-fidelity derivation of wind perturbations for the identification of the flow-field characteristics of trailing pair vortex circulation, separation, axis orientation, descent path and perturbation state. For such identifications, the technique of trial-and-error kinematic fitting of the derived wind perturbations in the time domain was used. In regions of highly-perturbed vortex states,

with attendant highly dynamic flight attitude changes and possibly frequent but poorly-defined vortex core passages, a time domain kinematic fitting process lacked accuracy. Rather, moving-crossplane, open path, and contour path integral methodologies are proposed and applied. Whilst the association between contour path integrals of induced velocity fields and the enclosed field total circulation is well understood (an application of Stokes' Theorem), the relationship between open path integrals of induced velocity and the induced-velocity field motive circulation, and the application thereof to the derivation of wake vortex total circulation, are perhaps less used. Examples from the NRC wake flight measurement program are provided. The usage of open path integrals provides insight into planning optimal wake vortex flight measurement profiles, in order to maximize the effective data return per task flight hour.

Brown, A. P., Bastian, M. and Canteenwalla, P.

"CONTRAIL FLIGHT DATA FROM A VARIETY OF JET FUELS"

AIAA Paper 2018-3188, June 2018, Atlanta, GA.

In 2017/18, the NRC undertook biofuel contrail flight research from several jet transport aircraft and jet fuels, including petroleum JetA1, JP-5, HEFA and ethanol-derived ATJ biofuels. The flight contrail data, consisting of derived ice particle number, size, spherical mass, and the FSSP-100 optical properties of effective size, extinction coefficient, optical depth, and laterally-integrated optical depth, was obtained and compared for JetA1, JP-5 and biofuels (43 percent HEFA-SPK blend with Jet A1 and 92 percent ethanol-derived ATJ-SPK blend with aromatics). Contrail conditions covered sublimating to persistent. Contrail properties were compared with aerosol and non-volatile particulate emissions, and with previous soot modeling of young contrails. Results showed progressive reduction in persistent contrail ice particle number with biofuel blend percentage, almost log-linear reductions with non-volatile aerosol emissions, a slight increase in ice particle size with 92 percent ATJ-SPK. The lateral integrands of optical depth showed 30-50 percent reductions for the 92 percent blend ATJ-SPK, compared to Jet A1.

Brown, A. P., Mokry, M. and Bastian, M.

"FLIGHT MEASUREMENTS OF WAKE VORTEX CIRCULATION IN CROSSFLOW SHEAR"

AIAA Paper No. 2007-285, Reno, NV, January 2007

NRC Aerospace has conducted flight measurements of the wake vortex flow fields of heavy jet transports. Reduction of B767-300 and B747-400 wake vortex flow-field flight data has been conducted. Contour path integrals have been used for the identification of net vortex circulation of the wake vortex trailing pair domain within the cross-plane flightpath contours and of the combined wake vortex trailing pair and jet wake (upper) domains of the wake, within larger flightpath contours. Thereafter, the derived circulations of the domains, which include the inherent circulation of the non-frozen background crossflow windshear, have been examined as functions of mean vertical crossflow windshear magnitude, or crossflow vorticity in the absence of any significant background vertical wind.

The derived circulation was approximately zero for the crossflow vorticity. Dependence upon cross flow vorticity was observed to be much greater than the variation of circulation with wake length. For the B767-300, derived circulation of the trailing vortex pair, including inherent background shear circulation, was about 400 m squared per s at a cross-plane vorticity magnitude of 0.35/s. For the combined wake vortex and jet wake domain, circulation was approximately 1000 m squared per s at a cross-plane vorticity magnitude of 0.020/s, again including the background shear circulation. Data-set standard deviations were approximately 100 m squared per s. As an endeavor to remove the inherent circulation of the background crossflow shear, the mean crossflow wind profiles were regressed to estimate the shear strength, and the circulation calculated for each contour path integral, for the assumed frozen shear. This was subtracted from the wake vortex and wake vortex plus jet wake circulation, to estimate the net circulation of the vortex flow fields. The so-estimated net circulations were approximately zero at a crossflow vorticity of about zero, rising a mean 150 m squared per s for a crossflow vorticity of 0.036/s, with no effective difference between wake vortex net circulation and wake vortex plus jet wake net circulation. There was no significant difference in net circulation for positive (crosswind speed increasing with height) or negative (crosswind speed reducing with height) vertical crossflow shear.

Brown, A. P., Ovenden, M. and Bastian, M.

"A FLIGHT STUDY OF UNSTEADY AERODYNAMIC LOADING INDUCED BY WAKE VORTEX ENCOUNTER"

AIAA Paper 2018-3023, June 2018, Atlanta, GA.

The NRC CT-133 research jet has been installed with a wing glove on the mid-span of the port wing. The wing glove has been installed with pressure transducers, for the measurement of unsteady surface pressures. In flight test, the wing glove has been applied to low-speed stalling and high-speed Mach buffet maneuvers. The wing glove has been applied to the measurement of unsteady lifting loads during wake vortex encounters (WVE), and appeared to faithfully represent surface flow conditions representative of the loading state experienced by the overall aircraft. Local Mach Number on the glove achieved 1.4, without the occurrence of significant shock-induced boundary layer separation (nor, buffet by the overall aircraft), evidential of an increase in the lifting capability of a wing section, under the energizing effect of wake vortex interaction with the wing boundary layer.

Brown, A. P., Politis, E. and Othman, A.

"LINE VORTEX MODELLING OF VORTICES ENCOUNTERED AS TAKEOFF WINDSHEAR BY A WIDEBODY JET TRANSPORT"

AIAA Paper No. 2003-5384, Austin, TX, August 2003

During the airborne phase of takeoff of a widebody jet transport, windshear was encountered. The airspeed increased about 40 knots shortly after liftoff, followed by an approximate 40 knot reduction, concurrent with a wind direction veer from northeast to southwest. The windshear alerting system activated at the completion of the wind veer and airspeed decay. The windspeed data trace from the

digital flight data recorder displayed characteristics that could be represented by an encounter with a discrete vortex of substantial size, followed by a train of encounters with moderately-sized vortices. It is postulated that the data is evidence of a traverse through an atmospheric shear layer consisting of a train of vortices of varying strengths. Simple line vortex models are assumed for each of the principal vortices. Accordingly, the DAR horizontal wind data and derived vertical wind data along the takeoff flight path has been parameter matched to discrete vortex train characteristics of vortex strength, core-axis separation distance, azimuthal vortex axis crossing angle, vortex axis elevation and ground-point origins for each vortex. Following the identification of the azimuthal-crossing and elevation angles of the largest vortex, 17 degrees and 26 degrees respectively, the angles are assumed to be the same for all other discrete vortices in the train. The strength of the largest has been identified as 36,000 ft²/sec (3346 m²/sec) at a vertical separation distance of 400 ft above the aircraft at the path-crossing point. The other discrete vortex strengths have been identified as varying between 4000 and 8000 ft²/sec (372 and 744 m²/sec). The shear intensity from the vortex-induced flow exceeded the 'must alert' cautionary and warning alert thresholds of the TSO-C117a design standards for windshear alerting and guidance systems, which are based upon downburst flow fields.

"ON THE AERODYNAMICS OF WAKE VORTICES"

AFOSR-TR-72-1209, October 1972, Hydronautics Inc., Laurel, Maryland.

The effect of wing span loading on the development of fully rolled up wing trailing vortices is discussed. It is shown that parabolic wing loadings produce potential flow maximum core rotary speeds which are finite and less than 50 percent of the downwash speeds at the plane of symmetry. The development of turbulent cores is analyzed and core growth is predicted to occur as the two thirds power of time whereas the peak velocities fall off as the inverse one third power. Axial flow effects of the wing profile drag and lifting system are shown to lead to axial jets on the vortex axis which may either follow the aircraft or exceed the free stream velocity depending on the ratio of profile drag to induced drag.

Brown, C. E.

"WAKE TURBULENCE IN A WATER ENVIRONMENT"

Proceedings of the AFFDL/NASA/FAA Wake Turbulence Work Shop, Air Force Flight Dynamics Laboratory, AFFDL-TM-75-16-FGC, 1974, pp. 43-49

A review of NASA tests conducted in the Hydronautics Ship Model Basin was given along with experiments with a thermally stratified environment. Vortices showed a definite slowing in their descent in a water environment even without stratification; this was probably related to the observed bursting and fringing of vortices. The tests with a stratified environment showed an additional slowing effect on vortex descent; the vortices leveled off sooner and even bounced back up in some cases.

Brown, C. E.

"PRESSURE FIELD OF A VORTEX WAKE IN GROUND EFFECT"

Journal of Aircraft, Vol. 12, No. 2, February 1975, pp. 120-121

The ground pressures under a descending pair of vortices such as might be generated by aircraft either landing or taking off are computed. It is found that as the vortices first approach the ground, only positive pressures are produced; however, as the descent continues the high velocity field of the vortices makes itself apparent in dips to sub-atmospheric pressure which lie closely beneath the vortex center. Nevertheless, a substantial positive pressure hill precedes the path of the vortex as it moves laterally in the 'ground effect'. The level of pressures produced is dependent only on the flight speed, lift coefficient and aspect ratio while the length scale of the pressure distribution is proportional to the span. These results may be useful in the development of systems to monitor multiple aircraft take-off and/or landing operations.

Brown, C. E.

"THE USE OF SHIP MODEL BASINS FOR THE STUDY OF VORTEX WAKE PHENOMENA"

AFOSR-TR-73-0567, March 1973, Hydronautics, Laurel, MD

The basic differences between test in air and in water are discussed relative to the study of aircraft vortex wake phenomena. It is shown that use of large ship model basins is valid for simulation up to critical Mach numbers of flight. Free surface interference is shown to be negligible for tests made at sufficient towing depths and it is concluded that cavitation must and can easily be avoided entirely at typical towing speeds. Effects of Reynolds number mismatch on the test results is analyzed and it is concluded that wing profile drag coefficients should be matched between full and model scale. Finally, consideration is given to the problem of stopping and starting disturbances in towed-model testing.

Brown, C. E.

"AERODYNAMICS OF WAKE VORTICES"

AIAA Journal, Vol. 11, No. 4, April 1973, pp. 531-536

The effect of wing span loading on the development of fully rolled-up wing trailing vortices is discussed. It is shown that parabolic wing loadings produce potential flow maximum core rotary speeds which are finite and less than 50% greater than the downwash speeds at the plane of symmetry. The development of turbulent cores is analyzed and core growth is predicted to occur as the two-thirds power of time, whereas the peak velocities fall off as the inverse one-third power. Axial flow effects of the wing profile drag and lifting system are shown to lead to axial jets on the vortex axis which may either follow the aircraft or exceed the freestream velocity, depending on the ratio of profile drag to induced drag.

"SIMULATION OF WAKE VORTICES DESCENDING IN A STABLY STRATIFIED ATMOSPHERE"

FAA-RD-74-116, July 1974, Hydronautics Inc., Laurel, MD

An experimental simulation of aircraft wake vortices descending in a stable atmosphere has shown that the atmospheric stability stops the downward movement and, in some cases, produces a subsequent rebound. The tests were carried out in a large ship model basin using a rectangular planform wing. Lift coefficients of 0.4 and 1.0 were selected and stable atmospheric conditions were obtained by temperature (density) stratification of the towing basin. Test conditions corresponding to Vaisala-Brunt periods of infinity, 109, and 51 seconds were obtained. The model parameters and stability conditions covered the most extreme cases to be expected in full scale flight.

"EXPERIMENTAL STUDY OF TRAILING VORTEX WAKES USING A LARGE TOWING TANK"

Tech Report 7105-1, August 1971, Hydronautics, Laurel, MD

An experimental study of the trailing vortex wake behind a 0.03 scale model of a Boeing 747 transport aircraft was carried out in the Hydronautics Ship Model Basin. The experimental equipment and techniques used are described in detail. Data are presented on vortex trajectories, core diameter and growth, and tangential and axial velocity profiles for the cruise and flaps 30 configuration. Distances behind the model equivalent to 3 miles full scale were achieved before disturbances due to stopping the model affected the results. It was concluded that the techniques developed were suitable for studying devices intended to speed vortex decay and that the results to date show good quantitative agreement with full scale observations.

"HIGH SPEED COMPUTER STUDIES OF VORTEX MOTIONS IN RELATION TO AIRCRAFT WAKE TURBULENCE"

AFOSR-TR-76-0481, January 1976, Hydronautics Inc., Laurel, MD

Computations are presented and compared with experimental data from other sources for basic and advanced problems in aircraft - wake vortex interactions. Results are presented for coalescence of corotation and counterrotating vortex groups and finally a complete high speed computer method is developed for simulating the roll reaction of an aircraft to the wake produced by a large aircraft with flaps deployed. Suggestions for improved experimental approaches are also appended.

Brown, C. E., Van Dyke, P. and Kloetzli, J. W.

"MEASUREMENTS AND ANALYSIS OF THE FORCES ACTING ON A SMALL AIRCRAFT FLYING IN THE UPWASH OF A LARGE AIRCRAFT"

AFOSR-TR-78-0903, April 1978, Hydronautics Inc., Laurel, MD

A study has been made of the forces and moments acting on a small aircraft while it is flying in the upwash field adjacent to and behind the wing tip of a larger airplane. Preliminary analysis of the expected ranges of forces and moments were made using available theoretical methods and confirming experiments were performed in the Hydronautics Ship Model Basin. The tests used a large model of the Boeing 747 transport aircraft and a smaller model typifying a fighter-type aircraft. The range of positions of the small model relative to the large model extended laterally 30 full-scale feet from the wing tip or from the tip vortex and downstream roughly 80 feet behind the wing tip. Consideration was given to the problem of maintaining steady position at a point that provided a maximum increase in the lift to drag ratio (L/D) of the small aircraft. The model tests have shown that an increase of 50% in L/D can be obtained by a small fighter-type aircraft fling close to the tip trailing vortex of a larger aircraft. Higher increases in L/D for the same relative aircraft positions would result if the smaller aircraft exhibited higher performance (maximum L/D was 8.9 in free air). Calculations made for the models tested indicate that control power of typical fighters would be sufficient to maintain level flight in the favorable positions close to a tip vortex. No influence of the small aircraft on the large should be felt because the most favorable locations for the small aircraft are well behind the wing tip of the large aircraft.

"HEATHROW MEASUREMENTS: WINTER 94/95"

Final Report, October 1995, Defence Research Agency, Malvern, UK

The DRA (Malvern) Lidar has been used to record the wake vortices of nearly 2,000 aircraft on approach to Heathrow. The measurements have been made in a wide range of atmospheric conditions and from five different sites near the airport. This report describes the measurements and presents analyses of a small sample of the data. Different characteristics of the vortices of different aircraft have been observed, and the records include many examples of persistent vortices with ages well over 60 seconds. In at least one case, a vortex returned to the glideslope with undiminished strength 70 seconds after its generation. A detailed analysis of the large amount of data gathered, and correlation with meteorological and other parameters, is continuing.

"AXISYMMETRIC VORTEX BREAKDOWN, PART 2, PHYSICAL MECHANISMS"

J. Fluid Mech., Vol. 221, December 1990, pp. 553-57.

The physical mechanisms for vortex breakdown which, it is proposed here, rely on the production of a negative azimuthal component of vorticity, are elucidated with the aid of a simple, steady, inviscid,

axisymmetric equation of motion. Most studies of vortex breakdown use as a starting point an equation for the azimuthal vorticity (Squire 1960), but a departure in the present study is that it is explored directly and not through perturbations of an initial stream function. The inviscid equation of motion that is derived leads to a criterion for vortex breakdown based on the generation of negative azimuthal vorticity on some stream surfaces. Inviscid predictions are tested against results from numerical calculations of the Navier-Stokes equations for which breakdown occurs.

Brown, R. E.

"ROTOR WAKE MODELING FOR FLIGHT DYNAMIC SIMULATION OF HELICOPTERS"

AIAA Journal, Vol. 38, No. 1, January 2000, pp. 57-63

A computational helicopter rotor wake model, based on the numerical solution of the unsteady fluid-dynamic equations governing the generation and convection of vorticity through a domain enclosing the helicopter, has been developed. The model addresses several issues of specific interest in the context of helicopter flight dynamic modeling. The problem of excessive numerical dissipation of vortical structure, common to most grid-based computational techniques, is overcome using a vorticity conservation approach in conjunction with suitable vorticity-flux limiter functions. Use of a time-factorization-type algorithm allows the wake model to avoid the stiffness that is introduced in flight dynamic applications by the disparity between the rotor and fuselage timescales and to generate rapid solutions to the time-varying vortical structure of the helicopter wake. The model is demonstrated to yield valid solutions to the blade loading and wake structure for isolated and interacting rotors in both hover and forward flight.

Brown, R. E. and Line, A. J.

"EFFICIENT HIGH-RESOLUTION WAKE MODELING USING THE VORTICITY TRANSPORT EQUATION"

AIAA Journal, Vol. 43, No. 7, July 2005, pp. 1434-1443

Computational fluid dynamic models, through their fundamental treatment of the flow physics, present a unique and powerful tool for analyzing the aerodynamics of helicopter rotors. Their effectiveness is often limited though by difficulties in retaining the structure and form of the rotor wake that result from their tendency to dissipate vorticity. The vorticity transport model, developed some years ago, addresses the problem of vorticity diffusion by solving the fundamental fluid dynamic equations in vorticity conservation form. A development of the original model is described that results in a more efficient computational implementation. The new model uses an adaptive grid system to increase grid resolution significantly, with minimal impact on computational cost. The new grid system is effectively boundary free, thus eliminating the need for numerical boundary conditions at the edges of the computational domain. In addition, the new grid system allows very efficient evaluation of the velocity field using a technique based on the Cartesian fast multipole method. The implementation of both the grid system and the velocity calculation is described, and the performance of the new model is validated against some well-known experimental data.

"BLADE TWIST EFFECTS ON ROTOR BEHAVIOUR IN THE VORTEX RING STATE"

European Rotorcraft Forum, Bristol, England, September 2002

Results are shown that give a better understanding of the factors that influence the initiation and subsequent development of the vortex ring state (VRS). It is suggested that the onset of VRS is associated with the collapse of the orderly structure of the rotor wake into a highly disturbed, irregular, aperiodic flow state. An analysis of the stability of the wake is presented to show that the location of the boundary of the VRS is influenced by the detailed structure of the rotor wake prior to its breakdown. Time-accurate calculations of the evolution of the rotor wake in the VRS are then presented to obtain more insight into the flows experienced by the rotor in the VRS. These calculations suggest that the location of the boundary of the VRS, and the depth of the VRS regime, is sensitive to the blade spanwise loading distribution, which is influenced by blade twist. The effects are significant even at low disk loading, but at high thrust where rotor stall may be encountered, rotors with and without significant blade twist show marked, and somewhat counterintuitive, differences in their behavior under VRS conditions.

Brown, S. N.

"THE COMPRESSIBLE INVISCID LEADING-EDGE VORTEX"

Journal of Fluid Mechanics, Vol. 22, Part 1, 1965, pp. 17-32.

The conically symmetric solution of the Eulerian equations of an incompressible fluid obtained by Hall, thought to be descriptive of flow properties in a leading-edge vortex, is generalized to include the effects of compressibility.

Brown, S. N. and Stewartson, K.

"ON COMPRESSIBILITY EFFECTS IN TIP VORTICES"

Proceedings IUTAM Symposium on Concentrated Vortex Motions, July 1964, Ann Arbor, Michigan.

The conically symmetric solution of the Eulerian equations of an incompressible fluid obtained by Hall, thought to be descriptive of flow properties in a tip vortex, is generalized to include the effects of compressibility. The governing equations have an energy integral, and the flow must be homentropic. Some comments are made about the solution when the Mach number of the flow at the outside edge of the vortex is small.

"THE DETERMINATION OF KINEMATIC PROPERTIES OF A WIND FIELD USING DOPPLER RADAR"

Journal of Applied Meteorology, Vol. 7, February 1968, pp. 105-113.

A technique is proposed for the measurement of kinematic properties of a wind field in situations of widespread precipitation, using a single Doppler radar to sense the motion of the precipitation particles. The technique is an extension of ideas put forward by Probert-Jones, Lhermitte, Atlas, Caton, and Harrold, and is based upon the Velocity-Azimuth Display (VAD) obtained by scanning the radar beam about a vertical axis at a fixed elevation angle. Harmonic analysis of the VAD permits divergence to be obtained from the magnitude of the 'zeroth' harmonic, wind speed and direction to be obtained from the amplitude and phase of the first harmonic, and resultant deformation and the axis of dilatation to be obtained from the amplitude and phase of the second harmonic. Although limitations to the accuracy of this technique are imposed by inhomogeneities in the horizontal distribution of precipitation fall speed and, in the presence of strong vertical wind shear, by elevation angle errors and reflectivity inhomogeneities, the error resulting from these effects can be made acceptably small by scanning at appropriate elevation angles and ranges. An optimum scanning procedure is suggested. A short case study is also presented to support the view that meaningful estimates of mesoscale divergence and deformation can be obtained using this technique.

Bruce, R. J.

"TRAILING EDGE STRIPS TO REDUCE THE DRAG OF SLENDER WINGS"

PhD Thesis, February 1988, Cranfield Institute of Technology, Cranfield, Bedfordshire, UK.

A slender delta is the ideal layout for good supersonic performance but the intense vorticity in the wake creates very high drag during maneuvering and at low speeds. It should be possible to recover some of the rotational energy from the wake by placing small fins in the strong sideways flows under the vortices to provide a thrust. A further development of this idea is to position long slender fins (or trailing edge strips) in the upwards flows around the vortices in the wake. They provide a lift and thrust over a wide CL range without harming the flow over the wing. This thesis traces the development of these strips in a series of low-speed wind tunnel tests. They were found to reduce the lift-dependent drag of a slender wing by 10 to 15 % at moderate angles of attack without penalizing the performance at very high angles of attack or in the cruise. A few inherent stability problems have been identified but ways to minimize them are suggested. During the course of the study the near-wake flow of a slender delta wing has been extensively studied. No supersonic tests have been carried out but the strips can be stored, if necessary, during supersonic flight.

Brucker, C.

"BREAKDOWN OF SPINNING TUBE FLOWS"

Proceedings IUTAM Symposium on Dynamics of Slender Vortices, September 1997, Aachen, Germany.

For our studies of turbulent vortex breakdown, a flow channel with a spinning tube was designed, where the swirl is introduced at the entrance by a honeycomb and maintained over the tube length. This provides a solid body rotation within the tube extending nearly over the complete diameter. Variation of the core Reynolds number and the swirl expressed through the Rossby number could be done independently. A diffuser at the end of the tube induces an adverse pressure gradient to promote vortex breakdown. In conclusion, a turbulent slender vortex is generated with a sharply defined core bounded by the spinning tube. In addition, through that the slender vortex core is axially forced by the spinning tube and the radial pressure gradient in the vortex is linear with the radius it let expect increased structural stability of near-axisymmetric modes of vortex breakdown. Therefore, these investigations could help to clarify the mechanism and conditions responsible for transition of the breakdown types and their stability/instability behavior.

Brucker, C.

"SOME OBSERVATIONS OF VORTEX BREAKDOWN IN A CONFINED FLOW WITH SOLID BODY ROTATION"

Flow, Turbulence and Combustion, Vol. 69, 2002, pp. 63-78

The occurrence of breakdown in slender vortex flows as a 'bubble' or 'spiral' pattern depends on the degree of radial deflection of the vortex core from its original axis. A smooth transition from a bubble to a spiral type 'mode' can be forced by inducing a small asymmetric disturbance which led to the conclusion, that the patterns do not represent different fundamental modes of breakdown. The subject presented herein addresses the following question: how does breakdown evolve in a swirling flow in which the vortex core is forced on a straight axis? In addition, what is the effect of turbulent inflow conditions? This type of vortex conditions is achieved in a spinning tube flow. The swirl is introduced at the entrance of the rotating tube with a honeycomb package and maintained by the viscous action in the boundary layer of the spinning tube. A diffuser at the end induces an adverse pressure gradient to force the breakdown. Flow visualization experiments are carried out to characterize the nature of breakdown over a range of different flow conditions. For some selected characteristic stages, detailed velocity fields were obtained using the method of Digital Particle-Image-Velocimetry (DPIV). The results show, that for the range of parameters investigated, breakdown is initiated at Rossby-numbers below a critical value of Ro about 0.6 like those observed in other experiments. The burst part of the vortex has a near axisymmetric slender conical shape containing approximately stagnant flow. Its downstream end is characterized by a jump-like contraction where the flow evolves into a jet with enhanced swirl on the axis. It is only in this region downstream of the jump-like contraction that asymmetric instabilities and wavy flow patterns could be observed. Perturbations caused by them travel upstream but do not change the near-axisymmetric shape of the burst part of the vortex.

Brucker, C.

"STUDY OF VORTEX BREAKDOWN BY PARTICLE TRACKING VELOCIMETRY (PTV). PART 2: SPIRAL-TYPE VORTEX BREAKDOWN"

Experiments in Fluids, Vol. 14, 1993, pp. 133-139.

The spiral-type breakdown of a slender vortex was quantitatively investigated with PTV. Multiexposed pictures of the illuminated meridional midplane were processed to obtain the instantaneous 2-D velocity field and vorticity distribution. The periodic change of flow patterns with respect to time is clearly shown in a time-series of pictures. The 2-D velocity fields contained a stagnation point in the midplane located outside of the centerline. Additionally, it was observed that this point rotates around the centerline in the same way as the outer flow. A comparison with measurements of a 'bubble-type' breakdown indicates a strong similarity to the spiral-type breakdown. The results reveal that the slope, winding end diameter of the spiral vortex cores determine the different observable forms. The first part of the deflected vortex core near the breakdown point causes an asymmetric backflow due to induction, the strength of which depends on the slope of the deflected vortex core. This is responsible for the radial distance between stagnation point and centerline. In case of the observed bubble-type breakdown the spiral is compressed which results in a stable stagnation point at the centerline.

Brucker, C. and Althaus, W.

"STUDY OF VORTEX BREAKDOWN BY PARTICLE TRACKING VELOCIMETRY (PTV). PART I: BUBBLE-TYPE VORTEX BREAKDOWN"

Experiments in Fluids, Vol. 13, 1992, pp. 339-349.

Using a quasi-three-dimensional instantaneous measurement technique, which combines particle tracking velocimetry (PTV) with volume scanning, first quantitative experimental results of the unsteady and asymmetric interior region of vortex breakdown were obtained. The study was carried out in a low-speed flow through a cylindrical tube. A vortex was generated by a set of guide vanes and subjected to an adverse pressure gradient causing its breakdown. By scanning a pulsed illuminated planar laser light sheet, a set of meridional and azimuthal 'cuts' of the flow were obtained. With PTV the recorded particle paths in the 'cuts' were processed to obtain the instantaneous two-dimensional velocity field, mean streamlines and vorticity distribution. Moreover, the three-dimensional shape of the appearing breakdown, visualized with fluorescent dye, was reconstructed from the 'cuts'. The results revealed that the shape of the bubble nearly equals the stream surface of the stagnation point. According to the conditions in the water tunnel a single tilted vortex ring at the open rear part of the bubble dominates the interior flow structure of the bubble as first noted by Sarpkaya. The vortical flow is bulged over the bubble, then restored and intensified at the lower end. The gathered data lead to the conclusion that the vortex axis remains parallel to the centerline.

Brucker, C. and Schroder, W.

"WAKE DYNAMICS OF AXI-SYMMETRIC BLUFF BODIES"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

With the measurement technique of time recording DPIV we obtained detailed quantitative results of the evolution of the velocity and vorticity field in the wake of axisymmetric bluff bodies. Experiments were carried out in a water tank for Reynolds numbers of $Re=500$, $Re=700$ and $Re=1000$ in the transition range from 'regular' to 'irregular' shedding. DPIV-recordings in radial cross-sections at several distances downstream of the bodies allowed us to reconstruct the dynamics of the streamwise vorticity over many shedding cycles. Our results demonstrate that the wake in this regime consists of a double-sided chain of oppositely oriented hairpin-vortices. One side of the chain is formed by the shed vortices while the other side is formed by induced hairpin vortices which are of considerably less circulation. The measurements revealed to the first time a low-frequency modulation of the vortex shedding with a distinct peak in the spectrum at a Strouhal number of about 0.03. This is best to be recognized in the time-variation of the amount of vorticity shed into the wake which we could analyze from our DPIV data. The frequency spectrum revealed that this peak persists even over the entire transition regime. The wake pattern in this 'irregular' shedding regime typically exhibits periodic packets of 3-4 'regular' shedding cycles which are interrupted by phases with less action. This is explained by the interaction of the helical waves in the wake of axisymmetric bodies.

Brune, G. W.

"QUANTITATIVE LOW-SPEED WAKE SURVEYS"

Journal of Aircraft, Vol. 31, No. 2, March-April 1994, pp. 249-255

Theoretical and practical aspects of conducting three-dimensional wake measurements in large wind tunnels are reviewed with emphasis on applications in low-speed aerodynamics. Such quantitative wake surveys furnish separate values for the components of drag such as profile drag and induced drag, but also measure lift without the use of a balance. In addition to global data, details of the wake flow field as well as spanwise distributions of lift and drag are obtained. This article demonstrates the value of this measurement technique using data from wake measurements conducted on a variety of low-speed configurations including the complex high-lift system of a transport aircraft.

Brune, G. W. and Hallstaff, T. H.

"WING SPAN LOADS OF COMPLEX HIGH-LIFT SYSTEMS FROM WAKE MEASUREMENTS"

Journal of Aircraft, Vol. 22, No. 9, September 1985, pp. 831-832

This note presents wake data of a twin-engine transport in a takeoff configuration and outlines a method of calculating wing loads based on well-known concepts that relate loading to the strength of trailing vortices. The measuring system consisted of a single five-hole conical probe (0.25-in. diameter) mounted on a mechanical traverse in the Boeing Transonic Wind Tunnel. The measured test data included total pressure and three components of wake velocity.

Brunet, S., Garnier, F. and Jacquin, L.

"NUMERICAL/EXPERIMENTAL SIMULATION OF EXHAUST JET MIXING IN WAKE VORTEX"

AIAA Paper No. 1999-3418, Norfolk, VA, June-July 1999

This study is a contribution to the understanding and modeling of engine jet dispersion of an aircraft in cruise condition. One presents a three-dimensional direct numerical simulation (DNS) of the interaction between jets and a vortex wake compare to the results of a wind tunnel experiment. The experimental data described herein comprises velocity fields measured by a Laser Doppler Velocimeter (LDV) and mean temperature fields delivered by thermocouples. The DNS is in qualitative agreement with the experiment but inspection shows departures caused by an underestimation of the jet mixing during the first phases of the jet development.

Brunet, S., Garnier, F. and Sagaut, P.

"CROW INSTABILITY EFFECTS ON THE EXHAUST PLUME MIXING AND CONDENSATION"

Proceedings of 3rd International Workshop on Vortex Flows and Related Numerical Methods, ESAIM, Vol. 7, 1999, pp. 66-79

Three-dimensional direct numerical simulation is performed to study the interaction of two engine jets with a pair of trailing vortices. First, a test panel of selected flux limiter has permitted to suppress spurious oscillations of the passive scalar and to enforce its positivity. Then, contours of a passive scalar (or a tracer concentration) are used to investigate the mixing and entrainment processes when the vortex pair goes through sinusoidal instability. The present results show that the dilution of the exhaust plume is less efficient when the flow undergoes this perturbation. However, the rate of mixing appears insensitive to the development of the Crow instability. Furthermore, to study the condensation process, results are presented involving the calculation of the saturation with respect to liquid water. This is performed by post-processing solution fields which provide a qualitative indicator where the condensation occurred in the aircraft wake.

Brusniak, L., Underbrink, J. R. and Stoker, R. W.

"ACOUSTIC IMAGING OF AIRCRAFT NOISE SOURCES USING LARGE APERTURE PHASED ARRAYS"

AIAA Paper No. 2006-2715, Cambridge, MA, May 2006

Increased restrictions on large commercial aircraft noise levels during takeoff and approach have spawned increased interest in the localization of subcomponent noise sources and quantification of their levels. Landing gear are the dominant sources of airframe noise during approach, with additional contributions from deployed slats, flaps, flaperons and so on. Jet noise, of course, dominates during takeoff. The acoustic phased array is a powerful flight test tool for imaging the noise sources on the aircraft. The acoustic phased array is a spatially distributed set of microphones which simultaneously sample the acoustic field. By appropriately time delaying the output of individual microphones, the origin and level of a given noise source can potentially be determined. The success of this approach

depends largely on 1) the actual character of the source (monopole, dipole, etc.), 2) the phased array design, and 3) the array data processing method. This paper focuses on aspects of the latter two areas. The objectives of this paper are to: a) present the flight test benefits accrued using large aperture phased arrays and, b) examine the utility of recently developed array processing methods for quantifying flight test aircraft subcomponent noise source levels.

Bryant, W. H.

"THE NASA/DOT VOLPE TRANSPORTATION CENTER WAKE ACOUSTIC DATA COLLECTION CAMPAIGN AT DENVER INTERNATIONAL AIRPORT"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

Analytical and experimental evidence suggests that a variety of atmospheric phenomena generate acoustic signals that might be exploited to provide some warning of the hazard's presence. Aircraft wake vortices created as a by-product of lift are among these phenomena. Existing knowledge suggests that wakes emit acoustic signals, but at very low frequencies and at low intensities. Preliminary acoustic signal findings from work conducted under the SOCRATES Program and independently by the German Aerospace Center (DLR-Berlin) suggested that an additional data collection experiment was justified to establish a better scientific understanding of the potential of this phenomenon. An experiment was designed to acquire the most pristine acoustic data ever collected to more fully understand the wake acoustic phenomena. Several sensors and equipment were deployed at the Denver International Airport to experimentally investigate the acoustic properties of wake vortices and to increase the scientific understanding of these acoustic signals. The hypothesis upon which this effort was done is that wake vortices generate unique, consistent acoustic signatures that may be exploited to mitigate the adverse effect of wake turbulence on airport operations. The Denver test was conducted during August/September 2003. The wake acoustic sensor for the Denver International Airport test was a 252-element phased microphone array and meteorological instruments to acquire data permitting a more thorough fundamental investigation of the wake acoustics phenomenon. Both pulsed lidar and CW lidars were used to provide an estimate of actual wake behavior. Additionally, a 4-beam SOCRATES wake acoustics research sensor was deployed to assess modifications made to the SOCRATES hardware and signal processing software in the past two years.

"WAKE VORTEX AVOIDANCE SYSTEM"

1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-175, September 2007, pp. 3357-3369

There is an urgent need to increase airport capacity without building new runways. Aircraft separation based on wake vortex (WV) mitigation significantly affects airport capacity. While the ICAO WV standards established in the 1970's are effective for safety, they are more conservative than

necessary to preserve safety; and thus, unduly reduce airport capacity. The FAA and NASA have developed an integrated, time-phased approach to meet the needs of the aviation community in lessening the impact of wake turbulence on airport operations. The U.S. National Airspace System (NAS) is developing transition plans to evolve from today's operations to a future system called Next Generation Air Transportation System, or NextGen. NextGen goals include a capacity improvement of 2 to 3 times today's system capacity. To achieve this goal, improvements in communications, navigation, surveillance, and weather technologies must be integrated with wake avoidance solutions and ATC and flight deck procedures and tools. In addition, the safety of the total solution must be demonstrable to the stakeholders and regulatory authorities. This paper presents the elements of a Wake Vortex Avoidance System (WakeVAS) and describes the progress made to date in maturing some of its elements and implementing them as evolutionary steps towards NextGen. Key system performance requirements and the process for defining them are presented for some of the matured elements. Less mature elements of a WakeVAS are also described in terms of observed performance characteristics when used in research mode (e.g., LIDARs) as well as fundamental research issues that need to be addressed before these elements can be considered for inclusion in a WakeVAS. Some of this work is being accomplished in cooperation with the European research community. Lessons learned from safety case development for Simultaneous Offset Instrument Approaches and Lambert - St. Louis International Airport (STL) dependent approach procedures are highlighted with insight into their extensibility to more complex solutions such as Wake Turbulence Mitigations for Departures (WTMD).

"EXPERIMENTAL INVESTIGATION OF THE VORTEX FLOW STRUCTURE"

In: Investigation of Vortex Wake Evolution and Flight Safety Problems - Collection of Papers, Trudy TsAGI, Vol. 2627, Publishing Dept. of TsAGI, Moscow, Russia, 1997, pp. 56-67

The paper deals with a new technique for visualizing 3D vortex flows with the aid of thin, long and practically weightless strips of synthetic foil. The methodology is developed for recording the visualization patterns first on the video camera then on the photo film from the display. Examples are given of visualization patterns of vortical and jet flows. Measurements of tangential and axial velocities in the vortex were conducted with the aid of the five-hole probe.

"AVIATION TURBULENCE ENSEMBLE TECHNIQUES"

In Aviation Turbulence, edited by R. Sharman and T. Lane, Chapter 14, 2016, Springer International Publishing Switzerland, pp. 285-296.

Global ensemble weather model forecasts have been available over several decades now. Ensemble forecasts allow uncertainties in even short-range forecasts to be quantified. This is achieved through the principle of running several slightly different but equally feasible forecasts. These forecasts can be used to generate probabilities of turbulence indicators exceeding certain key thresholds. Through calibration, these probability forecasts can be used to generate the likelihood of turbulence occurring. It is even possible to combine these probabilities with non-meteorological information (e.g. the purpose of the aircraft flight) to produce impact forecasts.

Buchholz, J. and Smits, A. J.

"UNSTEADY PROPULSION AND WAKE STRUCTURE OF A FINITE ASPECT RATIO PITCHING PLATE"

AIAA Paper No. 2007-128, Reno, NV, January 2007

Thrust performance and wake structure were investigated for a rigid rectangular panel pitching about its leading edge in a free stream. Thrust coefficient was found to depend primarily on Strouhal number St and the aspect ratio of the panel S/C . Propulsive efficiency was sensitive to aspect ratio only for S/C less than 0.83; however, the magnitude of the peak efficiency of a given panel with variation in Strouhal number varied inversely with the amplitude to span ratio A/S , while the Strouhal number of optimum efficiency increased with increasing A/S . Peak efficiencies between 9% and 21% were measured. Wake structures corresponding to a subset of the thrust measurements were investigated using dye visualization and Digital Particle Image Velocimetry. In general, the wakes divided into two oblique jets; however, when operating at or near peak efficiency, the near wake in many cases represented a von Karman vortex street with the signs of the vortices reversed. The three-dimensional structure of the wakes was investigated in detail for $S/C = 0.54$, $A/S = 0.31$, $Re = 640$. Three distinct wake structures were observed with variation in Strouhal number.

"DEVELOPMENT OF AN AIRCRAFT APPROACH AND DEPARTURE ATMOSPHERIC PROFILE GENERATION ALGORITHM"

NASA/CR-2004-213236, June 2004, AeroTech Research Inc., Hampton, VA

In support of NASA Virtual Airspace Modeling and Simulation project, an effort was initiated to develop and test techniques for extracting meteorological data from landing and departing aircraft, and for building altitude-based profiles for key meteorological parameters from these data. The generated atmospheric profiles will be used as inputs to NASA's Aircraft Vortex Spacing System (AVOSS) Prediction Algorithm for benefits and trade analysis. A Wake Vortex Advisory System (WakeVAS) is being

developed to apply weather and wake prediction and sensing technologies with procedures to reduce current wake separation criteria when safe and appropriate to increase airport operational efficiency. The purpose of this report is to document the initial theory and design of the Aircraft Approach Departure Atmospheric Profile Generation Algorithm.

Budlong, D. D.

"INTERACTIONS OF AIRCRAFT WAKE VORTICES AND SECONDARY VORTICAL STRUCTURES"

M.S. Thesis, 1999, University of South Alabama, Mobile, AL

The effects of secondary structures on aircraft wake vortices are numerically studied using a three-dimensional point vortex method. This method is first applied to simple vortex structures that have analytical solutions for validation of the computer code, determination of grid resolution requirements, and approximate cut-off distance criteria. Crow instability criteria for three-dimensional counter-rotating vortex-pair is simulated. Vortex rings are used as secondary vortical structures with various circulation strengths, sizes and locations to study the effects of atmospheric turbulence on aircraft wakes. It was determined that the point vortex method in three-dimensional space produced satisfactory results for the validation and Crow instability cases.

"VORTEX CREATION AND WING-TIP GEOMETRY DEPENDENCIES"

AIAA Paper No. 2012-2770, June 2012, New Orleans, LA.

This study presents experimental 3C-PIV investigations of the vortex topology at the wing-tip. The aim is to identify geometrical aspects of the wing-tip, which exert dominant influence on the production of the axial velocity component. Different wing-tip shapes are considered. Typical rectangular round and flat shapes as well as shapes, which feature a rounding of the layout are used. Special focus is placed upon vortex creation at the wing-tip, where vorticity is accumulated by primary and also to some extent by secondary vortices. The evolution and gradual enhancement of the radial circulation profile is displayed. A rounding of the side of the tip results in a more intensive vortex. An interesting rounding of the layout has the opposite effect. Correlation of vortex topology and therefore wing-tip shaping are shown. In a second step a calculation and analysis of the real, inviscid, as well as the viscous axial velocity component at the center of the vortex is performed. Therefore, the geometrical features of the tip can be related to the production and suppression of the axial velocity component during the vortex creation phase at the wing tip.

Bugala, P. and Dziubinski, A.

"INTERACTION OF HEAVY AIRCRAFT WAKES"

Transactions of the Institute of Aviation, No. 4, 2016, pp. 309-320.

In the next few years, the problem of heavy aircraft wakes may increase on the account of continuous air transport growth. However, it can be noticed that even today the number of accidents resulting from an interaction with wakes is increasing. That is the reason why methods of wake vortex description should be searched for. The aim of this study is to analyze interaction of example aircraft wakes. In this paper the characteristics of vortex wake behind three-dimensional wing are presented. It shows how a separation between aircraft affects the decay of vortex. Two- and three-dimensional calculations were performed using commercial RANS code. The following cases have been taken into consideration: flow past a full commercial aircraft, three-dimensional flow over the simplified wing and a two-dimensional analysis of vortex decay caused by the landing aircraft, including the separation effect. For all these cases a CFD simulation of the aircraft wakes was conducted. One of the main outcomes of this work is a confirmation that the interaction between wakes consists of spreading out and lifting wakes. The achieved results show that the two-dimensional simulation is a sufficient tool for a preliminary analysis of wake vortices. Conclusions from this analysis can be used by the managements of busy international airports to enhance safety.

Bulek, S. and Erdol, N.

"STUDY OF AIRPLANE WAKE VORTEX ACOUSTICS USING BLIND SIGNAL SEPARATION"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

In 2003 NASA and DOT acquired aero-acoustics data by placing a microphone array in the landing path of aircrafts at the Denver International Airport. Our group was charged with developing signal processing algorithms to characterize and isolate any sound associated with a wake vortex. In this paper we report the results of applying a technique broadly known as blind source separation (BSS) to a select number of microphone recordings with the goal of isolating a low power wake vortex sound from the engine and wind noise. We use a multistage approach to deconvolutive BSS on three microphone recordings of aero-acoustic data. The decomposition of the extracted signals into its independent components reveals a structure significantly differentiated from the recorded mix.

Bulek, S. and Erdol, N.

"APPLICATION OF BLIND SOURCE SEPARATION IN THE ANALYSIS OF AIRPLANE WAKE VORTEX ACOUSTICS"

18th International Conf. on Artificial Neural Networks, Prague, Czech Republic, Sept. 2008

Considerations of first principles of fluid dynamics reveal that sounds that are machine generated and sounds that arise from turbulent airflow may be represented as the outputs of linear filters and temporally independent and identically distributed and spatially independent input sequences. These sounds get mixed in the air in an unknown fashion. When we analyze the sound signals in relatively short time intervals, an instantaneous mixing model seems plausible. A blind source separation (BSS) algorithm may then be used to isolate a sound associated with a wake vortex generated by a landing

aircraft. A multistage deflation approach to BSS is applied to four microphone recordings of aero-acoustic data. The decomposition of the observed signals into its independent components reveals a structure significantly differentiated from the recorded mix. Observations also agree with data reported by aviation experts.

Burley, C. L., Brooks, T. F., Rozier, K. Y., van der Wall, B., Richard, H., Raffel, M., Beaumier, P., Deirieux, Y., Lim, J. W., Yu, Y. H., Tung, C., Pengel, K. and Mercker, E.

"ROTOR WAKE VORTEX DEFINITION-EVALUATION OF 3-C PIV RESULTS OF THE HART-II STUDY"

Aeroacoustics, Vol. 5, No. 1, 2006, pp. 1-38

An evaluation is made of extensive three-component (3-C) particle image velocimetry (PIV) measurements within the wake across a rotor disk plane. The model is a 40 percent scale BO-105 helicopter main rotor in forward flight simulation. This study is part of the HART II test program conducted in the German-Dutch Wind Tunnel (DNW). Included are wake vortex field measurements over the advancing and retreating sides of the rotor operating at a typical descent landing condition important for impulsive blade-vortex interaction (BVI) noise. Also included are advancing side results for rotor angle variations from climb to steep descent. Using detailed PIV vector maps of the vortex fields, methods of extracting key vortex parameters are examined and a new method was developed and evaluated. An objective processing method, involving a center-of-vorticity criterion and a vorticity 'disk' integration, was used to determine vortex core size, strength, core velocity distribution characteristics, and unsteadiness. These parameters are mapped over the rotor disk and offer unique physical insight for these parameters of importance for rotor noise and vibration prediction.

Burley, C. L., Brooks, T. F., van der Wall, B., Hughues, R., Raffel, M., Beaumier, P., Delrieux, Y., Lim, J. W., Yu, Y. H., Tung, C., Pengel, K. and Mercker, E.

"ROTOR WAKE VORTEX DEFINITION USING 3C-PIV MEASUREMENTS - CORRECTED FOR VORTEX ORIENTATION"

AIAA Paper No. 2003-3175, Hilton Head, SC, May 2003

Three-component (3-C) particle image velocimetry (PIV) measurements, within the wake across a rotor disk plane, are used to determine wake vortex definitions important for BVI (Blade Vortex Interaction) and broadband noise prediction. This study is part of the HART II test program conducted using a 40 percent scale BO-105 helicopter main rotor in the German-Dutch Wind Tunnel (DNW). In this paper, measurements are presented of the wake vortex field over the advancing side of the rotor operating at a typical descent landing condition. The orientations of the vortex (tube) axes are found to have non-zero tilt angles with respect to the chosen PIV measurement cut planes, often on the order of 45 degrees. Methods for determining the orientation of the vortex axis and reorienting the measured PIV velocity maps (by rotation/projection) are presented. One method utilizes the vortex core axial velocity component, the other utilizes the swirl velocity components. Key vortex parameters such as vortex core size, strength, and core velocity distribution characteristics are determined from the

reoriented PIV velocity maps. The results are compared with those determined from velocity maps that are not corrected for orientation. Knowledge of magnitudes and directions of the vortex axial and swirl velocity components as a function of streamwise location provide a basis for insight into the vortex evolution.

Burnham, D. C.

"WAKE VORTEX SEPARATION REQUIREMENTS FOR THE PROPOSED VERY LARGE AIRCRAFT"

AIAA Paper No. 1999-3422, Norfolk, VA, June 1999

Since the proposed Very Large Aircraft (VLA) is significantly larger than current jet transport aircraft, its introduction may require modification of existing wake vortex separation standards. This paper examines the potential impact of the VLA using two existing safe separation models: one based on wake turbulence encounter reports and the other based on wake decay measurements coupled with an encounter hazard model. The first model predicts that, for the same follower spacing, the encounter rate behind the VLA will be about twice that behind the B-747; hence, increased spacing may be justified behind the VLA. The second model suggests that current spacings are adequate if the VLA is simply treated as a Heavy aircraft. The limitations of the models and their applicability for defining safe separations are discussed.

Burnham, D. C.

"GROUND-BASED WAKE VORTEX SENSOR TECHNOLOGY: CURRENT CAPABILITIES, FUTURE PROSPECTS"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, December 1997, pp. 107-10.

Progress in understanding the behavior of aircraft wake vortices has been dependent upon the development of new measurement technologies. The critical sensor parameters are spatial coverage, location accuracy, capability of assessing vortex strength, unmanned operation, real-time processing, all-weather performance, and cost. Wake vortices have been measured by in-situ wind sensors and virtually all remote sensing technologies (sodar, lidar, radar, and RASS). The status and inherent limitations of these technologies will be reviewed and compared with the requirements for research on wake vortex behavior and operational wake vortex avoidance systems. Note that airborne sensors will not be considered. Suggestions will be made for future sensor development to provide capabilities not currently available. In some cases, a combination of sensors may be more useful than a single sensor for meeting all research/system requirements.

Burnham, D. C.

"REVIEW OF VORTEX SENSOR DEVELOPMENT SINCE 1970"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 47-66

The various sensing techniques developed since 1970 and used for studying aircraft wake vortices are described. The inherent advantages and limitations of each technique are discussed. Emphasis is placed on those sensors used for data collection at airports.

Burnham, D. C.

"CHICAGO MONOSTATIC ACOUSTIC VORTEX SENSING SYSTEM, VOLUME I: DATA COLLECTION AND REDUCTION"

FAA-RD-79-103,I, October 1979, DOT Transportation Systems Center, Cambridge, M.

A Monostatic Acoustic Vortex Sensing System (MAVSS) was installed at Chicago's O'Hare International Airport to measure the strength and decay of aircraft wake vortices from landing aircraft. The MAVSS consists of an array of acoustic antennas which measure the vertical profile up to 60 m altitude of the vertical component of the wind. The decay in wake vortex strength is measured as the vortex passes over successive antennas in the array. This volume describes the MAVSS principles of operation, the hardware developed, and data reduction methods employed.

Burnham, D. C.

"B-747 VORTEX ALLEVIATION FLIGHT TESTS: GROUND-BASED SENSOR MEASUREMENTS"

FAA-RD-81-99, January 1982, DOT Transportation Systems Center, Cambridge, MA

In 1979, a series of B-747 flight tests were carried out to study the wake-vortex alleviation produced by deploying spoilers in the landing configuration. The alleviation achieved was examined by encounters of probe aircraft and by velocity profile measurements made by a ground-based Laser Doppler Velocimeter. For the first time these two types of measurements were analyzed in a way which allowed direct comparison; they showed reasonable agreement. The velocimeter measurements can be used to evaluate the vortex-induced rolling moment on any following aircraft at any separation. The spoiler alleviation was found to be insufficient to assure safe landings of small aircraft at reduced separation behind the B-747. The persistence of the alleviated vortices appears to be due to the wing-tip vortices which dominate the roll-up of the spoiler-alleviated wake. The addition of rapid roll inputs to the spoiler deployment produced much more effective alleviation, but at the expense of an unacceptable ride quality in the generating aircraft.

Burnham, D. C.

"HOW TO USE WAKE VORTEX MEASUREMENTS TO SET SEPARATION STANDARDS"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 53-1 - 53-11

A procedure for setting separations from wake vortex measurements assumes that the current separation standards are 'safe.' A vortex hazard model is used to assess the hazard threshold for vortex strength. Vortex decay measurements are processed to give an empirical model for vortex decay, which specifies the probability of the vortex strength remaining above a given value as a function of vortex age. These two models can be combined to determine the vortex hazard probability at a given separation time. If the hazard probability under current standards for a frequently occurring aircraft pair is defined as safe, then the safe separation for other aircraft pairs can be determined. The sensitivity of the results to the assumed hazard model is then assessed. Two sample applications of this methodology are presented: (1) 2.5-mile separation of small and large aircraft (smaller than the B-757) and (2) reduction of Heavy-Heavy separation from 4 to 3 miles.

Burnham, D. C.

"ANALYSIS OF UK ENCOUNTERS 1982-1990"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 21-1 to 21-4

Wake vortex separation standards are used to limit the frequency and severity of wake vortex encounters under instrument flight rules (IFR). One of the goals of wake vortex research is to develop models that can specify the safe separation for any aircraft pair and hence can be used to judge the safety of proposed changes in separation standards. A direct approach to defining a safe separation model is presented in this paper. The observed UK vortex encounter rates are fitted to a model that defines equal-encounter-rate (EER) separations as a function of the parameters of the leading and following aircraft (specifically their wingspans). Safety is specified by defining the acceptable encounter rate. The first analysis fits the EER separation to powers of the wingspans of the leading and following aircraft. When these powers (1.13 and -0.95, respectively) are found to be close to one, the analysis is repeated using the leader-follower span ratio.

Burnham, D. C.

"NOVEMBER 1996 KENNEDY AIRPORT WAKE VORTEX TEST: SENSOR EVALUATION"

DOT-VNTSC-FA727-PM-27, August 1997, DOT Volpe National Transportation Systems Center, Cambridge, MA

In November 1996, a number of wake vortex and meteorological sensors were operated simultaneously in the middle marker region of Runway 31R at New York's Kennedy Airport. The vortex sensors included: 1) ground-based anemometer array, 2) cw 10-micron lidar, 3) fan-beam sodar, 4) RASS, 5) sonic anemometer, 6) scintillometer, and 7) vertical beam sodar. Comparisons of measurements from the different sensors are presented and used to analyze sensor capabilities and suitability for the NASA Aircraft Vortex Spacing System (AVOSS). Several new observations were made during this test: 1) boundary thickness under the wake vortex in ground effect, 2) high time resolution in situ temperature and velocity measurements inside the vortex recirculation oval, 3) directional

measurements of vortex-generated sound, and 4) the influence of aircraft on meteorological conditions.

Burnham, D. C.

"WAKE VORTEX CIRCULATION MEASUREMENTS"

Third Workshop on Atmospheric Acoustics, York University, Toronto, Canada, June 1975.

An acoustic sounder with separate transmitting and receiving antennas is used to measure the vertical wind profile of an aircraft wake between 20 and 150 feet. The velocity data are processed with correlation techniques to find the vortex locations. The vortex strength and core radius are obtained by fitting the data to a simple model.

Burnham, D. C.

"CHARACTERISTICS OF A WAKE-VORTEX TRACKING SYSTEM BASED ON ACOUSTIC REFRACTIVE SCATTERING"

J. Acoustical Soc. America, Vol. 61, March 1977, pp. 647-654

The theory of acoustic-ray bending by aircraft-generated vortices is developed in a form convenient for application to a practical vortex tracking system. The maximum scattering angle is proportional to the vortex circulation divided by the average core radius. Since the circulation for commercial jet transports is roughly proportional to the wingspan, the value of the maximum scattering angle depends little on aircraft size but strongly on the ratio of the core size to the wingspan. For landing aircraft, the maximum scattering angle varies from 0.5 to 1.4 rad depending upon the engine placement. The capabilities of a pulsed acoustic vortex tracking system depend strongly upon the maximum scattering angle and therefore upon aircraft type. The effects of timing errors, both vortex-induced and random, on tracking accuracy are derived. The fundamental differences between refractive scattering and turbulence scattering techniques are described.

Burnham, D. C.

"EFFECT OF GROUND WIND SHEAR ON AIRCRAFT TRAILING VORTICES"

AIAA Journal, Vol. 10, No. 8, August 1972, pp. 1114-1115

In ground effect, when the wind blows across the aircraft path, one often observes that the up-wind wake vortex consistently descends to a lower altitude than the down-wind vortex. The relationship of this effect to wind shear is illustrated by a simple calculation where the wind shear layer near the ground is modeled as a row of line vortices.

Burnham, D. C. and Abramson, S.

"DATABASE OF GROUND-BASED ANEMOMETER MEASUREMENTS OF WAKE VORTICES AT KENNEDY AIRPORT"

DOT/FAA/ND-97-6, July 1997, DOT Volpe National Transportation Systems Center, Cambridge, MA

A 700-foot array of horizontal and vertical single-axis anemometers was installed at New York's Kennedy Airport on 30-foot poles under the approach to Runway 31R. Although the original purpose for the anemometers was to track the lateral position of wake vortices, new processing algorithms were developed that permit assessment of vortex height and circulation. Data from more than 20,000 landings have been recorded and processed. This report documents the current state of algorithm development and provides processed data for other researchers to analyze.

Burnham, D. C. and Abramson, S.

"WIND DATA FROM MEMPHIS AIRPORT"

DOT/FAA/ND-97-5, June 1997, Scientific and Engineering Solutions, Inc., Orleans, MA.

A 1300-foot array of horizontal and vertical single-axis anemometers was installed at the Memphis, TN, Airport on 10- and 13-foot poles under the approach to Runway 27. One-minute average measurements were recorded continuously from mid-August 1995 through late December 1995. Although the original purpose for the anemometers was to track the lateral position of wake vortices, the measurements also provide a database of wind and turbulence that could be used for other purposes. For example, the crosswind data could be used to evaluate adaptive wake vortex separation systems based on the measured crosswind. The report documents the data formats and database characteristics.

Burnham, D. C. and Greene, G. C.

"WINDOWS-BASED REAL-TIME WAKE VORTEX DISPLAY"

XXV General Assembly, European Geophysical Society, Nice, France, April 2000

Real-time wake vortex measurements could improve the safety and efficiency of airport operations. However, no user requirements have been defined, in part because users have never seen real-time vortex tracking. The software presented here was developed to examine optional display formats that will assist users in developing wake vortex sensing requirements. Windline data from DFW, JFK and other airports will be presented.

Burnham, D. C. and Hallock, J. N.

"MEASUREMENTS OF WAKE VORTICES INTERACTING WITH THE GROUND"

j. Aircraft, Vol. 42, No. 5, Sept.-Oct. 2005, pp. 1179-1187

Although wake vortices are known to decay more rapidly near the ground than away from the ground, the details of the ground interaction are not well understood. Propeller anemometer arrays located under the approach path have been used to study vortex transport and provide some information about the vortex interaction with the ground, such as the generation of secondary vortices via boundary-layer detachment. A propeller array at Kennedy International Airport using 8.5-m poles was augmented with 1) a sonic anemometer measuring three-dimensional wind and temperature at 10 Hz and 2) a vertical array of vertical wind and crosswind anemometers, mounted at four additional levels (4.2, 3.2, 1.05 and 0.5 m). The sonic anemometer gave 1) measurements of turbulence inside the vortex flow field and 2) indications of vertical variations in the ambient headwind and temperature, which were brought down to the measurement level by the descent of the vortex recirculation oval. In general, under conditions of low to moderate turbulence, the turbulence level inside the wake vortex flow field is greater than that in the ambient wind. The vertical anemometer array showed that the crosswind profile under a wake vortex in ground effect has a very thin boundary layer, much thinner than that of the ambient wind. It also provided some details concerning the wind profile of the secondary vortex.

Burnham, D. C. and Hallock, J. N.

"WIND EFFECTS ON THE LATERAL MOTION OF WAKE VORTICES"

DOT/FAA/AAR-99/88, November 1999, DOT Volpe National Transportation Systems Center, Cambridge, MA

This report examines the influence of crosswind and other factors on the behavior of wake vortices. Data from acoustic remote sensors and in situ sensors were used to track to possible transport of wake vortices between parallel runways. The measurements used in the analysis came from landing (1976-77) and takeoff (1980) operations at O'Hare International Airport. As expected, wake vortices are observed to transport with the ambient wind; therefore, dangerous wake vortex encounters can be avoided on parallel runways with suitable assignment of aircraft to the two runways. The analyses of the report were carried out in the mid-1980s and serve to document the O'Hare landing and takeoff databases and how they can be used. The status of the acoustic and in situ wake vortex sensors is updated to the late 1990s.

Burnham, D. C. and Hallock, J. N.

"MOTION OF AIRCRAFT WAKE VORTICES IN GROUND EFFECT"

DOT-FAA-AAR-00-16, April 2000, DOT Volpe National Transportation Systems Center, Cambridge, MA

This report addresses the wake-turbulence separation standards for close-spaced parallel runways. Ground-wind anemometer data collected at Kennedy (landing) and O'Hare (takeoff) airports are analyzed to assess the lateral transport probability for wake vortices. A model is developed to predict the lateral transport probability and is used to analyze possible reductions in the wake-turbulence

limits on parallel runways for reduced ranges of aircraft classes (e.g., only small and large aircraft). Unfortunately, adoption of the calculated reduced separation standards cannot be recommended because of uncertainties in the analysis.

Burnham, D. C. and Hallock, J. N.

"WIND EFFECTS ON LATERAL MOTION OF WAKE VORTICES"

XXV General Assembly, European Geophysical Society, Nice, France, April 2000

Sodars and/or ground-based anemometers were used to track wake vortices for landing and/or takeoff operations at ORD and DFW airports. The ambient wind was measured by a separate tower (ORD) or the ground-based anemometers themselves (DFW). The study examined the influence of the ambient wind on the probability that vortices generated on one runway can migrate to a parallel runway.

Burnham, D. C. and Hallock, J. N.

"CHICAGO MONOSTATIC ACOUSTIC VORTEX SENSING SYSTEM, VOLUME II: DECAY OF B-707 AND DC-8 VORTICES"

FAA-RD-79-103,II, September 1979, DOT Transportation Systems Center, Cambridge, M.

A Monostatic Acoustic Vortex Sensing System (MAVSS) was installed at Chicago's O'Hare International Airport to measure the strength and decay of aircraft wake vortices from landing aircraft. The MAVSS consists of an array of acoustic antennas which measure the vertical profile up to 60-m altitude of the vertical component of the wind. The decay in wake vortex strength is measured as the vortex passes over successive antennas in the array. In this volume, the data are analyzed to examine whether landing B-707 and DC-8 aircraft need to be divided into heavy and non-heavy categories on the basis of wake vortex hazard.

Burnham, D. C. and Hallock, J. N.

"CHICAGO MONOSTATIC ACOUSTIC VORTEX SENSING SYSTEM, VOLUME III: EXECUTIVE SUMMARY: DECAY OF B-707 AND DC-8 VORTICES"

FAA-RD-79-103, III, January 1982, DOT Transportation Systems Center, Cambridge, MA.

A Monostatic Acoustic Vortex Sensing System (MAVSS) was installed at Chicago's O'Hare International Airport to measure the strength and decay of aircraft wake vortices from landing aircraft. The MAVSS consists of an array of acoustic antennas which measure the vertical profile up to 60-m altitude of the vertical component of the wind. The decay in wake vortex strength is measured as the vortex passes over successive antennas in the array. In this volume, the results of Volume II are summarized in terms of the safety implications of categorizing all landing B-707s and DC-8s as Large aircraft.

Burnham, D. C. and Hallock, J. N.

"CHICAGO MONOSTATIC ACOUSTIC VORTEX SENSING SYSTEM, VOLUME IV: WAKE VORTEX DECAY"

FAA-RD-79-103, IV, July 1982, DOT Transportation Systems Center, Cambridge, M.

A Monostatic Acoustic Vortex Sensing System (MAVSS) was installed at Chicago's O'Hare International Airport to measure the strength and decay of aircraft wake vortices from landing aircraft. The MAVSS consists of an array of acoustic antennas which measure the vertical profile up to 60-m altitude of the vertical component of the wind. The decay in wake vortex strength is measured as the vortex passes over successive antennas in the array. In this volume, the statistical methods used to understand wake vortex decay are described and the data on all common jet transport aircraft are presented.

Burnham, D. C. and Hallock, J. N.

"WAKE VORTEX SEPARATION STANDARDS: ANALYSIS METHODS"

DOT/FAA/ND-97-4, May 1997, DOT Volpe National Transportation Systems Center, Cambridge, MA

Wake vortex separation standards are used to prevent hazardous wake vortex encounters. A 'safe' separation model can be used to assess the safety of proposed changes in the standards. A safe separation model can be derived from an encounter hazard model and a vortex decay model. This report presents subsequent developments and applications of such a model which was first developed in the early 1980s. A static encounter hazard model is coupled with a decay model based on sodar measurements of vortex decay. The separation standards and procedures used from 1976 to 1994 are assumed to be safe based on the absence of IFR accidents. Various versions of the model are used to assess how aircraft should be classified and to evaluate the safety of a possible four-class aircraft separation system. Recommendations are made for ways of improving the safe separation models.

Burnham, D. C. and Hallock, J. N.

"MEASUREMENTS OF WAKE VORTICES INTERACTING WITH THE GROUND"

AIAA Paper No. 1998-0593, Reno, NV, January 1998

Although wake vortices are known to decay more rapidly near the ground than away from the ground, the details of the ground interaction are not well understood. Propeller anemometer arrays located under the approach path have been used to study vortex transport and provide some information about vortex interaction with the ground, such as the generation of secondary vortices via boundary layer detachment. A propeller anemometer array at Kennedy Airport was augmented with (a) a sonic anemometer measuring three-dimensional wind and temperature at 10 Hz and (b) a vertical array of vertical wind and crosswind anemometers, mounted at four additional levels (4.2, 3.2, 1.05, and 0.5 m). The sonic anemometer gave (a) measurements of turbulence inside the vortex flow field and (b) indications of vertical variations in the ambient headwind and temperature. In general, under

conditions of low to moderate turbulence, the turbulence level inside the wake vortex flow field is greater than that in the ambient wind. The vertical anemometer array showed that the crosswind profile under a wake vortex in ground effect has a very thin boundary layer, much thinner than that of the ambient wind.

"DECAY CHARACTERISTICS OF WAKE VORTICES FROM JET TRANSPORT AIRCRAFT"

Journal of Aircraft, Vol. 50, No. 1, January-February 2013, pp. 82-87.

In the 1970s the B747-100 alleviation tests, sponsored by NASA with FAA participation, provided unique continuous-wave lidar data, in which the vortex cores could be measured because they were marked with smoke. Measurements for both normal and alleviated wakes showed that the vortex core is persistent whereas the outer circulation of the vortex decays. This form of decay is exactly the opposite of what is observed at low Reynolds number for small aircraft or in wind tunnels. The stability of the core is consistent with the essentially laminar core observed via flow visualization. The circulation profile for the normal wake is well fitted by the Burnham-Hallock model both after initial rollup and after significant decay of the total circulation. The core size for the normal B-747-100 wake is larger (5 percent of wingspan) than typically observed for aircraft with zero or two wing-mounted engines. The observed wake decay means that the total vortex circulation is approximately equal to the popular vortex strength parameter: average circulation over vortex radii from 5 to 15 m.

Burnham, D. C. and Rudis, R. P.

"JFK-1 WAKE VORTEX SENSOR INTERCOMPARISONS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 333-341

Four wake vortex sensors were tested near the middle marker of JFK Runway 31R (aircraft at 50 m height above ground) in November 1996. The status of the sensors and the goals of this test were: (1) cw lidar - relatively mature - reference for vortex location and strength, (2) anemometer array - relatively mature - reference for lateral position - tested height and strength algorithms, (3) RASS - lateral position validated against anemometer array in prior tests - height and strength evaluated against cw lidar, (4) fan-beam sodar - first wake vortex data from final hardware configuration. The performance of each sensor was determined by intercomparisons with measurements of the other sensors for the same vortices. Conclusions were presented on the utility of each sensor technology for the AVOSS system.

Burnham, D. C. and Rudis, R. P.

"EXPECTED PERFORMANCE OF CROSSWIND-BASED WAKE VORTEX AVOIDANCE SYSTEMS AT DFW AIRPORT"

XXIII General Assembly, European Geophysical Society, Nice, France, April 1998

Relaxation of wake vortex separation standards is possible when the ambient crosswind is within certain limits. The feasibility of a wake vortex avoidance system (WVAS) based on such limits depends upon (1) how often suitable crosswinds occur, (2) how long the conditions last, and (3) whether separation changes can be forecast. The paper analyzes five different crosswind-based WVAS, which address landing, takeoff, single-runway and close-spaced-parallel-runway operations. The analysis uses minute-by-minute wind data collected at the Dallas-Ft. Worth Airport.

Burnham, D. C. and Sullivan, T. E.

"INFLUENCE OF FLAPS AND ENGINES ON AIRCRAFT WAKE VORTICES"

Journal of Aircraft, Vol. 11, No. 9, September 1974, pp. 591-592

Observed differences in aircraft wake vortex core structure are related to engine placement, engine thrust, and wing flap deflection angle. The vortices are divided into two main categories, tubular and non-tubular by two methods: visual observations and results from a pulsed bistatic acoustic vortex sensing system. The major difference is observed in landing configurations between aircraft with and without engines located very close to the outboard flap edge.

Burnham, D. C. and Wang, F. Y.

"DO WAKE VORTICES BEHAVE DIFFERENTLY UNDER NON-LIDAR-FRIENDLY WEATHER CONDITIONS?"

Journal of Aircraft, Vol. 52, No. 3, May-June 2015, pp. 993-996.

No indications were found to suggest that wakes near the ground at San Francisco International Airport might be more hazardous or behave differently under conditions unfriendly to pulsed lidar measurements. Some cases were found where the wake decay was slightly faster under lidar-unfriendly conditions than under lidar-friendly conditions. Thus, pulsed lidar measurements can capture the reasonable 'near-worse-case' wake turbulence hazard near the ground in routine data collection. This study covered many scenarios: 1) two conditions unfavorable for lidar operation (low ceiling and low visibility), 2) several aircraft types, 3) various crosswind conditions, and 4) various headwind conditions. This range of conditions gives confidence in the results.

Burnham, D. C., Clark, K. L., Hallock, J. N., Hannon, S. M., Jacobs, L. G., Rudis, R. P., Soares, M. A. and Wang, F. Y.

"SFO WAKE TURBULENCE MEASUREMENT SYSTEM: SENSORS AND DATA DESCRIPTIONS"

DOT/FAA/AR-07/11, October 2006, DOT Volpe National Transportation Systems Center, Cambridge, MA

This report addresses aspects of an extensive aircraft wake turbulence measurement program conducted at San Francisco International Airport (SFO) over a two-year period. Specifically, this report

describes the sensors used for data collection and the resulting data sets that were used for data collection and the resulting data sets that were used for analysis of the Simultaneous Offset Instrument Approach (SOIA) procedure proposed for use at SFO. Three anemometer Wind lines were deployed perpendicular to and between Runways 28L and 28R to measure and record wake vortex motion between the runways near the threshold and touchdown regions. Because Runways 28L and 28R are used for 80% of SFO arrivals, the SFO wake turbulence Windline dataset, comprising approximately 250,000 arrivals, is the largest ever accumulated. Pulsed lidar wake measurements were made for approximately one month at a location where aircraft were approximately 500 feet above San Francisco Bay (about 9,000 feet from the thresholds). The ambient wind at 20 feet above ground was monitored on either side of the two runways, and a wind Sodar was used to measure wind profiles up to a height of 656 feet. Automated Surface Observation System (ASOS) winds at 33 feet above ground were also obtained.

Burnham, D. C., Gorstein, M., Hallock, J. N., Kodis, R. D., Sullivan, T. E. and McWilliams, I. G.

"AIRCRAFT WAKE VORTEX SENSING SYSTEMS"

DOT-TSC-FAA-72-13, June 1971, DOT Transportation Systems Center, Cambridge, MA

The report summarizes and analyzes techniques, both active and passive, that could be used to detect and measure air movements associated with wingtip vortex generation within an area or throughout a volume of terminal airspace. The study indicates useable techniques with an appraisal of expected performance and inherent limitations. Results of preliminary feasibility tests employing available technology are presented. The report also discusses the systems studies to be performed on the wake vortex sensing problem.

Burnham, D. C., Hallock, J. N. and Greene, G. C.

"INCREASING AIRPORT CAPACITY WITH MODIFIED IFR APPROACH PROCEDURES FOR CLOSE-SPACED PARALLEL RUNWAYS"

Air Traffic Control Quarterly, Vol. 9, No. 1, 2001, pp. 45-58

Because of wake turbulence considerations, current instrument approach procedures treat close-spaced (i.e., less than 2,500 feet apart) parallel runways as a single runway. This restriction is designed to assure safety for all aircraft types under all crosswind conditions. Restricting crosswinds and/or aircraft types can permit safe operations for runways with smaller spacings than 2,500 feet. An alternative safety paradigm can be based on the pairing procedure commonly used for visual approaches to close-spaced parallel runways. In this case, wake turbulence is not a factor if there are appropriate limits on allowed longitudinal pair spacings and/or allowed crosswinds. This paper examines how these concepts can be formulated into safe instrument approach procedures.

Burnham, D. C., Hallock, J. N. and Greene, G. C.

"WAKE TURBULENCE LIMITS ON PAIRED APPROACHES TO PARALLEL RUNWAYS"

Journal of Aircraft, Vol. 39, No. 4, July-August 2002, pp. 630-637

Wake turbulence considerations currently restrict the use of parallel runways less than 2500 feet apart. However, wake turbulence is not a factor if there are appropriate limits on allowed longitudinal pair spacings and/or allowed crosswinds. The tradeoffs between longitudinal spacing and crosswind, needed to prevent wake encounters, are assessed by modeling and by examining wake lateral transport data from O'Hare and Dallas/Ft. Worth airports at distances of 1500 to 3000 feet from runway threshold.

Burnham, D. C., Hallock, J. N., and VanDuyne, E.

"SUMMARY OF WAKE VORTEX SENSOR RESEARCH AND DEVELOPMENT"

Proceedings NASA Wake Vortex Detection Technology Workshop, September 1983, Langley Research Center, Hampton, VA

In this summary paper the status of the wake vortex program from the FAA perspective is reviewed. Special attention is given to the vortex sensor technology as this is an area that NASA may be able to apply expertise gained in other similar programs. This paper first reviews what is and is not known about vortex behavior as one must know its behavior to mitigate its influence. Next, sensors that were developed to collect data on vortex behavior are discussed. Possible problems with an airborne sensor are noted. The paper concludes with a description of the current FAA wake vortex program where short-term solutions are being evaluated as well as the development of long-term research projects.

Burnham, D. C., Hallock, J. N., Kodis, R. D. and Sullivan, T. E.

"VORTEX SENSING TESTS AT NAFEC"

DOT-TSC-FAA-72-2, January 1972, DOT Transportation Systems Center, Cambridge, MA

This report describes the results of a series of tests conducted for the FAA at NAFEC by the DOT/Transportation Systems Center. The test objectives were to determine and evaluate some of the characteristics of three experimental techniques for the remote sensing of the wing-tip vortices generated by heavy commercial and military aircraft. These techniques involved (1) a pulsed, bistatic acoustic detection and ranging system (referred to as an acoustic radar); (2) a ground level pressure sensor; and (3) a ground level hot-wire anemometer. The tests were conducted both in conjunction with the instrumented tower and at the end of runway 13. Data were obtained and analyzed for a variety of aircraft including the DC-7, B-747, C-141 and C-5A. Results in the form of altitudes and times of tower hits and vortex tracks are presented and compared to the tower data wherever possible.

Burnham, D. C., Hallock, J. N., Tombach, I. H., Brashears, M. R. and Barber, M. R.

"GROUND-BASED MEASUREMENTS OF THE WAKE VORTEX CHARACTERISTICS OF A B-747 AIRCRAFT IN VARIOUS CONFIGURATIONS"

FAA-RD-78-146, December 1978, DOT Transportation Systems Center, Cambridge, MA

A Boeing 747 aircraft flew 54 passes at low altitude over ground-based sensors. Vortex velocities were measured by a laser Doppler velocimeter, an array of monostatic acoustic sounders, and an array of propeller anemometers. Flow visualization of the wake was achieved using smoke and balloon tracers and was recorded photographically. Data were obtained on vortex velocity fields, vortex decay, and the effects of spoilers and differential flap settings on the dissipation and structure of the vortices.

Burnham, D. C., Kodis, R. D. and Sullivan, T. E.

"OBSERVATIONS OF ACOUSTIC RAY DEFLECTION BY AIRCRAFT WAKE VORTICES"

J. Acoustical Society, Vol. 52, No. 1, Part 2, March 1972, pp. 431-433

Acoustic ray deflection by aircraft wake vortices has been observed during landing operations by large aircraft. The phenomenon has been used to detect and locate vortex tracks in a plane perpendicular to the runway centerline. The maximum deflection angles observed for a variety of aircraft show qualitative agreement with values predicted for a viscous core.

Burnham, D. C., Rudis, R. P. and Abramson, S.

"PERFORMANCE OF RASS VORTEX DETECTION/MEASUREMENT SYSTEM"

DOT-VNTSC-FAA-99-10, June 1999, DOT Volpe National Transportation Systems Center, Cambridge, MA

Preliminary tests conducted by WLR Research in the Fall of 1993 showed considerable promise that a Radio Acoustic Sounding System (RASS) could detect and tracking wake vortices located in the approach glide slope. Initial testing of the RASS created interest in the possibility of a relatively low cost RASS monitoring the entire approach glide slope out to the middle marker. As a result of the optimistic results of the initial tests, the Federal Aviation Administration Wake Vortex Program Office decided to fund additional testing of the RASS to resolve some remaining questions and to evaluate its performance in detecting wake vortices in both the longitudinal (along the approach path) and transverse (perpendicular to the approach path) modes. The purpose of this test program was to analyze and validate the longitudinal and transverse mode RASS capabilities to: (1) indicate vortex presence in the flight path during a variety of meteorological conditions and (2) track a vortex or pair of vortices during a variety of meteorological conditions.

Burnham, D. C., Sullivan, T. E. and Wilk, L. S.

"MEASUREMENT OF WAKE VORTEX STRENGTH BY MEANS OF ACOUSTIC BACK SCATTERING"

Journal of Aircraft, Vol. 13, No. 11, November 1976, pp. 889-894

A simple acoustic sounder is shown to produce reliable velocity profiles of aircraft wakes at altitudes below 50m. Data collection during normal airport landing operations was feasible because the sensor does not intrude into the airspace being measured. A spatial scan through the wake is obtained when the ambient wind transports the wake through the sounder beam. The data are processed to yield the radial dependence of the velocity and circulation in the wake vortices. The circulation data are fitted to a simple model with two parameters: strength and core radius. The spatial and velocity resolution of the sounder is adequate to measure vortex strength but not to probe details of the core structure.

Burton, G. R.

"ISOPERIMETRIC PROPERTIES OF LAMB'S CIRCULAR VORTEX-PAIR"

Journal of Mathematical Fluid Mechanics, Vol. 7, 2005, pp. S68-S80

Lamb's circular vortex-pair was shown by the author [4] to be the unique maximiser, up to axial translations, of a certain integral functional of the stream function subject to a kinetic energy constraint. The present paper proves that the axial translations of Lamb's circular vortex-pair are the unique maximisers of kinetic energy subject to constraints on the vorticity and impulse. This formulation is more natural, in that it involves only conserved quantities. The result is deduced from [4] by non-convex duality. The analogous theory for Hill's spherical vortex is also discussed briefly.

"EXPERIMENTAL INVESTIGATION OF THE VORTICAL ACTIVITY IN THE CLOSE WAKE OF A SIMPLIFIED MILITARY TRANSPORT AIRCRAFT"

Experimental Fluids, Vol. 54, 2013, pp. 1524-1538.

This paper focuses on the experimental characterization of the vortex structures that develop in the aft fuselage region and in the wake of a simplified geometry of a military transport aircraft. It comes within the framework of the military applications of airflow influence on airdrop operations. This work relies on particle image velocimetry measurements combined with a vortex-tracking approach. Complex vortex dynamics is revealed, in terms of vortex positions, intensities, sizes, shapes and fluctuation levels, for both closed and opened cargo-door and ramp airdrop configurations.

"MODELLING AND DESIGN OF WING TIP DEVICES AT VARIOUS FLIGHT CONDITIONS USING A DATABASED AERODYNAMIC PREDICTION TOOL"

Aerospace Science and Tech., Vol. 10, 2006, pp. 668-678

A design study of wing tip devices at high and low speeds is described. The basis of the design study is an equivalent drag approach containing both aerodynamic drag gain and structural weight penalty. A comprehensive parameter study is carried out using a rapid aerodynamic prediction tool named Lift

and Drag Component Analysis (LIDCA). Adding to an available lifting-line method a databased module for airfoil data is employed that uses results of two-dimensional flow simulations by multidimensional interpolation. Detailed validation studies of the method at high lift and high speed have demonstrated good accuracy. RANS computations of the selected wing tip designs confirm the predicted benefits at cruise condition. The results of the most effective wing tip designs are analyzed at both flight conditions. Finally, options for improving the performance at take-off are suggested.

Butler, K. M.

"ESTIMATION OF WAKE VORTEX ADVECTION AND DECAY USING METEOROLOGICAL SENSORS AND AIRCRAFT DATA"

DOT/FAA/RD-93/16, September 1993, MIT Lincoln Lab., Lexington, MA

The lift-generated wake vortices trailing behind an aircraft present a danger to aircraft following the same or a nearby path. The degree of hazard to the following aircraft depends on the nature of the wake encountered in its flight path and on the ability of the aircraft to counter its effects. This report describes the current state of understanding of the factors that influence the motion and dissipation of wake vortices. The relationships of these factors to parameters that are measurable through meteorological sensors and from a priori knowledge of the vortex generating aircraft characteristics are discussed as an aid to structuring development plans for the creation of wake vortex advisory products by the Integrated Terminal Weather System (ITWS) and by special wake vortex sensors.

Butler, V. and Poole, Jr., R. W.

"INCREASING AIRPORT CAPACITY WITHOUT INCREASING AIRPORT SIZE"

Policy Study 368, March 2008, Reason Foundation, Los Angeles, CA

The purpose of this policy study is to explore an array of new technologies that hold significant promise for expanding the functional capacity of airport runways. These technologies are planned for incorporation into a completely new air traffic control system to replace the current system over the next 20 years. The wake vortex related topic concerns the construction of new runways between existing runways and using new sensors to detect the motion and decay of wake vortices.

Butoescu, V.

"A VORTEX MODEL OF A HELICOPTER ROTOR"

INCAS - Bulletin, No. 1, 2009, pp. 23-27.

A vortex model of a helicopter rotor is presented. Each blade of the rotor has three degrees of freedom: flapping, lagging and feathering. The motions after each degree of freedom are also known for all blades. The blade is modeled as a thin vortex surface. The wakes are free fluid surfaces. A system of five equations are obtained: the first one is the integral equation of the lifting surface (rotor), the

next three describe the wakes motion, and the last one relates the vortex strength on the wakes and the variation of vorticity on the rotor. A numerical solution of this system is presented. To avoid the singularities that can occur due to the complexity of vortex system, a desingularized model of the vortex core was adapted. A Mathcad worksheet containing the method has been written.

Butsuntorn, N.

"TIME SPECTRAL METHOD FOR ROTORCRAFT FLOW WITH VORTICITY CONFINEMENT"

PhD Thesis, June 2008, Stanford University, Stanford, CA.

This thesis shows that simulation of helicopter flows can adhere to engineering accuracy without the need of massive computing resources or long turnaround time by choosing an alternative framework for rotorcraft simulation. The method works in both hovering and forward flight regimes. The new method has shown to be more computationally efficient and sufficiently accurate. By utilizing the periodic nature of the rotorcraft flow field, the Fourier based Time Spectral method lends itself to the problem and significantly increases the rate of convergence compared to traditional implicit time integration schemes such as the second order backward difference formula. A Vorticity Confinement method has been explored and has been shown to work well in subsonic and transonic simulations. Vortical structure can be maintained after long distances without resorting to the traditional mesh refinement technique.

"A NUMERICAL METHOD FOR CALCULATING THE TRAILING VORTEX SYSTEM BEHIND A SWEEPED WING AT LOW SPEED"

Aero. Journal, Vol. 75, August 1971, pp. 564-568

A method is presented for the prediction of the spatial distribution of the trailing vorticity during the rolling up process, thus giving the overall downwash field behind the wing.

Butterworth, P. J.

"FLOW MEASUREMENTS IN THE WAKE OF A WING FITTED WITH A LEADING-EDGE ROOT EXTENSION (STRAKE)"

RAE TR-79120, September 1979, Royal Aircraft Establishment, Farnborough, England

In a low-speed wind tunnel measurements have been taken of the velocity vector in the flow field behind the wing of a combat aircraft model. The wing was fitted with a leading-edge root extension (strake) and could have either a plain leading edge or a deployed slat outboard. Four flow investigations were made; at three angles of incidence with the plain leading edge and at one angle of incidence with the slat deployed. The data from each of these tests have been analyzed to give the

distribution of the total head deficit, the streamwise component of vorticity and a measure of the circulation distribution in the wake of the wing.

Butterworth-Hayes, P.

"LANDING IN THE WAKE OF EUROPEAN RESEARCH"

Aerospace America, Vol. 37, No. 6, June 1999, pp. 4-6

European communities have been researching aircraft wake vortices. Germany has been developing the High Approach Landing System/Dual Threshold Operation (HALS/DTS) to reduce aircraft separation distances and maximize runway capacity. A wake vortex (WV) warning system is also under way in Germany, which could result in up to a 33% increase in airport capacity. The U.K.'s National Air Traffic Services (NATS) has been keeping a comprehensive database of WV incidences. The Defence and Research Agency (DERA) was collecting data with a LIDAR earlier in the decade and in 1998. This data will be used to design the Airbus A3XX. The U.K. is also in the middle of a two-year European-wide study, the European Turbulent Wake Incident Report Log (ETWIRL). France has been studying WV's through SYAGE (Système Anticipatif de Gestion des Espacements). The EC is researching WV's through WAKENET and WAVENC as well as through ETWIRL.

Buzykin, O. G., Ivanov, S. V., Ionin, A. A., Kotkov, A. A. and Kozlov, A. Y.

"SPECTROSCOPIC DETECTION OF SULFUR OXIDES IN THE AIRCRAFT WAKE"

Journal of Russian Laser Research, Vol. 26, Number 5, 2005, pp. 402-426.

The absorption/emission spectral regions of SO, SO₂, SO₃, S₂O and HSO are analyzed for the range from UV to IR and are compared with the atmospheric transmission spectrum. It is shown that many vibrational bands of the compounds considered fall into atmospheric transmission windows. For the vibrational bands of SO, SO₂, SO₃ and HSO molecules there are some gases which hinder the absorption diagnostics of the indicated compounds. These interfering gases are natural components of atmospheric as well as specific gases of aircraft engine exhaust. It is found that the least influence of the interference takes place in the 2400-2700 1/cm IR region. The spectroscopic techniques used for the detection of aircraft exhaust compounds are briefly reviewed, with much consideration given to SO₂. The IR absorption spectra of SO₂ and other gases are calculated for the conditions of the aircraft engine nozzle exit. Narrow spectral intervals suitable for SO₂ detection in a hot flow are determined. An analysis is made for the detection capabilities of CO₂ lasers (including isotope CO₂ lasers) and CO lasers (both fundamental band and first-overtone ones) as applied to SO₂ detection in aircraft engine exhaust.

Cabot, M. A. and Chiang, N. Q.

"WAKE TURBULENCE WARNING AND CAUTION SYSTEM AND METHOD"

US Patent 6,177,888 B1, January 2001.

A wake turbulence warning and caution system and method for a protected aircraft tracks and stores a trajectory of a wake trailing behind a nearby aircraft and adjusts the wake position for the effect of local wind velocity, and then calculates a distance and time to closure between the protected aircraft and the wake. A caution is annunciated aurally and/or on a navigation map display and/or on a primary flight display if the distance or time to closure is less than a first predetermined threshold, and a warning is annunciated if the distance or time to closure is less than a second predetermined threshold. The wake trajectory is calculated based on range, bearing, and altitude information about the nearby aircraft supplied by a Traffic Collision Avoidance System (TCAS) aboard the protected aircraft, and based on inertial position and attitude of the protected aircraft supplied by an inertial reference system (IRS). Local wind velocity is calculated based on the aircraft inertial velocity from the IRS, true air speed from an air data computer (ADC), and angle of attack and sideslip angles provided by sensors aboard the aircraft. Wake tracking, wind velocity calculations, and caution and warning functions can be implemented in software within a TCAS computer and/or a flight management system aboard the protected aircraft.

"OVERVIEW OF ROTARY FLOW VISUUALIZATION RESULTS ON THE F/A-18 AIRCRAFT"

ICAS Paper 2002-3.10.4, September 2002, Toronto, Canada.

To understand the physics of the complex vortex flow field of the F/A-18 aircraft during maneuvering at high incidences, a series of flow visualizations were conducted in the Institute for Aerospace Research 0.38 x 0.51m water tunnel. A 1/72-scale model was tested on the new orbital-platform rotary apparatus at various angles of attack.

Cai, J., Chng, T. L. and Tsai, H. M.

"NUMERICAL STUDY OF VORTICAL FLOWS SHEDDING FROM A BLUFF BODY WITH A WAVY TRAILING EDGE"

AIAA Paper No. 2007-131, Reno, NV, January 2007

Previous experimental studies have shown that applying a geometric sinusoidal disturbance to the trailing edge of a quasi-streamlined bluff body can result in substantial base pressure recovery when compared against a normal straight edged configuration. Here, a numerical simulation at a Reynolds number of 2500 is used to examine in detail various aspects of the flow such as the base pressure distribution, vortex shedding mechanism and frequency selection in relation to a variation in the wavelength of the sinusoidal disturbance. The concentration of dye released along the upper trailing edge of the body is tracked by solving the scalar transport equation to facilitate visualization and comparison of the flow field analogous to the dye precipitation technique used in previous studies. The results show that a sinusoidally shaped trailing edge with fixed amplitude and a wavelength which is 5 times the base height displays a reduction of more than 36% in the mean drag coefficient when

compared to the straight edged case. This reduction is traced to a lengthening of the mean recirculation region, a marked drop in the velocity fluctuation at the dominant frequency of the wake and a reduction in the spanwise component of the wake vorticity. Conversely, this reduction in the drag coefficient is substantially diminished for a sinusoidal trailing edge with a longer wavelength. For such a configuration, the flow is characterized by the formation of vortex dislocations which causes the flow to have a less regular character. Finally, a shorter wavelength of four base heights results in a reduction of the mean recirculation region with an attendant increase in the spanwise vorticity. This leads to a drag coefficient similar to that of the straight trailing edge.

"LES INVESTIGATION OF NEAR FIELD WAKES BEHIND JUNCTURE OF WING AND PLATE"

AIAA Paper No. 2004-0262, Reno, NV, January 2004. (Also, Current Trends In High Performance Computing and Its Applications, Springer Berlin Heidelberg, December 2005)

This paper is a preliminary work on the numerical study of the near field wake and wingtip vortex behind the juncture of wing and plate. The object is to develop a LES-based code to simulate the near field wake and wingtip vortex, which will help understanding near field wakes and wake control. The filtered structure function subgrid model was applied on the simulation. The computational approach involves a fully implicit time-marching solver for the Navier-Stokes equation in the generalized curvilinear coordinates with a sixth order compact scheme and an eighth order filter. A one-block high-quality mesh is generated in the complex computation domain. The coordinate transformation metrics are calculated with the high-order compact scheme that is consistent with the flow solver. The parallel computation is accomplished by using domain decomposition and message passing interface (MPI). The code is validated for simulation of flow transition on a flat plate. The code is also used for simulation of 2-D airfoil vortex shedding. Then the flow field around NACA0014 airfoil is simulated with 8 million grid points. The preliminary results were obtained. To study the near field wake and wingtip vortex behind the juncture of wing and plate, a LES simulation with 25 million grid points is undergoing, in which the angle of attack of the wing is 10 degrees.

Cai, J., Deng, S., Xie, P. and Liu, C.

"HIGH-ORDER LES FOR WING TIP VORTEX IN THE NEAR FIELD"

AIAA Paper No. 2005-1125, Reno, NV, January 2005

The numerical study of wingtip vortex in the near field is presented in this paper. The object is to develop a LES-based code to simulate the wingtip vortex, which will help understanding near field wakes and wake control. The filtered structure function sub-grid model was applied on the LES simulation. The computational approach involves a fully implicit time-marching solver for the Navier-Stokes equation in the generalized curvilinear coordinates with a sixth order compact scheme and an eighth order filter. A one-block high-quality mesh is generated in the complex computation domain. The coordinate transformation metrics are calculated with the high-order compact scheme that is

consistent with the flow solver. The parallel computation is accomplished by using domain decomposition and message passing interface (MPI). The code is validated for simulation of flow transition on a flat plate. The code is also used for simulation of 2-D airfoil vortex shedding. Then the flow field around NACA0012 airfoil is simulated with 25 million grid points. The preliminary results were obtained.

"STABILITY OF VORTEX PAIRS OVER SLENDER CONICAL BODIES - THEORY AND NUMERICAL COMPUTATIONS"

AIAA Paper No. 2004-1072, Reno, NV, January 2004

Theoretical analyses and computational fluid dynamics (CFD) simulations are presented to study the formation and stability of stationary symmetric and asymmetric vortex pairs over slender conical bodies in an inviscid incompressible flow at high angles of attack with and without sideslip. The theoretical analysis is based on an eigenvalue analysis on the motion of the vortices under small perturbations. A three-dimensional time-accurate Euler code is used to compute five typical flows studied by the theoretical method on extraordinarily fine and overset grids with strict convergence criteria. The computational results agree well with the theoretical predictions and corroborate on the conclusion that an absolute type of hydrodynamic instability can be the mechanism for breaking of symmetry of the vortex flow over slender conical bodies at high angles of attack. The presented results demonstrate the usefulness of CFD for stability studies of vortex flow over slender bodies at high angles of attack.

Cai, J., Xie, P., Wei, H. and Liu, C.

"VERIFICATION AND VALIDATION OF LES FOR INTERACTION OF WINGTIP VORTEX AND WAKES"

AIAA Paper No. 2008-673, Reno, NV, January 2008

Large eddy simulation with filtered-structure-function subgrid model and implicit large eddy simulation (ILES without explicit subgrid model) using high-order accuracy and high-resolution compact scheme have been performed on the tip vortex shedding from a rectangular half-wing with a NACA 0012 airfoil section and a rounded wing tip. The formation of the tip vortex and its initial development in the boundary layer and the near field wake are investigated and analyzed in detail. The physics, why the tip vortex, which is originally turbulent in the boundary layer, is re-laminarized and becomes stable and laminar rapidly after shedding in the near field, is revealed by this simulation. The computation also shows the widely used second order subgrid model is not consistent to six-order compact scheme and would degenerate the six-order LES results to second order. Therefore, high order schemes, grid refinement and six order subgrid models are critical to LES approaches.

Caiger, B. and Gould, D. G.

"AN ANALYSIS OF FLIGHT MEASUREMENTS IN THE WAKE OF A JET TRANSPORT AIRCRAFT"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 125-136

Peak velocity vectors measured in the transverse plane of the wake of a Convair 880 aircraft were found to be four times as high as anticipated. The peak velocities are shown to occur in small intense vortices which are separate from the main tip vortices. These exist up to 30 seconds after generation. The main tip vortices are shown to have a core size which is roughly of the size anticipated but whose diameter does not increase significantly up to 30 seconds after generation.

Caillol, P. and Maslowe, S. A.

"THE SMALL VORTICITY NONLINEAR CRITICAL LAYER FOR KELVIN MODES ON A VORTEX"

Studies in Applied Mathematics, Vol. 118, Issue 3, April 2007, pp. 221-254.

We consider in this paper the propagation of neutral modes along a vortex with velocity profile being the radial coordinate. In the linear stability theory governing such flows, the boundary in parameter space separating stable and unstable regions is usually comprised of modes that are singular at some value denoted the critical point. The singularity can be dealt with by adding viscous and/or nonlinear effects within a thin critical layer centered on the critical point. At high Reynolds numbers, the case of most interest in applications, nonlinearity is essential, but it develops that viscosity, treated here as a small perturbation, still plays a subtle role. After first presenting the scaling for the general case, we formulate a nonlinear critical layer theory valid when the critical point occurs far enough from the center of the vortex so that the vorticity there is small. Solutions are found having no phase change across the critical layer thus permitting the existence of modes not possible in a linear theory. It is found that both the axial and azimuthal mean vorticity are different on either side of the critical layer because of the wave mean flow interaction. A long wave analysis with vorticity leads to similar conclusions.

"SY.A.G.E. - THE FRENCH WAKE VORTEX SPACING SYSTEM"

XXIII General Assembly, European Geophysical Society, Nice, France, April 1998

The STNA (Service Technique de la Navigation Aérienne) has been performing studies on wake vortices since 1992 for the DGAC (Direction Générale de l'Aviation Civile). Due to limited budget, the work progress is not as fast as expected. In this paper, we present SY.A.G.E. (SYstème Anticipatif de Gation des Espacements). This system intends to optimize the separation between aircraft at landing and takeoff. All the developments done in France are related to this definition. A first version of SYAGE has been set up and an experiment aiming at operationally verifying the system is presented. This first version concerns aircraft at departure and crosswind considerations. A windline of seven anemometers has been installed on Toulouse-Blagnac Airport to monitor the position of the vortices. This trial should assess the needed accuracy of the wind measurement for an operational system. The constituted wind

database will be used to develop short term forecasting compulsory to have in the landing version of SYAGE.

Calarese, W.

"CLOSE-COUPLED CANARD-WING VORTEX INTERACTION"

J. Aircraft, Vol. 21, No. 2, February 1984, pp. 99-100

The present experiment investigates the interaction of canard and wing vortices and their effect on the lifting wing's flow field turbulence and Reynolds stresses. Spanwise wing blowing was used to enhance the leading-edge vortex and alter the vortex trajectory to keep it locked to the wing's leading edge for lift enhancement. The turbulence intensity and Reynolds stress values, obtained by using hot film anemometers, illustrate the vortex structure.

"COMPARISON OF LIDAR DATA WITH TOWER, PROFILER, RADIOSONDE, AND TETHERSONDE DATA"

2nd Symposium on Lidar Atmospheric Applications, 85th AMS Annual Meeting, January 2005, San Diego, CA.

During July 2004, the Institut fuer Meteorologie und Klimaforschung, Tropospheric Section (IMK-TRO), Forschungszentrum Karlsruhe / Universitaet Karlsruhe, Germany, and the Lidar group of Arizona State University (ASU) collaborated to obtain a dataset for the comparison of IMK's new coherent Doppler lidar with data from a radar profiler, a 200m tower, tether sondes, radiosondes, and a sodar. The experiment took place near Karlsruhe, Germany, and was centered at the Forschungszentrum just north of the city of Karlsruhe. All field instruments were provided and operated by IMK, while ASU assisted in planning, post-processing, and some operation of the IMK coherent Doppler lidar and tether sondes. During the experimental period, occasional convective storms passed through the measurement domain providing at times relatively strong wind velocities. Mean and instantaneous velocities were compared between the instruments. In addition to mean velocities, the spectral properties of lidar 'staring' scans were explored. For the 'staring' scans, the lidar beam focused on two levels of the local 200-meter meteorological tower at which sonic anemometers obtained wind data at 20 Hz.

"IMPLICIT EULER CALCULATION OF SUPERSONIC VORTEX WAKE/ENGINE PLUME INTERACTION"

AIAA Paper No. 1993-0656, Reno, NV, January 1993. [Also, Cali, P. M., MS Thesis, MIT, Cambridge, MA.]

This paper presents the computational modeling of supersonic vortex wake/engine plume interaction. The evolution of the wake and plume was modeled in the Trefftz plane using the two-dimensional, unsteady Euler equations. The flow was initialized to a vortex sheet with adjacent engine plume and

integrated using a third-order accurate flux-difference-split, implicit algorithm. To minimize the effects of numerical diffusion, a Lagrangian correction technique was retrofitted to the implicit Euler code. Test cases varying the initial spanwise location of the plume were conducted. In all cases, the plume was seen to break apart into small bundles which then orbited the vortex core. Although the inward pressure gradient of the rolled-up vortex drove the hot effluent toward the center, the inward motion of the buoyant plume fluid was limited due to the lack of a diffusive model. Finally, the amount of effluent drawn tightly to the core increased as the initial plume location was moved outward along the span.

"HUMAN-IN-THE-LOOP INVESTIGATION OF INTEROPERABILITY BETWEEN TERMINAL SEQUENCING AND SPACING, AUTOMATED TERMINAL PROXIMITY ALERT, AND WAKE-SEPARATION RECATEGORIZATION"

AIAA Paper 2016-3300, June 2016, Washington, DC.

A human-in-the-loop simulation study addressed terminal-area controller-workstation interface variations for interoperability between three new capabilities being introduced by the FAA. The capabilities are Terminal Sequencing and Spacing (TSAS), Automated Terminal Proximity Alert (ATPA), and wake-separation recategorization, or 'RECAT.' TSAS provides controllers with Controller-Managed Spacing (CMS) tools, including slot markers, speed advisories, and early/late indications, together with runway assignments and sequence numbers, ATPA provides automatic monitor, warning, and alert cones to inform controllers about spacing between aircraft on approach. ATPA cones are sized according to RECAT, an improved method of specifying wake-separation standards. The objective of the study was to identify potential issues and provide recommendations for integrating TSAS with ATPA and

RECAT. Participants controlled arrival traffic under seven different display configurations, then tested an 'exploratory' configuration developed with participant input. All the display conditions were workable and acceptable, but controllers strongly preferred having the CMS tools available on Feeder positions, and both CMS tools and ATPA available on Final positions. Controllers found the integrated systems favorable and liked being able to tailor configurations to individual preferences.

"MOTION OF A CURVED VORTEX FILAMENT WITH DECAYING VORTICAL CORE AND AXIAL VELOCITY"

SIAM Journal of Applied Mathematics, Vol. 35, No. 1, 2006, pp. 148-175.

The motion and decay of a vortex filament with large axial and circumferential velocity components in a three-dimensional stream are studied. Solutions are constructed to the Navier-Stokes equations by use of matched asymptotic expansions; the small parameter used is a measure of the ratio of the viscous effects to the vortex strength. The outer flow, which corresponds to the classical Biot-Savart type analysis is matched to the solution in an inner viscous region. The radius of the viscous core is assumed to be much smaller than the radius of curvature. The present viscous analysis yields the classical inviscid theory as a limiting case for the leading term in the outer region and thus can be used to correct various deficiencies in the latter. We show, that the inner solution yields a finite velocity at all points in the filament and we determine how the components of both vorticity and velocity diffuse due to the viscous forces. The matching conditions guarantee the continuity of velocity components and define the velocity of the filament which depends not only on the geometry of the vortex filament but also on the circumferential and axial velocity variations in the inner core.

"ROTORCRAFT OUTWASH AND HUMAN STABILITY"

AIAA Paper 2019-1095, January 2019, San Diego, CA.

This paper documents an investigation of aerodynamic interactions between rotor design and human stability within the outwash region of hovering rotorcraft. The ability of rotorcraft to hover is a defining feature for rotorcraft, but the resulting downwash and outwash can be hazardous to people within proximity of the most energetic regions of the flow field. Most of the research up to this point has attempted to qualitatively describe the outwash environment in relation to existing rotorcraft. This paper documents an effort to use Design of Experiments with outwash flow-field models to identify characteristics that have the greatest influence on human destabilization. Factors such as rotor design parameters, human anthropometric data, and footwear/surface friction characteristics are assessed to gauge significance for human susceptibility to slipping and toppling. Qualitative parametric trends are identified that can be considered during rotorcraft design and operational planning to decrease the probability of human instability within the rotorwash footprint.

"TURBULENT DIFFUSION IN RAPIDLY ROTATING FLOWS WITH AND WITHOUT STABLE STRATIFICATION"

J. Fluid Mech., Vol. 499, 2004, pp. 231-255

In this work, three different approaches are used for evaluating some Lagrangian properties of homogeneous turbulence containing anisotropy due to the application of a stable stratification and a solid-body rotation. The two external frequencies are the magnitude of the system vorticity, chosen vertical here, and the Brunt-Vaisala frequency N , which gives the strength of the vertical stratification. Analytical results are derived using linear theory for the Eulerian velocity correlations (single-point, two-time) in the vertical and the horizontal directions, and Lagrangian ones are assumed to be equivalent, in agreement with an additional Corrsin assumption used by Kaneda (2000). They are compared with results from the kinematic simulation model (KS) by Nicolleau and Vassilicos (2000), which also incorporates the wave-vortex dynamics inherited from linear theory, and directly yields Lagrangian correlations as well as Eulerian ones. Finally, results from direct numerical simulations (DNS) are obtained and compared for the rotation-dominant case, the stratification dominant case, the non-dispersive case, and pure stratification and pure rotation. The last situation is shown to be singular with respect to the mixed stratified/rotating ones. We address the question of the validity of Corrsin's simplified hypothesis, which states the equivalence between Eulerian and Lagrangian correlations. Vertical correlations are found to follow this postulate, but not the horizontal ones. Consequences for the vertical and horizontal one-particle dispersion are examined. In the analytical model, the squared excursion lengths are calculated by time integrating the Lagrangian (equal to the Eulerian) two-time correlations, according to Taylor's procedure. These quantities are directly computed from fluctuating trajectories by both KS and DNS. In the case of pure rotation, the analytical procedure allows us to relate Brownian t-asymptotic laws of dispersion in both the horizontal and vertical directions to the angular phase-mixing properties of the inertial waves. If stratification is present, the inertia-gravity wave dynamics, which affects the vertical motion, yields a suppressed vertical diffusivity, but not a suppressed horizontal diffusivity, since part of the horizontal velocity field escapes wavy motion.

"AN EXPERIMENTAL STUDY INTO THE TURBULENCE CHARACTERISTICS OF LAMINAR, TRANSITIONAL AND TURBULENT IMPINGING JETS"

AIAA Paper 2011-3085, June 2011, Honolulu, Hawaii.

Particle Image Velocimetry has been utilized to obtain instantaneous velocity fields for water jets impinging perpendicularly on a solid surface. Time-averaged turbulence statistics are presented for laminar, transitional and turbulent jets in the Reynolds number range 3000 - 10000. A vortex identification algorithm is also employed to calculate the probability of a vortex existing at each discrete grid point based on all of the instantaneous fields. Significant turbulent mixing is induced by increasing the Reynolds number from 3000 to 4000, indicating transition commences in this range. The transition onset is characterized by a sudden increase in mean turbulent kinetic and velocity fluctuations as well as the coalescence of small-scale vortices into large scale coherent structures.

Further increasing the Reynolds number results in a decrease in the levels of non-dimensional turbulent kinetic energy in the shear layer implying a lesser proportion of the initial energy possessed by the jet is lost through dissipation resulting in favorable heat transfer characteristics at the impingement surface. The transitional jet with $Re = 4000$ proves to be an interesting case producing a strong wall jet with intense turbulent fluctuations that may result in large heat transfer rates over a greater radial distance.

Campbell, G. S.

"TURBULENCE IN THE WAKE OF A THIN AIRFOIL AT LOW SPEEDS"

NACA TM-1427, 1957, Langley Aeronautical Lab., Langley Field, VA

Experiments have been made to determine the nature of turbulence in the wake of a two-dimensional airfoil at low speeds. The experiments were motivated by the need for data which can be used for analysis of the tail-buffeting problem in aircraft design. Turbulent intensity and power spectra of the velocity fluctuations were measured at Reynolds number of 160,000 for several angles of attack.

Campbell, J. F. and Chambers, J. R.

"PATTERNS IN THE SKY: NATURAL VISUALIZATION OF AIRCRAFT FLOW FIELDS"

NASA SP-514, January 1994, NASA Langley Research Center, Hampton, VA

The objective of the current publication is to present the collection of flight photographs to illustrate the types of flow patterns that were visualized and to present qualitative correlations with computational and wind tunnel results. Initially in section 2, the condensation process is discussed, including a review of relative humidity, vapor pressure, and factors which determine the presence of visible condensate. Next, outputs from computer code calculations are postprocessed by using water-vapor relationships to determine if computed values of relative humidity in the local flow field correlate with the qualitative features of the in-flight condensation patterns. The photographs are then presented in section 3 by flow type and subsequently in section 4 by aircraft type to demonstrate the variety of condensed flow fields that was visualized for a wide range of aircraft and flight maneuvers.

Campbell, J. F., Chambers, J. R. and Ramsey, C. L.

"OBSERVATION OF AIRPLANE FLOWFIELDS BY NATURAL CONDENSATION EFFECTS"

Journal of Aircraft, Vol. 26, No. 7, July 1989, pp. 593-604

Flight condensation patterns illustrate a variety of airplane flowfields, such as attached and separated flows, vortex flows, and expansion and shock waves. Analysis shows vortex cores have a low relative humidity which may help explain the voids in condensed vortex flows.

Campbell, S. D. and Evans, J. E.

"GROUND-BASED WAKE VORTEX MONITORING, PREDICTION, AND ATC INTERFACE"

Airborne Windshear Detection and Warning Systems - Fifth and Final Combined Manufacturers' and Technologists' Conference, DOT/FAA/RD-94/14-II, July 1994, Langley Research Center, Hampton, VA, pp. 569.

Three elements of a proposed Wake Vortex Advisory Service are presented: monitoring, prediction, and ATC interface. The monitoring element is needed to ensure safety by warning controllers of hazardous wake vortex conditions. Such conditions exist when wake vortices persist in the approach/departure flight paths due to advection or to atmospheric conditions which prevent their decay. The prevention element is needed to provide ATC supervisors with advance warning that wake vortex separation conditions are about to change (i.e., require increased or decreased wake vortex separation). The ATC interface is needed to provide controllers with adaptive wake vortex separations. A 10.6-micron CO₂ CW lidar system will be developed for characterizing the behavior of wake vortices in an operational airport setting. Wide-area weather data will be gathered by an Integrated Terminal Weather System (ITWS) testbed. Interface to the terminal ATC system will be accomplished using the TATCA (Terminal Air Traffic Control Automation) Interface Unit (TIU), which would allow wake vortex separation symbology to be inserted onto a TRACON controller's Full Digital ARTS Display System (FDADS) radar screen.

"WAKE VORTEX FIELD MEASUREMENT PROGRAM AT MEMPHIS, TN"

AIAA Paper No. 1996-0399, Reno, NV, January 1996.

This paper describes wake vortex field measurements conducted during August 1995 at Memphis, TN. The objective of this effort was to record wake vortex behavior for varying atmospheric conditions and aircraft types. Wake vortex behavior was observed using a mobile continuous-wave coherent laser Doppler radar (lidar) developed at Lincoln Laboratory. This lidar features a number of improvements over previous systems, including the first-ever demonstration of an automatic wake vortex detection and tracking algorithm. An extensive meteorological data collection system was deployed in support of the wake vortex measurements, including a 150' instrumented tower, wind profiler/RASS (radio acoustic sounding system), sodar and balloon soundings. Aircraft flight plan and beacon data were automatically collected to determine aircraft flight number, type, speed and descent rate. Additional data was received from airlines in post-processing to determine aircraft weight and model. Over 600 aircraft wakes were recorded over the one-month period during 29 traffic pushes. Preliminary results from the field measurement program are presented illustrating differences in wake vortex behavior depending on atmospheric conditions and aircraft type.

"WAKE VORTEX FIELD MEASUREMENT PROGRAM AT MEMPHIS, TENNESSEE: DATA GUIDE"

NASA CR-201690, April 1997, Lincoln Laboratory, Lexington, M.

Eliminating or reducing current restrictions in the air traffic control system due to wake vortex considerations would yield increased capacity, decreased delays, and cost savings. Current wake vortex separation standards are widely viewed as very conservative under most conditions. However, scientific uncertainty about wake vortex behavior under different atmospheric conditions remains a barrier to development of an adaptive vortex spacing system. The objective of the wake vortex field measurement efforts during December 1994 and August 1995 at Memphis, TN, were to record wake vortex behavior for varying atmospheric conditions and types of aircraft. Wake vortex behavior was observed using a mobile continuous-wave (CW) coherent laser Doppler radar (lidar) developed at Lincoln Laboratory. This lidar features a number of improvements over previous systems, including the first-ever demonstration of an automatic wake vortex detection and tracking algorithm.

"OVERVIEW OF 1994 MEMPHIS WAKE VORTEX TESTING PROGRAM"

Proceedings Sixth Conf. on Aviation Weather Systems, American Meteorological Society, Dallas, TX, January 1995, pp. 515-520

This paper outlined a comprehensive field measurement program for automated collection of wake vortex, atmospheric and aircraft data in an operational airport environment. These measurements will provide a valuable data base to aid in the validation of wake vortex behavior models and techniques for atmospheric diagnosis/prognosis.

Campobasso, M. S., Zanon, A., Minisci, E. and Bonfiglioli, A.

"WAKE-TRACKING AND TURBULENCE MODELLING IN COMPUTATIONAL AERODYNAMICS OF WIND TURBINE AEROFOILS"

Proceedings of the Institution of Mechanical Engineering, Part A: Journal of Power and Energy, Vol. 223, No. 8, 2009, pp. 939-951.

This article addresses two modelling aspects of wind turbine airfoil aerodynamics based on the solution of the Reynolds-averaged Navier-Stokes (RANS) equations. One of these is the effect of an a priori method for structured grid adaptation aimed at improving the wake resolution. The presented results emphasize that the proposed adaptation strategy greatly improves the wake resolution in the far field, whereas the wake is completely diffused by the non-adapted grid with the same number and spacing patterns of grid nodes. The proposed adaptation approach can be easily included in the structured generation process of both commercial and in-house-structured mesh generators. The other numerical aspect examined herein is the impact of particular choices for turbulence modelling on the predicted solution. This includes the comparative analysis of numerical solutions obtained by using different turbulence models, and aims at quantifying the solution inaccuracy arising from not modelling

the laminar-to-turbulent transition. It is found that the drag forces obtained by considering the flow as transitional or fully turbulent may differ by 50 per cent. All these issues are investigated using a special-purpose hyperbolic grid generator and two multi block structured finite volume RANS codes. The numerical experiments consider the flow field past a wind turbine airfoil for which an exhaustive campaign of steady and unsteady experimental measurements was conducted. The predictive capabilities of the CFD solvers are validated by comparing experimental data and numerical predictions for selected flow regimes. The incompressible analysis and design code XFOIL is also used to support the findings of the comparative analysis of numerical RANS-based results and experimental data.

Campos, L. M. B. C.

"ON RUNWAY CAPACITY AND WAKE VORTEX SAFE SEPARATION DISTANCE"

Third SESAR Innovation Days, November 2013, Stockholm, Sweden.

The capacity of ATM is limited by the runway availability at airports. The number of takeoff and landings from the same runway is limited by wake vortex separation distances. Currently the safe separation distances (SSD) are established by empirical rules using as sole criterion the classification of the leading and following aircraft into three weight categories 'light', 'medium' and 'heavy'. The Boeing B757 has been the subject of an exception to the rules increasing the separation distance based on flight incidents; the Airbus A380 has been subject of an extended separation distance for 'super heavy' aircraft as a safety precaution. The purpose of the present paper is to obtain a formula for wake vortex separation distances that involves a number of assumptions and simplifications, but does include more parameters rather than just the weight of the leading and following aircraft. The predicted SSD for pairs of typical light (Citation 500), medium (B737-300) and heavy (B747-400) aircraft are comparable to the ICAO minimum separation rules, suggesting that the latter are moderately conservative on the safe side. The special case of B757-200 is considered justifying the increased separation. In the case of A380-100, the special 'ultra-heavy' rules appear to be excessively conservative highlighting the need for a more scientific approach to the subject, especially in cases where a long experience from the past is not available.

Campos, L. M. B. C. and Marques, J. M. G.

"ON WAKE VORTEX RESPONSE FOR ALL COMBINATIONS OF FIVE CLASSES OF AIRCRAFT"

Aeronautical J., Vol. 108, Issue 1084, June 2004, pp. 295-310

The present paper concerns the response of a following airplane to a pair of wing tip vortices left by a leading aircraft, represented by the Hallock-Burnham model, including the effect of vorticity decay between the two aircraft. The effect of vorticity is evaluated in terms of the induced rolling moment and also the lift loss; these specify the roll acceleration and the downward acceleration, respectively. The corresponding two response equations can be put into the same dimensionless form, and integrated using exponential integrals. This specifies the roll rate and sink rate as a function of time; besides the latter, the bank angle and altitude loss, are also plotted, all also as a function of time, for all

combinations of leading and following aircraft in five classes. These are the three ICAO weight categories of light, medium and heavy, plus two other cases, viz the special case of the Boeing 757, which requires larger separation distances, and the case of a future very large transport aircraft exceeding significantly the size of a Boeing 747.

Campos, L. M. B. C. and Marques, J. M. G.

"ON AIRCRAFT RESPONSE AND CONTROL DURING A WAKE ENCOUNTER"

In Progress in Industrial Mathematics at ECMI 2008, Springer-Verlag, Berlin Heidelberg, 2010, pp. 747-752.

In this paper the exact analytical solution of the airplane response to a wake encounter appears as a power series of a damping factor, whose coefficients are exponential integrals in time. It is shown that in the absence of control action, the roll response tends to an asymptotic bank angle.

Campos, L. M. B. C. and Marques, J. M. G.

"ON AN ANALYTICAL MODEL OF WAKE VORTEX SEPARATION OF AIRCRAFT"

The Aeronautical Journal, Vol. 120, No. 1232, October 2016, pp. 1534-1565.

A theory is presented on the effect of wake turbulence of a leading aircraft on the roll stability of a following aircraft, leading to a simple formula for the safe separation distance between the two aircraft that provides estimates of aircraft separation distances comparable to existing empirical regulations, based on experience. The formula includes the effects of flight and atmospheric conditions, and the characteristics of the leading and following aircraft; it applies to similar or dissimilar aircraft, and it indicates the parameters and conditions leading to increasing or decreasing separation. The formula is applied not only to the three International Civil Aviation Organization (ICAO) categories of aircraft (light, medium and heavy, respectively, Cessna Citation, B737 and B747) but also to 'special' aircraft requiring larger separation distance (Boeing 757) and to the world's largest airliner (Airbus A380).

Campos, L. M. B. C. and Marques, J. M. G.

"ON WAKE VORTEX RESPONSE FOR SEVERAL COMBINATIONS OF LEADING AND FOLLOWING AIRCRAFT"

ICAS-2002-7.9.4, Toronto, Canada, September 2002

The response of a following airplane to a pair of wing tip vortices left by a leading aircraft, represented by the Hallock-Burnham model, with added vorticity decay between the two aircraft. The effect of vorticity is evaluated as concerns the induced rolling moment and the lift loss; these specify respectively the roll acceleration and the downward acceleration. The corresponding two response equations can be put into the same dimensionless form, and integrated using exponential integrals. In the present paper we study the three ICAO weight categories of light, medium and heavy, plus two

other cases, vis-a-vis the special case of Boeing 757, which requires larger separations distances, and the case of very large aircraft, like the VLTA.

Campos, L. M. B. C. and Marques, J. M. G.

"ON THE COMPENSATION AND DAMPING OF ROLL INDUCED BY WAKE VORTICES"

Aeronautical Journal, Vol. 118, No. 12207, September 2014, pp. 1039-1061.

The effect of the wake of a leading aircraft on a following aircraft is demonstrated by calculating the rolling motion consisting of three terms: (i) the free rolling motion due to initial bank angle and roll rate; (ii) the forced wake response due the rolling moment induced by the wake encounter; (iii) the forced control response due to aileron deflection to counter the wake vortex effects. It is shown that in the absence of control action, the roll rate of the following aircraft goes through a peak, and then decays, leading to a constant asymptotic bank angle; the latter is a measure of the magnitude of the wake effect, e.g. is larger for weaker damping. The exact analytical solution of the roll equation appears as a power series of a damping factor, whose coefficients are exponential integrals of time; it is shown that the first two terms give an accuracy better than 2 percent. The theory is used to simulate 15 combinations of wake vortex encounters between leading and following aircraft in the five ICAO/FAA weight categories: light, medium, heavy, special (B757) and very large (A380).

Campos, L. M. B. C. and Marques, J. M. G.

"ON THE EFFECT OF DAMPING AND CONTROLS ON AN AIRCRAFT WAKE ENCOUNTER"

ICAS 2006, Sept. 2006, Hamburg, Germany.

The effect of damping and controls on an aircraft wake encounter is modeled using the following assumptions: (i) the wake of the leading aircraft is represented by a pair of counter-rotating Hallock-Burnham vortices, with arbitrary circulations and core radii; (ii) the vorticity decays with distance due to a turbulent kinematic viscosity, according to a law which is consistent with flight data from the Memphis data base; (iii) the rolling moment induced in the following aircraft is calculated assuming it flies aligned behind the leading aircraft; (iv) the rolling moment equation is solved analytically including the effect of the control surface deflection (e.g., ailerons) and of aerodynamic damping; (v) the airplane response, in terms of roll rate and bank angle is plotted for a Boeing B757-200 flying behind another. It is shown that in the absence of control action, the roll rate of the following aircraft goes through a peak, and then decays, leading to a constant asymptotic bank angle; the latter is a measure of the magnitude of the wake effect, e.g. is larger for weaker damping. The exact analytical solution of the roll equation appears as a power series of a damping factor, whose coefficients are exponential integrals of time; it is shown that the first two terms give an accuracy better than 2 percent.

Campos, L. M. B. C. and Serrao, P. G. T. A.

"ON THE ACOUSTICS OF UNBOUNDED AND DUCTED VORTEX FLOWS"

The propagation of sound is considered in a potential cylindrical vortex, with superimposed axial flow, by means of explicit analytical solutions. The sound waves are sinusoidal in time, and in the axial and azimuthal directions; the convected wave equation leads to a radial dependence specified by an ordinary second-order differential equation, with two singularities, at the origin and at infinity. Both singularities are irregular, implying that the acoustic fields have an essential singularity. In the neighborhood of the vortex axis, the essential singularity of the acoustic field is specified by an exponential of the integrated Doppler shift; using the latter as a factor, the acoustic fields are specified by asymptotic expansions in ascending powers of the radius. In the neighborhood of the point at infinity, where the tangential mean flow velocity vanishes, the leading terms are outward or inward propagating cylindrical waves; these factors multiply asymptotic expansions in descending powers of the radius. The two pairs of solutions, around the vortex axis and the point-at-infinity are valid in all space or overlapping regions, as far as the asymptotic expansions can be calculated. The case of an annular nozzle, with uniform axial flow, and potential swirl is used as an example; the eigenvalues are obtained for rigid wall boundary conditions and the corresponding eigenfunctions are plotted.

Candelier, F., Angilella, J. R. and Souhar, M.

"ON THE EFFECT OF THE BOUSSINESQ-BASSET FORCE ON THE RADIAL MIGRATION OF A STOKES PARTICLE IN A VORTEX"

Physics of Fluids, Vol. 16, No. 5, May 2004, pp. 1765-1776

The trajectory of an isolated solid particle dropped in the core of a vertical vortex is investigated theoretically and experimentally, in order to analyze the effect of the history force on the radial migration of the inclusion. Both the Stokes number (based on the particle radius and the fluid angular velocity) and the particle Reynolds number are small. The particle is heavier than the fluid, and is therefore expelled from the center of the vortex. An experimental device using spherical particles injected in a rotating cylindrical tank filled with silicone oil has been built. Experimental trajectories are compared to analytical solutions of the motion equations, which are obtained by making use of classical Laplace transforms. The analytical expression of the history force and the ejection rate are carried out. This force does not vanish, but increases exponentially and must be considered for efficient predictions. In particular, calculation without history force overestimates particle ejection. The relative difference between the ejection rate with and without history force scales like the square root of the Stokes number, so that differences of the order of 10% are visible as soon as the Stokes number is of the order of 0.01. Also, agreement between experimental and theoretical trajectories is observed only if the acceleration term in the history integral involves the time derivative of the fluid velocity following the particle, rather than the acceleration of fluid points at the particle location, even for small particle Reynolds numbers. Finally, analytical calculations show that the particle ejection rate is more sensitive to the Boussinesq-Basset force than to Saffman's lift.

Cann, S. R.

"AIRCRAFT VORTEX WAKE"

Shell Aviation News, No. 394, 1971, pp. 8-9

Consideration is given to the trailing vortices shed by the lifting surfaces of an aircraft. Vortex strength varies directly with the lift being produced by the wing and inversely as the speed and the span. Thus, it is that at low speeds - i.e., in control zones - that wake effects become important. Encounters of aircraft with wakes produced by other aircraft can result in uncontrollability. Current UK separation standards are summarized.

Canonne, E., Benoit, C. and Jeanfaivre, G.

"CYLINDRICAL MESH ADAPTATION FOR ISOLATED ROTORS IN HOVER"

Aerospace Science and Technology, Vol. 8, 2004, pp. 1-10

This paper presents inviscid computations of an isolated rotor in hover using a specific mesh adaptation technique. The proposed adaptation method is simple, efficient, and dedicated to this type of application. The user provides a short and fine grid around each blade; an overset cylindrical grid that discretizes the remaining part of the computational domain is then automatically generated and periodically adapted to improve the capture of the wake. This technique can also be applied to a portion of a multi-bladed rotor by using periodic boundary conditions. Transfers between blade and cylindrical grid are completed through the Chimera method. Results show that, with about 600,000 points, the tip vortex can be followed for approximately 380 degrees of age. Also, this paper proposes a deep insight into different refinement indicators for this problem.

CAO, Y.

"METHOD FOR PREDICTING ROTOR VORTEX WAKE AND DOWNWASH VELOCITY FIELD"

Journal of Beijing University of Aeronautics and Astronautics, Vol. 26, Issue 2, 2000, pp. 174-177.

An analytical method for predicting rotor vortex wake in low speed and hovering flight is described to investigate the motion of the helical tip vortex. Beginning with the prescribed wake model, a semi-empirical correction for the vortex core effect on rotor wake is made and free wake calculation is carried out. Then on the condition of circulation and wake geometry convergence, the rotor thrust is calculated to satisfy convergence criterion of thrust. Finally, as an example of its engineering application, the calculated downwash velocity field along the rocket launch line is presented and simply analyzed. In terms of theory, the calculating method developed here may provide referable basis for further studying the formation mode of the tip vortex and vortex core interior structure. Also the method is practical for predicting rotor induced flow field in engineering applications.

Cao, Y.

"A NEW METHOD FOR PREDICTING ROTOR WAKE GEOMETRIES AND DOWNWASH VELOCITY FIELD"

Aircraft Engineering and Aerospace Technology, Vol. 71, No. 2, 1999, pp. 129-135.

A new method for predicting rotor wake in low speed and hovering flight is described to investigate the motion of the helical tip vortex. Beginning with the generalized wake model, a semi-empirical correction for the vortex core effect on rotor wake is made and free wake calculation is carried out. As an example of its engineering application, the calculated downwash velocity field along the rocket launch line is presented and simply analyzed. In terms of theory, the method developed here may provide a referable basis for further study of the formation mode of the tip vortex and vortex core interior structure.

Cao, Y. and Su, Y.

"INSIGHT INTO THE EFFECTS OF ROTOR DOWNWASH ON ENGINE JET"

Aircraft Engineering and Aerospace Technology, Vol. 75, No. 4, 2003, pp. 345-349

An analytical method to predict the effects of rotor downwash on engine jet was proposed to investigate the flow pattern of helicopter engine jet. First, free wake analysis was carried out to calculate the rotor wake geometry and the downwash around the engine jet space. Then the engine jet path, cross section shape and physical variants were calculated and analyzed. Finally, an example was given to show the typical results for an insight into the influence of engine jet upon the temperature distribution around a helicopter. The method developed here can be used to predict rotor wake, engine jet and temperature distribution of a helicopter.

Cao, Y. and Zhao, M.

"NUMERICAL SIMULATION OF ROTOR FLOWFIELDS BASED ON SEVERAL SPATIAL DISCRETIZATION SCHEMES"

Journal of Aircraft, Vol. 49, No. 5, September-October 2012, pp. 1535-1540.

A method of unsteady rotor flow field simulation was developed. Several spatial schemes were used for comprehensive comparison, some advantages and disadvantages of which were assessed. The overset grid technique was implemented, and the grid system was proven to have the capability to establish inter-grid communication accurately. Comparisons among experimental data, previous references, and present simulation results were carried out to verify the accuracy and feasibility of the current methodology. Vorticity contours were also analyzed. With the help of a dual time-stepping method, an unsteady solution of the rotor flowfield was eventually obtained.

Cao, Y., Su, Y. and Zhang, Q.

"NUMERICAL SIMULATION OF HELICOPTER ENGINE JET AND FUSELAGE TEMPERATURE FIELD"

Journal of Aircraft, Vol. 43, No. 6, November-December 2006, pp. 1949-1953.

This paper presents a numerical simulation method to predict helicopter engine jet and fuselage temperature field. Rotor free wake analysis was first carried out to calculate rotor wake geometry and the downwash velocity field around the engine jet space. Then engine jet path, cross section shape, and physical variants were calculated and analyzed. Finally, an engineering method was given to calculate the fuselage temperature for insight into the influence of engine jet upon the temperature distribution around a helicopter. The method established here can be used to predict rotor wake, engine jet, and temperature distribution of a helicopter.

"A COUPLED FREE WAKE -- CFD METHOD FOR THE SIMULATION OF HELICOPTER ROTOR FLOW"

Canadian Aeronautics and Space Journal, Vol. 48, No. 4, December 2002, pp. 251-258

A new coupled wake -- CFD method is used to include realistic wake effects in CFD solutions for rotor flow in hover. The analytical method for predicting hovering rotor wake is described to investigate the motion of the helical tip vortex. Beginning with the generalized wake model, a semi-empirical correction for the vortex core effect on rotor wake is made. Then on the condition of circulation and wake geometry convergence, the free wake calculation is accomplished. Finally, Euler-Navier-Stokes equations are solved for transonic rotor flow employing Jameson's finite-volume explicit Runge-Kutta time-stepping scheme. The results are compared with the respective references and experimental data.

"DESIGN PRINCIPLES FOR A SEPARATION SUPPORT TOOL ALLOWING OPTIMIZED RUNWAY DELIVERY"

AIAA Paper 2018-4237, June 2018, Atlanta, GA.

The research in the wake vortex domain made possible in the last years to tackle airport capacity issues by designing new concepts for wake separations between aircraft on approach and departure. These new solutions allow for dynamic wake separation reduction depending on aircraft characteristics and weather conditions. Amongst those concepts are found Time-Based Separation (TBS), RECAT Pairwise (RECAT-PWS) and Weather Dependent Separation (WDS). However, the application of dynamic separations entails the use of a spacing delivery support tool. This tool shall compute the applicable time- or distance-based separation minima and provide distance indicators supporting their correct delivery by the controller. Distance indicators have hence to account for aircraft separation compression effects but also for the uncertainties related to aircraft speed and wind evolution. This paper presents the principles used for the design of a demonstrator of such a separation delivery platform called LORD. The LORD tool makes use of a methodology to mitigate separation infringement

and to prevent aircraft under spacing by using an additional buffer on the spacing computation. The use of such buffers allows the separations to be correctly delivered up to a certain 'failure rate' equivalent to what is currently observed at airports while still providing capacity benefits with a better spacing management by the controller in different separation modes (e.g. distance based or time based). To prevent spacing infringement, different support warnings are also implemented in the tool. These warnings are to be used as safety nets to quickly identify potential issues in the approach/landing phase and allow the controller to take corrective actions. The LORD tool was successfully tested by Air Traffic Controllers during Real-Time Simulation campaigns. The use of the new separation concepts together with the LORD tool is seen to allow for an increase of throughput and reduction of separation infringement, while maintaining workload and situation awareness at an acceptable level.

Caradonna, F.

"PERFORMANCE MEASUREMENT AND WAKE CHARACTERISTICS OF A MODEL ROTOR IN AXIAL FLIGHT"

J. American Helicopter Society, Vol. 44, No. 2, April 1999, pp. 101-108

This paper studies the concept of extracting hover performance from model rotor climb data by extrapolating to the limit of zero climb speed. A 2-bladed rotor was mounted horizontally and tested in the 30' x 31' settling chamber of the Ames 7' x 10' #1 wind tunnel. Video cameras were used to visualize the flow field illuminated by pulsed white light sheets. With a steady, non-recirculating flow, the rotor wake was seen to be fully periodic, with little diffusion of the vortices for several rotor cycles. The transition to the far wake was seen to occur through a periodic pairing of the tip vortices, followed by their merging into a single diffuse vortex for each rotor cycle. The number of discrete vortices turns in the near wake before the pairing varied with the thrust coefficient and rate of climb.

Caradonna, F. X. and Tung, C.

"EXPERIMENTAL AND ANALYTICAL STUDIES OF A MODEL HELICOPTER ROTOR IN HOVER"

NASA TM-81232, September 1981, US Army Research and Technology Laboratories, Moffett Field, CA.

The present study is a benchmark test to aid the development of various rotor performance codes. The study involves simultaneous blade pressure measurements and tip vortex surveys. Measurements were made for a wide range of tip Mach numbers including the transonic flow region. The measured tip vortex strength and geometry permit effective blade loading predictions when used as input to a prescribed wake lifting surface code. It is also shown that with proper inflow and boundary layer modeling, the supercritical flow regime may be accurately predicted.

"ADVANCES IN ROTORCRAFT WAKE AERODYNAMICS"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001.

Subsonic aerodynamics encompasses a wide array of problems. Of these, it may be that rotorcraft aerodynamics is the most varied and complex, a major cause for difficulty being the dominance of wake flows. While such flows have been the subject of both experimental and computational studies for many years, the field of study is far from being exhausted. Indeed, the need and opportunity for new studies and new ideas seems to be as great as ever. This presentation is intended to illustrate this point with a number of computational and experimental developments under recent or current development at or with the U.S. Army Aeroflightdynamics Directorate (AFDD). Wakes have probably constituted the largest single area of experimental rotor study over the years. And yet new phenomena are always being discovered. For instance, a vortex-pairing phenomenon was discovered by several different researchers recently using stroboscopic smoke flow visualization and shadowgraph. Particle Image Velocimetry (PIV) has been shown to be particularly useful in a water facility. The small rotor scale combined with the use of PIV permits a visualization and measurement of an entire rotor wake flow, clearly showing the convection and dissipation of the starting vortex, blade tip vortices and shed vorticity sheets. The prediction of such wake flows using CFD is a very difficult matter because of the grid sizes that are required to avoid numerical dissipation. Two new efficient schemes, designed to counteract the effects of this dissipation, will be described. The first, an Eulerian-Lagrangian scheme, called 'vortex embedding', is a potential-based method wherein vortex particles undergo Lagrangian convection with the induced flow predicted by a solution of the Potential equation. Because there is no vorticity dissipation here, the method requires only a coarse grid. Another method, that is more general, is the method of 'vorticity confinement'. This approach applies an artificial antidiffusive correction term that assures the non-spreading of thin vortical regions. Because diffusive spreading does not occur with this method, relatively coarse grids again can be used and the method is highly versatile.

"DEVELOPMENT OF THE WAKE OF AN AIRFOIL WITH RIBLETS"

AIAA Journal, Vol. 30, No. 12, December 1992, pp. 2817-2818

Tests were conducted on a NACA 0012 airfoil with riblets at a freestream Reynolds number of 2.5×10^5 in the Texas A&M University indraft wind tunnel. The riblets used in the investigation were of symmetric v-groove type with the heights of 0.0229, 0.076, and 0.152 mm. Measurements of the mean velocity profiles, turbulence, and integral quantities in the near and intermediate wakes indicated that the growth of the wake of an airfoil with riblets was like that of a clean airfoil. It was also observed that even at a distance of 600 momentum thicknesses downstream of the trailing edge wake equilibrium had not been reached for any of the configurations tested; however, riblet effectiveness was indicated by a marked decrease in the level of maximum shear stress, especially for the 0.152 mm riblets.

Caram, J. M. and Ahmed, A.

"EFFECTS OF RIBLETS ON THE WAKE CHARACTERISTICS OF AN AIRFOIL"

AIAA Paper No. 1989-2199, Seattle, WA, August 1989

Near- and intermediate-wake region boundary layer profile and skin friction coefficient measurements have been conducted for a NACA 0012 airfoil incorporating 0.0229, 0.076, and 0.152 mm symmetric v-groove riblets at a freestream Reynolds number of 250,000. While the growth of the wake was found to be similar for both the clean and the riblet-surfaces airfoils, riblet effectiveness in drag reduction was indicated by a significant decrease in wake turbulence levels. A drag reduction of as much as 13.3 percent was achieved, perhaps due to a combination of skin friction diminution in the riblet valleys and a decrease in turbulent shear stress.

Carbaugh, D. C. and Forsythe, W. D.

"WAKE TURBULENCE TRAINING AND REGULATION: AN INDUSTRY TEAM APPROACH"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 12-1 to 12-6

This paper describes the development and content of the industry endorsed Wake Turbulence Training Aid and Industry's input to regulators regarding wake turbulence efforts. The Wake Turbulence Training Aid is a safety document aimed at both pilots and air traffic controllers. The aid consists of a manual with pull out sections for easy use and a video of about 25 minutes in length. The reason for developing the aid is discussed. Increased traffic, mixed traffic, accidents and incidents, ASRS reports, and calls for action all culminated in needing training to step up to the need for more awareness and education for pilots and controllers. Who was involved in the development of the aid is discussed to highlight its international scope, as well as the time progression towards completion. The content of the aid is then discussed in detail. Lastly the efforts of the industry team to make specific inputs to the FAA regarding efforts to reduce wake turbulence encounters and to improve safety is presented.

"ONSET OF THE SPIRAL MODE OF VORTEX BREAKDOWN"

AIAA Paper No. 1997-0439, Reno, NV, January 1997

The three-dimensional nature of vortex breakdown, while widely recognized, has seldom been included in the analytical investigations and, until recently, the numerical simulations of this phenomenon. The principle asymmetric effects are examined by considering the impact that a weak perturbation has on an axisymmetric vortex. It is demonstrated that large axisymmetric strain rates are required for a non-axisymmetric perturbation to grow. Simulations bear out this fact by showing significant asymmetric behavior only after a critical swirl is exceeded which leads to breakdown in an axisymmetric flow. This result supports previous investigations which predict breakdown for an axisymmetric flow, despite their inability to fully capture the complexity of the breakdown topology.

Furthermore, this finding indicates that vortex breakdown may be a predominantly axisymmetric occurrence which is complicated by three-dimensional effects.

"HELIUM-FILLED SOAP BUBBLES FOR VORTEX CORE VELOCIMETRY"

Experiments in Fluids, Vol. 58, 2017, pp. 130-1 to 130-12.

Velocity measurements within the core of high-swirl vortices are often hampered by heavier-than-air particle tracers being centrifuged outside the vortex core region. The use of neutrally buoyant and lighter-than-air tracers is investigated to aim at homogeneous tracers' concentration in air flow experiments dealing with high-swirl vortices using particle image velocimetry. Helium-filled soap bubbles (HFSB) of sub-millimeter diameter are employed as flow tracers. Their density is controlled varying the relative amount of helium and soap solution composing the bubbles. The dynamics of HFSB and micro-size droplets is modeled within a Lamb-Oseen vortex to retrieve the order of magnitude of the tracers slip velocity. A positive radial drift for heavier-than-air tracers leads to an empty vortex core. In contrast, the concentration at the vortex axis is expected to increase for lighter than air tracers. Experiments are conducted on a sharp-edged slender delta wing at 20 degrees incidence. At chosen chord-based Reynolds numbers of 200,000 and 600,000, a stable laminar vortex is formed above the delta wing. Laser sheet visualization is used to inspect the spatial concentration of tracers. A comparison is made between micron-sized fog droplets and HFSB tracers in the nearly neutrally buoyant condition. Stereo-PIV measurements with fog droplets return a systematically underestimated axial velocity distribution within the vortex core due to drop-out of image cross-correlation signal. The nearly neutrally buoyant HFSB tracers appear to maintain a homogeneous spatial concentration and yield cross-correlation signal up to the vortex axis. The resulting velocity measurements are in good agreement with literature data.

"ASSESSING THE METROLOGICAL CAPABILITIES OF WIND DOPPLER LIDARS"

17th Coherent Lidar Conference, June 2013, Barcelona, Spain.

Since lidars are becoming industrial instruments, it is mandatory to ensure a good traceability of parameters and performances for all users. For most Doppler lidar applications, an accurate metrology is required, first of course for the radial wind component, but also for range and line of sight direction. To give to the user the more reliable information about its products, Leosphere is conducting a metrology plan, based on theoretical assumptions, simulation computations and experimental validations.

Cariou, J.-P. and Ludovic, T.

"COLLECTING LARGE WAKE VORTEX DATA WITH OPERATIONAL DOPPLER LIDARS FOR OPERATIONAL IMPLEMENTING OF NEW WAKE TURBULENCE REGULATIONS AT MAJOR AIRPORTS"

19th Coherent Laser Radar Conference (CLRC), Paper Th4, June 2018, Okinawa, Japan.

For twenty years, coherent Doppler LIDAR systems (CDL) have been used for better understanding wake vortices (WV) behaviors at airports. All these studies helped to design new concepts of wake separations like the RECAT regulation consisting in redefining new WT categories. These new regulations are now under investigation by many airports worldwide in order to validate their operational implementation. A review of the different technologies of CDLs used for wake vortex measurements is performed, as well as a review of the different types of wake vortex (WV) algorithm. The presentation describes in more detail one robust, automatic and accurate algorithm based on radial wind speeds designed for collecting large WV data for operational projects. It shows several examples of operational projects at major airports in the world like Paris-Charles de Gaulle airport or Hong Kong airport where wake vortex data collection has been started with CDLs.

Cariou, J.-P., Ludovic, T. and Sebastien, C.

"END-TO-END SIMULATION OF A COHERENT LIDAR IN A TURBULENT WIND FIELD"

19th Coherent Laser Radar Conference (CLRC), Paper P26, June 2018, Okinawa, Japan.

For operational applications such as wind resource assessment or turbine control, to warranty the performances in velocity accuracy and data availability is required. A Lidar simulator (Simulid TM) has been developed for assessing the velocity accuracy and the data availability of pulsed coherent wind Doppler Lidar system worldwide. This simulator considers both the Lidar parameters (instrument hardware, signal processing, beam propagation...) and the aerosol properties. Recently, Simulid TM has been coupled with a 3D wind model (Turbsim) to perform simulated wind measurements in any representative wind field, including turbulence. We present the methodology and the validation process. Velocity accuracy is compared with experimental tests performed in a frozen propagation medium and the representativeness of the simulated wind measurements is discussed.

Cariou, J.-P., Ludovic, T. and Spencer, P.

"FROM WINDCUBE#0001 TO WINDCUBE#1000: DOPPLER LIDAR AS A MATURE TECHNOLOGY"

19th Coherent Laser Radar Conference (CLRC), Paper Th14, June 2018, Okinawa, Japan.

10 years after the Windcube #0001, Leosphere has delivered its 1000th Windcube Doppler Lidar. Still based on pulsed fibered technology at 1.5 microns, the Windcube is now an industrial product widely used for Wind Resource Assessment and Weather Monitoring. Tracing the path of technological progress from laboratory to industry in hardware and software, but also the progress in metrology, the presentation expresses the various and demanding application requirements, the continuous

improvements of coherent lidar solutions and the slow but inexorable acceptance of remote sensors in wind energy and meteorological applications.

Cariou, J.-P., Pureur, V. and Hwryniack, E.

"ALL SEMICONDUCTOR PULSED DOPPLER LIDAR FOR WIND SENSING"

19th Coherent Laser Radar Conference (CLRC), Paper P18, June 2018, Okinawa, Japan.

Coherent Doppler lidars are usually powered by optical fiber amplifiers or solid-state bulk amplifiers. Thanks to recent improvements of semiconductor optical amplifiers (SOA), we have demonstrated the first 1.5 micron all semiconductor pulsed Doppler lidar for wind sensing. Low pulse energy typically available in SOAs is balanced by high pulse repetition frequency, allowing range resolved measurement of wind from 40 m to about 200 m with 20 m range resolution. While amplifying, the SOA shapes the light pulse leading to a quite simple, compact, and cost-effective setup. First results are shown and early atmospheric wind measurements are compared with a reference Windcube fibered lidar.

Cariou, J.-P., Thobois, L., Germon, Q., Dolfi-Bouteyre, A. and Durecu, A.

"DEVELOPMENT OF A HIGH-POWER DOPPLER WIND LIDAR FOR MEASURING WIND AND EDR ALONG AIRCRAFT APPROACHES"

18th Coherent Laser Radar Conference, June 2016, Boulder, CO.

Air flows in the troposphere have a major impact on air traffic safety and operations. In the framework of the European UFO project, LEOSPHERE and ONERA have developed a new high powered scanning Doppler LIDAR using an innovative powerful Erbium doped fiber laser amplifier. The performances of this prototype have been evaluated through a campaign in 2014 performed at Toulouse airport, France. In addition, specific algorithms have been developed for retrieving wind and EDR quantities along aircraft approaches and in 3D around airport. The wind and EDR measurements have been then compared to reference sensors in order to assess their accuracy.

Carley, M.

"A TRIANGULATED VORTEX METHOD FOR THE AXISYMMETRIC EULER EQUATIONS"

Journal of Computational Physics, Vol. 180, 2002, pp. 616-641

A new method is presented for the prediction of unsteady axisymmetric inviscid flows. By combining a triangulated vortex approach with a novel evaluation technique for the Biot-Savart integrals, a Lagrangian vortex method is developed which eliminates the singularities usually present in axisymmetric methods, without recourse to normalization or other approximations. Furthermore, the computational effort scales as the number of control points N and, in the large N limit, depends only on the order of quadrature employed. The accuracy and computational effort are assessed by comparison

with the velocity field of a Gaussian core vortex ring and the use of the technique is illustrated by computation of the motion of Norbury rings and of vortex ring pairing.

Carlisle, D.

"AIRCRAFT WAKE TURBULENCE"

Business and Commercial Aviation, Vol. 85, No. 5, November 1999, pp. 72-78

Understanding the physical characteristics of wake turbulence vortices and the hazard they represent is the key to developing effective strategies for avoiding wake turbulence encounters.

Carmer, C. F. v., Heider, A., Schroder, A., Konrath, R., Agocs, J., Gilliot, A. and Monnier, J.-C.

"EVALUATION OF LARGE-SCALE WING VORTEX WAKES FROM MULTI-CAMERA PIV MEASUREMENTS IN FREE-FLIGHT LABORATORY,:"

Topics in Applied Physics, Vol. 112, 2008, pp. 377-39.

Multiple-vortex systems of aircraft wakes have been investigated experimentally in a unique large-scale laboratory facility, the free-flight B20 catapult bench, ONERA Lille. 2D/2C PIV measurements have been performed in a translating reference frame, which provided time-resolved cross-velocity observations of the vortex systems in a Lagrangian frame normal to the wake axis. A PIV setup using a moving multiple-camera array and a variable double-frame time delay has been employed successfully. The large-scale quasi-2D structures of the wake-vortex system have been identified and illustrate the temporal development of unequal-strength corotating vortex pairs in aircraft wakes for nondimensional times up to 45.

Carmer, C. F. v., Konrath, R., Schroder, A. and Monnier, J.-C.

"IDENTIFICATION OF VORTEX PAIRS IN AIRCRAFT WAKES FROM SECTIONAL VELOCITY DATA"

Exp Fluids, Vol. 44, 2008, pp. 367-380

The dynamics of multiple-vortex wake systems behind aircraft endangering air traffic can be assessed also from physical modelling. Large-scale laboratory investigations of multiple-vortex systems have been performed in a free-flight laboratory and in a water towing tank. Specialized PIV measurements provide time-resolved flow velocity fields normal to the wake axis. The applicability of various velocity-gradient tensor-based vortex identification schemes to planar velocity data is addressed and demonstrated for unequal-strength co- and counter-rotating vortex pairs. Large vortices shed off the wing tips and flaps are identified employing a velocity-gradient tensor criterion. Their cooperative mechanisms of generation and decay are evidenced from iso-surfaces of squared swirling strength and from further characteristic vortex parameters.

Carnevale, G. F., Kloosterziel, R. C., Orlandi, P. and van Sommeren, D. D. J. A.

"PREDICTING THE AFTERMATH OF VORTEX BREAKUP IN ROTATING FLOW"

Journal of Fluid Mechanics, Vol. 669, 2011, pp. 90-119.

A method for predicting the outcome of vortex breakup in a rotating flow is introduced. The vortices dealt with here are subject to both centrifugal and barotropic instabilities. The prediction of the aftermath of the breakup relies on knowing how both centrifugal and barotropic instabilities would equilibrate separately. A theoretical model for non-linear equilibration in centrifugal instability is wedded to two-dimensional simulation of barotropic instability to predict the final vortices that emerge from the debris of the original vortex. This prediction method is tested against three-dimensional Navier-Stokes simulations. For vortices in which a rapid centrifugal instability triggers a slower barotropic instability, the method is successful both qualitatively and quantitatively. The skill of the prediction method decreases as the time scales of the two instabilities become comparable.

Carpenter, A. G.

"SUMMARY AND EVALUATION OF THEORETICAL DEVELOPMENTS RELATING TO TRAILING WING TIP VORTICES GENERATED BY AIRCRAFT"

SAC-NR-76-01, May 1976, Strategic Air Command, Offutt AFB, NB

This report presents a summary of theories and measurements which are believed to be applicable to the prediction of details concerning the structure and behavior of wing tip vortices created by large aircraft. Emphasis is placed upon the chronological development of theories, their comparison, and the selection of those which are believed to be most useful in predicting detailed velocity profiles of and within vortices from the moment of wing tip shedding until considerable trailing distances have been established with the passage of time.

Carr, J. W.

"SURFACE VELOCITIES AND TEMPERATURE CHANGES FOR C-130, C-141, AND C-5A EXHAUST BLASTS AND C-5A WING-TIP VORTEX"

AEWES-S-73-61, June 1973, Army Engineer Waterways Experiment Station, Vicksburg, M.

The report describes a series of field investigations conducted to determine exhaust-blast velocities and temperatures at the ground level for various aircraft and the wing-tip vortex velocity of the C-5A. Measurements of exhaust-blast velocities and temperature rise during static conditions were collected for C-130, C-141, and C-5A aircraft. Taxi, breakaway, and liftoff tests were conducted with the C-141 and C-5A to record velocity during actual aircraft operations. Wind velocity created by the wing-tip vortex of the C-5A was recorded during actual aircraft operations. Results of these tests indicate that temperature increases from engine exhaust blasts are not sufficient to cause detrimental effects on runway surfacing in use to date.

Carr, Z., Chen, C. and Ringuelette, M. J.

"THE EFFECT OF ASPECT RATIO ON THE THREE-DIMENSIONAL VORTEX FORMATION OF ROTATING FLAT-PLATE WINGS"

AIAA Paper No. 2012-0912, January 2012, Nashville, Tennessee.

We investigate experimentally the effect of aspect ratio (AR) on the unsteady, three-dimensional vortex structure of low-AR, flat-plate wings rotating from rest with a 45-degree angle of attack. This configuration is a simplified model of a flapping-wing hovering half-stroke. The objectives are to quantitatively characterize the evolution of the detailed, three-dimensional vortex structure and its variation with AR. The experiments are conducted in a glass tank facility containing a mixture of glycerin and water. Plates of AR=2 and 4 are tested, using a trapezoidal velocity program with a tip Reynolds number of 5,000 for each and a total rotation of 120 degrees. The unsteady, three-dimensional, volumetric velocity data are reconstructed from phase-locked and phase-averaged stereoscopic digital particle image velocimetry measurements in multiple, closely-spaced chordwise planes. The three-dimensional vortex formation is characterized using the Q-criterion and the helicity density. For each AR we find that the overall vortex structure is a loop consisting of a connection among the leading-edge, tip, and trailing edge vortices. For both AR's the leading-edge vortex (LEV) is larger with increasing span, i.e. conical, which is more pronounced for AR=4. The LEV for each AR is attached over the inboard portion of the plate up to about 50 percent span throughout the motion. However, after approximately 30 degrees of rotation it detaches from the plate in the outboard region near the tip, forming an arch-like structure. The arch is anchored at the tip due to the influence of the tip vortex. A second LEV then forms in front of the arch and does not exhibit shedding into the wake. In contrast, for AR=4 the flow structure in the tip region breaks down significantly and the flow appears to be fully separated for the remainder of the run. A Kelvin-Helmholtz instability is observed in the separated shear layers at the tip and trailing edges for both AR's.

"UNDERSTANDING WIND-TURBINE WAKE BREAKDOWN USING COMPUTATIONAL FLUID DYNAMICS"

AIAA Journal, Vol. 53, No. 3, March 2015, pp. 588-602.

This work explores the breakdown of the wake downstream of the Model Experiments in Controlled Conditions Project (known as the MEXICO project) wind-turbine rotor and assesses the capability of computational fluid dynamics in predicting its correct physical mechanism. The wake is resolved on a fine mesh able to capture the vortices up to eight rotor radii downstream of the blades. At a wind speed of 15 m/s, the main frequency present in the computational fluid dynamics signals for up to four radii was the blade-passing frequency (21.4 Hz), where the vortex cores fall on a perfect spiral. Between four and five radii downstream, higher-frequency content was present, which indicated the onset of instabilities and results in vortex pairing. The effect of modeling a 120 deg azimuthally periodic domain and a 360 deg three-bladed rotor domain was studied, showing similar predictions for the location of the onset of instabilities. An increased frequency content was captured in the latter

case. Empirical and wake models were also explored, they were compared with computational fluid dynamics, and a combination of kinematic and field models was proposed. The obtained results are encouraging and suggest that the wake instability of wind turbines can be predicted with computational fluid dynamics methods, provided adequate mesh resolution is used.

Carten, Jr., A. S.

"AIRCRAFT WAKE TURBULENCE - AN INTERESTING PHENOMENON TURNED KILLER"

Air University Review, Vol. XXII, No. 5, July/August 1971, pp. 12-24

The Aircraft Wake Turbulence problem is described in operational terms and is compared with another environmentally oriented problem: Clear Air Turbulence. The history of the investigation of wing tip vortices is traced from the earliest days of manned flight to the present time of crisis. A simplified theoretical explanation (based on the work of Spreiter and Sacks) is given for the phenomenon. Various possible methods of alleviation and problem control are described along with current on-going research efforts by various concerned groups.

Carten, Jr., A. S.

"THE AIRCRAFT WAKE TURBULENCE PROBLEM"

AIAA Student Journal, Vol. 10, No. 4, December 1972, pp. 8-13

This paper reports on the potential hazard resulting from the wake vortices generated by the heavy aircraft. An account is given of the conventional theory used to describe the vortex.

Carten, Jr., A. S.

"WARNING: WAKES"

Astronautics and Aeronautics, Vol. 8, No. 4, April 1970, pp. 76-81

This paper is written from the point of view of the airfield meteorological equipment designer. It considers the new problems associated with the just-introduced wide-body jet aircraft and assesses their probable impact on airfield meteorological equipment performance and siting requirements. Jet exhaust wakes caused by taxiing and takeoff operations are treated in detail. Wing tip vortex characteristics are discussed, citing the findings of other authors.

"A TWO-DIMENSIONAL VORTEX MERGER IN AN EXTERNAL STRAIN FIELD"

Journal of Turbulence, Vol. 3, Paper 045, October 2002, pp. 1-7

In a two-dimensional incompressible fluid, the merger of two Rankine vortices in an external strain field is studied analytically and numerically. In the absence of merger, the trajectory of the vortex centers is elliptical near the center of the plane and hyperbolic at larger distances. When merger occurs, it can be accelerated or decelerated by the external strain field depending on the orientation of the strain axes, but in all the cases studied here, external strain decreases merger efficiency.

"ONSET OF THE SPIRAL MODE OF VORTEX BREAKDOWN"

AIAA Paper No. 1997-0439, Reno, NV, January 1997

The three-dimensional nature of vortex breakdown, while widely recognized, has seldom been included in the analytical investigations and, until recently, the numerical simulations of this phenomenon. The principle asymmetric effects are examined by considering the impact that a weak perturbation has on an axisymmetric vortex. It is demonstrated that large axisymmetric strain rates are required for a non-axisymmetric perturbation to grow. Simulations bear out this fact by showing significant asymmetric behavior only after a critical swirl is exceeded which leads to breakdown in an axisymmetric flow. This result supports previous investigations which predict breakdown for an axisymmetric flow despite their inability to fully capture the complexity of the breakdown topology. Furthermore, this finding indicates that vortex breakdown may be a predominantly axisymmetric occurrence which is complicated by three-dimensional effects.

"ON THE CONNECTION BETWEEN FLAP SIDE-EDGE NOISE AND TIP VORTEX DYNAMICS"

AIAA Paper 2015-2992, June 2015, Dallas, TX.

The goal of the present work is to investigate how the dynamics of the vortical flow about the flap side edge of an aircraft determine the acoustic radiation. A validated lattice-Boltzmann CFD solution of the unsteady flow about a detailed business jet configuration in approach conditions is used for the present analysis. Evidence of the connection between the noise generated by several segments of the inboard flap tip and the aerodynamic forces acting on the same segments is given, proving that the noise generation mechanism has a spatially coherent and acoustically compact character on the scale of the flap chord, and that the edge-scattering effects are of secondary importance. Subsequently, evidence of the connection between the kinematics of the tip vortex system and the aerodynamic force is provided. The kinematics of the dual vortex system are investigated via a core detection technique. Emphasis is placed on the mutual induction effects between the two main vortices rolling up from the pressure and suction sides of the flap edge. A simple heuristic formula that relates the far-field noise spectrum and the cross-spectrum of the unsteady vortical positions is developed.

"A LAGRANGIAN APPROACH FOR VORTICITY INTENSIFICATION IN SWIRLING RINGS"

Computational Mechanics, Vol. 21, 1998, pp. 276-282

The Lagrangian approach, adopted in vortex methods for incompressible Euler flows, is reconsidered here as the most appropriate technique to track the dynamical evolution of organized vorticity structures in free space. We analyze in this paper a specific initial condition, the swirling ring with azimuthal perturbations, from which originate vortex dynamics events leading to a localized but strong vorticity intensification. The aim is to understand the possible development of a finite time singularity, in the context of inviscid flows, and its relevance for the study of intermittency, as one of the most challenging aspects of turbulence.

"LOW-ALTITUDE ATMOSPHERIC TURBULENCE AROUND AN AIRPORT"

Journal of Aircraft, Vol. 10, No. 3, March 1973, pp. 157-163.

A small airplane was used to measure vertical accelerations due to atmospheric turbulence around an airport surrounded by large buildings, trees, and other objects. The vertical and lateral extent and the intensity of turbulence in the wake of buildings and at other locations around the airport were measured. Results are presented which indicate that the vertical accelerations of the airplane are related to gust intensities measured by conventional anemometers, and that reasonable forecasts of atmospheric turbulence which an airplane could expect to encounter near an airport surrounded by buildings, etc. may be made from wind data appropriately measured and analyzed.

"UNSTEADY SEPARATION IN VORTEX-INDUCED BOUNDARY LAYERS"

Philosophical Transactions, Vol. 372, Issue 2020, July 2014, Article 20130348.

This paper provides a brief review of the analytical and numerical developments related to unsteady boundary-layer separation, in particular as it relates to vortex-induced flows, leading up to our present understanding of this important feature in high-Reynolds-number, surface-bounded flows in the presence of an adverse pressure gradient. In large part, vortex-induced separation has been the catalyst for pulling together the theory, numerics, and applications of unsteady separation. Particular attention is given to the role that Prof. Frank T. Smith, FRS, has played in these developments over the course of the past 35 years. The following points will be emphasized: (i) unsteady separation plays a pivotal role in a wide variety of high-Reynolds-number flows, (ii) asymptotic methods have been instrumental in elucidating the physics of both steady and unsteady separation, (iii) Frank T. Smith has served as a catalyst in the application of asymptotic methods to high-Reynolds-number flows, and (iv) there is still much work to do in articulating a complete theoretical understanding of unsteady boundary-layer separation.

"OBSERVATIONS OF UNSTEADY FLOW ARISING AFTER VORTEX BREAKDOWN"

J. Fluid Mech., Vol. 41, Part 4, 1970, pp. 727-736.

In rotating flow moving axially through a straight tube, a helical vortex will be generated if the angular momentum flux is sufficiently large relative to the flux of linear momentum. This paper describes an experimental study of the occurrence, frequency and peak-to-peak amplitude of the wall pressure generated by this vortex. The experimental results are displayed in dimensionless form in terms of a Reynolds number, a momentum parameter and tube geometry.

"EQUILIBRIUM OF VENTILATED CAVITIES IN TIP VORTICES"

Journal of Fluids Engineering, Vol. 119, Dec. 1997, pp. 759-767.

The behavior of air cavities formed in the tip vortex trailing from rectangular and elliptical planform hydrofoils has been examined both theoretically and experimentally. These cavities have some peculiarities, in particular their ability to move upstream and reach a stable position near the hydrofoil. Detailed measurements of the velocity components and the cavity characteristics have been made. The results are compared with the predictions of a theoretical model based on the equilibrium balance of a cavity developing in a Lamb vortex.

"EXPERIMENTAL ANALYSIS OF AERODYNAMICS CHARACTERISTICS OF ADAPTIVE MULTI-WINGLETS"

AIAA Paper No. 2005-1231, Reno, NV, January 2005

The research aim is the study of the potential use of adaptive multi-winglets to get reductions in the induced drag through variations of cant and incidence angle of the winglets. Different studies have been showing that the flow at the wing tip can be redirect using small aerodynamics superficies, thus reducing the induced drag. The model tested was composed of a rectangular wing built from an airfoil NACA 65-018 constituted of three winglets called tip-sails, which are small wings without sweep at 25% chord. The tests were conducted at a Reynolds number of 650,000. The results are analyzed by the interpretation of lift; drag and mapping of the wake through hot-wire anemometry. Results showed that it is possible to find the best configuration of the three wing-lets in order to get the optimum aerodynamic performance for each flow regime from climb to cruise.

"EXPERIMENTS ON SHOCK/VORTEX INTERACTION"

AIAA Paper No. 92-0315, Reno, NV, January 1992

The interaction between a shock wave and a supersonic streamwise vortex is a fundamental fluid dynamics problem with numerous practical applications. However, very little research has been conducted on this topic. This paper describes an experimental study of this phenomenon. In particular, supersonic streamwise vortices of varying strength and Mach number were generated and measured using five-hole and total temperature probes. In addition, the interaction between a vortex and either an oblique or a normal shock wave were visualized using schlieren and Planar Laser Scattering (PLS) techniques. The mean-flow measurements show both similarities and differences between the supersonic streamwise vortex and its incompressible counterpart, while the flow visualization results show that the shock/vortex interaction is always unsteady and that, under certain conditions, the vortex can burst. The conditions necessary for supersonic vortex breakdown are presented.

"TWO-EQUATION MODELING OF TURBULENT ROTATING FLOWS"

Physics of Fluids, Vol. 17, No. 5, May 2005, pp. 005110-1-0555110-14

The possibility to take into account the effects of the Coriolis acceleration on turbulence is examined in the framework of two-equation eddy-viscosity models. General results on the physical consistency of such turbulence models are derived from a dynamical-system approach to situations of time-evolving homogeneous turbulence in a rotating frame. Application of this analysis to a model fitted with an existing Coriolis correction [J. H. G. Howard, S. V. Patankar, and R. M. Bordyniuk, 'Flow prediction in rotating ducts using Coriolis-modified turbulence models' ASME Trans. J. Fluids Eng. 102, 456 (1980)] is performed. Full analytical solutions are given for the flow predicted with this model in the situation of homogeneously sheared turbulence subject to rotation. The existence of an unphysical phenomenon of blowup at finite time is demonstrated in some range of the rotation-to-shear ratio. A direct connection is made between the slope of the mean velocity profile in the plane-channel flow with spanwise rotation, and a particular fixed point of the dynamical system in homogeneously sheared turbulence subject to rotation. The general analysis, and the understanding of typical inaccuracies and misbehavior observed with the existing model, are then used to design a new model which is free from the phenomenon of blowup at finite time and able to account for both main influences of rotation on turbulence: the inhibition of the spectral transfer to high wave numbers and the shear/Coriolis instability.

"SCATTERING OF SOUND WAVES BY A TURBULENT WAKE"

Journal of Sound and Vibration., Vol. 35, No. 2, 1994, pp. 231-252

In this investigation, the Doppler shifted power spectrum of the scattering cross-section is obtained for plane acoustic waves scattered by fluid flow fluctuations appropriate to a turbulent wake. The wake considered in this paper is assumed almost homogeneous and isotropic and of low Reynolds number. It is shown that the evaluation of the Doppler scattering cross-section essentially reduces to the calculation of the wave number converted and frequency shifted energy spectrum function of the turbulent flow fluctuations. In prescribing the low Reynolds number turbulence spectrum, inertial forces are assumed negligible. Convective effects of the macro-eddies, which cause a Doppler shift in the scattered waves, are considered using a Lagrangian-type of space-time velocity correlation. After finding the spectrum of turbulent fluctuations, the Doppler shifted power spectrum of the scattering cross-section, which characterizes the scattered waves, is obtained explicitly for the far field approximation.

Centolanzi, F. J.

"MEASURED AND THEORETICAL FLOW FIELDS BEHIND A RECTANGULAR AND A TRIANGULAR WING UP TO HIGH ANGLES OF ATTACK AT A MACH NUMBER OF 2.46"

NASA TN-D-92, Sept. 1959, Ames Research Center, Moffett Field, CA.

Measurements were made of the flow field behind a rectangular and a triangular wing of aspect ratio 2 up to angles of attack of 30 degrees. The wings had a 4-inch semispan and were 5 percent thick with maximum thickness at midchord. Tests were performed at a Mach number of 2.46 and a Reynolds number of 3.12 million per foot. Flow-field measurements were taken for wing angles of attack of 0, 6, 20 and 30 degrees. The downwash, sidewash, Mach number, and dynamic pressure in the wakes of both wings are compared with the predictions of various theoretical methods. The results show that for angles of attack up to 20 degrees these flow quantities can be calculated with sufficient accuracy for most engineering purposes. The measured downwash, dynamic pressure, and Mach number in the wake of the rectangular wing were used to estimate the effectiveness of a hypothetical tail placed at various heights above and below the chord plane of the wing. The effectiveness was also computed using shock-expansion theory to determine the required flow quantities. These two calculations of the tail effectiveness are in fair agreement.

"EXPERIMENTAL INVESTIGATION OF WING-TIP DEVICES ON THE REDUCTION OF INDUCED DRAG"

Journal of Aircraft, Vol. 50, No. 2, March-April 2013, pp. 441-449.

Wind tunnel testing was carried out to evaluate the reduction of induced drag using wing-tip blowing, fixed and adaptive multi-winglets. Different arrangements of each device were tested on a semi-span wing, with additional investigation performed on a half-body model of a trainer aircraft. Results include: aerodynamic coefficients; surface pressure distributions; and wake surveys with a multi-hole Pitot probe. The influence of each wing-tip arrangement on aircraft performance was estimated,

considering the energy requirements of the blowing system. All devices tested were able to minimize induced drag; however, for practical applications in commercial airplanes, multi-winglets are a more promising alternative due to the large amount of energy required by wing-tip blowing.

Cerretelli, C. and Williamson, C. H. K.

"A NEW FAMILY OF UNIFORM VORTICES RELATED TO VORTEX CONFIGURATIONS BEFORE MERGING"

J. Fluid Mech., Vol. 493, 2003, pp. 219-229

Stimulated by experimental observations of vortex merging, we compute a new family of uniform-vorticity steady solutions of the Euler equations in two dimensions. In experiments with two co-rotating vortices, one finds that, prior to the convective merging phase, and the formation of vortex filaments, the initial pair diffuses into a single structure (with two vorticity peaks) in the form of a symmetric 'dumb-bell'. In the present computations, our exploration of the existence of vortex solutions has been guided by the streamline patterns of the co-rotating reference frame, and by the simple concept that the vortex boundary must be one of these streamlines. By varying the parameters which define the vortex patches, we find a family of vorticity structures which pass from the limiting case of point vortices, through the case of two equal co-rotating uniform vortices, to the regime where the vortices touch in the form of a dumb-bell. Further exploration of this family of solutions leads to an elliptic vortex, which joins precisely to the local trans-critical bifurcation from elliptic vortices with $n = 4$ perturbation symmetry that was found by Kamm (1987) and Saffman (1988). Finally, one reaches a limiting 'cat's-eye' vortex patch of two-fold symmetry ($m = 2$), which constitutes an extension to the limiting shapes of m -fold symmetry (m greater than 2) found by Wu, Overman and Zabusky (1984).

"THE PHYSICAL MECHANISM FOR MERGING OF TRAILING VORTICES"

J. Fluid Mech., Vol. 475, 2003, pp. 41-77

In this paper, we study the interaction of two co-rotating trailing vortices. It is well known that vortices of like-sign ultimately merge to form a single vortex, and there has been much work to measure and predict the initial conditions for the onset of merger, especially concerning the critical vortex core radius. However, the physical mechanism causing such merger has received little attention. In this work, we directly measure the structure of the antisymmetric vorticity field that causes the co-rotating vortices to be pushed towards each other during merger. We discover that the form of the antisymmetric vorticity comprises two counter-rotating vortex pairs, whose induced velocity field readily pushes the two centroids together. The merging velocity, computed from the antisymmetric vorticity field, agrees closely with such velocity measured directly from the total (original) flow field. The co-rotating vortex pair evolves through four distinct phases. The initial stage comprises a diffusive growth, which can be either viscous or turbulent. In either case, the number of turns that they rotate around one another until the vortices start to merge increases with Reynolds number (Re). If one observes the streamlines in a rotating reference frame (moving with the vortices), then one finds an

inner and outer recirculating region of the flow bounded by a separatrix streamline. When the vortices grow large enough in the first stage, diffusion across the separatrix places vorticity into the outer recirculating region of the flow, and this leads to the generation of the antisymmetric vorticity, causing convective merger. This second (convective) stage corresponds to the motion of the vortex centroids towards each other, and is a process which is almost independent of viscosity. During the late part of this stage, the antisymmetric vorticity is diminished by a symmetrization process, and the final merging into one vorticity structure is achieved by a second diffusive stage. The fourth and ultimate phase is one where the merged vortex core grows by diffusion.

"AIRFLOW CHARACTERIZATION BY RAYLEIGH-MIE LIDARS"

Onera Journal, Issue 1, December 2009, pp. 1-4.

This paper deals with lidar systems applied to airflow measurements. The properties of the two main light scattering processes, Rayleigh and Mie scattering, are presented and correlated to general but important rules for lidar design. The Rayleigh lidar developed at Onera for short-range wind speed measurements is also presented, and the Doppler analysis technique using Michelson fringe imagery is briefly discussed.

Chaderjian, N. M.

"ADVANCES IN ROTOR PERFORMANCE AND TURBULENT WAKE SIMULATION USING DES AND ADAPTIVE MESH REFINEMENT"

Seventh International Conference on Computational Fluid Dynamics, July 2012, Big Island, Hawaii.

Time-dependent Navier-Stokes simulations have been carried out for a rigid V22 rotor in hover, and a flexible UH-60A rotor in forward flight. Emphasis is placed on understanding and characterizing the effects of high-order spatial differencing, grid resolution, and Spalart-Allmaras (SA) detached eddy simulation (DES) in predicting the rotor figure of merit (FM) and resolving the turbulent rotor wake. The FM was accurately predicted within experimental error using SA-DES. Moreover, a new adaptive mesh refinement (AMR) procedure revealed a complex and more realistic turbulent rotor wake, including the formation of turbulent structures resembling vortical worms. Time-dependent flow visualization played a crucial role in understanding the physical mechanisms involved in these complex viscous flows. The predicted vortex core growth with wake age was in good agreement with experiment. High-resolution wakes for the UH-60A in forward flight exhibited complex turbulent interactions and turbulent worms, similar to the V22. The normal force and pitching moment coefficients were in good agreement with flight-test data.

Chadwick, E.

"THE VORTEX LINE IN STEADY, INCOMPRESSIBLE OSEEN FLOW"

Proceedings of the Royal Society, Vol. A 462, Nov. 2005, pp. 391-401.

The horseshoe vortex is given in Oseen flow as a constant spanwise distribution of lift Oseenlets. From these, the vortex line is represented in steady, incompressible Oseen flow. The velocity near to the vortex line is determined, as well as near to and far from the far field wake. The velocity field in the transverse plane near to the vortex line is shown to approximate to the two-dimensional Lamb-Oseen vortex, and the velocity field in the streamwise direction is generated by the bound vortex line of the horseshoe vortex giving a streamwise decay much faster than that of the Batchelor vortex. The far field wake description is shown to be consistent with laminar wake theory.

Chadwick, E. and Rahulan, T.

"A THEORETICAL MODEL EVALUATING LEADING ORDER VORTEX DECAY BEHIND AN AIRCRAFT"

Proc. IMechE, Vol. 225, Part G, 2011, pp. 657-663.

A theoretical model in this article which is used to evaluate leading order vortex decay behind an aircraft, is presented. This model is then applied to two important problems. The first evaluates safety separation distances for the super class of aircraft exemplified by the Airbus A380. The second evaluates the swirl parameter which is shown to decay to a sufficiently low level that short-wave instabilities are likely to be instigated. The model uses the Oseen approximation, which assumes that in the far-field the ratio of the perturbed velocity to the aircraft velocity is small, and developed from recent publications by the first author. The atmospheric turbulence is incorporated into the model by using effective viscosity.

Chadwick, R. B., Jordan, J. and Detman, T.

"RADAR DETECTION OF WINGTIP VORTICES"

Proceedings 9th Conf. on Aerospace and Aeronautical Meteorology, American Meteorological Society, Omaha, NE, June 1983, pp. 235-240

It is possible to detect wingtip vortices in airport approach zones using inexpensive (<400 K) clear-air Doppler radar systems. Calibration-free techniques for determining if a vortex is in a resolution cell can probably be developed. Further work is necessary to determine if the detection capability is degraded by rain or fog. Since clear-air Doppler radars can measure hazardous wind shear, Chadwick et al. (1979), it is possible that the same radar system could be used to locate vortex hazards and detect wind shear hazards in approach zones. The operational methods for using the same radar system to solve two important problems would have to be developed, but the radar technology for detecting wind shear and wingtip vortices does exist.

Chadwick, R. B., Moran, K. P., Campbell, W. C., Earnshaw, K. B. and Detman, T. R.

"DEVELOPMENT OF A CLEAR AIR RADAR TO DETECT METEOROLOGICAL HAZARDS AT AIRPORTS"

AFGL TR-81-0268, September 1981, NOAA Wave Propagation Lab., Boulder, CO

To be useful in detecting meteorological hazards such as low-level wind shear near airports, a radar must be able to: (1) detect backscatter from both clear air and rain; (2) operate at short ranges and low elevation angles; and (3) measure Doppler frequencies caused by air motion. The development of a radar with these characteristics is described and the results of testing this radar at airports are presented. Special emphasis is placed on the problems of low elevation angle operation and clutter suppression. The importance of proper siting is pointed out. In addition, it is demonstrated that the radar can readily detect the turbulent wakes of large jet aircraft.

Chakraborty, B. B. and Chandra, J.

"RAYLEIGH-TAYLOR INSTABILITY IN THE PRESENCE OF ROTATION"

Physics of Fluids, Vol. 19, No. 12, December 1976, pp. 1851-1852

A heavy uniform fluid is superposed on a lighter one. The two uniform fluids are separated by a layer of transition of finite thickness in which the density increases exponentially in the vertical direction. The growth rate and the wavenumber of the mode of maximum instability are obtained when the whole system rotates uniformly about a vertical axis.

Chamorro, L. P. and Porte-Agel, F.

"A WIND-TUNNEL INVESTIGATION OF WIND-TURBINE WAKES: BOUNDARY-LAYER TURBULENCE EFFECTS"

Boundary-Layer Meteorology, Vol. 132, 2009, pp. 129-149.

Wind-tunnel experiments were performed to study turbulence in the wake of a model wind turbine placed in a boundary layer developed over rough and smooth surfaces. Hot-wire anemometry was used to characterize the cross-sectional distribution of mean velocity, turbulence intensity and kinematic shear stress at different locations downwind of the turbine for both surface roughness cases. Special emphasis was placed on the spatial distribution of the velocity deficit and the turbulence intensity, which are important factors affecting turbine power generation and fatigue loads in wind energy parks. Non-axisymmetric behavior of the wake is observed over both roughness types in response to the non-uniform incoming boundary-layer flow and the effect of the surface. Nonetheless, the velocity deficit with respect to the incoming velocity profile is nearly axisymmetric, except near the ground in the far wake where the wake interacts with the surface. It is found that the wind turbine induces a large enhancement of turbulence levels (positive added turbulence intensity) in the upper part of the wake. This is because of relatively large velocity fluctuations associated with helicoidal tip vortices near the wake edge, where the mean shear is strong. In the lower part of the wake, the mean shear and turbulence intensity are reduced with respect to the incoming flow. The non-axisymmetry of the turbulence intensity distribution of the wake is found to be stronger over the rough surface, where the incoming flow is less uniform at the turbine level. In the far wake the added turbulent intensity, its positive and negative contributions, and its local maximum decay as a power law of downwind distance

(with an exponent ranging from -0.3 to -0.5 for the rough surface, and with a wider variation for the smooth surface). Nevertheless, the effect of the turbine on the velocity defect and added turbulence intensity is not negligible even in the very far wake, at a distance of fifteen times the rotor diameter.

Chamorro, L. P. and Porte-Agel, F.

"EFFECTS OF THERMAL STABILITY AND INCOMING BOUNDARY-LAYER FLOW CHARACTERISTICS ON WIND-TURBINE WAKES: A WIND-TUNNEL STUDY"

Boundary-Layer Meteorology, Vol. 136, 2010, pp. 515-533.

Wind-tunnel experiments were carried out to study turbulence statistics in the wake of a model wind turbine placed in a boundary-layer flow under both neutral and stably stratified conditions. High-resolution velocity and temperature measurements, obtained using a customized triple wire (cross-wire and cold wire) anemometer, were used to characterize the mean velocity, turbulence intensity, turbulent fluxes, and spectra at different locations in the wake. The effect of the wake on the turbulence statistics is found to extend as far as 20 rotor diameters downwind of the turbine. The velocity deficit has a nearly axisymmetric shape, which can be approximated by a Gaussian distribution and a power-law decay with distance. This decay in the near-wake region is found to be faster in the stable case. Turbulence intensity distribution is clearly non-axisymmetric due to the non-uniform distribution of the incoming velocity in the boundary layer. In the neutral case, the maximum turbulence intensity is located above the hub height, around the rotor tip location and at a distance of about 4-5.5 rotor diameters, which are common separations between wind turbines in wind farms. The enhancement of turbulence intensity is associated with strong shear and turbulent kinetic energy production in that region. In the stable case, the stronger shear in the incoming flow leads to a slightly stronger and larger region of enhanced turbulence intensity, which extends between 3 and 6 rotor diameters downwind of the turbine location. Power spectra of the streamwise and vertical velocities show a strong signature of the turbine blade tip vortices at the top tip height up to about 1-2 rotor diameters. This spectral signature is stronger in the vertical velocity component. At longer downwind distances, tip vortices are not evident and the von Karman formulation agrees well with the measured velocity spectra.

Chamorro, L. P., Arndt, R. and Sotiropoulos, F.

"TURBULENCE PATTERNS AROUND A LARGE WIND FARM"

AIAA Paper 2011-0457, January 2011, Orlando, FL.

A wind-tunnel investigation was performed at the St. Anthony Falls Laboratory atmospheric boundary layer wind tunnel to study fundamental properties of the turbulent flow around a perfectly staggered wind turbine array. The staggered wind farm consisted on a series of 10 rows by 2-3 columns of miniature wind turbines spaced 5 and 4 rotor diameters in the streamwise and spanwise directions, respectively. The wind turbine array was placed in a boundary layer flow developed over a smooth surface under neutrally stratified conditions. Cross-wire anemometry was used to obtain high

resolution measurements of streamwise and vertical velocity components at locations within and above the wind farm. Results show that the staggered configuration is much more efficient in terms of momentum transfer from the background flow to the turbines compared to the case of an aligned wind turbine array under similar turbine separations in the streamwise and spanwise directions. This led to improved power output of the overall wind farm. A simplified analysis suggests that the change of power in the two configurations is on the order of 10 percent. Maximum levels of turbulence intensity in the wind farm were found to be very similar to that of observed in the wake of a single wind turbine, differing substantially with that observed in an aligned configuration under similar spacings. The dramatic changes in momentum and turbulence characteristics in the two configurations shows the importance of turbine layout in engineering design. Lateral homogenization of the turbulence statistics above the wind farm allows the development of simple parameterizations for the adjustment of flow properties, like the case of a surface roughness transition. The development of an internal boundary layer was observed above the wind farm. In this layer, flow statistics are affected by the background flow and wind turbines. The adjustment of the flow in this layer is much slower in the staggered situation (respect to its aligned counterpart) which implies change in the momentum/power available at turbine locations.

"THREE-DIMENSIONAL FLOW VISUALIZATION IN THE WAKE OF A MINIATURE AXIAL-FLOW HYDROKINETIC TURBINE"

Experimental Fluids, Vol. 54, 2013, pp. 1459-1470.

Three-dimensional 3-component velocity measurements were made in the near wake region of a miniature 3-blade axial-flow turbine within a turbulent boundary layer. The model turbine was placed in an open channel flow and operated under subcritical conditions ($Fr = 0.13$). The spatial distribution of the basic flow statistics was obtained at various locations to render insights into the spatial features of the wake. Instantaneous and phase-averaged vortical structures were analyzed to get insights about their dynamics. The results showed a wake expansion proportional to the one-third power of the streamwise distance, within the first rotor diameter. Wake rotation was clearly identified up to a distance of roughly three rotor diameters. In particular, relatively high tangential velocity was observed near the wake core, but it was found to be nearly negligible at the turbine tip radius. In contrast, the radial velocity showed the opposite distribution, with higher radial velocity near the turbine tip and, due to symmetry, negligible at the rotor axis. Larger turbulence intensity was found above the hub height and near the turbine tip. Strong coherent tip vortices, visualized in terms of the instantaneous vorticity and the lambda sub two criterion, were observed within the first rotor diameter downstream of the turbine. These structures, influenced by the velocity gradient in the boundary layer, appeared to lose their stability at distances greater than two rotor diameters. Hub vortices were also identified. Measurements did not exhibit significant tip-hub vortex interaction within the first rotor diameter.

Champniss, G. A.

"AIR TRAFFIC MANAGEMENT - THE IMPACT AT THE AIRPORT"

Proceedings of Spring Convention, Royal Aeronautical Society, London, England, May 1982

The introduction of wide-bodied aircraft has led to the adoption of increased separation standards to minimize the effects of wake turbulence. This use of increased separation standards, while of relatively minor significance when the total number of movements by wide bodied aircraft is low, results in a significant reduction in the sustainable capacity of a dedicated landing runway as the proportion of such aircraft increases. The reduction of separation standards currently in use without adverse effects on safety may be achieved by means of more efficient airport surface movement guidance and control, which optimizes the capacity of a given runway. The aircraft whose impact will be most strongly felt are the 757, 767, and 737, all new generation airliners capable of Category III visibility conditions operations which will require airport facilities to accommodate their expanded capabilities.

Chan, A. S., Dewey, P. A., Jameson, A., Liang, C. and Smits, A. J.

"VORTEX SUPPRESSION AND DRAG REDUCTION IN THE WAKE OF COUNTER-ROTATING CYLINDERS"

Journal of Fluid Mechanics, Vol. 679, 2011, pp. 343-382.

The flow over a pair of counter-rotating cylinders is investigated numerically and experimentally. It is demonstrated that it is possible to suppress unsteady vortex shedding for gap sizes from one to five cylinder diameters, at Reynolds numbers from 100 to 200, expanding on the more limited work of Chan and Jameson. The degree of unsteady wake suppression is proportional to the speed and the direction of rotation, and there is a critical rotation rate where a complete suppression of flow unsteadiness can be achieved. In the doublet-like configuration at higher rotational speeds, a virtual elliptic body that resembles a potential doublet is formed, and the drag is reduced to zero. The shape of the elliptic body primarily depends on the gap between the two cylinders and the speed of rotation. Prior to the formation of the elliptic body, a second instability region is observed, similar to that seen in studies of single rotating cylinders. It is also shown that the unsteady wake suppression can be achieved by rotating each cylinder in the opposite direction, that is, in a reverse doublet-like configuration. This tends to minimize the wake interaction of the cylinder pair and the second instability does not make an appearance over the range of speeds investigated here.

"TURBULENCE MEASUREMENTS BY THE DC-8 METEOROLOGICAL MEASUREMENT SYSTEM"

Geophysical Research Letters, Vol. 25, No. 9, May 1998, pp. 1355-1358

The instrumentation of a new MMS on the NASA DC-8 aircraft is briefly described. A method to compute the turbulent dissipation rate is discussed considering some apparent inconsistencies between high and medium altitude aircraft data and available theory. Examples of turbulence

measurements during encounters of a wake vortex, a field of wave clouds, and persistent contrails are illustrated.

Chan, P. W.

"MEASUREMENT OF TURBULENCE INTENSITY PROFILE BY A MINI-SODAR"

Meteorological Applications, Vol. 15, 2008, pp. 249-258.

Low-level turbulence can bring about rapid bumps and jolts to an aircraft. In severe turbulence, the aircraft may suffer momentary loss of control. In accordance with the practice of ICAO, turbulence intensity is expressed in terms of the cube root of the eddy dissipation rate (EDR). Measurement of the EDR is an important component in the provision of turbulence alerting services for arriving and departing aircraft at an airport. This article describes a method to calculate the EDR profile using the wind measurements from a ground-based mini-sodar located near the Hong Kong International Airport (HKIA). The method makes use of the vertical wind data at 0.25 or 0.5 Hz provided by the mini-sodar (depending on the maximum measurement range) and searches for the inertial sub-range in the frequency spectrum of the vertical wind. The accuracy of the wind and EDR measurements of the mini-sodar is first established by comparison with meteorological tower data in a field experiment. The potential application of the EDR profiles in terrain-disrupted airflow at HKIA is then demonstrated through two case studies. The EDR profiles obtained from the mini-sodar are found to be of good quality and could be useful in the monitoring of low-level turbulence for aviation applications.

Chan, P. W.

"DETERMINATION OF RICHARDSON NUMBER PROFILE FROM REMOTE SENSING DATA AND ITS AVIATION APPLICATION"

14th International Symposium for the Advancement of Boundary Layer Remote Sensing, published in IOP Conf. Series: Earth and Environmental Science, Vol. 1, 2008, pp. 012043-1 - 012043-8.

A number of remote-sensing wind-measuring instruments, such as LIDAR and radar wind profilers, have been set up in the vicinity of the Hong Kong International Airport (HKIA) for monitoring of low-level windshear and turbulence. The combined usage of wind data from a radar wind profiler and boundary layer temperature profiles from a ground-based microwave radiometer in turbulence application is studied in this paper. Data collected in a field experiment of the radiometer conducted in Hong Kong in February 2006 were used to obtain the Richardson number profile up to 1.5 km above ground. Two examples of atmospheric turbulence reported by the pilots are considered. The Richardson number profiles are found to capture the turbulence events reasonably well. The evolution of these profiles and airflow disruption by the nearby terrain as a possible cause of the turbulence will also be discussed.

Chan, P. W.

"LIDAR-BASED TURBULENCE INTENSITY FOR AVIATION APPLICATIONS"

In *Aviation Turbulence*, edited by R. Sharman and T. Lane, Chapter 9, 2016, Springer International Publishing Switzerland, pp. 193-209.

Turbulence could increase the workload of pilots, and timely provision of turbulence information would be beneficial to aircraft operation. This paper summarizes the use of a Doppler Light Detection and Ranging (LIDAR) system to measure turbulence intensity at an operating airport. The cube root of eddy dissipation rate (ERD) is used for representing the turbulence intensity, according to the requirement of the International Civil Aviation Organization (ICAO). The quality of EDR so calculated is established by comparing with the aircraft data. Examples of EDR maps based on conical scans of the LIDAR are presented. The EDR maps so obtained should be useful for aviation operations, and the EDRs calculated from the glide-path scans of the LIDAR may be used for turbulence alerting applications.

Chan, P. W.

"PERFORMANCE AND AVIATION APPLICATIONS OF MINISODARS AT HONG KONG INTERNATIONAL AIRPORT"

Meteorological Applications, Vol. 21, 2014, pp. 62-73.

The performance and aviation application of mini-sodars at Hong Kong International Airport are discussed in this paper. There are two mini-sodars at the airport and they have been in use for more than 2 years. The data availability at various measurement heights shows that the mini-sodars in general provide reasonably good coverage for aviation applications. The mini-sodar's wind data compare well with other measurements, including the anemometer data and LIDAR (light detection and ranging) data. The applications of mini-sodar data are then described. They are found to provide useful indications of low-level windshear, mechanical turbulence associated with complex terrain, and downburst associated with a thunderstorm. Through these case studies, the mini-sodars are found to provide good supplementary data to other remote sensing meteorological instruments, such as LIDAR and radar, in the monitoring of low-level wind changes that may be encountered by the aircraft.

"COMPARISON OF TURBULENCE INTENSITY COMPUTED FROM LIDAR AND AIRCRAFT DATA"

24th International Laser Radar Conference, June 2008, Boulder, CO.

The glide-path scans of the LIDARs at the Hong Kong International Airport (HKIA) are used to calculate the eddy dissipation rate (EDR), the internationally adopted metric for turbulence reporting/alerting, by using the structure function approach based on the radial velocity data. The EDR so determined is compared with the turbulence intensity calculated from the Quick Access Recorder (QAR) data of transport category commercial aircraft landing at HKIA. The two sets of EDR data are well correlated, though there is considerable spread of the data points in the scatter plot. The spread may be related to

the discrepancy between the LIDAR velocity data and the actual wind encountered by the aircraft, as well as the transient and sporadic nature of the turbulence itself. Two examples of the EDR profiles from the LIDAR and the QAR data are discussed.

"INSTABILITIES OF TWO-DIMENSIONAL INVISCID COMPRESSIBLE VORTICES"

Journal of Fluid Mechanics, Vol. 253, 1993, pp. 173-209.

The linear stability and subsequent nonlinear evolution and acoustic radiation of a planar inviscid compressible vortex is examined. Linear-stability analysis shows that vortices with smoother vorticity profiles than the Rankine vortex considered by Broadbent & Moore (1979) are also unstable. However, only neutrally stable waves are found for a Gaussian vorticity profile. The effects of entropy gradient are investigated and for the particular entropy profile chosen, positive average entropy gradient in the vortex core is destabilizing while the opposite is true for negative average entropy gradient. The linear initial-value problem is studied by finite-difference methods. It is found that these methods are capable of accurately computing the frequencies and weak growth rates of the normal modes. When the initial condition consists of random perturbations, the long-time behavior is found to correspond to the most unstable normal mode in all cases. In particular, the Gaussian vortex has no algebraically growing modes. This procedure also reveals the existence of weakly decaying and neutrally stable waves rotating in the direction opposite to the vortex core, which were not observed previously. The nonlinear development of an elliptic-mode perturbation is studied by numerical solution of the Euler equations. The vortex elongates and forms shocklets; eventually, the core splits into two corotating vortices. The individual vortices then gradually move away from each other while their rate of rotation about their mid-point slowly decreases. The acoustic flux reaches a maximum at the time of fission and decreases as the vortices move apart.

Chang, C.-C.

"A SIMPLIFIED METHOD OF OBTAINING DRAG OF A HIGH-SPEED BODY FROM WAKE SURVEYS"

Journal of the Aeronautical Sciences, Vol. 15, No. 2, February 1948, pp. 123-127.

Jones' drag integral equation is re-examined in the light of the known experimental fact that nearly constant stagnation temperature exists across the wake of a body moving at high speed in air. It is found that the integrand of the equation can be separated into the product of two functions -- namely, one function containing the ratio of the static to total head pressure at the measuring station in the body's wake and the second function containing two similar pressure ratios that correspond to conditions far up and far downstream along the same stream line. Each of the two functions can be conveniently plotted in a graph. With the aids of such graphics, this analysis makes the pitot-transverse method practical and easy to apply in determining drag of flight at subsonic speed. An example of application is shown. Some justifications of the assumption are made, and the limitations of application are explained. It is further found that the method can be applied approximately to flow around a two-dimensional body with shock and possibly to supersonic flow, as long as at and behind the measurement station no shock waves of appreciable strength exist. Of course, some development work has to be done before this method can be successfully applied to the supersonic case.

Chang, J. W.

"NEAR-WAKE CHARACTERISTICS OF AN OSCILLATING NACA 4412 AIRFOIL"

Journal of Aircraft, Vol. 41, No. 5, September-October 2004, pp. 1240-1243

This experimental study was carried out to measure phase-averaged mean velocity and its turbulent intensity in the near-wake region of an oscillating NACA 4412 airfoil at the Reynolds numbers $Re = 5.3 \times 10,000$, $1.9 \times 100,000$, and $4.1 \times 100,000$. All cases in these measurements show that the velocity defects were coupled with both the camber effect and the Reynolds-number effect and that the Reynolds-number effect may be associated with the laminar or turbulent boundary layer on the airfoil surface. The near-wake characteristics of an oscillating NACA 4412 airfoil are insensitive to Reynolds numbers between $Re = 1.9 \times 100,000$ and $4.1 \times 100,000$. At $Re = 5.3 \times 10,000$, test results show that the magnitude and width of the velocity defect are much larger than those in the range between $Re = 1.9 \times 100,000$ and $4.1 \times 100,000$. A critical value of the Reynolds number in the near wake of an oscillating NACA 4412 airfoil, which includes either cases of lamina separation or cases of no separation or turbulent separation, exists in the range between $5.3 \times 10,000$ and $1.9 \times 100,000$. The near-wake characteristics of the NACA 4412 airfoil at $\alpha = 0$ deg are considerably different depending on motion direction due to the slightly sharper-edged nose shape of the lower surface of the NACA 4412 airfoil compared to the nose shape of the upper surface as well as the phase lag in the near-wake region of the airfoil oscillation.

Chang, J. W. and Park, S. O.

"AN EXPERIMENTAL STUDY OF TIP VORTEX ROLL-UP OF AN OSCILLATING WING"

AIAA Paper No. 1999-0142, Reno, NV, January 1999.

An experimental study was made to quantitatively examine the tip vortex roll-up in the near field of an oscillating wing. A NACA 0012 rectangular planform wing with an aspect ratio of 4.0 was mounted on the bottom of the wind tunnel test section, and the wing was sinusoidally pitched about the quarter chord. Both the mean incidence and the amplitude of oscillation were set at 15 degrees. Measurements by using a triple hot-film probe were made for the case of the reduced frequency of 0.09 and the chord Reynolds number of 34,000. The phase-averaged mean velocity, vorticity, and turbulence intensity profiles in the wing tip vortex region are presented and variations of these with respect to the instantaneous angle of attack are discussed in detail. 'Phase-lag' compensated variation of the circulation of the tip vortex during the cycle of oscillation is also included.

Chang, J. W. and Yoon, Y. H.

"CAMBER EFFECTS ON THE NEAR WAKE OF OSCILLATING AIRFOILS"

Journal of Aircraft, Vol. 39, No. 4, July-August 2002, pp. 713-716.

Phase-averaged mean velocity and its fluctuations in the near wake of oscillating airfoils are presented. The near-wake characteristics of a NACA 0012 airfoil at + and - instantaneous angle of attack AOA show symmetric profiles about the X axis because of the symmetry of motion and airfoil shape. The velocity profiles and the turbulent intensity profiles of a NACA 4412 airfoil have small difference with those of a NACA 0012 airfoil except upstroke motion case at a negative angle of attack. These are attributable to either similar upper shape or the motion direction of the leeward surface, which result in the flow attachment to the surface. On the other hand, the significant difference of near-wake characteristics between NACA 0012 and NACA 4412 airfoil is observed in the case of upstroke motion at negative angle of attack. It is found that the streamwise velocity and turbulent intensity of the NACA 4412 airfoil in the wake region of lower surface are considerably large. These differences in streamwise velocity and turbulence intensity of two airfoils are caused by the different lower shape and the motion direction.

"CAVITATION INCEPTION DURING THE INTERACTION OF A PAIR OF COUNTER-ROTATING VORTICES"

Physics of Fluids, Vol. 24, 2012, pp. 014107-1 - 014107-15.

Pairs of unequal strength, counter-rotating vortices were produced to examine the inception and dynamics of vortex cavitation as the vortices undergo a long wavelength instability. The instability causes the weaker, secondary vortex to be turned and stretched by the stronger primary vortex. Folding and stretching of the secondary vortices result in sharp reductions of the core pressure. Here, these sharp and transient reductions in the secondary vortex core pressure produced incipient cavitation at static pressures that were as much as 20 times higher than that required for inception in the core of the unstretched secondary vortex. In addition, most nuclei measured were of the order of 1 micron in size, which requires tension on the order of 100 kPa for cavitation inception to occur. The flow parameters

that lead to the instability and cavitation inception in the secondary vortex are examined, and the measured event rates are correlated to freestream nuclei populations and static pressure. These measurements, combined with observations of the elongated bubbles themselves, suggest that stretching produced large tensions in the core of the secondary vortex due to both a reduction in the secondary vortex core size and the creation of a jetting flow in the vortex core.

Chang, N., Ganesh, H., Yakushiji, R. and Seccio, S. L.

"TIP VORTEX CAVITATION SUPPRESSION BY ACTIVE MASS INJECTION"

Journal of Fluids Engineering, Vol. 133, November 2011, pp. 111301-1 to 111301-11.

Injection of water and aqueous polymer solutions in to the core of a trailing vortex was found to delay the inception of tip vortex cavitation (TVC). Optimal levels of mass injection reduced the inception cavitation number from 3.5 to 1.9, or a reduction of 45 percent. At the optimal fluxes, injection of water alone produced a reduction of 35 percent, and the addition of polymer solution led to a reduction of 45 percent. Stereo particle velocimetry was employed to examine the flow fields in the region of TVC inception and infer the average core pressure, and planar PIV was used to examine the flow unsteadiness in this region. The time-averaged pressure coefficients for the vortex core pressure were estimated and compared to the pressure needed for TVC inception and full development. Measurement of flow variability in the TVC inception region indicated that relatively low fluxes of mass injection in the TVC roll-up region led to a substantial decrease in flow unsteadiness in the core region near the observed location of inception, and this corresponded to a substantial decrease in the inception pressure. Increased injection of water or polymer solutions led to a modest increase in the average vortex core radius, which was discernable in the measured pressure needed for developed cavitation.

"THREE-DIMENSIONAL VORTEX/WALL INTERACTION: ENTRAINMENT IN NUMERICAL SIMULATION AND EXPERIMENT"

Physics of Fluids, Vol. 29, No. 1, January 1997, pp. 57-66.

Three-dimensional interactions between an elliptic vortex ring and two no-slip parallel walls are visualized in a numerical simulation and an experiment. The vortex ring induces a surface vorticity layer on the wall which reconnects with the vortex ring. During the interaction core-area-varying axial waves are generated and carry the surface layer away from the wall. The vortex ring then becomes two tornado-like structures with strong upward helical flows near the wall surface, which provides entrainment of the surface fluid into the vortex structure. Similarities between the entrainment mechanisms of vorticity in the simulation and dye in the experiment from the surface layer are identified.

"WAKE VORTEX DETECTION WITH UAV CLOSE FORMATION FLIGHT"

AIAA Paper 2015-2396, June 2015, Dallas, TX.

Birds fly in formation to benefit from the upwash wake vortices created by their peer leader. Similar strategies can be employed on aircraft for fuel saving or for range extension. However, further understanding of wake vortices in the near field and mid field is needed for close formation flight (less than 10 wingspans). This paper introduces a new method for wake vortex detection using small UAV formation. A NonLinear Dynamic Inversion (NLDI) based formation control law is adapted to the WVU Phastball UAV platform. The designed controller showed good tracking performance during close formation flight (5-10 wingspans) with typical errors of less than 3 meters during straight legs. Then, multiple sensor measurements from leader-follower UAV formation flights were used for the wake vortex detection, including angle of attack, angle of sideslip, accelerometers, and gyros. The collected flight data showed the feasibility of using UAV formation for the wake encounter detection.

Chappell, S. and Angland, D.

"ACTIVE CONTROL OF A WING TIP VORTEX WITH A DIELECTRIC BARRIER DISCHARGE PLASMA ACTUATOR"

AIAA Paper No. 2012-2952, June 2012, New Orleans, LA.

An experimental investigation has been conducted into the active control of a wing tip vortex with a dielectric barrier discharge plasma actuator. The actuator was placed around the wing tip with the momentum added in the opposite direction to that of the cross-stream flow. Particle image velocimetry measurements were performed on a low aspect ratio rounded tip NACA 0015 wing in a low-speed wind tunnel at a maximum Reynolds number of 280,000, based on the wing chord. Experiments were performed at various angles of attack. The current strength of the plasma actuator limited the maximum freestream velocity to 15 m/s. For low angles of attack (2 and 6 degrees), the near field results showed an increase in vortex size and a reduction in the core circulation when control was applied. The effectiveness of the actuator reduced with freestream velocity and angle of attack. The use of the plasma actuator was found to increase the velocity fluctuations close to the surface of the wing. At an angle of attack of 14 degrees, the actuator resulted in a smaller vortex and an increase in the core circulation. It was hypothesized that at this high angle of attack, the vorticity generated at the suction side electrodes was fed into the core, increasing the strength of the tip vortex. The results show that the potential of the plasma actuator for the near field control of the tip vortex is promising provided the angle of attack is low.

"A NEW EDDY DISSIPATION RATE FORMULATION FOR THE TERMINAL AREA PBL PREDICTION SYSTEM (TAPPS)"

AIAA Paper No. 2000-0624, Reno, NV, January 2000

The TAPPS employs the MASS model to produce mesoscale atmospheric simulations in support of the Wake Vortex project at Dallas Fort-Worth International Airport (DFW). A post-processing scheme uses the simulated three-dimensional atmospheric characteristics in the planetary boundary layer (PBL) to calculate the turbulence quantities most important to the dissipation of vortices: turbulent kinetic energy and eddy dissipation rate. TAPPS will ultimately be employed to enhance terminal area productivity by providing weather forecasts for the Aircraft Vortex Spacing System (AVOSS). The post-processing scheme utilizes experimental data and similarity theory to determine the turbulence quantities from the simulated horizontal wind field and stability characteristics of the atmosphere. Characteristic PBL quantities important to these calculations are determined based on formulations from the Blackadar PBL parameterization, which is regularly employed in the MASS model to account for PBL processes in mesoscale simulations. The TAPPS forecasts are verified against high-resolution observations of the horizontal winds at DFW. Statistical assessments of the error in the wind forecasts suggest that TAPPS captures the essential features of horizontal winds with considerable skill. Additionally, the turbulence quantities produced by the post-processor are shown to compare favorably with corresponding tower observations.

"VORTEX METHODS FOR MASSIVELY PARALLEL COMPUTER ARCHITECTURES"

VECPAR 2008, Lecture Notes in Computer Science, Vol. 5336, 2008, pp. 479-489.

We present Vortex Methods implemented in massively parallel computer architectures for the Direct Numerical Simulations of high Reynolds numbers flows. Periodic and non-periodic domains are considered leading to unprecedented simulations using billions of particles. We discuss the implementation performance of the method up to 16k IBM BG/L nodes and the evolutionary optimization of long wavelength instabilities in aircraft wakes.

Chatelain, P., Curioni, A., Bergdorf, M., Rossinelli, D., Andreoni, W. and Koumoutsakos, P.

"MASSIVELY PARALLEL VORTEX PARTICLE SIMULATIONS OF WAKES"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

We present the Direct Numerical Simulations of high Reynolds numbers aircraft wakes employing vortex methods. The simulations are based on a hybrid particle-mesh formulation and its scalable implementation for massively parallel distributed-memory computers. We develop efficient domain decompositions, Fourier parallel solvers and optimized data mappings that rely on the Message Passing Interface (MPI). The software is tested and run on the IBM Blue Gene/L parallel architecture using up to 16k nodes on unprecedented problem sizes of several billions of particles. We study the growth of the medium wavelength instability for counter-rotating vortex pairs as a wake alleviation mechanism. The calculation used a long domain (10 spans) and random noise to initiate the instability at Re of 6000.

This 1.5 billion particle system was run on 4096 IBM BG/L nodes and constitutes the largest DNS ever achieved for a vortex particle method. Ongoing code development includes further optimization for Blue Gene/L and modifications for the multicore architecture of Blue Gene/P. The code currently uses periodic boundary conditions in directions transverse to the wake; it is being extended to more efficient unbounded ones.

Chatelain, P., Curioni, A., Bergdorf, M., Rossinelli, D., Andreoni, W. and Koumoutsakos, P.

"BILLION VORTEX PARTICLE DIRECT NUMERICAL SIMULATIONS OF AIRCRAFT WAKES"

Compu. Methods Applied Mech. Engineering, Vol. 197, 2008, pp. 1296-1304

We present the Direct Numerical Simulations of high Reynolds numbers aircraft wakes employing particle methods. The simulations involve a highly efficient implementation of vortex methods on massively parallel computers, enabling unprecedented simulations using billions of particles. The method relies on the Lagrangian discretization of the Navier-Stokes equations in velocity-velocity form and relies on remeshing of the particles to ensure the convergence of the method. The results include unprecedented Direct Numerical Simulations of the onset and the evolution of multiple wavelength instabilities induced by ambient noise in aircraft vortex wakes at $Re = 6000$.

Chatelain, P., Gazzola, M., Kern, S. and Koumoutsakos, P.

"OPTIMIZATION OF AIRCRAFT WAKE ALLEVIATION SCHEMES THROUGH AN EVOLUTION STRATEGY"

9th International Meeting High Performance Computing for Computational Science, Lecture Notes in Computer Science, Vol. 6449, June 2010, Berkeley, CA, pp 210-221.

We investigate schemes to accelerate the decay of aircraft trailing vortices. These structures are susceptible to several instabilities that lead to their eventual destruction. We employ an Evolution Strategy to design a lift distribution and a lift perturbation scheme that minimize the wake hazard. The performance of a scheme is measured as the reduction of the mean rolling moment that would be induced on a following aircraft; it is computed by means of a Direct Numerical Simulation using a parallel vortex particle code. We find a configuration and a perturbation scheme characterized by an intermediate wavelength about 4.64, necessary to trigger medium wavelength instabilities between tail and flap vortices and subsequently amplify long wavelength modes.

Chatterjee, A. and Janus, J. M.

"ON THE USE OF A WAKE-INTEGRAL METHOD FOR COMPUTATIONAL DRAG ANALYSIS"

AIAA Paper No. 95-0535, Jan. 1995, Reno, NV.

In this expository paper, a practical software implementation for calculating induced drag based on a wake-integral approach is presented. The procedures required to produce satisfactory performance predictions are disclosed. The flow solver used to numerically simulate the flowfield about the

geometries studied herein is based on a finite-volume method to solve the three-dimensional Euler equations. Interface fluxes are determined using a high-resolution Riemann scheme. The post-processing software is versatile and is capable of handling different grid topologies on the transverse plane. To test the software, an elliptic wing is analyzed and a comparison is made with lifting-line theory. Further tests are conducted with isolated rectangular wings of varying aspect ratios under different lifting conditions. Finally, the software is applied to some wing-body combinations (tip-engine configurations) and a comparison is made with experimental results.

Chattot, J.-J.

"HELICOIDAL VORTEX MODEL FOR STEADY AND UNSTEADY FLOWS"

AIAA Paper No. 2004-0829, Reno, NV, January 2004

A helicoidal vortex model is used to predict the flow past the blades of a wind turbine. As the tip speed ratio varies, the environment in which the blades operate varies, and for low enough TSR, the local angle of attack will be larger than the incidence of maximum lift. The problem becomes highly nonlinear and it is shown that adding an artificial viscosity term to the equation allows the iterative algorithm to converge toward a smooth solution that is physically acceptable. The introduction of unsteady effects is useful to understand the cyclic forces and moments due to yaw or tower interaction, both for the design of blades to account for fatigue and for power output prediction. The 2-D impulsively plunging plate problem is solved with a semi-implicit scheme and the integral and numerical solutions compared and shown to be in excellent agreement. A 2-D test case to study the convection of a periodic shedding of vorticity downstream of a blade element is analyzed using the same semi-implicit algorithm and a stretched mesh like that used to model a turbine vortex sheet. The scheme captures accurately the vorticity distribution in the wake. Finally, the scheme is applied to the simulation of the NREL two-bladed rotor in yaw to assess the validity of the approach.

Chattot, J.-J.

"TOWER SHADOW MODELIZATION WITH HELICOIDAL VORTEX METHOD"

AIAA Paper No. 2007-420, Reno, NV, January 2007

The helicoidal vortex model developed by the author is compared with data of the National Renewable Energy Laboratory (NREL) Unsteady Aerodynamics Experiment (UAE). The B Sequence has been used for this purpose. It corresponds to the 'downward configuration' where the blades cross the tower shadow. Several cases have been analyzed with wind speeds of $V = 5, 7, 10$ and 12 m/s and yaw angles of up to 30 degrees. The results indicate that the modelization of the tower shadow gives good results in the range of applicability of the vortex model, at a low computer cost, and demonstrates further the versatility of this approach.

Chawla, K. and Chow, C.-Y.

"ACOUSTIC CONTROL OF VORTICES"

AIAA Paper No. 1989-1042, San Antonio, TX, April 1989

Effect of traveling acoustic waves on vortices is analyzed. Computational models are presented for two-, three- and four-vortex systems in the presence of acoustic waves; models can be generalized for any number of vortices. Time dependent vortex trajectories are presented for a few representative cases. It is shown that for different systems, at certain acoustic frequencies, amplitude of vortex displacement away from the mean path is substantial, implying wave induced velocity may play a significant role in re-orienting vortices. Vortex trajectories indicate that for systems with more than two vortices, the amplitude of vortex displacement away from the mean path does not have discrete maxima/minima; it fluctuates between higher and lower values, as the systems are subjected to a range of frequencies.

Chen, A. L., Jacob, J. D. and Savas, O.

"DYNAMICS OF COROTATING VORTEX PAIRS IN THE WAKES OF FLAPPED AIRFOILS"

J. Fluid Mech., Vol. 382, March 1999, pp. 155-193

The behavior of a pair of corotating vortices in the wake of a flapped airfoil is experimentally studied in a water towing tank. Reynolds numbers based on total circulation of the vortices range from $1.0 \times 10,000$ to $6.4 \times 10,000$. Planar velocity vector fields and their gradients are derived from PIV images using an adaptive Lagrangian parcel tracking algorithm. Isovorticity surfaces are extracted from time series of planar vorticity data. The behavior of the vortices is tracked by using various moments of both the probability density distribution and the spatial distribution of their streamwise vorticity. All vortices show a Lamb-Oseen circulation distribution when they are clearly identifiable. Further, vortices from the flapless wing exhibit Lamb-Oseen velocity and vorticity distributions with slow growth. All corotating vortex pairs are observed to merge at about 0.8 orbit periods. First-order statistics of the flow field remain invariant during the merger. The higher-order moments of the vorticity distribution show strong time dependence, which implies three-dimensionality of the flow resulting from vortex stretching. The strengths of the individual vortices before merger are constant, and the total circulation before and after merger remains constant within the range of observations. The trajectory of the center of vorticity remains unaffected by the merger process. The merger is preceded by a splitting of the weaker vortex into filaments which, depending on the relative strengths of the vortices, can occur in the radial direction, the axial direction, or a combination of the two. Mechanisms contributing to the merger dynamics are discussed.

Chen, C. and Prasad, J. V. R.

"A SIMPLIFIED INFLOW MODEL OF A HELICOPTER ROTOR IN FORWARD DESCENT"

AIAA Paper No. 2005-0622, Reno, NV, January 2005

A helicopter rotor in a descent flight encounters its own wake, resulting in a doughnut-shaped ring around the rotor disk, known as the Vortex Ring State (VRS). To investigate flight dynamic behavior of a helicopter in VRS condition, a new inflow model called the 'Vortex Rings Model' has recently been proposed for axial descent. The current study extends the Vortex Rings Model to the case of inclined descent, i.e., forward flight descent. The new model is validated using flight test results of the Dauphin helicopter from the literature. It is shown that the VRS boundary prediction using the new model correlates well with flight test results of the Dauphin helicopter.

Chen, C. and Prasad, J. V. R.

"SIMPLIFIED ROTOR INFLOW MODEL FOR DESCENT FLIGHT"

Journal of Aircraft, Vol. 44, No. 3, May-June 2007, pp. 936-944.

A simplified inflow model called the 'ring vortex model' is developed for a rotor in descent condition. The ring vortex model accounts for interaction between rotor wake and surrounding airflow in descent flight by using a series of vortex rings along the rotor wake. Important features of the ring vortex model are illustrated in detail, including the convection speed, the vortex strength, and the number of vortex rings. An augmentation to total mass flow parameter in the existing inflow equation is proposed to create a steady-state transition between the helicopter and the windmill branches. With the ring vortex model, it is feasible to predict rotor inflow over a wide range of descent conditions. Numerical results show good correlation with experimental data for both axial and inclined descent. In addition, the ring vortex model is used to explain the influence of model parameters (such as blade twist and blade taper) on rotor-induced velocity during descent flight.

"UNSTEADY NATURE OF VORTEX PAIR IN FORMATION FLIGHT"

AIAA Paper 2017-3306, June 2017, Denver, CO.

The interaction of trailing vortices from a leading wing with rigid and flexible downstream wings has been investigated experimentally in an open jet wind tunnel using force measurements, particle image velocimetry measurements, hotwire measurements and deformation measurements. Counter-rotating leading vortex has been found to have substantial meandering when it is close to the tip of the downstream wing. The leading vortex forms a pair with the vortex from the downstream wing, and then exhibits large displacements around the wing tip. This has been found to cause the largest lift fluctuations on the downstream wing. The meandering of the vortex pair occurs at the natural meandering frequency of the isolated vortex, with a low Strouhal number, and is not affected by the frequency of the wing bending oscillations if the downstream wing is flexible. While the displacement of the leading vortex is larger than that of the trailing vortex, time-dependent variations of the core radius, core vorticity and circulation are evident for the trailing vortex. In contrast, co-rotating vortices do not exhibit any increased meandering.

Chen, C., Wang, Z. and Gursul, I.

"EXPERIMENTS ON TIP VORTICES INTERACTING WITH DOWNSTREAM WINGS"

Experiments in Fluids, Vol. 59, 2018, pp. 82-1 to 82-24.

The interaction of meandering tip vortices shed from a leading wing with a downstream wing was investigated experimentally in a water tunnel using flow visualization, particle image velocimetry measurements, and volumetric velocity measurements. Counter-rotating upstream vortices may exhibit sudden variations of the vortex core location when the wing-tip separation is within approximately twice the vortex core radius. This is caused by the formation of vortex dipoles near the wing tip. In contrast, co-rotating upstream vortices do not exhibit such sensitivity. Large spanwise displacement of the trajectory due to the image vortex is possible when the incident vortex is further inbound. For both co-rotating and counter-rotating vortices, as long as there is no direct impingement upon the wing, there is a little change in the structure of the time-averaged vortex past the wing, even though the tip vortex shed from the downstream wing may be substantially weakened or strengthened. In the absence of the downstream wing, as well as for weak interactions, the most energetic unsteady modes represent the first helical mode.

Chen, C., Wang, Z., Cleaver, D. J. and Gursul, I.

"INTERACTION OF TRAILING VORTICES WITH DOWNSTREAM WINGS"

AIAA Paper 2016-1848, January 2016, San Diego, CA.

The interaction of trailing vortices from a leading wing with a downstream wing and its tip vortex was investigated experimentally in a water tunnel using flow visualization, particle image velocimetry measurements and volumetric velocity measurements. When the wing tip lateral spacing becomes small, sudden variations in the trajectory of the vortices are possible. The tip vortex from the downstream wing can be weakened or strengthened depending on the sign of the upstream vortex. The strongest interactions take place when the upstream vortex directly impinges on the downstream wing and loses its coherency or when the counter-rotating vortex forms a couple with the downstream vortex. In all cases, the axial velocity in the vortex core experiences a sudden acceleration over the downstream wing. Unsteadiness in the upstream vortex was found in the form of first helical mode of displacement. This long wavelength instability in the upstream vortex is not affected much by the interaction and may even excite a similar instability in the downstream vortex.

"VORTEX INTERACTIONS WITH JOUKOWSKI AIRFOIL ON ELASTIC SUPPORTS"

AIAA Paper 2018-2907, June 2018, Atlanta, GA.

The dynamic interaction between a line vortex and a Joukowski airfoil on elastic supports are formulated analytically and computed numerically. The vortex motion and the fluid forces on the airfoil are derived from inviscid potential flow, and the emended Brown and Michael equation describes the

unsteady shedding of vorticity into the wake. Special attention is paid to the limiting cases of flat plate airfoils that are stationary or under prescribed motions for which validation data exist. The present effort extends beyond these restrictions to include the geometric effects of the Joukowski airfoil profile and its aeroelastic influence on the incoming vortex path and the unsteady fluid loading.

"THE EFFECT OF MACH NUMBER ON THE STABILITY OF A PLANE SUPERSONIC WAKE"

Phys. Fluids A, Vol. 2, No. 6, June 1990, pp. 984-1004

Recent interest in supersonic combustion and problems of trans-atmospheric flight has prompted research efforts in laminar-turbulent free-shear flow transition. In the present work, the influence of Mach number on the stability of supersonic planar wake flows is investigated to gain insight into the physics of linear, nonlinear, and three-dimensional (3-D) stages of transition. The effect of varying the relative phase difference between a fundamental instability mode and its subharmonic is investigated as a possible means of controlling the evolution of a wake. From a linear stability analysis, it is found that the influence of increasing Mach number is stabilizing, resulting in a growth rate at a Mach number of 3 which is 60% that of an incompressible wake. Direct numerical simulations of the time-dependent compressible Navier-Stokes equations in two and three dimensions are performed for a forced time-developing wake using a spectral collocation method. The results of the two-dimensional (2-D) simulations show the slow rollup of spanwise vortices at high Mach numbers that is attributed to the influence of baroclinic and dilatational effects. Finally, the results of three-dimensional simulations forced with the most unstable Kelvin-Helmholtz wave and a pair of oblique three-dimensional waves show that, depending on the initial phasing between the 2-D and 3-D waves, vortex loops may or may not form as a result of the interaction between the streamwise and spanwise vorticity.

"UNSTEADY PRESSURE MEASUREMENTS FOR PARALLEL VORTEX-AIRFOIL INTERACTION AT LOW SPEED"

J. Aircraft, Vol. 34, No. 3, May-June 1997, pp. 330-336

Two-dimensional vortex-airfoil interaction at airfoil chord Reynolds number $6 \times 10,000$ is studied experimentally by immersing an instrumented NACA 0012 airfoil downstream of a vortex generator airfoil that pitches in a tailored non-sinusoidal form. A clockwise rotating vortex is generated to approach the target airfoil from left to right. When the vortex interacts with a non-lifting airfoil, it creates rather sharp and local variations of surface pressure in the vicinity of the leading edge. For airfoils at an angle of attack ($\alpha = 5$ and 10 deg), the pressure variations appear to be spread over nearly the entire surface. Nevertheless, a greater magnitude in the amplitude of transient lift is noted on the airfoil at high angle of attack ($\alpha = 10$ deg), primarily because of a low-pressure plateau region formed on the upper surface that occurs when the vortex moves downstream of the trailing edge. The amplitude of transient lift is also found to increase with a reduction in the vertical separation between the vortex generator and the airfoil.

"LATERAL OSCILLATIONS OF AN AIRCRAFT MODEL AT HIGH ANGLES OF ATTACK"

Journal of Fluids and Structures, Vol. 10, Issue 6, August 1996, pp. 601-614

Lateral oscillations occurring on the aircraft model of NASA TP 1803 at angles of attack ranging from 25 degrees to 60 degrees have been investigated in a low-speed wind tunnel for configurations including fuselage with wing or with a combination of wing and leading-edge extension (LEX). The wind tunnel experiment was conducted in the range of Mach number from 0.1 to 0.2, and the range of the Reynolds number based on the body diameter from $2.8 \times 100,000$ to $5.6 \times 100,000$. The time-varying side force coefficients, which may represent the displacements of oscillation in the lateral direction, were measured to obtain the root-mean square values and the power spectra. Flow visualization of the vortices generated from the forebody, wing and LEX of the model has also been performed in a water tunnel. It was found that the entire system of the flow and the sting-supported model locks-in at the resonant oscillation frequency as the lateral oscillation occurs. The enhancement of the lateral oscillation, as suggested by the water tunnel visualization, seems closely related to the breakdown of the LEX vortices in general and the location of breakdown in particular.

"EFFECT OF SIDESLIP ON HIGH-ANGLE-OF-ATTACK VORTEX FLOW OVER CLOSE-COUPLED CANARD CONFIGURATION"

Journal of Aircraft, Vol. 53, No. 1, January-February 2016, pp. 217-230.

The aerodynamic response to sideslip is crucial for an aircraft's lateral stability, especially for configurations incorporating vortex flow, on which sideslip causes asymmetric vortex behavior and brings extra complexity. In this work, vortex flow over a close-coupled canard configuration under sideslip is simulated using delayed detached-eddy simulation, with the angle of attack varying up to the post stall regime. Sideslip-induced distinctions in both vortex dynamics and canard/wing-vortex interaction are analyzed to explain the nonlinear response of the configuration. The results reveal that the effect of sideslip differs significantly upon different angle-of-attack regimes. At a medium angle of attack, the spanwise extension of the low-pressure area due to windward vortex core expansion results in superior windward lift against the leeward side, but the relatively low pressure retained due to delay of the leeward vortex breakdown is the main motivation that leeward lift surpasses windward at a high angle of attack. The canard vortex trajectory deflected under sideslip induces asymmetric vortex interaction, enhancing the leeward side, which not only leads to an unusual rolling moment toward the higher lift side at a medium angle of attack but also causes an abrupt loss of lateral stability at the post stall angle of attack. A featured demarcation line exists on both the canard and the wing to separate the lift imbalance area, which is found useful in interpreting the nonlinear behavior.

Cheng, H. K.

"AERODYNAMICS OF A RECTANGULAR PLATE WITH VORTEX SEPARATION IN SUPERSONIC FLOW"

Journal of the Aeronautical Sciences, Vol. 22, No. 5, April 1955, pp. 217-226.

A solution is obtained for the supersonic flow field in the tip region of a rectangular flat plate, in which the phenomenon of vortex separation from the side-edge is approximated by introducing into the analytic flow a ray of singularity possessing the vortex behavior. The strength and the location of the vortex singularity, and thus the solution, are determined by imposing additional conditions to the problem, namely, (1) that the flow velocity around the edge be bounded, and (2) that the vortex system be dynamically free. The mathematical model employed in describing the vortex separation phenomenon is essentially the same as that used in the treatment of the leading-edge separation from slender delta wings. The solution exhibits certain general characteristics of side-edge separation which have been observed at low speed for low-aspect-ratio airfoils.

"THE DEVELOPMENT OF WAKE TURBULENCE RECATEGORIZATION IN THE UNITED STATES"

AIAA Paper 2016-3434, June 2016, Washington, DC.

This paper describes the background information and provides a status update on a specific aspect of the Federal Aviation Administration (FAA) wake turbulence program known as RECAT (i.e., Recategorization). The fundamental premise of RECAT is that, instead of using the existing FAA Order JO 7110.65 categorical wake turbulence separation minima based on maximum takeoff weight, wake separation can be refined using a more complete set of wake related parameters. This process then leads to a safe reduction of wake turbulence separation minima over those specified in FAA Order JO 7110.65. This paper describes the overall three-phased approach of RECAT, with the ultimate goal of achieving dynamic pairwise separation. Currently, Phase II, or a static pairwise based wake turbulence separation is ready for implementation by the Federal Aviation Administration. The paper describes the analysis approach, including the data sources and severity metrics used in the development of RECAT Phase II.

"VORTEX RING WITH SWIRL: A NUMERICAL STUDY"

Physics of Fluids, Vol. 22, 2010, pp. 097101-1 - 097101-9.

In this paper, we use a lattice Boltzmann method to study the effect of swirl on the dynamics of an isolated three-dimensional vortex ring in a viscous incompressible fluid. We focus on a fixed Reynolds number of 800 and vary swirl magnitude and vortex core size. Results show that increasing swirl for a fixed core size or increasing core size for a fixed swirl causes vortex ring to slow down or even travel backward initially. A simplified physical explanation for this dynamic behavior is proposed. Our results further show that while a weak swirl causes vortex filaments to undergo helical winding, a sufficiently

strong swirl transforms these windings into convoluted three-dimensional vortex structure with vortex loops trailing behind it. Each of these vortex loops may reconnect with itself, through the process of vortex reconnection, to form a ringlet.

"MOTION OF A VORTEX RING IN A SIMPLE SHEAR FLOW"

Physics of Fluids, Vol. 21, 2009, pp. 081701-1 - 081701-4.

The motion and deformation of a vortex ring in a linear or simple shear flow have been simulated numerically by using the lattice Boltzmann method with multiple relaxation times. The study is motivated by a recent experiment which shows that a vortex ring propagating in a uniform cross flow does not experience Kutta lift and undergo tilting and deformation. The focus of the present study is to examine the effect of a simple shear in a cross flow on the motion of a vortex ring. Numerical approach is adopted here because a truly simple shear flow is difficult to generate experimentally. Our computation shows that a vortex ring tilts and deforms in a simple shear flow, and the tilting can be attributed to the modification of the vorticity distribution of the vortex ring because of the entrainment of background vorticity by the vortex core. It is further shown that although the shear in the flow has the tendency to elongate the vortex ring, the tilting angle of the ring increases with the shear ratio.

Cheng, M., Lou, J. and Luo, L.-S.

"NUMERICAL STUDY OF A VORTEX RING IMPACTING A FLAT WALL"

Journal of Fluid Mechanics, Vol. 660, 2010, pp. 430-455.

We numerically study a vortex ring impacting a flat wall with an angle of incidence I greater than or equal to 0 degrees in three dimensions by using the lattice Boltzmann equation. The hydrodynamic behavior of the ring-wall interacting flow is investigated by systematically varying the angle of incidence I in the range of 0-40 degrees and the Reynolds number Re in the range of 100-1000, where the Reynolds number is based on the translational speed and initial diameter of the vortex ring. We quantify the effects of I and Re on the evolution of the vortex structure in three dimensions and other flow fields in two dimensions. We observe three distinctive flow regimes in the I - Re parameter space. First, in the low-Reynolds-number region, the ring-wall interaction dissipates the ring without generating any secondary rings. Second, with a moderate Reynolds number Re and a small angle of incidence I , the ring-wall interaction generates a complete secondary vortex ring, and even a tertiary ring at higher Reynolds numbers. The secondary vortex ring is convected to the center region of the primary ring and develops azimuthal instabilities, which eventually lead to the development of hairpin-like small vortices through ring-ring interaction. And finally, with a moderate Reynolds number and a sufficiently large angle of incidence I , only a secondary vortex ring is generated. The secondary vortex wraps around the primary ring and propagates from the near end of the primary ring, which touches the wall first, to the far end, which touches the wall last. The rings develop a helical structure. Our

results from the present study confirm some existing experimental observations made in the previous studies.

"CIVIL AIRCRAFT VORTEX WAKE, TSAGI'S RESEARCH ACTIVITIES"

Progress in Aerospace Sciences, Vol. 71, 2014, pp. 150-166.

This paper provides a review of research conducted in TsAGI (Central AeroHydrodynamic Institute) concerning a vortex wake behind an airliner. The research into this area of theoretical and practical importance have been done both in Russia and in other countries, for which these studies became a vital necessity at the end of the 20th century. The paper describes the main methods and ratios on which software systems used to calculate the evolution of a vortex wake in a turbulent atmosphere are based. Verification of calculation results proved their acceptable consistency with the known experimental data. The mechanism of circulation loss in a vortex wake which is based on the analytical solution for the problem of two vortices diffusing in a viscous fluid is also described. The paper also describes the model of behavior of an aircraft which has deliberately or unintentionally entered a vortex wake behind another aircraft. Approximated results of calculations performed according to this model by means of artificial neural networks enabled the researchers to model the dynamics of an aircraft in a vortex wake on flight simulators on-line.

"A DETAILED EXPERIMENTAL FLOW-FIELD STUDY OF AN ISOLATED VORTEX"

AIAA Paper No. 1996-2515, New Orleans, LA, June 1996

This paper presents measurements and analyses of a vortex created by the differential deflection of two adjoining, rectangular wings, used in an experimental study of spiral vortex breakdown. The experimental circulation profile was implemented into a theoretical description of spiral breakdown, motivated by an effort to resolve discrepancies between theoretical and experimental values of the geometric compatibility condition, found to be a constant in spiral vortex breakdown.

Cheung, P. and Lam, C. C.

"OBJECTIVE CALIBRATED WIND SPEED AND CROSSWIND PROBABILISTIC FORECASTS FOR THE HONG KONG INTERNATIONAL AIRPORT"

2nd Aviation, Range and Aerospace Meteorology Special Symposium on Weather-Air Traffic Management Integration, January 2011, Seattle, WA.

Wind is a critical weather element in formulating Terminal Aerodrome Forecast (TAF), especially in tropical cyclone (TC) situations for assessment of crosswind which is known to be one of the top weather factors causing significant flight delay and cancellation at the Hong Kong International Airport

(HKIA). In Hong Kong, the wind and crosswind forecasts and their probability, amongst other weather information, are also contained in the Weather Summary for HKIA which serve as a supplement to TAF to facilitate decision making and cost-benefit analysis by the aviation users. If the forecast uncertainty is high, an alternative scenario is also included in the Weather Summary. To assist aviation forecasters in assessing the possibility of different scenarios in the preparation of wind and crosswind forecasts in TC situations, the Observatory developed objective wind speed and crosswind probabilistic forecasts for HKIA based on the European Centre for Medium-Range Weather Forecasts (ECMWF) Ensemble Prediction System (EPS) outputs. As an enhancement to the aviation weather service, the wind speed and crosswind probabilistic forecasts are also made available to the aviation users up to 36 hours ahead as a trial product. The products are updated every 12 hours at around 21 UTC and 09 UTC upon available of the latest ECMWF EPS data. Recently, post-processing using Model Output Statistics (MOS) technique is applied to the ensemble mean wind speed forecast with a view to calibrating the forecast by removing the systematic bias. This paper describes the methodology for generating the probabilistic forecast and the calibration method. Verification results based on the TC cases in 2009 are also presented.

Chevalier, H.

"FLIGHT TEST STUDIES OF THE FORMATION AND DISSIPATION OF TRAILING VORTICES"

Journal of Aircraft, Vol. 10, No. 1, January 1973, pp. 14-18

A flight test program has been conducted to measure experimentally parameters which describe the characteristics of vortex behavior and their instability. Three basic atmospheric flight conditions were investigated: steady level flight in calm air, steady level flight in light gusting air and light winds, and unsteady flight produced by control surface oscillations in calm air. A DeHavilland Beaver DHC-2 airplane and a Beechcraft T-34B airplane were used in the investigation. Smoke grenades were located near the wing tips of each airplane so that the vortices could be seeded with smoke and thus made visible. This made it possible to photograph the vortices and make measurements from the photographs obtained. The experimental results show wavelengths of vortex instabilities, dissipation time of trailing vortices, effects of atmospheric current or gust, and the effect of control surface oscillation. These results provide additional experimental verification of the existence of vortex wake instability predicated by theory and show that small oscillations in pitch at a critical frequency accelerate the dissipation of high-intensity vortices.

Chevalier, H.

"FLIGHT TEST STUDIES OF THE FORMATION AND DISSIPATION OF TRAILING VORTICES"

SAE Paper No. 73-0295, April 1973, Wichita, Kansas.

A flight test program has been conducted to measure experimentally parameters which describe the characteristics of vortex instability and behavior. Three basic atmospheric flight conditions were investigated: steady level flight in calm air, steady level flight in light gusting air and light winds, and

unsteady flight produced by control surface oscillations in calm air. A DeHavilland Beaver DHC-2 airplane and a Beechcraft T-34B airplane were used in the investigation. Smoke grenades were located near the wing tips of each airplane such that the vortices could be seeded with smoke and thus made visible. This made it possible to take measurements from photographs of the visible vortices. The experimental results show wavelengths of vortex instabilities, dissipation time of trailing vortices, effects of atmospheric current or gust, and the effect of control surface oscillation. These results provide additional experimental verification of the existence of vortex wake instability predicated by theory and show that small oscillations in pitch at a critical frequency accelerate the dissipation of high-intensity vortices.

"ASSESSING THE POTENTIAL OF A COMMERCIAL PULSED LIDAR FOR WIND CHARACTERISATION AT A BRIDGE SITE"

Journal of Wind Engineering and Industrial Aerodynamics, Vol. 161, 2017, pp. 17-26.

Characterization of atmospheric turbulence is a central step prior to the construction of long-span bridges. The present paper investigates the potential of a long-range scanning pulsed coherent lidar to measure the wind field at the inlet of a fjord. The wind velocity data acquired by the lidar is compared to the data recorded by sonic anemometers installed on the bridge. The focus is on the ability of the lidar to capture single and two-point statistics of turbulence in complex terrains. Satisfying results are obtained with the Line-of-Sight scanning mode, which provides the best sampling frequency (1 Hz). The low temporal resolution and the low signal-to-noise ratio for the Range Height Indicator and the Plan Position Indicator scanning modes are important limiting factors in the pilot study performed. Better results may be achieved for a lidar measurement set-up which is adapted specifically for investigating coherence.

"PEAK-SEEKING CONTROL FOR DRAG REDUCTION IN FORMATION FLIGHT"

Journal of Guidance, Control, and Dynamics, Vol. 29, No. 5, September-October 2006, pp. 1221-1230.

Formation flight is a known method of improving the overall aerodynamic efficiency of a pair of aircraft. In particular, one craft flying in the correct position in the vortex wake of another can realize substantial reductions in drag, with the amount of the reduction dependent on the relative position of the two craft. This paper looks at such a pair, with one craft flying behind and to the side of the lead plane. The precise position of the second craft relative to the first to maximize the drag reduction is to be determined online, leading to a peak-seeking control problem. A new method of speak-seeking control, using a Kalman filter to estimate the characteristics of the drag reduction, is derived and discussed. A simple model of the two-plane formation using horseshoe vortices is defined, and the peak-seeking controller is applied to this model. The method is demonstrated using this simplified model.

Chigier, N. A.

"MEASUREMENT OF VORTEX BREAKDOWN OVER A DELTA WING USING A LASER ANEMOMETER"

NEAR TR-62, January 1974, Nielsen Engineering and Research Inc., Mountain View, CA

A preliminary experimental study has been made on vortex breakdown over and in the wake of a slender delta wing at low speed. The investigation was made in the NASA/Ames 7- by 10-Foot Wind Tunnel on a slender sharp-edged delta wing with aspect ratio of 1.56 and sweep angle of 70 deg. Smoke visualization showed the presence and structure of the vortex core and feeding sheet over the wing surface. Vortex breakdown occurred in the wake of the wing at an angle of attack of 20 deg. Photographs show a clear distinction between the core structure in the pre- and post-breakdown conditions. As the angle of attack was increased further to 35 deg., the location of vortex breakdown moved upstream over the wing surface. Secondary vortices could be clearly distinguished, formed at the trailing edge near the wing tips. Wind-tunnel balance measurements of lift and drag forces show reduction in lift and drag coefficients due to vortex breakdown for angles of attack above 20 deg. The NASA/Ames two-color laser Doppler velocimeter was used to measure streamwise and circumferential velocity distributions through the vortex centers at various planes over the wing surface and at a distance of half-chord downstream of the wing trailing edge.

Chigier, N. A.

"VORTEXES IN AIRCRAFT WAKES"

Scientific American, Vol. 230, No. 3, March 1974, pp. 76-83

The advent of the jumbo jets has turned the well-known aerodynamic phenomenon of trailing-vortex air turbulence into a potentially serious hazard to smaller following aircraft. The three main objectives of current research programs are reviewed: (1) ascertaining the nature, strength and persistence of the vortexes for various kinds of aircraft; (2) developing a practical means of reducing the hazard on existing aircraft by artificially inducing the vortexes to break up; and (3) setting up monitoring and control systems at airports to prevent aircraft from entering the vortex-wake turbulence of larger aircraft.

Chigier, N. A.

"EXPERIMENTAL STUDIES OF TURBULENT AIRCRAFT WAKES"

Israel Journal of Technology, Vol. 11, No. 6, December 1973, pp. 367-372

A review of wind tunnel test data obtained for tip vortex studies on a square-tipped rectangular wing. The results include wing surface pressure distributions, three-dimensional velocity components in the wake, and principal vortex characteristics such as peak tangential velocity and core size distribution. The wind tunnel measurements are compared with flight test data. These comparisons show that the

magnitudes of circumferential velocities, normalized by flight speed and lift coefficient, as well as the vortex core radius, normalized by wing span, are in close agreement. The data obtained make possible the calculation of turbulence stress distributions and the formulation of models for the prediction of downstream flow field.

Chigier, N. A.

"VELOCITY MEASUREMENT IN VORTEX FLOWS"

Flow: Its Measurement and Control in Science and Industry, Vol. 1, Part 1, edited by R. B. Dowdell, Instrument Society of America, 1974, pp. 399-408

Measurements have been made in swirling circular and annular free jets using five-hole pressure probes and a disk static pressure probe for determination of mean flow and static pressure fields. A 3-wire, hot wire anemometer probe has been used for measuring velocity components in wing tip trailing vortices. Turbulence measurements in recirculation zones of a swirl generator have been made by placing hot wire anemometers in six different orientations, plus or minus 45 degrees to each of the coordinate axes. Details of measuring systems and instruments are discussed and examples of measurements in vortex flows are presented.

Chigier, N. A. and Corsiglia, V. R.

"TIP VORTICES-VELOCITY DISTRIBUTIONS"

NASA TM X-62887, September 1971, NASA Ames Research Center, Moffett Field, CA

Detailed measurements of velocity distributions have been made in vortices generated at the tip of a square-tip, 18-inch-chord, 48-inch semispan blade mounted in the NASA-Ames 7-by 10-foot wind tunnel. Time-mean-average velocity components were measured using a triple-sensor hot wire probe operated by three separate anemometers. The dimensions of the vortex increase with distance downstream over the blade surface, and at $X/C=4$ the vortex core radius is 1.7% of the span.

Chigier, N. A. and Corsiglia, V. R.

"WIND TUNNEL TEST DATA FOR WING TRAILING VORTEX FLOW SURVEY"

NASA TM-X-62148, May 1972, NASA Ames Research Center, Moffett Field, CA

Data are presented on velocity measurements made with hot wire anemometers in the wake of a model of the CV-990 aircraft and a rectangular wing in the NASA-Ames 2.14x3.05 meter (7- by 10-foot) wind tunnel. Variables included angle of attack, tunnel speed and axial distance up to 12 chord lengths downstream from the wing trailing edge. Effects of deflecting trailing edge flaps and small spoiler panels are shown.

Chigier, N. A. and Corsiglia, V. R.

"WIND TUNNEL STUDIES OF WING WAKE TURBULENCE"

Journal of Aircraft, Vol. 9, No. 12, December 1972, pp. 820-825

Velocity measurements have been made in the wake of wings in the Ames 7- by 10-foot Wind Tunnel. Distributions of velocity components were measured with a three-wire anemometer up to 12 chord lengths downstream of a CV-990 aircraft model and a rectangular wing. Results show that increasing the drag increases the vortex core radius, reduces the maximum tangential velocities and increases the magnitude of axial velocity defects.

"VIDEO PHOTOGRAPHIC CONSIDERATIONS FOR MEASURING THE PROXIMITY OF A PROBE AIRCRAFT WITH A SMOKE SEEDED TRAILING VORTEX"

NASA TM-102691, June 1990, NASA Langley Research Center, Hampton, VA.

Considerations for acquiring and analyzing 30 Hz video frames for CCD cameras mounted in the wing tips of a Beech T-34 aircraft are described. Particular attention is given to the characterization and correction of optical distortions inherent in the data.

Chiu, Y. D. and Peters, D. A.

"NUMERICAL SOLUTIONS OF INDUCED VELOCITIES BY SEMI-INFINITE TIP VORTEX LINES"

J. Aircraft, Vol. 25, No. 8, August 1988, pp. 684-694

The method of Rand and Rosen (for improving convergence on computed axial induced velocity for a helical wake) is extended to include all velocity components, all points in the wake, and nonhelical vortex lines (contraction). The method is based on finding upper and lower bounds on the truncated integral. Comparisons with other methods show that the present approach is efficient and accurate. Further, it avoids the errors associated with discretization of the vortex lines. Convergence occurs in only three to five revolutions, about 10% of the normal requirement.

"LARGE EDDY SIMULATION OF WIND TURBINE WAKES IN PRESCRIBED NEUTRAL AND NON-NEUTRAL ATMOSPHERIC BOUNDARY LAYERS"

The Science of Making Torque from Wind 2012, published in IOP Journal of Physics: Conference Series Vol. 555, 2014, pp. 012087-1 - 012087-8.

Large eddy simulation (LES) of an infinitely long wind farm in a fully developed flow is carried out based on solution of the incompressible Navier-Stokes equations. The wind turbines are modeled as

equivalent actuator disks by applying aerodynamic loads on the flow field using tabulated aerodynamic lift and drag coefficients to save computational time. As a substitute to standard wall modeling LES, a 'prescribed mean shear' profile (hereafter called PMS) approach has been implemented and analyzed for generating the desired turbulent shear flow. It is applied on Neutral, Stable and Convective atmospheric boundary layers in presence of the -actuator disc represented- wind turbines and qualitatively meaningful results of mean and fluctuating velocity field is obtained. The effect of four different sub-grid scale (SGS) models on the flow structure is investigated and it is seen that sub-grid scale modeling (in particular, the Mix-O and Smagorinsky models) improves the accuracy of the simulations. An optimal grid resolution is also proposed for this kind of simulation.

Chizhov, V. A. and Kuznetsov, O. A.

"PROBABILISTIC EVALUATION OF AIRPLANE DESTRUCTION AT ENCOUNTER WITH VORTEX WAKE"

In: Flight Safety, Aircraft Vortex Wake and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 283-288

The paper addresses likelihood destruction of airplane at encounter with a vortex wake generated by a preceding airplane. The danger of flying through vortex wakes is compared with natural atmospheric hazards.

Cho, J., Jeong, S. and Yee, K.

"APPLICATION OF PROPER ORTHOGONAL DECOMPOSITION FOR AVIATION SAFETY"

ICAS-2016-0576, September 2016, Daejeon, Korea.

In this study, the proper orthogonal decomposition reduced order method using various basis weight estimation methods is examined for efficient prediction of wake vortices. The proper orthogonal decomposition cannot guarantee the accurate prediction for the variation of a meteorological condition, in this research introduces neural network as basis weight estimation method which can perceive the nonlinear relationship between the input variables and the reduced variables. The neural network is trained with pairs of design variables and reduced variables, which are obtained from snapshot data of the LES simulation of the wake turbulence. The constructed POD/NN is applied to wake turbulence prediction for validations, and its results are compared to those of the full order analysis (LES simulations). As a result, it is found that the POD/NN has the capability to predict behavior and dissipation of wake vortices accurately.

"NON-SPHERICAL BUBBLE BEHAVIOR IN VORTEX FLOW FIELDS"

Computational Mechanics, Vol. 32, Issue 4-6, December 2003, pp. 281-290.

The boundary element method is applied to solve the unsteady behavior of a bubble placed in a vortex flow field. The steady vortex field is given in terms of the viscous core radius and the circulation, both of which may vary along the vortex axis. For this study, 2DynaFS, an axisymmetric potential flow code which has been verified successfully for diverse type of fluid dynamic problems, is extended. The modifications to accommodate the ambient vortex flow field and to model the extreme deformations of the bubble are presented. Through the numerical simulations, the time history of the bubble geometry and the corresponding pressure signal at a fixed field point are obtained. A special effort is made to continue the numerical simulation after the bubble splits into two or more sub-bubbles. Indeed, it is found that an elongated bubble sometimes splits into smaller bubbles, which then collapse with the emission of strong pressure signals. The behavior of the axial jets after the split is also studied in more detail.

Choi, S.

"EXPERIMENTAL INVESTIGATION OF WING-TIP VORTEX EVOLUTION BEHIND A HALF-DELTA WING EQUIPPED NACA0012 WING"

Master of Engineering Thesis, 2015, McGill University, Montreal, Quebec, Canada.

The modification of the tip vortex, generated by a rectangular NACA0012 wing, was attempted using four different tip-mounted half-delta wing (HDW) models at a chord Reynolds number of 245,000. The HDW models used in this experiment were i) $\lambda = 65$ degrees, $c_{sub r} = 1c$, ii) $\lambda = 50$ degrees, $c_{sub r} = 1c$, iii) $\lambda = 50$ degrees, $c_{sub r} = 0.5c$ and iv) $\lambda = 50$ degrees, $c_{sub r} = 0.3c$ where c , $c_{sub r}$ and λ are baseline chord, root chord and slenderness, respectively. In addition to the cases listed above, the impact of the deflection was also investigated. Because of the vortex breakdown, the roll-up process of the tip vortex was found to be significantly modified. Especially, HDWs with the $c_{sub r}$ less than or equal to 50 percent exhibited a unique double-vortex pattern, one originating from the tip of the baseline wing and the other one from the leading-edge of the HDW. HDWs with the $c_{sub r}$ less than or equal to 50 percent also caused a rapid diffusion of vorticity and rendered a weak circulation flow-like tip vortex, suggesting an enhanced wake-vortex decay and alleviation. The interaction and merging of double-vortex were expedited by both increasing the angle of attack and deflecting the HWD upward. Regardless of the vortex breakdown, the lift of the HWDs was found to increase with the increasing angle of attack and stayed above the value of the baseline wing. The $c_{sub r} = 0.5c$ produced an improved lift-to-drag ratio.

"THREE-DIMENSIONAL INSTABILITIES AND TRANSIENT GROWTH OF TRAILING VORTICES IN HOMOGENEOUS AND STRATIFIED FLOWS"

AIAA Paper 2008-3800, Seattle, WA, June 2008

An aircraft wake is made up counter-rotating vortices and is known to be affected by a long (Crow) and a short (elliptic) wavelength instability. Numerical investigations on the three-dimensional and

transient growth of such dipole are performed. By means of a three-dimensional linear stability analysis, we retrieve the instability bands corresponding to the Crow and elliptic modes but we also observe less unstable oscillatory modes with very broad peaks. The transient growth of perturbations on this dipole, investigated by computing the optimal linear perturbations with a direct-adjoint technique, demonstrates the crucial role of the region of maximal strain at short time and of the hyperbolic point at intermediate time. Investigations on the three-dimensional dynamics of trailing vortices in stratified fluids are performed. The elliptic instability is almost unaffected by weak and moderate stratifications.

"STUDY ON THREE DIMENSIONAL SEPARATED FLOWS, RELATION BETWEEN INDUCED DRAG AND VORTEX DRAG"

European Journal of Mechanics, B/Fluids, Vol. 9, No. 5, 1990, pp. 437-45.

The origin of drag of high aspect ratio bodies is well known, and is usually split into two categories, profile drag and induced drag. For simple shapes, these quantities can be obtained through computation, and/or through measurements in wind tunnels. For low aspect ratio bodies like road vehicles such an analysis is not easy, and the idea of induced drag is replaced by the notion of vortex drag. The goal of this paper is to clarify vortex drag, particularly in comparison to induced drag as introduced by Prandtl. This is achieved by experimentation on a finite aspect ratio wing where these two types of drag can be more easily separated and quantified. Finally, an experimental method based on the lifting line theory is proposed for measurement of the induced drag of an airfoil through downstream velocity surveys.

"THE STABILITY OF SHORT WAVES ON A STRAIGHT VORTEX FILAMENT IN A WEAK EXTERNALLY IMPOSED STRAIN FIELD"

J. Fluid Mech., Vol. 73, Pt. 4, February 1976, pp. 721-733

The stability of short-wave displacement perturbations on a vortex filament of constant vorticity in a weak externally imposed strain field is considered. The circular cross-section of the vortex filament in this straining flow field becomes elliptical. Instability of short waves on this strained vortex can occur only for wavelengths and frequencies at the intersection points of the dispersion curves for an isolated vortex. The vortex is unstable at wavelengths for which $\Omega = 0$, thus giving some support to the instability mechanism for the vortex ring proposed recently by Widnall et al., (1974). The growth rate is calculated by linear stability theory.

"DISCRETIZATION OF A VORTEX SHEET WITH AN EXAMPLE OF ROLL UP"

FM-72-5, November 1972, Univ. of California, Berkeley, CA

The point vortex approximation of a vortex sheet in two space dimensions is examined and a remedy for some of its shortcomings is suggested. The approximation is then applied to the study of the roll-up of a vortex sheet induced by an elliptically loaded wing.

Choroba, P.

"A VISION OF WAKE VORTEX RESEARCH FOR NEXT 20 YEARS"

Fifth EUROCONTROL/FAA ATM R&D Seminar, June 2003, Budapest, Hungary.

International regulations require commercial airliners to be separated in flight by up to six nautical miles (11.12 km) due to the potential hazard caused by the swirling air left in their wakes. This 'wake vortex' is now the subject of intense worldwide research to understand the nature of the phenomenon, to develop reliable technology for its detection and prediction and thus find ways of making air travel safer while reducing congestion around airports. This paper describes author's beliefs on current and future research in wake vortex domain in relation to survey research being currently conducted within his PhD thesis.

Choroba, P.

"COMPREHENSIVE STUDY OF THE WAKE VORTEX PHENOMENA TO THE ASSESSMENT OF ITS INCORPORATION TO ATM FOR SAFETY AND CAPACITY IMPROVEMENTS"

Ph.D. Thesis, 2006, University of Zilina, Slovak Republic

Wake turbulence is one of the main causes for airport capacity problems in air transportation. The lift force exerted on aircraft wings produces vortices with long life-times in their wake. Especially during an aircraft's critical landing phase vortices can endanger any aircraft trailing behind. Serious problems with wake vortices were first recognized back in the 1970s when the Boeing 747 came into service. Pilots of smaller aircraft who followed the much heavier B 747 in to landing reported suddenly strong turbulence that even caused some aircraft to crash. Safe separation distances (ICAO) are prescribed to ensure that an aircraft does not enter an unsafe situation due to the wake turbulence of a preceding aircraft. These separation distances have been defined in the past based on aircraft weight classes. Some modifications of these rules have been introduced by the regulating authorities that reflect the experience obtained over the years. Nevertheless, neither the original proposals nor these modified rules can always be explained by rigorous physically-based reasoning. It also resulted in a lack of harmonization between the various airports or authorities. It is felt that the regulations that prescribe the separation distances might be too conservative in most cases or too optimistic for very specific meteorological conditions. The overall objective of this thesis is the understanding of the nature of wake turbulence phenomena in Air Traffic Management (ATM) for potential safety and capacity improvements. Therefore, this study was defined in four main research axes: state-of-the-art of physics, technology and operational procedures, definition of users' (pilots and air traffic controllers) requirements by operational survey, estimation of capacity benefit through fast-time simulations and

safety analysis including probabilistic risk assessment of wake vortex safety. We also introduce a new concept of dynamic separations with transitions between two separation modes depending on the actual meteorological conditions, and within the safety analysis part of the thesis we propose a new conservative probabilistic model for wake vortex safety assessment.

"THE CONCEPT OF INTEGRATED AIR TRAFFIC CONTROL WAKE VORTEX SAFETY AND CAPACITY SYSTEM"

IEEE Proceedings, Intelligent Transportation Systems, Vol. 1, October 2003, pp. 684-688

International regulations require commercial airliners to be separated in flight by up to six nautical miles (11.12 km) due to the potential hazard caused by the swirling air left in their wakes. This 'wake vortex' is now the subject of intense worldwide research to understand the nature of the phenomenon and find ways of making air travel safer while reducing congestion around airports. 'With the world airline fleet expected to double in size over the next 15 years and the giant A380 entering service in 2005, solutions to the wake-vortex problem cannot come too soon for the aerospace industry and therefore there is a strong need for developing a dynamic air traffic control wake vortex safety and capacity system.' This paper describes the concept of integrated transportation system regarding the current state-of-the-art technologies.

"THE AERODYNAMIC BEHAVIORAL STUDY OF TWO WING'S WAKE FLOW IN TANDEM ARRANGEMENT"

Procedia Engineering, Vol. 67, 2013, pp. 1-14.

This paper is aimed to study the aerodynamic properties and flow structures of flow field between two wings in tandem arrangement, including the experiments of force and velocity measurement in the wind tunnel. From the hot-wire velocity measurements, the spectral analysis is also conducted to observe the flow development of the trailing vortices. It is found that there is a sudden drop of shedding frequency distribution at the distance of 4 to 5 times the chord length from the front wing when AOA=10 degrees, which determines the distance between the front wing and following wing, and understand the dynamic response of following wing under the effect of trailing vortices from the front wing at constant angle of attacks. In addition, the aerodynamic performance of the following wing is drastically affected due to the impingement of the tip vortices or wake from the front wing as well.

"EFFECTS OF WAKE INTERACTION ON DOWNSTREAM WIND TURBINES"

Wind Engineering, Vol. 38, No. 5, 2014, pp. 535-548.

The present article revisits the wake studies behind the NREL (National Renewable Energy Laboratory) Phase VI wind turbine inside a virtual wind tunnel that were recently performed at the University of

Adelaide using Large Eddy Simulation (LES). A notable observation has been made in the current article, through comparisons of instantaneous contours of vorticity, velocity, and turbulence intensity, that the regions of velocity deficits and high turbulence intensities in the wake are restricted to the region of high vorticity. Therefore, for a downstream wind turbine, the smaller power production, the increased unsteady loads and the noise produced can directly be associated with the turbine blades passing through the streamwise vortices generated by the upstream wind turbine. In addition, a comparative analysis has been performed between the LES and semi-empirical models, used in the industry, to better understand the development of the wake inside the wind tunnel model. Finally, to illustrate the effects of wake on downstream wind turbines, a dynamic stall prediction model was used to determine the regions of the turbine blade affected by dynamic stall as a function of spacing between the turbines.

"UNSTEADY FLOWS ABOUT A JOUKOWSKI AIRFOIL IN THE PRESENCE OF MOVING VORTICES"

AIAA Paper No. 1983-0129, Reno, NV, January 1983

The motion of discrete vortices in the vicinity of a Joukowski airfoil and the influence of these vortices on airfoil lift and drag are computed using a computer code that has been written based on conformal mapping and unsteady flow analyses. With this computer code, studies are made on the stability of a trapped vortex when perturbed away from its equilibrium position with a finite displacement, on the release of a free vortex at a location upstream from an airfoil, and on the behavior of a moving vortex of increasing strength. Numerical results indicate that under proper arrangements free vortices can be utilized to generate high lift or thrust on an airfoil.

Chow, J. S.

"TURBULENCE MEASUREMENTS IN THE NEAR-FIELD OF A WINGTIP VORTEX"

PhD Thesis, August 1994, Stanford University, Palo Alto, CA.

The roll-up of a wingtip vortex, at Reynolds number based on chord of 4.6 million, was studied with an emphasis on suction side and near wake measurements. The research was conducted in a 32 in. x 48 in. low-speed wind tunnel. The half-wing model had a semi-span of 36 in., a chord of 48 in. and a rounded tip. Seven-hole pressure probe measurements of the velocity field surrounding the wingtip showed that a large axial velocity, of up to $1.77U$, developed in the vortex core. This level of axial velocity has not been previously measured. Triple-wire probes have been used to measure all components of the Reynolds stress tensor. It was determined from correlation measurements that meandering of the vortex was small and did not appreciably contribute to the turbulence measurements. The flow was found to be turbulent in the near-field (as high as 24 per cent RMS w-velocity on the edge of the core) and the turbulence decayed quickly with streamwise distance because of the nearly solid body rotation of the vortex core mean flow. A streamwise variation of the location of peak levels of turbulence, relative to the core centerline, was also found. Close to the trailing edge

of the wing, the peak shear stress levels were found at the edge of the vortex core, whereas in the most downstream wake planes they occurred at a radius roughly equal to one-third of the vortex core radius. The Reynolds shear stresses were not aligned with the mean strain rate, indicating that an isotropic-eddy-velocity based prediction method cannot accurately model the turbulence in the vortex. In cylindrical coordinates, with the origin at the vortex centerline, the radial normal stress was found to be larger than the circumferential.

Chow, J. S., Zilliac, G. G. and Bradshaw, P.

"MEAN AND TURBULENCE MEASUREMENTS IN THE NEAR FIELD OF A WINGTIP VORTEX"

AIAA Journal, Vol. 35, No. 10, October 1997, pp. 1561-1567

The rollup of a wingtip vortex, at a Reynolds number based on chord of 4,600,000, was studied with an emphasis on suction side and very near-wake measurements (up to $x/c = 0.678$ downstream of the trailing edge). The research was conducted in a 32 x 48 in. (0.81 x 1.22 m), low-speed wind tunnel. The rectangular half-wing model had a semispan of 36 in. (0.91 m), a chord of 48 in. (1.22 m), and a rounded tip. Seven-hole pressure probe measurements of the velocity field surrounding the wingtip showed that a large axial velocity, up to levels not previously measured, developed in the vortex core. Triple-wire probes were used to measure all components of the Reynolds stress tensor. It was determined from correlation measurements that meandering of the vortex was small and did not contribute appreciably to turbulence measurements. The flow was found to be turbulent in the near field (as high as 24% rms velocity), and the turbulence decayed quickly with streamwise distance because of the stabilizing effect of the nearly solid body rotation of the vortex-core mean flow. A streamwise variation of the location of peak levels of turbulence, relative to the core centerline, was also noted. Close to the trailing edge of the wing, peak shear stress levels were measured at the edge of the vortex core, whereas in the most downstream wake plane, the peak levels were measured at a radius roughly equal to one-third of the vortex core radius. The Reynolds shear stress (in Cartesian coordinates) was not aligned with the mean strain rate, indicating that an isotropic-eddy-viscosity-based prediction method cannot fully model the turbulence in the vortex. In cylindrical coordinates, with the origin at the vortex centerline, the radial normal stress was found to be larger than the circumferential component.

"MEASUREMENTS IN THE NEAR-FIELD OF A TURBULENT WINGTIP VORTEX"

AIAA Paper No. 1993-0551, Reno, NV, January 1993

The roll-up of a wingtip vortex, at Reynold's numbers based on chord of 4.6 million, was studied with an emphasis on suction side and near wake measurements. The research was conducted in a 32 in. x 48 in. low-speed wind tunnel. The half-wing model had a semi-span of 36 in., chord of 48 in. and a rounded tip. Surface oil flow and laser smoke flow studies were conducted, showing the highly three-dimensional nature of the flow around the wingtip, the formation of the feeding sheet, and the viscous

core region of the vortex. Airfoil surface pressure measurements clearly showed a chordwise line of large suction under the primary vortex. Seven-hole pressure probe measurements of the velocity field surrounding the wingtip showed that a large axial velocity developed in the vortex core and is not currently being computed correctly by Navier Stokes codes. A 'kink' in the path of the vortex core was discovered slightly downstream of the trailing edge. Triple-wire probes have been used to measure all components of the Reynolds stress tensor. It was determined from flow visualization and correlation measurements that meandering of the vortex was small and did not appreciably contribute to the turbulence measurements. All the turbulent normal stress components recorded high levels in the vortex core. The contours of Reynolds shear stress differed in shape to those found by previous researchers on fully rolled-up vortices.

Chow, J. S., Zilliac, G. G. and Bradshaw, P.

"INITIAL ROLL-UP OF A WINGTIP VORTEX"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 35-1 - 35-17

The roll-up of a wingtip vortex, at high Reynolds number, was studied with an emphasis on suction side and near wake measurements. Research was conducted in the 32 in x 48 in low-speed wind tunnel at the Fluid Mechanics Laboratory of NASA Ames Research Center. The half-wing model has a 3-ft semispan and 4-ft chord, with a NACA 0012 airfoil section and rounded tip. Angle of attack of the wing was set at 10 degrees and the Reynolds number based upon chord was 4.6 million. Flow visualization studies using surface oil flow and laser smoke flow techniques were conducted, showing the highly three-dimensional nature of the flow around the wingtip and illuminating the formation of the feeding sheet and the viscous core region of the vortex. Airfoil surface pressure measurements, taken at over 450 locations on the upper and lower surface of the wing, clearly showed a suction peak associated with the development of the primary vortex. Seven-hole pressure probe measurements of the velocity field surrounding the wingtip showed an axial core velocity magnitude of approximately 1.7 times the freestream velocity. This level of axial velocity is not currently being computed correctly by Navier Stokes codes.

Chow, K. W.

"INVISCID SECONDARY INSTABILITY OF THE FAR WAKE"

Phys. Fluids A, Vol. 2, No. 7, July 1990, pp. 1149-1157

The three-dimensional (3-D) instability of a parallel mean flow and a two-dimensional (2-D) wave is examined. Such secondary instability is shown to exist for the Gaussian profile as a model for the wake. Numerical results are obtained based upon a recently proposed wave-mean-flow interaction mechanism, with the assumptions of temporal problem and inviscid flows. Classical 2-D instability is strong in the near wake but decays to zero in the far wake, where it is overwhelmed by 3-D instability.

It is conjectured that this will qualitatively explain the emergence of three-dimensionality in the far wake.

Chowdhury, H., Mustary, I., Loganathan, B. and Alam, F.

"ADJACENT WAKE EFFECT OF A VERTICAL AXIS WIND TURBINE"

Procedia Engineering, Vol. 105, 2015, pp. 692-697.

The main objective of this study is to understand the effect of turbine placement and surrounding structures. Using Urban Green Energy's UGE-4K vertical axis wind turbine and the ANSYS computational fluid dynamics package (CFX), a dynamic fluid analysis was undertaken looking at the wake of the turbine through a variety of different inlet speeds and rotational frequencies to determine suitable flow recovery for optimal placement of subsequent turbines. The results showed that the wake interference is minimal at around 5 times the diameter of the turbine downstream. Results also show that flow recovery was a lot slower to the right of the turbine especially along a line 15 degrees from the center of the turbine to the right as this is coincident with the vortices generated from the turbines rotation.

Christiansen, J. P.

"VORTEX: A 2-DIMENSIONAL HYDRODYNAMICS SIMULATION CODE"

CLM-R-106, July 1970, United Kingdom Atomic Energy Authority, Culham, England

Program VORTEX is a computer code which simulates the behavior of an incompressible, inviscid homogeneous fluid in two dimensions by following the motion of a large number of point vortices. The theory behind the program and the program itself are described.

Christiansen, J. P.

"NUMERICAL SIMULATION OF HYDRODYNAMICS BY THE METHOD OF POINT VORTICES"

Journal of Computational Physics, Vol. 135, 1997, pp. 189-197

The motion of a two-dimensional incompressible inviscid and homogeneous fluid can be thought of in terms of the gradual evolution of a continuous vorticity distribution, each scalar vortex element interacting with every other by an instantaneous action at a distance law. It is of particular interest that this model can be expressed in Hamiltonian form and that it shows many analogies with similar systems in plasma physics. In addition to the standard mesh techniques, a computational description can be obtained if the continuous vorticity distribution is replaced by a finite set of point vortices interacting through a stream function which satisfies Poisson's equation. The point vortices move in a velocity field given on a Cartesian mesh such that there is a close resemblance to particle models used in plasma simulations. The point vortex model is presented with a calculation on a test model and the sources of numerical errors are explained. Graphical results from several calculations are shown and it

is concluded that the point vortex model is useful and versatile for a variety of problems in hydrodynamics as well as in plasma physics.

"AN EXTENDED ANALYSIS OF SEQUENCING ARRIVALS AT THREE MAJOR EUROPEAN AIRPORTS"

AIAA Paper 2018-3843, June 2018, Atlanta, GA.

This paper presents an analysis of the sequencing of arrival flights at three major European airports representative of different types of operation with more than 24000 aircraft pairs. The motivation is to better understand and characterize how sequencing is performed in dense and complex environments during peak periods. The analysis, purely data driven, focuses on the dynamic of spacing over time, investigating in particular, convergence and reactionary aspects. The two main results are: (1) progressive convergence of the spacing with a deviation up to ± 2.5 min at 10min to final, and ± 50 s at 5min to final; and (2) noticeable reactionary effect with a queue additional time up to 3min at 10min to final and 50s at 5min to final. These values may reflect the level of difficulty and sensitivity of sequencing during peak periods in such dense and complex environments. Future work will involve analyzing high and late reactionary situations, investigating how this approach may help identifying improvement areas, and assessing the impact of a change for future operations.

"HEAD-ON COLLISION OF TWO COAXIAL VORTEX RINGS: EXPERIMENT AND COMPUTATION"

Journal of Fluid Mechanics, Vol. 296, 1995, pp. 39-71.

Head-on collision of two coaxial vortex rings has been studied by joint experimental and numerical investigation. The Reynolds number, Re , based on the initial circulation of the vortex rings, ranged from 400 to 2700. Besides numerical data, the vorticity field was also resolved by a non-intrusive visualization technique, LIPA, which enabled simultaneous measurement of velocities at multiple locations on a plane area. It was found that the enstrophy, rather than circulation, revealed three stages of evolution of the vortex rings prior to their breakdown. These include the free-traveling stage, stage of vortex stretching and the stage of viscous dissipation dominance. The results indicate that it would be incorrect to neglect the viscous effect, in particular, for the latter two stages of flow development. In fact, the rebound behavior of the vortex rings for lower Re is essentially a viscous phenomenon and is found to be closely related to the dissipation of enstrophy when the vortex rings are brought to interact actively with each other and is also related to the increase of the vorticity core diameter in the stage of dominance of viscous dissipation. Furthermore, an instant dimensionless group, N/Re , based on the local vorticity distribution and the radius of a vortex ring, is found to be appropriate to characterize the onset of instability. Our investigation indicates that, in the range of observation, bulging instability will be observed during collision when N/Re exceeds a critical value which is a function of the initial core-size of the vortex ring. Comparisons showed that the numerical, measured, and visualization results were in consistent agreement; this not only enables us to assess the

range of validity of the axisymmetry assumed for the numerical simulation, but also provides us with a rational basis for further analysis of azimuthal instability.

"SOUND GENERATION AND RADIATION FROM ROTOR TIP-VORTEX PAIRING PHENOMENON"

AIAA Journal, Vol. 44, No. 6, June 2006, pp. 1181-1187

Sound generation and radiation from rotor-tip-vortex pairing are calculated numerically. Wake geometries of a two-bladed rotor in axial flights are calculated using a time-marching free-wake method without a nonphysical model of the far wake. The acoustic field can be obtained using acoustic analogy. To show the accuracy of the flow calculation scheme, the tip-vortex geometries of the present calculation are compared with those done in the previous publication of a small-scaled rotor experiment. The accuracy of the vortex sound calculation scheme is validated by comparing its numerical and the analytic solution of circular vortex-ring interaction. The tip-vortex pairing consists of a turn of the tip-vortex from one blade rolling around the tip-vortex from the other blade. The tip-vortex pairing amplifies the noise and generates new dominant frequencies. The tip-vortex pairing noise has a quadrupole directivity pattern, and it is especially dominant in the direction of the rotation axis. The peak components of the noise spectrum represent the pairing period and an instability mode.

Chung, K. H., Kim, J. W., Ryu, K. W., Lee, K. T. and Lee, D. J.

"SOUND GENERATION AND RADIATION FROM ROTOR TIP-VORTEX PAIRING PHENOMENON"

AIAA Journal, Vol. 44, No. 6, June 2006, pp. 1181-1187.

Sound generation and radiation from rotor tip-vortex pairing are calculated numerically. Wake geometries of a two-bladed rotor in axial flights are calculated using a time-marching free-wake method without a nonphysical model of the far wake. The acoustic field can be obtained using acoustic analogy. To show the accuracy of the flow calculation scheme, the tip-vortex geometries of the present calculation are compared with those done in the previous publication of a small-scaled rotor experiment. The accuracy of the vortex sound calculation scheme is validated by comparing its numerical and the analytic solution of circular vortex-ring interaction. "NEAR FIELD WINGTIP VORTEX COMPUTATION USING THE WIND CODE"

AIAA Paper No. 2006-633, Reno, NV, January 2006

The accuracy of current state-of-the-art turbulence models and a compressible Reynolds-averaged Navier-Stokes (RANS) solver in simulating the formation of wingtip vortices in the near field is investigated. The RANS solver used for this investigation is NPARC's WIND 5.0 code. Turbulence models explored are the standard Spalart-Allmaras model, the Spalart-Allmaras model with correction for system rotation and streamline curvature, and Menter's Shear Stress Transport model. Effect of grid resolutions and order of accuracy of numerical schemes are explored. Computational results are compared with the data of a reliable and thorough experiment. A comparison of these cases shows clear gains in accuracy when the flow field is computed using the rotation corrected Spalart-Allmaras turbulence model and a fifth-order numerical scheme on a computation grid of 4.5 million points. Both mean and turbulence quantities are studied.

Churchfield, M. J. and Blaisdell, G. A.

"A REYNOLDS STRESS RELAXATION TURBULENCE MODEL APPLIED TO A WINGTIP VORTEX FLOW"

AIAA Paper 2011-0663, January 2011, Orlando, FL.

A Reynolds stress relaxation model, specifically Olsen and Coakley's lag Reynolds stress transport (RST) model, is applied to a wingtip vortex flow, and its performance is assessed and compared with other aerospace standard turbulence models. A Reynolds stress relaxation model allows for Reynolds stress history effects due to streamline curvature, which are seen to play an important role in the non-diffusive nature of turbulent vortices. This study shows that the lag RST turbulence model is capable of predicting mean flow results as accurate as those of the well-performing Spalart-Allmaras model with correction for streamline curvature and system rotation (SA-RC). Furthermore, in this wingtip vortex flow, the lag RST model predicts turbulence quantities more accurately than the SA-RC model. Although the lag RST model performs well in predicting this flow, it has some deficiencies such as an inability to independently control the Reynolds stress magnitude and relaxation amount.

Churchfield, M. J. and Blaisdell, G. A.

"REYNOLDS STRESS RELAXATION TURBULENCE MODELING APPLIED TO A WINGTIP VORTEX FLOW"

AIAA Journal, Vol. 51, No. 11, November 2013, pp. 2643-2655.

A Reynolds stress relaxation model, specifically the lag Reynolds stress transport model, is applied to a wingtip vortex flow, and its performance is assessed and compared with other aerospace standard turbulence models. A Reynolds stress relaxation model allows for Reynolds stress history effects due to streamline curvature, which are seen to play an important role in the nondiffusive nature of turbulent vortices. This study shows that the lag Reynolds stress transport turbulence model can predict mean flow results as accurately as those of the well-performing Spalart-Allmaras model with correction for streamline curvature and system rotation. Furthermore, in this wingtip vortex flow, the lag Reynolds stress transport model predicts turbulence quantities more accurately than the rotation/curvature-corrected Spalart-Allmaras model. Although the Reynolds stress transport model well predicts this flow, it is more computationally intensive to solve than the rotation/curvature-corrected Spalart-

Allmaras model, and it has some deficiencies, such as an instability to independently control the Reynolds stress magnitude and relaxation moment.

Churchfield, M. J. and Blaisdell, G. A.

"NUMERICAL SIMULATIONS OF A WINGTIP VORTEX IN THE NEAR FIELD"

J. Aircraft, Vol. 46, No. 1, Jan.-Feb. 2009, pp. 230-243

We investigate the accuracy of current state-of-the-art turbulence models and a compressible Reynolds-averaged Navier-Stokes solver in computing the formation of a wingtip vortex in the near field. The Reynolds-averaged Navier-Stokes solvers used in this investigation are the NPARC WIND 5.0 and WIND-US 1.0 codes. The turbulence models explored are the standard Spalart-Allmaras model, the Spalart-Alimaras model with correction for system rotation and streamline curvature, the Menter shear stress transport model, and the Rumsey-Gatski explicit algebraic stress model. Additionally, we study how solution accuracy is affected by using higher-order numerical schemes as opposed to more grid points. Accuracy is assessed by comparing the results of the wingtip-vortex computations with the data of a reliable, thorough experiment. The solutions obtained using a fifth-order-accurate numerical scheme show that the Spalart-Alimaras turbulence model with corrections for rotation and streamline curvature predicts the mean flow most accurately. However, we find that within the vortex, none of the turbulence models explored accurately captures the magnitudes of the turbulence quantities or the lag of the Reynolds stress components behind the corresponding strain-rate components.

"CORRELATION FOR ESTIMATING VORTEX ROTATIONAL VELOCITY DOWNSTREAM DEPENDENCE"

Journal of Aircraft, Vol. 11, No. 11, November 1974, pp. 716-717

The wake velocity profile was examined up to 200 span lengths in a water tank, and comparisons were made of measured and predicted maximum tangential velocities downstream. Two characteristic flow regions were identified. First, a 'plateau' region with little if any change in maximum tangential velocity downstream as great as 100 span lengths. This is followed by a decay region in which the maximum tangential velocity decreases with downstream distance at a rate nominally proportional to the inverse one-half power.

Ciffone, D. L.

"VORTEX INTERACTIONS IN MULTIPLE VORTEX WAKES BEHIND AIRCRAFT"

Journal of Aircraft, Vol. 14, No. 5, May 1977, pp. 440-446

A flow visualization technique has been developed that allows the nature of lift-generated wakes behind aircraft models to be investigated. The technique is applicable to models being towed underwater in a ship model basin. Several different configurations of a 0.61-m (2-ft) span model of a

Boeing 747-type transport aircraft were tested to allow observation of typical vortex interactions and merging in multiple vortex wakes. The vortices were identified by emitting tracer dyes from selected locations on the model. Their trajectories were obtained from photographs of the wake. Wingspan loading and model attitude were found to effect both vortex motions within the wake and resulting far-field wake velocity. Landing-gear deployment caused a far-field reformation of vorticity behind a model configuration which dissipated concentrated vorticity in the near-field wake. Circulation from the wing always caused a downward movement of the horizontal tail vortices, which merged with wing vortices. A modified landing configuration was developed that appeared to significantly alleviate the concentrated wake vorticity associated with the current landing configuration.

Ciffone, D. L.

"MEASUREMENTS OF AIRCRAFT WAKE ALLEVIATION AND GROUND PLANE EFFECTS"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 173-182

In support of the NASA wake vortex alleviation program, vortex trajectories and velocity profiles were measured in lift-generated wakes. The wakes were generated by towing 0.61-m (2-ft) span models of B-747 and DC-10-30 aircraft under water in a ship model basin. The effects of flaps, spoilers, and ground plane on these wakes were investigated. A laser velocimeter was used to measure vertical (tangential) velocity profiles through primary vortices from 5- to 100-wingspan lengths behind the generating model. A 45° deflection of the two outboard flight spoilers on the B-747 model in the landing configuration resulted in a 40% reduction in wake maximum tangential velocity, in altered velocity profiles, and in erratic vortex trajectories. Similar reductions in maximum tangential velocity were obtained for this model when the outboard flaps were retracted. Presence of a ground plane used to simulate full-scale distances above the ground of 38 m (125 ft) and 21 m (70 ft) modified the vortex trajectories but did not appreciably change vortex interactions and merging. However, at 21 m above the ground plane, the alleviation appeared to be enhanced due to vortex viscous interactions with the ground plane.

"FLOW VISUALIZATION OF VORTEX INTERACTIONS IN MULTIPLE VORTEX WAKES BEHIND AIRCRAFT"

NASA TM X-62459, June 1975, NASA Ames Research Center, Moffett Field, CA. (Also, AIAA Paper 76-62.)

A flow visualization technique has been developed which allows the nature of lift-generated wakes behind aircraft models to be investigated. The technique has been applied to models being towed underwater in a ship model basin. Seven different configurations of a small-scale model of a 747 transport aircraft were used to allow observation of typical vortex interactions and merging in multiple vortex wakes. It was established that the motion of the wake vortices is often sensitive to small changes in either wing span loading or model attitude. Landing gear deployment was found to cause a

far-field reformation of vorticity behind a model configuration which dissipated concentrated vorticity in the near-field wake. Alleviation of wake vorticity is achievable by configuring the wing span loading to cause the wake vortices to move in paths that result in their interactions and merging.

Ciffone, D. L. and Orloff, K. L.

"AXIAL FLOW MEASUREMENTS IN TRAILING VORTICES"

AIAA Journal, Vol. 12, No. 8, August 1974, pp. 1154-1155

A scanning laser Doppler velocimeter was used to measure the axial velocity defect in the cores of trailing vortices behind a lifting airfoil of rectangular planform. Data were obtained at several different angles of attack and downstream distances ranging from 30 to 103 chord lengths.

Ciffone, D. L. and Orloff, K. L.

"FAR-FIELD WAKE-VORTEX CHARACTERISTICS OF WINGS"

Journal of Aircraft, Vol. 12, No. 5, May 1975, pp. 464-470

Velocity measurements have been made in the wake of wings that were being towed underwater. As the wake aged, measurements of the tangential and axial velocity profiles were made with a two-dimensional scanning laser velocimeter at downstream distances of 5 to 200 span lengths behind wings with different span loadings. The results identify two characteristic flow regions for the dependence of vortex maximum tangential velocity on downstream distance. The first, a region with little, if any change in maximum tangential velocity, extends from wake rollup to downstream distances as great as 100 span lengths, depending on span loading and angle of attack. This is followed by a decay region in which the maximum tangential velocity decreases with downstream distance at rates nominally proportional to the inverse one-half power. It is shown that tailoring the wingspan loading by either planform or flap deflection can reduce the maximum vortex tangential velocity by a factor of 2 and thus broaden the vortex core. Vortex mutual interactions and instabilities were introduced by alternate up-down flap deflections, delaying vortex rollup to downstream distance of 45 spans.

"APPLICATION OF LASER VELOCIMETRY TO AIRCRAFT WAKE-VORTEX MEASUREMENTS"

Proceedings Wake Vortex Minimization Symposium, NASA, SP-409, 1977, pp. 157-192,

The theory and use of a laser velocimeter that makes simultaneous measurements of vertical and longitudinal velocities while rapidly scanning a flow field laterally are described, and its direct application to trailing wake-vortex research is discussed. Pertinent measurements of aircraft wake-vortex velocity distributions obtained in a wind tunnel and water towing tank are presented. The utility of the velocimeter to quantitatively assess differences in wake velocity distributions due to wake dissipating devices and span loading changes on the wake-generating model is also demonstrated.

Ciffone, D. L. and Pedley, B.

"MEASURED WAKE-VORTEX CHARACTERISTICS OF AIRCRAFT IN GROUND EFFECT"

AIAA Paper 1978-0109, January 1978, Huntsville, AL.

In support of the NASA wake vortex alleviation program, measurements were made of the influences of a ground plane on vortex trajectories and velocity profiles within lift-generated wakes. The wakes were generated by towing 0.61-m (2-ft) span models of a B-747 and DC-10-30 under water in a ship model basin. The models were configured with landing flaps and flight spoilers to investigate the wake characteristics of these aircraft in ground effect at simulated full-scale distances of 19 m (62 ft) to 116 m (380 ft) above the ground. The ground plane caused modifications in the vortex trajectories but did not alter vortex interactions and merging patterns in these multiple vortex wakes. Some distortions in vortex vertical (tangential) velocity profiles were recorded because of vortex lateral motions and vortex interactions with the viscous boundary layer on the ground plane; however, maximum tangential velocities remained unchanged.

Ciffone, D. L. and Pedley, B.

"MEASURED WAKE-VORTEX CHARACTERISTICS OF AIRCRAFT IN GROUND EFFECT"

Journal of Aircraft, Vol. 16, No. 2, February 1979, pp. 102-109

In support of the NASA wake vortex alleviation program, measurements were made of the influences of a ground plane on vortex trajectories and velocity profiles within lift-generated wakes. The wakes were generated by towing 0.61-m span models of a B-747 and DC-10-30 under water in a ship model basin. The models were configured with landing flaps and flight spoilers to investigate the wake characteristics of these aircraft in ground effect at simulated full-scale distances of 19-116 m above the ground. The ground plane caused modifications in the vortex trajectories but did not alter vortex interactions and merging patterns in these multiple vortex wakes. Some distortions in vortex vertical (tangential) velocity profiles were recorded as a result of vortex lateral motions and vortex interactions with the viscous boundary layer on the ground plane; however, maximum tangential velocities remained unchanged.

"LASER DOPPLER VELOCIMETER INVESTIGATION OF TRAILING VORTICES BEHIND A SEMI-SPAN SWEPT WING IN A LANDING CONFIGURATION"

NASA TM-X-62294, August 1973, NASA Ames Research Center, Moffett Field, CA

Measured axial and tangential velocity profiles in the near wake vortices of a semi-span model of the Convair 990 wing in the NASA-Ames 7- by 10-foot wind tunnel are presented. A scanning laser Doppler velocimeter was used to obtain data at two different downstream stations (0.49 and 1.25 wing spans)

at various angles of attack and configurations from wing alone to wing plus nacelles, anti-shock bodies, and flaps deflected 27 deg (landing configuration). It is shown that the velocity distributions within the wake are quite sensitive to span loading. Specifically, it is illustrated that an aircraft flying at given lift coefficient, can substantially reduce its trailing vortex upset potential by deploying its flaps and altering its flight attitude to maintain the same lift coefficient. This might be taken into consideration along with performance and noise considerations in the selection of aircraft approach lift over drag.

Clark, D. R. and Landgrebe, A. J.

"WAKE AND BOUNDARY LAYER EFFECTS IN HELICOPTER ROTOR AERODYNAMICS"

AIAA Paper No. 1971-0581, Palo Alto, CA, June 1971

Theoretical methods recently developed within United Aircraft are discussed in light of the new understanding they give to the aerodynamics of the helicopter rotor. Results of wake geometry prediction methods, supported by experimental data, emphasize the importance of wake effects on rotor performance and behavior. These effects are shown to be especially important in hover and low speed forward flight as well as for high-speed flight at low disc angles. The influence of viscosity has been studied with particular emphasis on the development of the blade boundary layer. Using two independent boundary layer calculation methods, centrifugal pumping has been shown to play only a minor role with Coriolis forces and streamline curvature effects predominating. Away from separation and in the absence of large crossflows or excessive streamline curvature the boundary layer flow appears to be essentially two dimensional when taken in the direction of the external stream.

Clark, I. O.

"LIDAR AND ELECTRO-OPTICS FOR ATMOSPHERIC HAZARD SENSING AND MITIGATION"

AIAA Paper 2012-2788, June 2012, New Orleans, Louisiana.

This paper provides an overview of the research and development efforts of the Lidar and Electro-Optics element of NASA's Aviation Safety Program. This element is seeking to improve the understanding of the atmospheric environments encountered by aviation and to provide enhanced situation awareness for atmospheric hazards. The improved understanding of atmospheric conditions is specifically to develop sensor signatures for atmospheric hazards. The current emphasis is on kinetic air hazards such as turbulence, aircraft wake vortices, mountain rotors, and windshear. Additional efforts are underway to identify and quantify the hazards arising from multi-phase atmospheric conditions including liquid and solid hydrometeors and volcanic ash. When the multi-phase conditions act as obscurants that result in reduced visual awareness, the element seeks to mitigate the hazards associated with these diminished visual environments. The overall purpose of these efforts is to enable safety improvements for air transport class and business jet class aircraft as the transition to the Next Generation Air Transportation System occurs.

"WAKE VORTEX ACOUSTIC CHARACTERISTICS AND SOCRATES SENSOR PERFORMANCE"

DOT-VNTSC-NASA-07-01, July 2007, Volpe National Transportation Systems Center, Cambridge, MA

This report provides an evaluation of the current state of the SOCRATES sensor and its readiness for use as an operational sensor for active monitoring of aircraft wake turbulence. SOCRATES is a laser opto-acoustic array designed to passively detect and track the sound emissions of aircraft vortices. The evaluation period, January 2003 to December 2006, included two field tests designed to improve understanding of the fundamentals of wake acoustic phenomenology and aspects of the SOCRATES sensor performance.

Clark, M.

"WAKE TURBULENCE - GONE WITH THE WIND"

Journal of Traffic Control, Vol. 19, October-December 1977, pp. 10-12

In May 1976 a Vortex Advisory System (VAS) was installed at Chicago's O'Hare airport. The VAS is based on wind measurements around the airport which make it possible to predict movement and behavior of aircraft generated wake vortices. The VAS installation includes a network of meteorological towers sited near the middle marker locations. The wind data from the anemometers on the towers are transmitted to a central computer. The computer transmits through a digital display to the controller advising whether he can use reduced (3 n mi) separations in place of standard separation between arriving aircraft. NASA has been engaged in an extensive research program for the aerodynamic alleviation of wake vortices. Aerodynamic alleviation is a general term describing modifications to the aircraft or airfoil to alter the vortex structure and thereby minimize the adverse effects of the wake.

"LITTLE KNOWN FORMS OF INVISIBLE TURBULENCE MAY PRESENT SEVERE CHALLENGE TO PILOTS"

ICAO Journal, Vol. 56, No. 7, September 2001, pp. 5-7, 28

Recent research using observations and computer modelling has helped improve our understanding of the nature of clear air turbulence. The next step in studying phenomena such as vortex tubes is to extend modelling efforts to yet finer resolutions.

Clawson, K. L.

"VORTEX CIRCULATION VALUES FROM HOT FILM ANEMOMETER-MEASURED VORTEX VELOCITY PROFILES"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 83-89

Vortex circulation has been used to indicate vortex strength, but circulation cannot be directly determined from hot film anemometers. This paper describes several vortex circulation calculation methods that were developed and evaluated using the 1990 Idaho Falls hot film anemometer velocity profile data from B-727, B-757, and B-767 aircraft. Visual inspection of graphs of relative circulation as a function of vortex age showed vortex strength to be a clear function of aircraft model. The smallest relative circulation values were observed for the B-727, while the B-767 exhibited largest values at increasing vortex age. Although the highest tangential velocities were recorded for the B-757, this aircraft fits as expected into its weight category when the velocity values are converted to circulation values.

Clawson, K. L.

"NOAA METEOROLOGICAL DATA SUMMARY (LEVEL 2 DATA)"

Wake Vortex Research Data Package No. NOAA-2, December 1990, Environmental Research Laboratories, Idaho Falls, ID.

This document contains the Level 2 processed meteorological data collected by the National Oceanic and Atmospheric Administration (NOAA) during the 1990 spring and fall field vortex measurement periods at the NOAA test facility near Idaho Falls, Idaho. It updates the previously issued data packet NOAA-1 which describes the test site, the type and amount of meteorological data collected, and includes various data tables. This packet does not duplicate the information found in NOAA-1, but does provide updated data tables and graphs of the data. Two different types of data were collected during the measurement periods. The data are comprised of (1) tower data, and (2) tethered balloon data. The tower data consists of air temperatures, wind speeds, and wind directions measured concurrently at heights of 6.25, 12.5, 25, 50, 100, 150, and 200 feet above ground level. Each instrument was scanned every second. The data reported here are Level 2 three-minute averages obtained prior to the time the aircraft was abeam of the tower. The tethered balloon data consists of air temperatures, humidity, wind speeds, and wind directions measured at various heights up to approximately 1000 feet above ground level. The actual height of each measurement was determined by pressure relationships. Hence, the height of each measurement was not constant from sounding to sounding.

"VORTEX CORE DYNAMICS IN A SWIRLING JET NEAR VORTEX BREAKDOWN"

AIAA Paper 2018-0052, January 2018, Kissimmee, FL.

The dynamics of the vortex core are investigated in a swirling jet at swirl numbers in the range of the critical swirl number for vortex breakdown. Vortex breakdown, a bifurcation in the structure of a swirling jet, results in the establishment of a stagnation point and recirculation region along the centerline of the jet. In this study, we explore the dynamics of the swirling jet near vortex breakdown.

Investigation of time-averaged velocity fields and profiles leads to the identification of three flow regimes: pre-breakdown, near-breakdown, and post-breakdown. Velocity fields in these regimes are further analyzed using dynamic mode decomposition, Rankine-vortex fitting, and proper orthogonal decomposition to characterize jet dynamics with a particular focus on the development of the recirculation region characteristic of vortex breakdown. A precessing vortex core is also identified in the post-breakdown regime and its behavior is discussed.

Clements, R. R. and Maull, D. J.

"THE ROLLING UP OF A TRAILING VORTEX SHEET"

Aeronautical Journal, Vol. 77, No. 745, January 1973, pp. 46-51

The investigation is oriented towards finding circulation distributions which alter the rolling up characteristics of the sheet in such a way as to retard the rolling up and decrease the vorticity finally contained in such rolled up vortex cores. Because the aircraft concerned have, typically, aspect ratios of about 7 and lift coefficients of about 1.0, the Westwater model was used.

"GROUND-BASED REMOTE PROFILING IN ATMOSPHERIC STUDIES: AN OVERVIEW"

Proceedings of the IEEE, Vol. 82, No. 3, March 1994, pp. 313-355.

Over the last 25 years, ground-based profiling has found increasing applications in atmospheric studies where its high vertical and temporal resolution and extended vertical coverage are giving scientists a clearer understanding of atmospheric processes in the troposphere. In this paper we describe the status of techniques for vertical profiling of mean wind speeds, temperature, and humidity, and discuss options for combining them.

Clive, P. J. M., Dimwoodie, I. and Quail, F.

"DIRECT MEASUREMENT OF WIND TURBINE WAKES USING REMOTE SENSING"

European Wind Energy Association (EWEA) 2011, March 2011, Brussels, Belgium.

Understanding wind turbine wakes is vitally important in both the onshore and offshore wind power context, and during both the development phase and post-construction. The accuracy of the wake models used during the development phase of a wind power project to evaluate the losses and loads arising from wind turbine wakes has historically been assessed with references to power output at operational wind farms under a variety of waked conditions. This method of assessment however introduces some ambiguity due to the assumptions that must be made about the status of the wind power assets themselves and the influence this has on the power which is being used fundamentally as a proxy of free stream wind speed. A more satisfactory approach is to deploy remote sensing devices such as Lidar to measure the flow field under waked conditions directly. This presentation will review

the use of Lidar devices with fully steerable beams and long ranges (about 4km) sufficient to perform the sorts of wide area detailed and precise surveys of the wind flow through large arrays of wind turbines to investigate the formation, propagation and interaction of wind turbine wakes with each other and wind power assets. In essence there are many occasions where wind turbines themselves have been employed as large expensive anemometers for the assessment of wake models. This assessment can be more properly conducted using the remote sensing techniques now available which are reviewed in this presentation.

Cochran, L., Peterka, J. and Petersen, R.

"PHYSICAL MODELLING OF ROOF-TOP HELICOPTER EXHAUST FLOW DISPERSION"

Journal of Wind Engineering and Industrial Aerodynamics, Vol. 83, 1999, pp. 347-360.

A technique for physically modelling the interaction of helicopter rotor flows with the natural wind in a boundary-layer wind tunnel is described. This technique is used to measure the dilution of helicopter exhaust fumes at the roof-level air intakes near the heliports on top of the new American Stores Company Headquarters building in Salt Lake City, Utah. The dilution values may then be compared to odor and health threshold limits in the literature. Physical modelling of the interaction of the helicopter rotor downwash and the ambient wind around a complex architectural roof shape was used to determine the suitability of the locations chosen for the building air intakes. This approach is appropriate where any heliport operation interacts with the HVAC system of an office building or hospital.

Cocle, R., Dufresne, L. and Winckelmans, G.

"INVESTIGATION OF MULTISCALE SUBGRID MODELS FOR LES OF INSTABILITIES AND TURBULENCE IN WAKE VORTEX SYSTEMS"

Lecture Notes in Computational Science and Engineering, Vol. 56, 2007, pp. 141-159.

This paper investigates the capabilities of different sub-grid scale (SGS) models, including the recent 'multiscale' models, for large-eddy simulation (LES), here in a vortex-in-cell method, of complex wake vortex dynamics. More specifically, we here consider the multiscale dynamics developing in a counter-rotating four-vortex system, that evolves from a simple state to a turbulent state. The various SGS models are tested and compared on this complex and transitional flow. Comparisons are also made with results obtained using a pseudo-spectral method. Energy diagnostics (global and modal) and spectra are provided and used to support the comparisons. A discussion on the applicability of the various models to LES of complex wake vortex flows is made. The multiscale models are seen to be the most appropriate.

Cohen, B. and Smith, A.

"IMPLEMENTATION OF A LOW-COST SSR/ADS-B AIRCRAFT RECEIVER DECODER"

Proceedings of the 17th AIAA/IEEE/SAE Digital Avionics Systems Conference, Bellevue, WA, October-November 1998. Institute of Electrical and Electronics Engineers, Inc., 1998, Vol. 2, pp. F44-1 - F44-8

A real-time stand-alone radar receiver decoder system has been developed and implemented. The system decodes all radar data on the 1090- and 1030-MHz downlink and uplink, including Mode S, TCAS, ATCRBS, ADS-B, and IFF. In a typical terminal area, the system decodes real-time aircraft radar data at up to 10 Hz from each aircraft. This paper describes the application of the system to assist with several ATC research programs, including wake vortex research. The equipment set up and integration with a wake vortex sensor suite are described, and results are presented from field trials at JFK International Airport.

Cohen, D.

"A METHOD FOR DETERMINING THE CAMBER AND TWIST OF A SURFACE TO SUPPORT A GIVEN DISTRIBUTION OF LIFT"

NACA TN-855, August 1942, Langley Aeronautical Lab., Langley Field, VA

A graphical method is described for finding the shape (camber and twist) of an airfoil having an arbitrary distribution of lift. The method consists in replacing the lifting surface and its wake with an equivalent arrangement of vortices and in finding the associated vertical velocities. By a division of the vortex pattern into circular strips concentric about the downwash point instead of into the usual rectangular strips, the lifting surface is reduced for each downwash point to an equivalent loaded line for which the induced velocity is readily computed. The ratio of the vertical velocity to the stream velocity is the slope of the surface in the free-stream direction. As an illustration, the shape of the wing consistent with the pressure distribution derived from the two-dimensional theories is found for two wings: a straight elliptical wing and one with 30-degree sweepback. Application of the method to solve the reverse problem - finding the lift distribution over a given surface - is briefly discussed.

Cohen, S., editor

"CONCEPT PAPER FOR SEPARATION SAFETY MODELING: AN FAA/EUROCONTROL COOPERATIVE EFFORT ON AIR TRAFFIC MODELING FOR SEPARATION STANDARDS"

Concept Paper, FAA/Eurocontrol, May 1998

In today's air traffic environment, there is an emphasis on economic, cost-efficient operations and the need to not just maintain aviation safety, but dramatically improve it. With this emphasis has come the requirement to modernize en-route and terminal air traffic operations. This is being accomplished by transitioning to satellite-based navigation and surveillance, the equipage of ground facilities and aircraft cockpits with new technology, and the introduction of new airspace procedures and rules. Both the FAA and EUROCONTROL face this challenge of airspace modernization. An overriding concern of both organizations is that as the modernization occurs, aviation safety is maintained and improved. This paper describes the beginnings of an attempt to create a model for the use in airspace where radar separation is provided, one that will enable the estimation of the risk of a midair collision or other

safety problem (e.g., serious wake vortex encounter) as a function of parameters such as separation minima, accuracy of position information, integrity of systems, and controller automation aids.

Cohn, R. K. and Koochesfahani, M. M.

"EFFECT OF BOUNDARY CONDITIONS ON AXIAL FLOW IN A CONCENTRATED VORTEX CORE"

Physics of Fluids, Vol. A5, No. 1, January 1993, pp. 280-282.

The character of axial flow in the core of a concentrated line vortex is studied using flow visualization. Results show that axial flow can be initiated when the no-slip boundary condition is imposed on the vortex core over a spatial extent comparable to the core diameter. It is further demonstrated that no-slip is not a necessary condition to generate the axial flow; a region of spanwise shear (i.e., a slip boundary) is sufficient. Two distinct axial flow velocity profiles are observed; they are either jet-like or spatially undulated corresponding to a maximum axial speed occurring at the core center or outer edge, respectively.

Coimbra, R. F. F. and Catalano, F. M.

"THE EFFECT OF WING TIP BLOWING ON THE VORTEX DRAG"

ICAS-2002-3.10.2, Toronto, Canada, September 2002

Experimental work has been conducted to evaluate the effect of wing tip blowing on the vortex drag of a rectangular low aspect wing at low speed. A novel tip blowing system is presented which consist of three Coanda type jets. The jets can be vectored to produce a better tip vortex attenuation. Wind tunnel tests were performed for measurements of Lift, Drag and Pitching moment for many combinations of jet vertical angles and position. The tests were conducted at constant Reynolds number for incidence angles from -4 to 22 degrees. Results indicated an increase in Lift and pitching moment with an inherent decrease in drag for most of the configurations tested.

Coiro, D. P., Nicolosi, F., Scherillo, F. and Maisto, U.

"SINGLE VERSUS MULTIPLE WINGLETS: NUMERICAL AND EXPERIMENTAL INVESTIGATION"

ICAS Paper 2008-2.7.3, September 2008, Anchorage, Alaska.

The main goal of the paper is the numerical and experimental investigation of multiple winglets influence on the reduction of induced drag. This results in the improvement of climbing performances of a motor-glider or hang-glider. In a precedent work a set of multiple winglets, very similar to the bird tip feathers called remiges, were designed and optimized for the hang-glider belonging to Angelo D'Arrigo, a world champion hang-glider pilot and record holder. The research aims were to optimize the endurance parameter since this is directly proportional to the sink rate. In this work the effects of the multiple winglets, set on an elliptical wing and tested in a wind tunnel, are compared to the effects of three different single 'classical' winglets that were designed using a panel method code and were also

tested in the same wind tunnel in order to compare their span efficiency to the one of the multiple winglets.

Cole, J. A., Maughmer, M. D., Bramesfeld, G. and Kinzel, M.

"A PRACTICAL APPLICATION OF AN UNSTEADY FORMULATION OF THE KUTTA-JOUKOWSKI THEOREM"

AIAA Paper 2017-3904, June 2017, Denver, CO.

In this paper, a practical application of the unsteady Kutta-Joukowski theorem to a higher-order potential flow method is developed and discussed. The formulation of the unsteady version of the Kutta-Joukowski theorem is compared with a pressure integration on a flat plate to assess the origins of the non-circulatory term. The approach is varied through comparison with classical unsteady thin-airfoil solutions for the lift response to a sharp-edged gust a sinusoidal gust. Finally, the approach is used to predict the unsteady lift response of a propeller-wing system and the results are compared with a fully unsteady Reynolds-Averaged Navier Stokes analysis.

Cole, R.

"WIND PREDICTION TO SUPPORT REDUCED AIRCRAFT WAKE VORTEX SEPARATION STANDARDS"

Second Workshop WakeNet2-Europe, 'Capacity Gains as Function of Weather and Weather Prediction Capabilities', Langen, November 2004.

Air traffic delays were a major problem in the US prior to September 11, 2001, and are expected to climb to record levels in the near future. Wake vortex separation standards are an important contributor to the delay problem. Wake vortices are narrow diameter vortices generated as a function of aircraft lift that trail behind an aircraft generating a potential hazard to following aircraft. In certain circumstances, inter-aircraft spacing is increased to alleviate this hazard. The current aircraft separation standards are formulated to keep aircraft safe in the worst-case situation, and do not consider the fact the vortices may have blown out of the way or may have decayed due to atmospheric turbulence. When wake vortex separations are applied, spacing between aircraft is increased from a minimum of 2.5 nm to 4-6 nm (depending on the weight of the following aircraft), decreasing the number of operations per hour below demand at busy airports. The initial work in developing algorithms to predict when surface crosswinds will stay strong enough to ensure that wake vortex separations can safely be removed from behind the downwind aircraft departing from closely spaced parallel runways is discussed, along with some ideas on extending the initial work to improve reliability and forecast lead time. The work to date focuses on using anemometer data. A proof-of-concept study evaluated the applicability of the surface crosswind prediction algorithm used in the Frankfurt wake prediction system and a new candidate statistical prediction algorithm at four USA airports. This was followed by a study to extend the new surface crosswind prediction algorithm to use the Low Level Windshear Alert System network of anemometers at the St. Louis airport, so that predictions can be provided for a broader area. Statistical techniques to predict surface crosswinds in the airport region with long enough

prediction horizons to apply to departure operations have been shown to perform with a significant level of skill.

Cole, R. E. and Winkler, S.

"WIND PREDICTION TO SUPPORT REDUCED WAKE SEPARATION STANDARDS FOR CLOSELY SPACED PARALLEL RUNWAY DEPARTURES"

Proceedings of the 11th Conference on Aviation, Range, and Aerospace Meteorology, Hyannis, MA, 2004.

The FAA is considering the issue of how to reduce the use of wake avoidance separation for closely spaced parallel runway departures (runways separated by less than 2500 ft.). The ability to safely remove the wake avoidance separation requires the ability to predict when the crosswind will stay above some, yet unspecified, threshold level. There is a candidate surface wind prediction algorithm in a prototype system operating at Frankfurt. This led the FAA to pose the question: Is there enough to surface wind prediction based on anemometer measurements to warrant further investigation? To answer this question the Frankfurt algorithm was examined, as well as a new algorithm developed at MIT Lincoln Laboratory. The results show that the number of prediction failures (type 1 errors) is low enough, possibly as low as a few tens of minutes per year, and the possible benefits high enough, 30-60% of the time wake avoidance separation can be removed, that further development is warranted. These results are based on data from a single point at the airport. Before this technology can be used in an operational system the results must be extended to cover the entire airspace where the departing aircraft remain separated laterally by less than 2500 ft.

"THE AVOSS WINDS ANALYSIS SYSTEM"

NASA/L-5, February 2001, MIT Lincoln Laboratory, Lexington, MA

Due to wake turbulence, aircraft operating in the terminal area must maintain minimum separations on instrument approaches. This can be a significant constraint on the airport arrival rate. NASA's Aircraft Vortex Spacing System (AVOSS) project was undertaken to develop the technology to dynamically change aircraft arrival separations based upon atmospheric conditions and an understanding of vortex behavior. As part of this effort, a collection of meteorological sensor systems were deployed by Lincoln Laboratory and NASA at the Dallas/Fort Worth International Airport (DFW). These sensors, along with existing FAA and NWS systems, are used to create profiles of the atmosphere at the DFW airport. Scientific concept prototypes of the AVOSS were operated at Dallas/FT. Worth in the summer of 1997-2000. The greatest challenge in preparing a single atmospheric profile for the wake vortex behavior models is merging data from sensors yielding different measurements of the same atmosphere. To meet this challenge, the AVOSS Winds Analysis System (AWAS) was developed to perform the data quality editing and fusion of sensor data.

Coleman, C. P.

"A SURVEY OF THEORETICAL AND EXPERIMENTAL COAXIAL ROTOR AERODYNAMIC RESEARCH"

NASA Technical Paper TP-3675, March 1997, Ames Research Center, Moffett Field, CA.

The recent appearance of the Kamov Ka-50 helicopter and the application of coaxial rotors to unmanned aerial vehicles have renewed international interest in the coaxial rotor configuration. This report addresses the aerodynamic issues peculiar to coaxial rotors by surveying American, Russian, Japanese, British, and German research. (Herein, 'coaxial rotors' refers to helicopter, not propeller, rotors. The intermeshing rotor system was not investigated.) Issues addressed are separation distance, load sharing between rotors, wake structure, solidity effects, swirl recovery, and the effects of having no tail rotor. A general summary of the coaxial rotor configuration explores the configuration's advantages and applications.

"DNS OF AIRCRAFT WAKE VORTICES: THE EFFECT OF STABLE STRATIFICATION ON THE DEVELOPMENT OF THE CROW INSTABILITY"

Direct and Large-Eddy Simulation VII, Vol. 13, Part 7, 2010, pp. 505-511.

A numerical experiment is performed to determine the likelihood that the Crow instability will mitigate the potentially hazardous effects of the buoyancy-induced rebound of initially parallel line vortices. Parameters are chosen to correspond to wake vortices downstream of an elliptically loaded wing with large span (typical of the A380) landing in very stable conditions. The DNS is initiated by perturbing the vortex pair into the shape of the linearly most unstable Crow eigenmode, with a maximum displacement of 1 percent of the initial distance between the pair. Under these conditions, the Crow instability progresses fast enough to break the two dimensionality of the vortex system before it returns to its original elevation. This suggests that in many cases the Crow instability will prevent the rebounding vorticity from being a danger to following aircraft. Whether or not this will always happen in practice is an open question, requiring further investigation.

Collar, A. R.

"ON THE ACCURACY OF THE REPRESENTATION OF A LIFTING LINE BY A FINITE SET OF HORSESHOE VORTICES"

The Aeronautical Quarterly, Vol. 9, Issue 3, August 1958, pp. 232-250.

The paper examines the error involved when the continuous distribution of lift on an unswept lifting surface is represented by a finite number of horseshoe vortices, the strengths of which are determined by a prescribed downwash. Attention is directed mainly to the case of elliptic loading, but an anti-symmetrical case is also studied to ensure that the conclusions are not peculiar to the elliptic case. Sensitivity analyses on the loading were examined for prescribing the downwash at the center of each

horseshoe vortex equal to that for the continuous case, as well as if circulation is determined for a wing of finite aspect ratio by its geometric incidence.

Collins, R. L.

"WAKE TURBULENCE MYSTERY"

Flying, Vol. 121, No. 7, July 1994, pp. 52-56

The 757's wake seems to be more powerful than those of similar-sized airplanes. But its takeoff and approach capability are what adds the unexpected dimension.

Colmer, M. J.

"SOME FULL-SCALE MEASUREMENTS OF THE FLOW IN THE WAKE OF A HANGAR"

C. P. No. 1166, November 1970, Royal Aircraft Establishment, Bedford, UK.

An experiment to measure the flow behind a full-scale building at RAE Bedford is described. The results of one set of data show that the whole wake was slowly oscillating and that the turbulence intensity in the wake was greater than upstream. An hypothesis for the wake motion is put forward and the effect of the wake behind a building on conventional V/STOL aircraft is considered.

Colonius, T., Lele, S. and Moin, P.

"SCATTERING OF SOUND WAVES BY A VORTEX: NUMERICAL SIMULATIONS AND ANALYTICAL SOLUTIONS"

J. Fluid Mech., Vol. 260, February 1994, pp. 271-298

The scattering of plane sound waves by a vortex is investigated by solving the compressible Navier-Stokes equations numerically, and analytically with asymptotic expansions. Numerical errors associated with discretization and boundary conditions are made small by using high-order accurate spatial differentiation and time marching schemes along with accurate non-reflecting boundary conditions. The accuracy of computations of flow fields with acoustic waves of amplitude five orders of magnitude smaller than the hydrodynamic fluctuations is directly verified. The properties of the scattered field are examined in detail. The results reveal inadequacies in previous vortex scattering theories when the circulation of the vortex is non-zero and refraction by the slowly decaying vortex flow field is important. Approximate analytical solutions that account for the refraction effect are developed and found to be in good agreement with the computations and experiments.

Colonius, T., Lele, S. K. and Moin, P.

"THE FREE COMPRESSIBLE VISCOUS VORTEX"

Journal of Fluid Mechanics, Vol. 230, 1991, pp. 45-73.

The effects of compressibility on free (unsteady) viscous heat-conducting vortices are investigated. Analytical solutions are found in the limit of large, but finite, Reynolds number, and small, but finite, Mach number. The analysis shows that the spreading of the vortex causes a radial flow. This flow is given by the solution of an ordinary differential equation (valid for any Mach number), which gives the dependence of the radial velocity on the tangential velocity, density, and temperature profiles of the vortex; estimates of the radial velocity found by solving this equation are found to be in good agreement with numerical solutions of the full equations. The experiments of Mandella also report a radial flow in the vortex, but their estimates are much larger than the analytical predictions, and it is found that the flow inferred from the experiments violates the Second Law of Thermodynamics for two-dimensional axisymmetric flow. It is speculated that three-dimensionality is the cause of this discrepancy. To obtain detailed analytical solutions, the equations for the viscous evolution are expanded in powers of Mach number, M . Solutions valid to order M^2 , are discussed for vortices with finite circulation. Two specific initial conditions - vortices with initially uniform entropy and with initially uniform density - are analyzed in detail. It is shown that swirling axisymmetric compressible flows generate negative radial velocities far from the vortex core owing to viscous effects, regardless of the initial distributions of vorticity, density and entropy.

Colonus, T., Lele, S. K. and Moin, P.

"SCATTERING OF SOUND WAVES BY A COMPRESSIBLE VORTEX"

AIAA Paper No. 91-0494, Reno, NV, January 1991

Scattering of plane sound waves by a compressible vortex is investigated by direct computation of the 2-d Navier-Stokes equations. Non-reflecting boundary conditions are utilized, and their accuracy is established by comparing results on different sized domains. Scattered waves are directly measured from the computations. The resulting amplitude and directivity pattern of the scattered waves is discussed, and compared to various theoretical predictions. For compact vortices (zero circulation), the scattered waves directly computed are in good agreement with predictions based on an acoustic analogy. Strong scattering at about plus or minus 30 degrees from the direction of incident wave propagation is observed. Back scattering is an order of magnitude smaller than forward scattering. For vortices with finite circulation refraction of the sound by the mean flow field outside the vortex core is found to be important in determining the amplitude and directivity of the scattered wave field.

"ON-BOARD WAKE VORTEX DETECTION"

Presentation at the Third Wake-Net Workshop, Great Malvern, England, May 22-23, 2000

After collection of user requirements for airborne detection of wake-vortices and other atmospheric hazards, a future equipment has been defined and a demonstrator has been built. The demonstrator has been installed at the extremity of a runway on Toulouse airport so as to enable measurements in a

configuration very close to an on-board detection from a follower aircraft. This 'airborne-like' detection has been successful. The tracking method as well as the signal processing constitutes a world premiere that has demonstrated the feasibility of an airborne equipment. Industrial equipment for detection, warning and avoidance of wake-vortex, windshear and other atmospheric hazards could be brought to market within 5 to 8 years. To achieve this goal, it is important to progress in the system integration of the MFLAME concept. This global approach should be the subject of further work with two major objectives: (1) On board system integration with study of detection, warning and avoidance aspects, including avoidance maneuver trials in a flight simulator and flight tests; and (2) ATC and ground system integration, considering links with board system, to finally demonstrate how the operational capacity and safety of aircraft can be improved.

Condit, P. M.

"RESULTS OF THE BOEING COMPANY WAKE TURBULENCE TEST PROGRAM"

FAA Compilation of Working Papers Concerning Wake Turbulence Tests, April 1970

The results of a flight test investigation of vortex wake turbulence generated by large jet transport aircraft are presented. Test results showing the dynamic response of aircraft which were flown in the wakes of large jet transports, are discussed. Experimental results are compared to theoretical predictions. Test program results are applied to the problem of air traffic control and specific recommendations are presented for air traffic separations.

Condit, P. M.

"SUMMARY OF PANEL STATEMENT REGARDING WAKE TURBULENCE"

FAA Symposium on Turbulence, Federal Aviation Administration, Washington, DC, March 1971, p. 20

The Boeing Wake Turbulence Test Program is presented; the goal was to provide a comparison between the 747 wake and the wake of a smaller jet transport and to provide insight into the factors which are important when defining the hazards associated with wake turbulence. A B-737 and a CV-990 were flown behind a B-747 and a B-707. Little differences in the responses of the encountering aircraft were observed. It was concluded that: (1) the relative size of the generating and encountering airplanes is important and (2) the span ratio is the best parameter for defining 'hazard'.

Condit, P. M. and Tracy, P. W.

"RESULTS OF THE BOEING COMPANY WAKE TURBULENCE TEST PROGRAM"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 473-508

The Boeing Company initiated a study of large jet aircraft wake turbulence in mid-1969. The Boeing flight test program was undertaken to evaluate the behavior of trailing vortices and to obtain a direct comparison between the turbulent wakes of the 747 and a 707-320C. A fully instrumented Boeing 737-

100 was used as the primary wake probing aircraft. Additional probes were made with the Boeing owned F-86 and NASA's CV-990. It was found that the dynamic response of the chase airplanes was essentially the same when flying in the turbulent wakes of either the 747 or 707. It was observed that the wake leveled off and never descended more than 900 feet below the generating airplane. In the approach and landing tests it was found that the wake generated in ground effect does not 'roll up' into strong trailing vortices.

Cone Jr, C. D.

"THE THEORY OF INDUCED LIFT AND MINIMUM INDUCED DRAG OF NONPLANAR LIFTING SYSTEMS"

NASA TR R-139, 1962, Langley Research Center, Hampton, VA.

The basic theory of the induced lift and drag of nonplanar, circulation lifting systems is developed, and methods are evolved for determining the span force loading intensity necessary for minimum induced drag. It is shown that the aerodynamic efficiency of such optimally loaded systems can be expressed in terms of an effective aspect ratio which depends in value upon the spatial distribution of the vorticity of the system. Methods for determining the maximum effective aspect ratio of arbitrary lifting systems of given span by use of conformal transformation and electrical potential-flow analog techniques are developed and illustrated. The value of the induced-drag efficiency factor is determined for the families of circular, semi-ellipse, and complete-ellipse area and for several more complex forms. The result of the theory are interpreted in terms of the physical airfoil requirements necessary for successful realization of the theoretical induced-drag reductions. The practical application aspects of nonplanar wing systems are briefly considered.

Cone, Jr., C. D.

"A THEORETICAL INVESTIGATION OF VORTEX-SHEET DEFORMATION BEHIND A HIGHLY LOADED WING AND ITS EFFECT ON LIFT"

NASA TN-657, April 1961, Langley Research Center, Langley Field, VA

The induced drag polar is developed for wings capable of attaining extremely high loadings while possessing an elliptical distribution of circulation. This development is accomplished through a theoretical investigation of the vortex-wake deformation process and the deduction of the airfoil forces from the impulse and kinetic energy contents of the ultimate wake form. The investigation shows that the induced velocities of the wake limit the maximum lift coefficient to a value of 1.94 times the wing aspect ratio, for aspect ratios equal to or less than 6.5, and that the section properties of the airfoil limit the lift coefficient to 12.6 for aspect ratios greater than 6.5. Relations are developed for the rate of deformation of the vortex wake. It is also shown that linear wing theory is applicable up to lift coefficients equal to 1.1 times the aspect ratio.

Conlisk, A. T.

"MODERN HELICOPTER ROTOR AERODYNAMICS"

Progress in Aerospace Sciences, Vol. 37, Issue 5, July 2001, pp. 419-476.

The helicopter rotor wake is among the most complex fluid dynamic structures being three dimensional and, in many cases, unsteady. The wake begins at the blade(s) where the flow can be transonic near the blade tip and undergo compressible dynamic stall. Farther down in the wake, the flow is essentially incompressible. Moreover, the rotor blades undergo complex unsteady motions because of the necessity to balance moments; they are elastic as well. In this paper, the fundamental aeromechanics of the wake and the flow on the blade is discussed and the primary methods of analysis, computation, and experiment employed to uncover the physics of the rotor wake are described.

Conlisk, A. T.

"A THEORY OF VORTEX-SURFACE COLLISIONS"

AIAA Paper 1998-2858, June 1998, Albuquerque, NM.

The interaction of vortices with solid surfaces occurs in many different situations including, but not limited to tornadoes, propeller wakes, flows over swept wings and missile forebodies, turbomachinery flows, blade-vortex interactions and tip vortex-surface interactions on helicopters. Often, parts of a system must operate within such flows and thus encounter these vortices. In the present paper we discuss the nature of a particular subset of interactions called 'collisions'. A 'collision' is characterized by the fact that the core of the vortex is permanently altered; usually the core is locally destroyed. The focus is on fully three-dimensional collisions although two-dimensional collisions are discussed as well. Examples of collisions in helicopter aerodynamics and turbomachinery flows are discussed and the dynamics of the vortex core during a collision process are illustrated for a 90-degree collision.

Conlisk, A. T.

"MODERN HELICOPTER AERODYNAMICS"

Annual Review of Fluid Mechanics, Vol. 29, Ann. Rev. Inc., Palo Alto, CA, 1997, pp. 515-567.

Modern helicopter aerodynamics is challenging because the flow field generated by a helicopter is extremely complicated and difficult to measure, model, and predict; moreover, experiments and computational techniques have been employed to predict performance parameters. Of particular interest is the structure of the rotor wake, which is highly three-dimensional and unsteady, and the rotor-blade pressure distribution, which is significantly affected by the strength and position of the wake. We describe the various modern methods of computation and experiment which span the range from vortex techniques to full three-dimensional Navier-Stokes computations, and from classical probe methods to laser velocimetry techniques. Typical results for the structure of the wake and the blade pressure distribution in both hover and forward flight are presented despite the complexity of the

helicopter flow, significant progress has been made within the last ten years and the future will likely bring marked advances.

Conlisk, A. T. and Komerath, N. M.

"VORTEX SURFACE COLLISIONS"

ARO 30707.4-EG, March 1998, Ohio State University Research Foundation, Columbus, OH.

Many flows of practical interest contain discrete vortices. These include tornadoes, propeller wakes, and flows over swept wings and missile forebodies. The encounter of a vortex with a solid body is always a complex event involving very large gradients of pressure and velocity. We consider the problem in which a rotor-tip vortex collides with a helicopter airframe. The primary objective of this work is to describe both experimentally and computationally the interaction when the vortex 'collides' directly with the airframe in the sense that at some point the flow in the vortex core must be altered to accommodate the presence of the airframe. The pressure field caused by the collision is also described. The dominant physics of the collision process may be described by inviscid flow theory and it is the component directed along the tip-vortex axis, termed the axial flow, which is the major cause of the collision.

Conlisk, A. T. and Komerath, N. M.

"THE ORIGIN AND STRUCTURE OF TRAILING VORTICES IN AERODYNAMICS"

School of Aerospace Engineering, Report 733920, March 2001, Ohio State Univ., Columbus, OH

The helicopter rotor wake is among the most complex flow-fields in aerodynamics. Even though a large amount of computational and experimental work on the rotor wake has been published, little of a quantitative nature is known about the origin of the main component of the rotor wake, the tip-vortex, as a function of the rotor speed, rotor blade geometry and angle of attack. The primary objective of this work is to predict the formation of the rotor tip vortex as a function of physical parameters such as angle of attack, rotor speed, and blade aspect ratio. While the rotor-blade tip-vortex is of primary interest, the techniques developed are applicable to fixed wings as well.

"THE GENERATION OF NOISE IN IMPINGING VORTEX MOTION PAST A STEP"

Physics of Fluids, Vol. 28, No. 10, October 1985, pp. 3004-3012.

The noise field generated by the motion of one, two, or several rectilinear vortices in an inviscid, irrotational mean flow past a step is considered for low Mach number. The streak-line patterns of an impinging vortex are compared with flow visualization studies, and qualitative agreement between the present analytical results and the experiments is achieved. Both acoustic pressure and intensity are strong functions of the vortex motion near the step which, because of the complexity of the geometry,

must be computed numerically. Results for the acoustic pressure and intensity are presented for a variety of incident vortex arrays.

Conlisk, A. T., Li, H., Mei, N. and Budic, J.

"VORTEX-VORTEX INTERACTIONS IN THE WAKES OF THREE AND FOUR BLADED ROTORS"

American Physical Society, Fluid Dynamics Meeting, Nov. 1999, New Orleans, LA.

In recent experiments on a two-bladed rotor in low axial climb it was observed that vortices shed from each of the blades interacted significantly at approximately one rotor radius below the rotor disk plane. This phenomenon was verified by numerical solutions of the rotor wake for the same experimental conditions. In this paper we consider the case of three and four blades in hover. A lifting line is used to model each blade and a fully unsteady computation of the motion of each tip-vortex is carried out using a highly accurate Adams-Moulton method to advance the vortices. The vortex-vortex interaction is particularly complicated and several vortices are observed to become locally intertwined. It is suggested that this kind of behavior can be explained on the basis of classical vortex dynamics. Conditions under which the motion of the vortices is steady are also examined.

"PASSENGER RIDE COMFORT TECHNOLOGY FOR TRANSPORT AIRCRAFT SITUATIONS"

TM X-73953, October 1976, NASA Langley Research Center, Hampton, VA.

A brief overview is given of NASA research in ride comfort and of the resultant technology. Three useful relations derived from the technology are presented together with five applications of these relations to illustrate their effectiveness in addressing various ride comfort situations of passenger transports.

Connolly, S. T. and Dagle, W. R.

"THE MEASUREMENT OF WAKE VORTICES WITH A CLEAR-AIR DOPPLER RADAR"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 38-1 - 38-11

A Doppler radar system is currently under development by Applied Technologies and the U.S. Army to measure wind velocity and turbulence and to detect the atmospheric boundary layer height. For this type of radar high resolution is of prime concern since the top of the atmospheric boundary layer is characterized by small-scale turbulence which can be overlooked by instruments with coarser resolution. Because of the features designed into the radar to accomplish these tasks, a radar of this type may be feasible for operational airport monitoring of aircraft wake vortices to determine if wake vortex separation constraints may be relaxed. The all-weather ability of this radar may be used to determine the influence of weather on the persistence and decay of wake turbulence and to assess the

hazard presented by weather-reduced strength vortices. Applied Technologies has applied the technologies of pulsed radar wind profiles to duplicate the results of earlier work done with the FM-CW radars. This radar has been designed for continuous, unattended meteorological monitoring by including sophisticated signal processing, built in test equipment, and remote communications. This paper discusses the design features of this radar and how they could be applied to wake vortex detection and monitoring.

Connor, A. B. and O'Bryan, T. C.

"A BRIEF EVALUATION OF HELICOPTER WAKE AS A POTENTIAL OPERATIONAL HAZARD TO AIRCRAFT"

NASA TN D-1227, March 1962, NASA Langley Research Center, Langley AFB, VA

Flight tests with a single-rotor helicopter and a fixed-wing airplane are reported which show that helicopter wake presents a potential hazard to aircraft operating near the wake, particularly with regard to airport traffic situations. Operating practices suggested for reducing this hazard potential include reminding pilots of aircraft following a helicopter to remain above the helicopter flight path and, if in doubt about relative positions, to extend the separation interval between aircraft. An exact time interval was not determined, but a separation estimated to be about 1 minute appears to be a reasonable time with most of the present generation helicopters.

"CONCEPT OF INTEGRATION FOR UAS OPERATIONS IN THE NAS"

ICAS Paper 2012-10.7.1, September 2012, Brisbane, Australia.

One of the major challenges facing the integration of Unmanned Aircraft Systems (UAS) in the National Airspace System (NAS) is the lack of an onboard pilot that can comply with the legal requirement identified in the US Code of Federal Regulations that pilots see and avoid other aircraft. UAS will be expected to demonstrate the means to perform the function of see and avoid while preserving the safety level of the airspace and the efficiency of the air traffic system. This paper introduces a Sense and Avoid concept for integration of UAS into the NAS that is currently being developed by NASA and identifies areas that require additional experimental evaluation to further inform various elements of the concept. The concept design rests on interoperability principles that take into account both the Air Traffic Control environment as well as existing systems such as the Traffic Alert and Collision Avoidance System (TCAS). Specifically, the concept addresses the determination of well clear values that are large enough to avoid issuance of TCAS corrective Resolution Advisories, undue concern by pilots of proximate aircraft and issuance of controller traffic alerts. The concept also addresses appropriate declaration times for projected losses of well clear conditions and maneuvers to regain well clear separation.

"COHERENT LASER RADAR AND THE PROBLEM OF AIRCRAFT WAKE VORTICES"

Journal of Modern Optics, Vol. 41, No. 11, 1994, pp. 2153-2173

Aircraft wake vortices have been studied with a 10.6-micron coherent c.w. lidar. Good agreement is found between the form of experimentally observed Doppler spectra and theoretical calculations and modelling. Detailed measurements of spectra have yielded core radii, tangent velocities and vortex velocity profiles which are in reasonable accord with theoretical formulations. During a two-week trial, over 130 aircraft passages were recorded with the lidar equipment. Even in low signal to noise conditions vortex spectra were recorded on most occasions at a level above expectation. The characteristic cusp-like features of such spectral records are illustrated with a novel color display.

Constant, G., Foord, R., Forrester, P. A. and Vaughan, J. M.

"COHERENT LASER-RADAR AND THE PROBLEM OF AIRCRAFT WAKE VORTICES"

"ATMOSPHERIC DISPERSION OF AIRCRAFT EXHAUST"

AIAA Paper No. 1973-0100, January 1973, Washington, DC.

A model for the dispersal of exhaust from high-flying aircraft is proposed. This model was developed as part of a study to predict stratospheric pollution from supersonic transports and other aircraft that may be operating by 1990. The model addresses the exhaust trail from the engines to the point at

which aircraft-induced effects become negligible compared with natural atmospheric transport. This may involve lengths of trail on the order of 100 km. The model was developed from simple theoretical arguments and a study of condensation trails from jet aircraft.

"VORTEX INFORMATION DISPLAY SYSTEM PROGRAM DESCRIPTION MANUAL - DATA ACQUISITION FROM LASER DOPPLER VELOCIMETERS AND REAL TIME OPERATION"

NASA CR-120703, February 1975, M&S Computing, Huntsville, AL

A vortex information display system is described which provides flexible control through system user interaction for collecting wing-tip-trailing vortex data, processing this data in real time, displaying the processed data, storing raw data on magnetic tape, and post processing the raw data. The data is received from two asynchronous laser Doppler velocimeters and includes position, velocity, and intensity information. Both raw data and processing can be continually upgraded during flyby testing to improve vortex behavior studies.

"NUMERICAL SOLUTIONS TO THREE-DIMENSIONAL SHOCK WAVE/VORTEX INTERACTION AT HYPERSONIC SPEEDS"

AIAA Paper No. 1989-0674, January 1989, Reno, NV.

An upwind difference, finite volume algorithm was used to numerically solve the full three-dimensional Euler equations for two flow fields, Mach numbers 2.28 and 5.00, each containing a helical-type vortex impinging on an oblique shock wave. These solutions showed several interesting and unexpected results. In neither case did the jump across the shock cause the vortices to breakdown. However, two unusual structures were observed. The first was common to both flow fields and was seen as areas of flow reversal around the outside of the post-shock vortex. The second unexpected structure was observed only in the Mach 5.00 flow field and was seen as the formation of a trough-like structure around the outside of the post-shock vortex. Further study is needed to determine the cause of these structures. They may possibly be a result of vorticity generation due to the nonuniform pre-shock flow field combined with the shock curvature. To the best of the author's knowledge, this is the first time these two structures have been observed.

"MIXING INDUCED BY RALEIGH-TAYLOR INSTABILITY IN A VORTEX"

Physics of Fluids, Vol. 17, February 2005, 021703-1 to 021703-4

The direct numerical simulation (DNS) of a two-dimensional Lamb-Oseen vortex with a heavy internal core has been performed. Linear stability theory predicts the existence of Rayleigh-Taylor (RT)

instabilities due to the destabilizing effect of the centrifugal force on the radial flow nonhomogeneities. The DNS first exhibits wavy azimuthal perturbations which are nonlinearly distorted into bubble-like patterns, characteristic of the standard development of the RT instabilities, i.e., instabilities obtained in a planar nonhomogeneous flow in the presence of gravity. Nevertheless, important differences may be observed in the late-stage development of the instability: contrary to the standard case, the bubbles are then stretched in the azimuthal direction leading to a strong radial filamentation of the flow.

"BEHAVIOR OF WAKE VORTICES NEAR GROUND"

AIAA Journal, Vol. 35, No. 5, May 1997, pp. 849-855

Direct numerical simulations of a vortex pair embedded in a stable atmospheric boundary layer are presented. The effects of various crosswind conditions are studied. These computations demonstrate the creation of secondary vortices for the range of Reynolds numbers (3,770) to (113,100). The physics of wake vortex interactions with the ground for different values of crosswind are discussed. The redistribution of vorticity between the atmospheric boundary layer and the vorticity induced by the primary vortices may explain the vortex tilting phenomenon. A parameterization of the effect of crosswind on the minimum altitude reached by the two vortices is given.

Corjon, A. and Poinso, T.

"VORTEX MODEL TO DEFINE SAFE AIRCRAFT SEPARATION DISTANCES"

Journal of Aircraft, Vol. 33, No. 3, May-June 1996, pp. 547-553

An approximate model of wake vortices behavior is presented. We have introduced modifications in the Greene's model to consider the effects of ground (divergence, rebound) and crosswind (advection, shear). Direct numerical simulations of laminar flows with and without lateral wind are performed to validate these extensions. The first results are encouraging and efforts are carried on to derive a more reliable model. The capability of this model to mimic the reality is shown by comparison with an experimental test case.

Corjon, A. and Poinso, T.

"A MODEL TO DEFINE AIRCRAFT SEPARATIONS DUE TO WAKE VORTEX ENCOUNTER"

AIAA Paper 95-1776-CP, June 1995, San Diego, CA, pp. 117-124.

An approximate model of wake vortices behavior is presented. Based on a modification of the Greene's model, it allows to consider the effects of ground (divergence, rebound) and crosswind (advection, shear). To validate these modifications, direct numerical simulations are performed in laminar flows with and without lateral wind. The first results are encouraging and this approach will be carried on to derive a more reliable simple model.

Corjon, A. and Poinso, T.

"WAKE VORTICES BEHAVIOR NEAR THE GROUND"

ESAIM Proceedings, Vol. 1, 1996, pp. 279-294.

Direct numerical simulations of a vortex pair embedded in a stable atmospheric boundary layer are presented. The effects of various crosswind conditions are studied. These computations demonstrate the creation of secondary vortices for the range of Reynolds numbers (3,770 to 7540). The physics of wake vortex interactions with the ground for different values of crosswind are discussed. The redistribution of vorticity between the atmospheric boundary layer and the vorticity induced by the primary vortices may explain the vortex tilting phenomenon. A parameterization of the effect of crosswind on the minimum altitude reached by the two vortices is given.

Corjon, A. and Stoessel, A.

"THREE-DIMENSIONAL INSTABILITY OF WAKE VORTICES NEAR THE GROUND"

AIAA Paper No. 1997-1782, Snowmass Village, CO, June 1997

This paper presents three-dimensional direct numerical simulations of a vortex pair. The computations consider a vortex pair placed in a laminar flow field near the ground. This laminar flow is representative of a neutral surface boundary layer. The effect of variable crosswind shear on the rebound is studied with the effect of an axial wind. It is shown that long wavelength variations of the crosswind induce a curvature of the secondary vortices. This curvature is self-amplified and leads to their reconnection with the primary vortices. This linking makes them collapse. In a second part, Crow's instabilities near the ground are studied. The results show that the same phenomenon can explain the shortened lifetime of the vortices near the ground. The conclusions differ from the previous one talking about the vortex interacting with its ground image.

"S.Y.A.G.E. - THE FRENCH WAKE VORTEX SPACING SYSTEM"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 33-38.

The STNA (Service Technique de la Navigation Aérienne) has been performing studies on wake vortices since 1992 for the DGAC (Direction Générale de l'Aviation Civile). Due to limited budget, the work progress is not as fast as expected. In this paper, we will present SY.A.G.E. (SYstème Anticipatif de Gestion des Espacements). This system intends to optimize the separation between aircraft at landing and take-off. All the developments done in France are related to this definition. A first version of SYAGE has been set-up and an experiment aiming at operationally verifying the system is presented. This first version concerns aircraft at departure and crosswind considerations. A wind line of seven

anemometers has been installed on Toulouse-Blagnac airport to monitor the position of the vortices. This trial should assess the needed accuracy on the wind measurement for an operational system. The constituted wind database will be used to develop short term forecasting compulsory to have the landing version of SYAGE.

Corjon, A., Bouhours, G. and Caisso, P.

"SYAGE2: 3D SONIC ANEMOMETERS WINDLINE"

XXV General Assembly, European Geophysical Society, Nice, France, April 2000

The STNA (Service Technique de la Navigation Aérienne) is performing studies on wake vortices since 1992 for the DGAC (Direction Générale de l'Aviation Civile). In this paper, we will present an experiment related to SY.A.G.E. (Système Anticipatif de Gestion des Espacements). This system intends to optimize the separation between aircraft at landing and take-off. All the developments done in France are related to this system. A first version of the experiment aiming at operationally verifying the system was running since June 1997 and its evolution is presented. This concerns aircraft at departure and crosswind considerations. A wind line of seven 3D sonic anemometers coupled with a microphone has been installed on Toulouse-Blagnac airport to monitor the lateral position of the vortices. This trial should assess the needed accuracy on the wind measurement for an operational system. The constituted wind database will be used also to develop short term forecasting compulsory to have the landing version of SYAGE. The results presented here show the efficiency of the wind line for a moderate cost.

"LARGE EDDY SIMULATIONS OF REBOUND AND AGING OF THREE-DIMENSIONAL WAKE VORTICES WITHIN THE ATMOSPHERIC BOUNDARY LAYER"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206233, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 145-168

Included in the presentation are details of the MFLAME Project, real test cases, including Idaho Falls experimental data, idealized test cases - concentrating on aging due to turbulence, ground effect with 3D wind, and Crow instability near the ground, theoretical modeling, lidar simulation and concluding remarks.

Corjon, A., Darracq, D. and Ducros, F.

"ATMOSPHERIC TURBULENCE EFFECTS ON WAKE VORTICES"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 65-68

The increasing traffic is constrained on the airport by the separation standards dictated by ICAO. All aircraft produce wake vortices more or less related to their gross weight. If there were no effect of the atmosphere, no decay will occur and the actual separation should have been increased. The paper will deal with the background turbulence effect on the trailing vortices. Following direct numerical simulations, CERFACS has performed large eddy simulations to reach realistic Reynolds number. The decay of the vortices induced by the turbulence is explained by vortex stretching. Due to the shear, the eddies of the atmospheric turbulence are stretched and roll around the aircraft vortices. They induce deformation that leads to Crow instability. As the turbulence level increases the vortices decay faster. Looking at the simulations, the turbulence influence on the trailing vortices is modeled by a vortex ring rolling around a rectilinear vortex. The theoretical law of decay is linear and seems to be confirmed by the simulations.

"WAKE ROLL-UP SIMULATION UP TO THE FAR-FIELD"

AIAA Paper No. 1999-3201, Norfolk, VA, June-July 1999.

This paper presents a method to compute the roll-up phase and far field evolution of the vortex sheet developing behind a commercial transport aircraft using Large-Eddy Simulations (LES). The computations consider an aircraft out of ground effect and are restricted to the wake. They are initialized using either a point vortex method or experimental data, which provides the inlet plane. Then, the simulation is performed in two steps: first, steady computation of the roll-up phase using Euler simulations and second, Large-Eddy Simulations of the wake. The length of the presented far-field simulated wake is 50 wingspans and represents about 30s of flight. This method could permit to define a new standard separation matrix and also investigate new ways to accelerate vortex decay.

"THREE-DIMENSIONAL LARGE EDDY SIMULATION OF WAKE VORTICES. COMPARISON WITH FIELD MEASUREMENTS"

AIAA Paper No. 1997-2309, Atlanta, GA, June 1997.

This paper presents three-dimensional large eddy simulations and two-dimensional direct numerical simulations of wake vortices of an aircraft in a realistic atmospheric boundary layer. These calculations are performed to parametrize an operational model aiming at managing the separations between aircraft at take-off and landing. The computation considered here is taken from twelve selected cases corresponding to trials made at Idaho Falls sponsored by the Federal Aviation Administration in 1990. After computing the evolution of a convective atmospheric boundary layer with a non-hydrostatic meteorological model, the evolution of the wake vortices (with their characteristics measured during the experiments) is computed. The three-dimensional behavior of the wake vortices as well as the effects of the atmospheric parameters are shown. The results of the simulations are compared to experimental data.

Corjon, A., Laporte, F. and Leweke, T.

"TOWARDS WAKE ALLEVIATION FOR TRANSPORT AIRCRAFT"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

Airport congestion is a combination of several factors and the one linked to wake vortices is not obvious to solve. One of the possibilities is to act on the generating aircraft's trailing vortices. Two strategies have to be considered: (1) Suppressing completely the constraints linked to wake vortices, i.e. ensuring that the lifetime of the vortices is always shorter than the time needed to travel 2.5 nm (about 70s), whatever the meteorological conditions. Results in this direction have been obtained (uncoupled ailerons, splines), but their operational cost is too high. (2) Alleviation of the wake vortex hazard, i.e. ensuring a known level of hazard compatible with current separation standards. This approach is based on a better knowledge of the behavior of trailing vortices in the atmosphere. In fact, there is not too much difference between these two strategies. The main one is on the cost-effectiveness of such a system. A methodology has been developed that allows characterization of the wake of an Airbus type aircraft, identification of control parameters of the unique counter-rotating vortex pair that generally remains in the far wake, and control of the identified parameters. Modifying these parameters has effects on the development of short-wavelength instabilities (elliptic), long-wavelength (Crow) instability, decay in the atmosphere, and induced rolling moment. Alleviation devices based on this approach will allow to create 'older' vortices with much more favorable conditions for decay in the atmosphere and will then permit to rate the equipped aircraft in a lower class.

"THREE-DIMENSIONAL DIRECT NUMERICAL SIMULATIONS OF WAKE VORTICES: ATMOSPHERIC TURBULENCE EFFECTS AND REBOUND WITH CROSSWIND"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 28-1 to 28-21

This paper presents three-dimensional direct numerical simulations of a vortex pair. Two types of computations are conducted. The first type considers a vortex pair placed in a homogeneous turbulent field. The phenomenon of interaction between the vortices and the turbulence is analyzed in details from two simulations calculated on a 1353 nodes mesh grid (one case with axial core velocity, the other without). The results show that the role of large and small turbulent eddies can be separated into two independent mechanisms. The large structures are stretched by velocity gradients induced by the vortex pair. That leads to the formation of both tubes of vorticity spinning azimuthally around each vortex and associated axial velocity sheets. These turbulent structures cause a strong decrease of the maximal velocity and curvature of the vortices. These deformations of the vortex induced by the turbulence initiate an antisymmetric long-wave instability of the pair which will probably lead to the collapse of the vortices. Concurrently, the small structures can enhance the diffusion of the vorticity out of the vortex core. From this analysis and dimension considerations, the correct form for a model

of decay of the vortices is derived. The second type of computations considers a vortex pair placed in a laminar flow field near the ground. This laminar flow is representative of a neutral surface boundary layer. The effect of variable cross-wind shear is studied with the effect of an axial wind. A comparison between the two-dimensional and the three-dimensional results shows that the main phenomenon is not modified but that the altitude of rebound depends on the three components of the wind. Furthermore, the curvature of the secondary vortices due to long wavelength crosswind variation leads to their reconnection with the primary and makes them burst.

Corjon, A., Zheng, Z. C. and Greene, G. C.

"MODEL OF THE BEHAVIOR OF AIRCRAFT WAKE VORTICES EXPERIENCING CROSSWIND NEAR THE GROUND"

AIAA Paper No. 1996-2516, New Orleans, LA, June 1996

VORTEX, an approximate model of wake vortex behavior is presented. Based on a modification of the Greene's model which includes the effects of viscosity, atmospheric turbulence, and stratification, it takes into account also the effects of ground (separation, rebound) and crosswind (advection, shear). To validate these modifications, Navier-Stokes computations are performed in laminar and turbulent flows. The first comparisons are encouraging and this approach will be carried on to develop a more reliable simple model.

Cornelius, K. C.

"ANALYSIS OF VORTEX BURSTING UTILIZING THREE-DIMENSIONAL LASER MEASUREMENTS"

J. Aircraft, Vol. 32, No. 2, March-April 1995, pp. 297-306

From the analysis of experimental three-dimensional laser velocimeter data of a vortex burst condition on a generic fighter configuration, a criterion for vortex breakdown has been evaluated. The measured velocity vectors were rotated from the tunnel coordinate system to the vortex core trajectory to examine the relevant parameters for vortex instability. The Rossby parameters that govern stability were formulated in terms of the local vortex flow variables. The ratio of axial-to-crossflow energy evaluated from the data encompassing a region bounded by the vorticity provides for a parameter that is consistent with Ludwig's spiral instability analysis for conical flow. Benjamin's analysis for supercritical flow transition is correlated with a parameter for the mean flow vortex variables. The magnitudes of the critical parameters decrease downstream from the adverse pressure gradient along the vortex trajectory providing a threshold that correlates with the vortex breakdown position.

Cornish III, J. J.

"VORTEX FLOWS"

Eighth Quick-Goethert Lecture Series, The University of Tennessee Space Institute, October 1982, Tullahoma, Tennessee

The intent of the lecture is to introduce the concept of vortex flows by way of flow visualization examples, instead of attempting to rigorously define a vortex. Topics covered included vortex interactions, instabilities and breakdown, as well as wing tip vortices.

Cornman, L. B.

"AIRBORNE IN SITU MEASUREMENTS OF TURBULENCE"

In *Aviation Turbulence*, edited by R. Sharman and T. Lane, Chapter 5, 2016, Springer International Publishing Switzerland, pp. 97-120.

Airborne in situ measurements of turbulence play a key role in mitigating the operational turbulence problem for aviation. These measurements can be used for warning following aircraft, used in turbulence forecasting and nowcasting algorithms, and assisting in the development and verification of those algorithms. Furthermore, in situ measurements are useful in furthering the phenomenological understanding of turbulence in terms of climatologies and case studies. In this chapter, we focus on energy dissipation rate (EDR) calculations for both homogeneous and inhomogeneous turbulence and describe the connection between EDR and aircraft vertical acceleration response. The chapter concludes with a simulation analysis comparing EDR estimates from vertical velocity, from scaling the root mean square of the velocities and accelerations, and from scaling peak accelerations.

Cornman, L. B. and Goodrich, R. K.

"DOPPLER RADAR MEASUREMENTS OF TURBULENCE"

In *Aviation Turbulence*, edited by R. Sharman and T. Lane, Chapter 6, 2016, Springer International Publishing Switzerland, pp. 121-148.

A first-principal analysis of Doppler radar measurements of turbulence is presented. A set of limited, though practical, conditions are assumed to make the problem more tractable, with the primary condition being the discrete and finite temporal sampling of the radar signals. A theoretical derivation of the Doppler spectrum under these conditions is performed, and the distinction between what the radar actually measures and what results after a theoretical ensemble averaging is delineated. This is an important consideration, as all of the theoretical development in the literature is based upon ensemble averaging. It is shown that in the limit of an infinite number of samples, and after ensemble averaging, the Doppler spectrum can be represented by a sum of Dirac delta distributions and furthermore that the normalized spectrum will equal the probability distribution of the scatterer velocities. We show that the correlation structure of the velocity field manifests itself primarily in the square of the first moment. That is, a correlated field will have a certain degree of patchiness, which leads to variations in the first moments from realization to realization. These theoretical considerations are then studied via simulation. Parameters for a typical X-band Doppler radar are used, and correlated von Karman and uncorrelated random fields are employed. Energy dissipation rate estimates are

calculated from the simulated Doppler spectra, and the performance based on moment averaging and spectral averaging is presented. Real-world application of the turbulence measurement methods is then shown with airborne X-band detection of convective turbulence.

"REAL-TIME ESTIMATION OF ATMOSPHERIC TURBULENCE SEVERITY FROM IN-SITU AIRCRAFT MEASUREMENTS"

Journal of Aircraft, Vol. 32, No. 1, January-February 1995, pp. 171-177.

The quality of atmospheric turbulence detection and forecast information for the operational meteorology and aviation communities is directly linked to the quality of real-time measurements. Currently, the only direct data are subjective, qualitative, and intermittent pilot reports. This article describes techniques, suitable for real-time application on commercial transport aircraft, to generate quantitative and comprehensive turbulence measurements. These algorithms build on standard methods used in the analysis of aircraft response to turbulence, but are specifically designed to address the limitations of the available on-board data and computational resources.

Corpening, G.

"NUMERICAL SOLUTIONS TO THREE-DIMENSIONAL SHOCK WAVE / VORTEX INTERACTION AT HYPERSONIC SPEEDS"

PhD Thesis, 1988, University of Maryland, College Park, MD.

A recent study at the University of Maryland has been undertaken to numerically solve the interaction flow field between a helical-type vortex and an oblique shock wave. The study develops solutions to three-dimensional shock wave/vortex interaction at two Mach numbers, namely Mach 2.28 and 5.00. The numerical model used is based on a scheme developed by P. A. Gnoffo of the NASA Langley Research Center. It is a finite volume, implicit upwind differencing method which is used to solve the integral form of the Euler equations. In each case, a vortex was input into a flow field containing a 46.4-degree shock wave. These solutions showed several interesting results. Because of the different angles which the vortex velocity vector would strike the shock wave an asymmetry across the post-shock vortex was observed. However, neither this asymmetry nor the pressure-jump across the shock was enough to cause the vortices to breakdown. In fact, the vortex strength did not change appreciably between the input and the post-shock vortex. However, two unusual structures were observed. The first was common to both flow fields and was seen as areas of flow reversal around the outside of the post-shock vortex. The second unexpected structure was observed only in the Mach 5.00 flow field and was seen as the formation of a trough-like structure around the outside of the post-shock vortex. Further study is needed to determine the cause of these structures. They may possibly be a result of vorticity generation due to the nonuniform pre-shock flow field combined with the shock curvature. To the best of the author's knowledge, this is the first time these two structures have been observed. They presented an interesting conclusion to this study.

"AIRCRAFT WAKE-VORTEX MINIMIZATION BY USE OF FLAPS"

Proceedings Wake Vortex Minimization Symposium, NASA, SP-409, 1977, pp. 305-338

A survey was made of research on the alleviation of the trailing vortex hazard by altering span loading with flaps on the generator airplane. Flap configurations of the generator that shed multiple vortices were found to have wakes that dispersed by vortex merging and sinusoidal instability. Reductions of approximately 50 percent in both the wake rolling moment imposed on a following aircraft and the aircraft separation requirement were achieved in the ground based and flight test experiments by deflecting the trailing edge flaps more inboard than outboard. Significantly, this configuration did not increase the drag or vibration on the generating aircraft compared to the conventional landing configuration. Ground based results of rolling moment measurement and flow visualization are shown, using a water tow facility, an air tow facility, and a wind tunnel. Flight test results are also shown, using a full-scale B-747 airplane. General agreement was found among the results of the various ground-based facilities and the flight tests.

"SCANNING LASER-VELOCIMETER SURVEYS AND ANALYSIS OF MULTIPLE VORTEX WAKES OF AN AIRCRAFT"

Proceedings of the Aircraft wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 114-123

A laser velocimeter capable of rapidly scanning a flow field while simultaneously sensing two components of the velocity was used to measure the vertical and streamwise velocity structure 1.5 spans downstream in the wake of a model typical of a large subsonic transport (Boeing 747). This flow field was modeled by a superposition of axisymmetric vortices with finite cores. The theoretical model was found to agree with the measured velocities everywhere except where two vortices were in close proximity. Vortex strengths derived from the span loading on the wing as predicted by vortex-lattice theory also agree with the present measurements. It was, therefore, concluded that the axisymmetric vortex model used herein is a useful tool for analytically investigating the vortex wakes of aircraft.

"WIND-TUNNEL INVESTIGATION OF THE EFFECT OF POROUS SPOILERS ON THE WAKE OF A SUBSONIC TRANSPORT MODEL"

NASA TM-X-73091, January 1976, NASA Ames Research Center, Moffett Field, CA

Tests were conducted in the Ames Research Center 40- by 80-Foot Wind Tunnel to determine how porosity of wing spoilers on a B-747 airplane would affect the rolling moments imposed on an aircraft

following in the wake. It was found that spoilers with 40 percent porosity and hole diameter to thickness ratio of 1.1 were just as effective in reducing the rolling moment imposed on the follower as solid spoilers, for the case of two spoilers per wing panel (6.4 percent semispan each) with a following model whose span was 20 percent of the span of the generator. When a larger following model was tested, whose span was 50 percent of that of the generator, the effectiveness of the two spoilers per wing was substantially reduced.

"LASER-VELOCIMETER SURVEYS OF MERGING VORTICES IN A WIND TUNNEL - COMPLETE DATA AND ANALYSIS"

NASA Technical Memorandum 78449, 1978, Ames Research Center, Moffett Field, CA

The merger of two corotating vortices was studied with a laser velocimeter designed to measure the two cross-stream components of velocity. Measurements were made at several downstream distances in the vortex wake shed by two semispan wings mounted on the wind tunnel walls. The velocity data provided well-defined contours of crossflow velocity, stream function, and vorticity for a variety of test conditions. Downstream of the merger point, the vorticity was found to be independent of the downstream distance for radii smaller than $r/b=0.05$. For larger radii, the vorticity depended on the distance from the wing. Upstream of the merger point, a multicell vorticity pattern was found.

Corsiglia, V. R., Iversen, J. D. and Orloff, K. L.

"LASER-VELOCIMETER SURVEYS OF MERGING VORTICES IN A WIND TUNNEL"

Journal of Aircraft, Vol. 15, No. 11, November 1978, pp. 762-768

The merger of two vortices was studied with a laser velocimeter designed to measure the two cross-stream components of velocity. Measurements were made at several downstream distances in the vortex wake shed by two semispan wings mounted on the wind tunnel walls. The velocity data provided well-defined contours of cross-flow velocity, stream function, and vorticity. Downstream of the merger point the vorticity was shown to be independent of the downstream distance for small radii. Upstream of the merger point a multicell vorticity pattern was shown.

"AN EXPERIMENTAL INVESTIGATION OF TRAILING VORTICES BEHIND A WING WITH A VORTEX DISSIPATOR"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 229-242

An experimental study was carried out on a rectangular wing in the NASA-Ames 7- by 10-foot Wind Tunnel. Flow visualization studies were made using a tuft grid and smoke. Studies showed that a small vertical panel, termed a vortex dissipater, mounted on the wing upper surface near the wing tip caused

a modification of the vortex. Both the smoke and tuft grid visualization studies indicated that the dissipater caused a significant reduction in the maximum tangential velocities in the trailing vortex. Additional studies using a hot wire anemometer showed significant reductions in the magnitude of the tangential velocities, increases in the cross-sectional dimensions of the core of the dissipated vortex and changes in the turbulence structure. Limited flight tests with a dissipator fitted to a Convair-990 wing tip and using a Lear jet as a probe indicated that the rolling acceleration and the degree of roll control required was less in the modified vortex than in the unmodified vortex.

Corsiglia, V. R., Rossow, V. J. and Ciffone, D. L.

"EXPERIMENTAL STUDY OF THE EFFECT OF SPAN LOADING ON AIRCRAFT WAKES"

Journal of Aircraft, Vol. 13, No. 12, December 1976, pp. 968-973

Measurements of the rolling moment induced on a wing trailing in the wake 13.6 spans behind a subsonic transport model were made in the NASA-Ames 40-by 80-Foot Wind Tunnel. It was found that the rolling moment induced on the trailing wing was reduced substantially by reshaping the span loading on the generating model. This was accomplished by retracting the outboard trailing edge flaps. It was concluded from wind tunnel and water tow facility flow visualization studies that this flap arrangement redistributes the vorticity shed by the wing along the span to form three vortex pairs that interact to disperse the wake.

Corsiglia, V. R., Schwind, R. G. and Chigier, N. A.

"RAPID SCANNING, THREE-DIMENSIONAL HOT-WIRE ANEMOMETER SURVEYS OF WING-TIP VORTICES"

Journal of Aircraft, Vol. 10, No. 12, December 1973, pp. 752-75.

A rapid-rotation arm traversing mechanism with a three-wire, hot-wire anemometer at the tip was developed for surveying trailing vortices whose paths were distorted over long distances by wind-tunnel turbulence. Measurements were obtained behind two geometrically similar rectangular wings up to 31 span lengths in the Ames 40- by 80-foot wind tunnel. Peak tangential velocities normalized by free-stream velocity and lift coefficient decreased from 0.8 at the trailing edge to 0.6 at 31 span lengths downstream while the circulation within the core remained constant. Measured tangential velocity distributions had the same functional form as that determined by Hoffmann and Joubert.

"AERODYNAMIC ANALYSIS OF MULTI-WINGLETS FOR LOW SPEED AIRCRAFT"

27th International Congress of the Aeronautical Sciences, ICAS 2010, September 2010, Nice, France

An analysis of multi-winglets as a device for reducing induced drag in low-speed aircraft is carried out, based on experimental investigations of a wing-body half model at $Re = 40,000$. A baseline and six other different multi-winglets configurations were tested. The device led to 32 percent improvement in

the Oswald efficiency factor, representing an increase of 7 percent in the maximum aerodynamic efficiency. Improvements of 12 percent in the maximum rate of climb and 7 percent in the maximum range were also obtained. The pressure distribution was measured to verify global and local effects of the multi-winglets, showing only a small influence of the device on the wing loading. Structural investigations were also carried out, as well as wake surveys using a seven-hole Pitot probe that indicated significant changes in the flow field near the wingtip.

Costen, R. C.

"NONLINEAR EFFECTS OF THE DRIFT OF BUOYANT VORTICES"

AIAA Paper No. 1971-0604, Palo Alto, CA, 1971

A new equation is formulated for the motion of buoyant free vortices in an inviscid fluid. Such vortices have fluid in the core of lower density than the surrounding fluid. A criterion is given for such vortices to persist. A method is outlined for obtaining approximate solutions of the equation of motion, and results are presented for a number of cases. A horizontal buoyant vortex with positive circulation in an unbounded fluid subject to gravity drifts horizontally toward the left when viewed along its axis. Aircraft trailing vortices, if made buoyant by injection of hot gas into the vortex cores, are shown to approach each other as they descend, unless they are near the ground in which case the ground effect dominates and makes them separate. Twin buoyant vortices of like sense revolve about each other with a slower revolution rate than nonbuoyant twin vortices. Formulas are presented for calculating each of these effects.

Costen, R. C.

"DRIFT OF BUOYANT WING-TIP VORTICES"

Journal of Aircraft, Vol. 9, No. 6, June 1972, pp. 406-412

An exact solution is derived for the trochoidal motion of a single horizontal buoyant vortex drifting under gravity, and a criterion is given for such vortices to persist. Approximate solutions are obtained for the two-dimensional drift of buoyant wing tip vortices descending in a neutrally stable atmosphere where the buoyancy is achieved by injecting hot gas from the engine exhaust or auxiliary burners into the vortex cores. The vortices are found to approach each other as they descend. At low altitudes the effect may accelerate their breakup and thus reduce the period of time when wake from a large aircraft is dangerous to other aircraft. At low altitudes the ground effect may dominate and cause buoyant wing-tip vortices to separate instead of approach each other. A weakly stable atmosphere should increase the buoyancy and the convergence rate of descending wing-tip vortices, and a method is presented for calculating the combined effect of core heating and atmospheric stability.

Costen, R. C.

"AN EQUATION FOR VORTEX MOTION INCLUDING EFFECTS OF BUOYANCY AND SOURCES WITH APPLICATIONS TO TORNADOES"

NASA TN D-5964, October 1970, NASA Langley Research Center, Hampton, VA

A new equation is derived for the motion of vorticity in a general fluid, including the effects of viscosity, compressibility, nonhomogeneity, and nonconservative forces. The equation holds, in particular, for vortices which may not move with the fluid. A linearized form of the equation is applied to tornado cyclones.

Costen, R. C., Davidson, R. E. and Rogers, G. T.

"WIND-TUNNEL TESTS AND COMPUTER SIMULATIONS OF BUOYANT WING-TIP VORTICES"

Proceedings of the Sixth Conference on Aerospace and Aeronautical Meteorology, American Meteorology Society, 1974, pp. 378-386

Wind-tunnel tests have demonstrated that buoyant fluid ejected downstream at a wing tip or flap tip will enter the core of the trailing vortex and cause it to drift horizontally in accordance with the theory for buoyant-core vortices. These tests have also confirmed the results of previous experimenters that sufficiently high injection rates cause the vortices to undergo transition from small laminar cores to diffuse turbulent cores. Also, the thrust of the injection jets for this transition was shown to be less than the induced drag of the wings tested. These results indicated that placing the propulsion engines of a jet aircraft at the wing tips and flap tips would aid in alleviating the aircraft wake (1) by causing the vortices from the two wings to drift toward each other as they descend and thus break up more quickly through the Crow or burst instability, and (2) by making the vortex cores more diffuse and turbulent. Computer simulations showed that buoyant wing-tip vortices in near proximity continue to be driven together despite elongation of the cores parallel to the symmetry plane. They also showed that engine placement is critical if jet exhaust is to drive the vortices together. Random engine placement and buoyancy obtained by descent of the wake in a stable atmosphere will, in general, not promote this drift because the buoyant fluid, while wrapping around the vortices, does not always converge on their cores.

Costen, R. C., Davidson, R. E. and Rogers, G. T.

"WIND-TUNNEL TESTS AND COMPUTER SIMULATIONS OF BUOYANT WING-TIP VORTICES"

Journal of Aircraft, Vol. 13, No. 7, July 1976, pp. 495-499

Wind-tunnel tests have demonstrated that buoyant fluid ejected downstream at a wing tip or flap tip will enter the core of the trailing vortex and cause it to drift horizontally in accordance with the theory for buoyant-core vortices. This result indicates that locating the propulsion engines of a jet aircraft at the wing-tips and/or flap tips would cause the vortices from the two wings to drift toward each other as they descend, and thus break up more quickly through the Crow or burst instability. Two-

dimensional computer simulations showed that engine placement is critical because distributed buoyancy resulting from general engine placement or from descent of the wake in a stable atmosphere does not promote this drift.

Costes, M. and Kowani, G.

"AN AUTOMATIC ANTI-DIFFUSION METHOD FOR VORTICAL FLOWS BASED ON VORTICITY CONFINEMENT"

Aerospace Science and Tech., Vol. 7, No. 1, January 2003, pp. 11-21

This paper describes an automatic Vorticity Confinement procedure in order to conserve vorticity in the resolution of the compressible Euler or Navier-Stokes equations. It is based on the cancellation of the leading truncation error terms in the numerical solution of the vorticity convection equation. Application to the simple case of the convection of a 2D vortex by considering the Euler equations shows that the procedure is adequate, although some problems lie at the vortex center, probably related to the compressible character of the equations and to the singularity associated to the confinement term at the vortex center. Further analysis suggests to consider the specific vorticity instead, thus imposing a corresponding density confinement term. The first results obtained so far indicate that this way of research is promising. However, it is shown that for fine grids, a regularization treatment must also be applied at the center of the vortex because of the Vorticity Confinement singularity. Finally, a first demonstration of the applicability of the method to 3D flows is given for the case of a vortex ring.

Costes, M., Beaumier, P., Bettschart, N., Coppens, G. and Servera, G.

"COMPUTATIONAL TOOLS USED AT ONERA FOR THE DESCRIPTION OF HELICOPTER ROTOR WAKES"

AIAA Paper No. 2000-0113, Reno, NV, January 2000

This paper deals with the aerodynamic methods which are used at ONERA for the computation of helicopter rotor wakes. They are split into two classes: Lagrangian and Eulerian methods. The first class of methods includes the well-known panel methods, which are efficiently used to compute the rotor wake in forward flight, with either a prescribed geometry at high speed or a computed free wake at low speed, for descent and maneuvering conditions. These methods must generally be coupled to Eulerian CFD codes to compute the compressible unsteady flow field, which may introduce losses of accuracy significant for aero-acoustic purposes. Eulerian methods have the advantage to capture the wake, but they are penalized by their numerical diffusion which does not allow to compute the rotor wake accurately enough for aeroacoustics at the present time. However, these methods are sufficiently efficient for computing rotor performance in hover and forward flight. Furthermore, a time averaged technique using an actuator disk approach also allows to efficiently simulate the main features of rotor-fuselage interactions.

Costes, P.

"A MODEL OF THE INFLUENCE OF A VORTEX ON A FOLLOWING AIRCRAFT"

AIAA Paper No. 2000-3981, Denver, CO, August 2000.

The present paper proposes a complete analytical formulation of the interaction between an infinite vortex line, representative of the vortex system generated by a wing tip, and a following aircraft, using the lifting line aerodynamic theory, and a Lamb Oseen vortex flow field model. A quasi-exact analytical expression is obtained, which is rather complex but much more suitable to real-time simulations than the existing strip-theory model, where the wing is divided into a discrete set of wing strips, and where a compromise must be found between model precision (which needs a high number of strips) and real-time capability. The model has been validated by comparison with a wing tunnel test, and proves to be quite representative of the problem.

Cotel, A. J.

"TURBULENCE INSIDE A VORTEX: TAKE TWO"

Physics of Fluids, Vol. 14, No. 8, August 2002, pp. 2933-2934

In this paper, a modified theory based on earlier work on stratified entrainment is proposed to explain the persistence of trailing vortices in the far field. These vortices grow at a laminar rate even though the Reynolds number is high and in the turbulent regime.

Cotel, A. J. and Breidenthal, R. E.

"TURBULENCE INSIDE A VORTEX"

Physics of Fluids, Vol. 11, No. 10, October 1999, pp. 3026-3029

Following Bradshaw's analogy between rotating and stratified flows, the turbulence within a vortex is analyzed using a new model for stratified entrainment. At the vortex radius where the tangential velocity is a maximum, the model predicts that the flow is so strongly 'stratified' that even the smallest turbulent eddies are incapable of transporting fluid there. The growth of the vortex is thus limited by molecular viscosity, even though the vortex Reynolds number is large. The model prediction is compared to experiments in the literature of wingtip vortices. The result is consistent with the remarkable observations of laminar-like growth of this turbulent flow.

"A WIND-TUNNEL BASED STUDY OF HELICOPTER TAIL ROTOR BLADE VORTEX INTERACTION"

Aeronautical Journal, May 2004, pp. 237-244

The interaction of a helicopter tail rotor blade with the tip vortex system from the main rotor is a significant source of noise and, in some flight states, can produce marked reductions in control effectiveness. This paper describes a series of wind-tunnel tests to simulate tail rotor blade vortex interaction with a view to providing data for the development and validation of numerical simulations of the phenomenon. In the experiments, which were carried out in the Argyll wind-tunnel of Glasgow University, a single-bladed rotor located in the tunnel's contraction was used to generate the tip vortex which travelled downstream into the working section where it interacted with a model tail rotor. The tail rotor was instrumented with miniature pressure transducers that measured the aerodynamic response during the interaction. The results suggest that the rotor blade vortex interaction is similar in form to that measured at much higher spatial resolution on a fixed, non-rotating blade. The combination of the two datasets, therefore, provides a valuable resource for the development and validation of predictive schemes.

"ANALYSIS OF MODEL ROTOR BLADE PRESSURES DURING PARALLEL INTERACTION WITH TWIN VORTICES"

Journal of Aircraft, Vol. 42, No. 6, Nov.-Dec. 2005, pp. 1553-1565

This paper presents and analyzes unsteady surface pressures measured on a model rotor blade as the blade experienced near-parallel blade-vortex interaction with a twin-vortex system. To provide a basis for analysis, the vortex system was characterized by hot-wire measurements made in the interaction plane but in the absence of the rotor. The unsteady-pressure response resulting from a single-vortex interaction is then presented to provide a frame of reference for the twin-vortex results. A series of twin-vortex interaction cases are then presented and analyzed. It is shown that the unsteady blade pressures and forces are very sensitive to the inclination angle and separation distance of the vortex pair. When the vortex cores lie almost parallel to the blade chord, the interaction is characterized by a two-stage response associated with the sequential passage of the two cores. Conversely, when the cores lie in a plane that is almost perpendicular to the blade chord, the response is like that of a single-vortex interaction. In all cases, the normal force response is consistent with the distribution of vertical velocity in the flow field of the vortex system. The pitching moment response, on the other hand, depends on the localized suction associated with the vortex cores as they traverse the blade chord.

"HELICOPTER TAIL ROTOR ORTHOGONAL BLADE VORTEX INTERACTION"

Progress in Aerospace Sciences, Vol. 40, 2005, pp. 453-486

The aerodynamic operating environment of the helicopter is particularly complex and, to some extent, dominated by the vortices trailed from the main and tail rotors. These vortices not only determine the form of the induced flow field but also interact with each other and with elements of the physical structure of the flight vehicle. Such interactions can have implications in terms of

structural vibration, noise generation and flight performance. In this paper, the interaction of main rotor vortices with the helicopter tail rotor is considered, and in particular, the limiting case of the orthogonal interaction. The significance of the topic is introduced by highlighting the operational issues for helicopters arising from tail rotor interactions. The basic phenomenon is then described before experimental studies of the interaction are presented. Progress in numerical modelling is then considered and, finally, the prospects for future research in the area are discussed.

"CARACTERISATION ET MODELISATION DU SILLAGE D'UN AVION A PARTIR D'ESSAIS EN VOL DE MAQUETTES EN LABORATOIRE"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 29-1 to 29-12

The paper first describes the experimental technique based on flight tests of scaled models performed in a laboratory. Some tests conducted with an Airbus A-300B2 model are presented. These tests are flow visualizations by means of smoke or helium bubbles. The first elements of a mathematical modelling of the wake behavior which has been developed for flight mechanics purposes and the further developments of this research are described. Finally, some prospecting directions concerning other non-intrusive measurement methods are presented.

Coton, P.

"A NEW FACILITY TO STUDY NEAR TO FAR VORTEX FIELDS"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

With the aim of studying aircraft behavior in the low-speed domain and demonstrating the performances of new concepts the Department for System Control and Flight Dynamics of ONERA has developed over many years a specific experimental method based on flight tests of scaled models performed in a laboratory. To take off the model is propelled by means of a catapult whose height and slope angle have been previously adjusted. Once the model is launched, it flies freely without any wall or mounting interference and is recovered in a volume of plastic foam. The experimental method has the peculiarity to allow the observation and the analysis of the wakes emitted in the ground-based reference frame contrary to the experiments carried out in a wind tunnel. The access to the far field is then possible, which is a very significant asset for this type of facility compared with wind tunnels where the observations are limited to some wing spans. In the new facility B20, considering its larger dimensions in length but also in height, and taking into account the descent speed of the wake, this observation could potentially be carried out on a distance approximately 200 spans before the effect of the ground proximity influences the dynamics of the wake. As an example, this distance represents 8.5 nautical miles behind a A3XX, which largely covers the current separation distances between the planes during the approach and landing phase. The use of this laboratory, which enables gathering, under the

best operating conditions, aerodynamic data which are inaccessible in a wind tunnel, requires for this type of study the implementation of specific measurement equipment. The laser tomography is one of this equipment which makes it possible to obtain images of the flow patterns and to identify according to time the sizes and positions of the emitted vortices. Then knowing the trajectories of these vortices, precise and quantitative measurements of the velocity fields of the sown flow can be carried out by means of the PIV technique (Particle Image Velocimetry). The data thus obtained are of major importance to study and understand the mechanisms which govern the development and the evolution of the wakes. The LIDAR technique enables to use the same tools as during full-scale flight tests. A direct link can thus be established between the observations carried out in the laboratory and the results of flight tests of the plane.

Coton, P.

"STUDY OF ENVIRONMENT EFFECTS BY MEANS OF SCALE MODEL FLIGHT TESTS IN A LABORATORY"

ICAS 1998 Paper 98-3.9.1, Sept. 1998, Melbourne, Australia.

For the purpose of studying aerodynamics and aircraft behavior in the low-speed domain, ONERA has developed over many years a specific experimental method based on flight tests of scale models performed in a laboratory. This method, specially used for the characterization and modeling of the handling qualities of aircraft flying in adverse environmental conditions, is particularly well adapted to the study of non-steady phenomena. This paper first describes the facility and the main aspects of the experimental techniques. The second part is relative to the modelling concepts specially developed to represent dynamic and non-steady aerodynamic effects. These concepts are presented through some applications of the experimental technique. These applications are respectively relative to flight in atmospheric turbulence, static, dynamic and non-steady ground effects and near and far-field characterization of aircraft wake vortices.

Cottet, G.-H. and Poncet, P.

"SIMULATION AND CONTROL OF THREE-DIMENSIONAL WAKES"

Computers and Fluids, Vol. 33, 2004, pp. 697-713

We illustrate the problem of wake optimization on two examples. In the first example, the destruction of trailing vortices, we show that stochastic optimization is a flexible tool to identify vortex systems enhancing natural instabilities. In the second example, the problem of drag reduction in a cylinder wake, a priori information on the flow dynamics is highly desirable and we give some preliminary results which should be useful to select the most efficient parameters in an optimization strategy based on differential rotation of the cylinder.

Cottet, G.-H., Sbalzarini, I., Muller, S. and Koumoutsakos, P.

"OPTIMIZATION OF TRAILING VORTEX DESTRUCTION BY EVOLUTION STRATEGIES"

Proceedings of the Summer Program 2000, Center for Turbulence Research, pp. 75-82

We apply evolution strategies to optimize the instability growth of several pairs of vortices which model the wake of airplanes in landing configuration. For the case of two pairs, the evolution strategy finds a set of optimal parameters strikingly similar to those found in the linear stability analysis of Crouch (1997). The case of four pairs is also considered and leads to a larger distortion of the tip vortex.

Cottin, C., Desenfans, O., Daeninck, G. and Winckelmans, G.

"TOWING-TANK VISUALIZATIONS OF TWO-VORTEX SYSTEMS IN GROUND EFFECT"

AST4-CT-2005-012238, Catholic Univ. of Leuven, Leuven, Belgium, January 2007

The case of a longitudinally developing wake vortex pair generated by a generic wing model is investigated at a moderate, yet significant, Reynolds number through towing tank visualizations. Laser Induced Fluorescence (LIF) visualizations are performed to study qualitatively the dynamics of both the primary vortices and the separating boundary layer at the ground. The configuration is a wake vortex pair generated by a wing model following a constant altitude track, at a constant velocity above a fixed ground. Three different altitudes of wake generation In Ground Effect (IGE) are investigated: $0.5b$, $0.25b$ and $0.125b$. The reference length scale, b , is the vortex spacing as measured experimentally Out of Ground Effect (OGE).

Cottin, C., Lonfils, T., Cocle, R. and Winckelmans, G.

"ROLL-UP OF WING AND PROPELLED-WING WAKES: TIME- AND SPACE-DEVELOPING LES INCLUDING COMPARISONS TO EXPERIMENTS"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008.

A series of numerical investigations dedicated to realistic wing wakes roll-up are presented. High Reynolds number wing and propelled-wing (including cold jets) wakes were considered. Large Eddy Simulations (LES) were performed using the Vortex-In-Cell Parallel Fast Multipole (VIC-PFM) method, an efficient hybrid approach combining Lagrangian and Eulerian methods. In the present approach, the flow past the wing was not computed. Instead, the vortex sheet shed at the trailing edge was used as initial condition. Both time-developing (i.e. longitudinally periodic) and space-developing simulations were performed to evaluate the former simplified approach, widely used to reduce computational costs and to allow the simulation of such complex configurations with classical methods. The present work was organized in three successive parts. First, the effect of the velocity deficit on the roll-up and on the resulting far-field two-vortex system was investigated. A wake model was developed for the initial condition: the axial vorticity component (representative of the induced drag) is obtained by applying Prandtl lifting line theory to an elliptic wing. Second, the dynamics of a propelled wing wake was investigated using the same wake model with two additional cold jets. The characteristics were determined to represent a cruise configuration. Due to the large initial jet/vortex separation distance,

the jets have negligible effects and the dynamics are very similar to the former configuration. Finally, experimental wake data measured behind a four engine powered aircraft half-model, in high-lift configuration, were used to initialize LES of the corresponding complete wake. Instabilities like those obtained with the wake models are observed. In this case, the jet velocity penetrates the vortex core due to the short initial jet/vortex distance.

"PROJECT SOCRATES: A NEW SENSOR TECHNOLOGY FOR ENHANCEMENT OF AVIATION SAFETY AND CAPACITY"

The 2002 FAA Airport Technology Conference, Atlantic City, N. J., May 5-8, 2002

Project SOCRATES is an applied research and development program aimed at exploiting sensing and processing technologies previously developed for military applications. The project objective is enhanced air safety and airport productivity, through remote, long-range detection of potentially hazardous atmospheric phenomena, using the previously untried sensing domain property of acoustics. Potential air safety applications include both ground-based and airborne systems for detecting and warning of such hazardous conditions. Airport productivity would be improved by changing the rules for separating aircraft from wake turbulence to reflect the measured location of these wakes.

Cotton, W. B.

"FOR SPACIOUS SKIES - THE 21st CENTURY PROMISE OF FREE FLIGHT"

AIAA Paper No. 2003-2667, Dayton, OH, July 2003.

The FAA's air traffic modernization programs called Free Flight Phase I and Phase II are worthwhile additions to the air traffic controller's tool kit, but they only scratch the surface of possible improvements to the flexibility and efficiency of flight under Instrument Flight Rules called for in the Free Flight definition. After systematically identifying the sources of delay and inefficiency experienced in today's air traffic management system, new operating concepts are described that overcome the bottlenecks while ensuring the continued safety of flight. Each major operating domain is examined for the delay or inefficiency-causing mechanism; airport surface, terminal area and enroute. The constraints imposed by separation minima, communications, navigation, surveillance, airspace organization and controller workload are each explored and alternative concepts proposed to remove the constraints. A system for mitigating the wake turbulence limitation is described and other airport throughput improvements are also identified. The transition from the current system to a different operating concept is the biggest challenge, and discreet steps to accomplish the transition are proposed, with incentives for aircraft operators to equip with required new onboard capabilities. The benefits to aircraft operators from all user classes, as well as to the air traffic service providers, are described, with an approximation of their value.

Cotton, W. B. and Fine, N. E.

"AIRCRAFT WAKE SAFETY MANAGEMENT SYSTEM"

U.S. Patent 2008/0030375 A1, Feb. 2008

The disclosure is directed toward a method for safely managing aircraft separation. The method comprises a data integration host configured for: receiving aircraft information from a first aircraft; receiving weather data from a weather-monitoring system; combining the aircraft information of the first aircraft with the weather data; formulating a position prediction of a wake vortex located within a critical safety volume of a runway; receiving from a sensor real time wake vortex data to the position prediction to validate the position prediction and to formulate a determination of whether the wake vortex is present in the critical safety volume; and utilizing the determination to transmit spacing data to air traffic control, wherein the spacing data is at least one of standard wake vortex spacing and minimum radar spacing.

"TWO DECADES OF PROGRESS IN SODAR TECHNIQUES: A REVIEW OF 11 ISARS PROCEEDINGS"

Meteorology and Atmospheric Physics, Vol. 85, 2004, pp. 3-19.

For 20 years the biennial symposia organized by the International Society for Acoustic Remote Sensing of the Atmosphere and Oceans and Associated Techniques (ISARS) have been held in different countries. The original papers collected in the proceedings of the symposia reflect the development of ideas, equipment, and methods, plus results obtained in the area. The spectrum of themes discussed at the symposia is broad. More than 60 percent of the papers were devoted to the role of SODARs in atmospheric boundary-layer research. This paper presents an overview of the development of SODAR technique as elucidated in the proceedings of 11 ISARS symposia. Topics include (1) instrumentation, (2) methods of measuring different meteorological quantities and their turbulence characteristics, and (3) validating the methods by comparison of SODAR data with in situ measurements.

"TESTING AND COMPARISON OF LIDARS FOR PROFILE AND TURBULENCE MEASUREMENTS IN WIND ENERGY"

14th International Symposium for the Advancement of Boundary Layer Remote Sensing, IOP Conf. Series: Earth and Environmental Science, Vol. 1, 2008, pp. 012021-1 to 012021-14.

Lidar profilers are beginning to gain a foothold in wind energy. Both currently available commercially systems have been extensively tested at the Hovsore facility in Denmark and valuable insights have been gained. The extensively instrumented facility will be described and some examples of the results given, illustrating the strength and weaknesses of the two contrasting profilers.

"WAKE VORTEX DYNAMICS: FROM CHARACTERISATION TO CONTROL"

Proceedings 3rd ONERA-DLR Aerospace Symposium, Paris, France, June 2001, pp. S1-2/1-14

The aim of this synthesis paper is to briefly sum-up the European research work which is under progress in the Wake Vortex field, regarding essentially dynamical aspects. Thus, these latter will involve characterization of wake vortex evolution and development of ideas for control, destruction or minimization of wake vortices intensity. Such work has been performed, for a large amount, within European projects, internal ONERA and DLR National programs. Emphasis is set upon both experimental and numerical investigations.

Coustols, E., Dor, J-B., Moens, F. and Jacquin, L.

"EXPERIMENTAL CHARACTERISATION OF THE EXTENDED NEAR-FIELD BEHIND A GENERIC-TYPE MODEL AND A VERY LARGE TRANSPORT AIRCRAFT-TYPE MODEL"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

A lot of research has been devoted to study aircraft wake vortices in order to understand their formation and development, to predict their decay and, then, to try to minimize their intensity, to disorganize their far-wake field evolution by suggesting approaches with potential to safely reduce such separation distances. Two experimental investigations have been recently defined and conducted in a low-speed research-type wind tunnel (F2 testing facility from ONERA Centre of Fuga-Mauzac). The steady and unsteady properties of the wake have been scrutinized to few wing spans downstream of the models, using 3D Laser Doppler Velocimetry and hot-wire anemometry. Mean and turbulent quantities, vorticity distributions in the wake as well as vortex trajectories will be provided and discussed in detail for the base line configuration.

Coustols, E., Geffroy, P. and Jacquin, L.

"EXPERIMENTAL CHARACTERISATION OF WAKES IN THE EXTENDED NEAR-FIELD BEHIND GENERIC-TYPE AND TRANSPORT AIRCRAFT-TYPE MODELS"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

To avoid any vortex hazardous encounter, minimum separation distances are imposed to aircraft on airport approach, under instrument flight rules. The separation rules, established in the early 1970's, should be re-examined according to the present and on-going knowledge about wake vortex formation and development. Such distances are a major source for airport congestion and delay, which could be relieved by reducing wake vortex impact on the following aircraft without degrading today's high safety standards. It is therefore mandatory to study aircraft wake vortex in order to understand their formation, development, and far-field behavior, to predict their decay and, then, to try to minimize their intensity, to disorganize or even destroy the vortices by suggesting approaches with potential to

safely reduce the separation distances. Depending upon model scale, the steady properties of the wake have been scrutinized to about five to nine wing spans downstream of the model, using complementary measurement techniques: laser sheet visualizations, hot-film, 5-hole probing and 3D Laser Doppler Velocimetry. The presentation summarizes wake vortex formation and evolution obtained for two specific sets of experiments. Mean and turbulent quantities, vorticity distributions in the wake as well as vortex trajectories will be provided and discussed in detail for the base line configurations. Furthermore, the outcome of the first attempts to control the wake vortices, using either flap and wing tip devices for the A300 model or spoiler type add-on devices for the SWIM model, will be also briefly evoked. It is therefore desirable that the consistent data base, generated from these two experiments, could be devoted to validate CFD tools for wake vortex prediction, within the framework of European projects or outside of them.

Coustols, E., Jacquin, L. and Schrauf, G.

"STATUS OF WAKE VORTEX ALLEVIATION IN THE FRAMEWORK OF EUROPEAN COLLABORATION: VALIDATION ATTEMPTS USING TESTS AND CFD RESULTS"

European Conference on Computational Fluid Dynamics (ECCOMAS CFD 2006), 2006, Technical University of Delft, Delft, The Netherlands.

This document provides a synthesis of recent research studies that have been conducted in the last decade within several European projects from the 5th and 6th Framework Programs. All these studies aimed at a better characterization of aircraft wake vortices and then at their subsequent control. In the latter case, the goal is to minimize the strength of such vortices in the far-field. At first, characterization of wake vortex using complementary tools (testing facilities, flight tests, simulations and theory) will be briefly evoked. Secondly, information will be provided on the main principles for wake vortex alleviation. At last, results and then recommendations will be detailed from the considered practical approaches.

Coustols, E., Jacquin, L., Moens, F. and Molton, P.

"STATUS OF ONERA RESEARCH ON WAKE VORTEX IN THE FRAMEWORK OF NATIONAL ACTIVITIES AND EUROPEAN COLLABORATION"

European Congress on Computational Methods in Applied Sciences and Engineering ECCOMAS 2004, Jyväskylä, Finland, July 2004

This document provides a synthesis of recent experimental research studies conducted at ONERA, aiming at a better characterization of aircraft wake vortex and its control. Thus, either generic, two-engine or four-engine transport aircraft-type models have been considered in existing complementary facilities from ONERA, being the most appropriate for scrutinizing different stages of wake evolution. Main results from several research programs are discussed. They have been obtained both from National and European activities, although emphasis has been set on the 5th Framework Program project 'C-Wake: Wake Vortex Characterization and Control'.

Coustols, E., Labbe, O., Moens, F., Molton, P. and Jacquin, L.

"STATUS OF ONERA RESEARCH ON WAKE VORTEX EVOLUTION AND ALLEVIATION IN THE FRAMEWORK OF NATIONAL ACTIVITIES AND EUROPEAN COLLABORATIONS"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

Projects and research programs dealt with both experimental and numerical investigations to characterize the wake flow field generated by generic very large or standard four-engine large transport-type aircraft models. Highly documented data bases were generated from various facilities up to full-scale flight trials. The different stages of the wake evolution were identified from two complementary ONERA facilities, using the most appropriate measurement techniques: the ONERA DSFM F2 low speed wind tunnel for scrutinizing the wake flow field down to couple of wing spans behind the model (near to extended near-wake field), the ONERA Lille free-flight B10 and B20 catapult facilities for focusing on the wake field more far downstream i.e., between 20 and 100 wing spans behind the model (mid- to far-wake fields). Additionally, means for control or minimizing wake vortex intensity through either devices or concepts have been deeply investigated. From extensive studies in the near- and extended near-wake field at the ONERA F2 wind tunnel, high-lift wing configurations were selected from specific flap arrangement, appropriate for wing loading variations, using a generic four-engine type aircraft model. Such tests confirmed the generation of a rather powerful vortex in the inner part of the wing, either co-rotating or counter-rotating with the ones generated at the outer part of the wing. Tests conducted at the free-flight catapult facilities allowed to show up the real potential of such a wing loading modification for altering vortex trajectories, by creating either closer or wider resulting vortices in the mid-wake field, inducing either larger or weaker descent speed. In parallel to testing campaigns, numerical simulations of the wake-vortex development behind an aircraft in high-lift configuration were performed from the near- to the mid-wake field.

Coustols, E., Prudhomme, S., Mignosi, A. and Destarac, D.

"REAR FUSELAGE FLOW STUDIES ON A MODERN TRANSONIC TRANSPORT AIRCRAFT"

J. Aircraft, Vol. 32, No. 6, November-December 1995, pp. 1183-1190

An experimental program was set up in the CERT/ONERA's T2 wind tunnel, which is transonic, pressurized, and has self-adaptive walls. A 1/80th-scale model of a modern transonic transport aircraft was tested in two configurations: 1) fuselage without horizontal stabilizer and 2) fuselage with horizontal stabilizer. Various measurements were performed: oil-flow visualizations, pressure distributions, boundary-layer surveys along the fuselage symmetry lines using a three-dimensional laser Doppler anemometry system, and wake surveys with both pressure and velocity measurements in a plane downstream of the fuselage base. Moreover, both inviscid and viscous computations were carried out separately under experimental conditions. This article reports a detailed analysis of the computations and experiments conducted on the model in both configurations; the objective of this study was to reach a better understanding of the flows developing along the rear part of a fuselage.

Coustols, E., Seraudie, A. and Mignosi, A.

"REAR FUSELAGE TRANSONIC FLOW CHARACTERISTICS FOR A COMPLETE WING-BODY CONFIGURATION"

J. Aircraft, Vol. 34, No. 3, May-June 1997, pp. 337-345

The study presents results for experiments conducted in the transonic pressurized T2 wind tunnel of Centre d'Etudes et de Recherches de Toulouse. The 1/80th scale model of a modern subsonic transport aircraft was mounted in the test section using a fin-sting. It consisted of a fuselage, a detachable horizontal rear stabilizer, a belly fairing, and tip-truncated wings. The tip-truncated wings were designed by Aerospatiale to reproduce the correct downwash in the rear fuselage region. Tests were conducted at a freestream Mach number of 0.82 and a Reynolds number evaluated with the model chord length of approximately $2.5 \times 1,000,000$. Various measurements were performed, mainly in the vicinity of the fuselage downstream rear part: oil-flow visualizations, pressure distributions, boundary-layer surveys along the fuselage symmetry lines and some lateral lines using a laser Doppler anemometry system, and near-wake surveys with both pressure and velocity measurements. These experiments were designed to allow a fine description of the flows developing along the rear part of a fuselage in a configuration similar to actual flight applications.

"MINIMISED WAKE': A COLLABORATIVE RESEARCH PROGRAMME ON AIRCRAFT WAKE VORTICES"

AIAA Paper No. 2003-0938, Reno, NV, January 2003.

The aim of this paper is to present the Collaborative Research Program on aircraft wake vortices between ONERA and DLR which was launched in 1999. Results of experimental investigations carried out within this framework are provided, with special emphasis set upon very large transport aircraft-type applications.

Cox, C. I., Fairbanks, M. C. and McCulloch, R. A.

"FUNCTIONAL DESIGN SPECIFICATION OF A MODEL OF AIRCRAFT WAKE VORTICES"

TR-92/232, Oct. 1992, Smith System Engineering, UK

This report is the functional design specification for a model of the formation, motion, and decay of aircraft wake vortices. The model will simulate the formation of the vortices behind the wing using a standard implementation of the point vortex method. The effects of engines will be included using additional point vortices with random circulations. After merging into a vortex pair, the properties of the vortices will be extracted to give expressions for the strength, separation, and turbulence level of the vortices. The model will simulate the evolution of the vortex pair by integrating the coupled equations which describe their motion and decay. The method is based on a standard description of

vortex behavior at high altitudes, adapted to take account of the interactions between vortices and the ground.

Cox, G., Billheimer, B., Reisweber, M., Greenhaw, R., Savage, J. and Walls, J.

"REDUCTION OF DIAGONAL SEPARATION FROM 1.5 NAUTICAL MILES TO 1.0 NAUTICAL MILE FOR PARALLEL DEPENDENT APPROACHES"

DOT-FAA-AFS-400-83, February 2014, FAA Flight Technologies and Procedures Division, Oklahoma City, OK.

The Federal Aviation Administration Flight Standards (AFS) Closely Spaced Parallel Operations team evaluated the risk of dual dependent parallel operations associated with reducing the diagonal separation between aircraft from 1.5 Nautical Miles (NM) to 1.0 NM for parallel dependent approaches at runway centerline spacing (RCLS) of 2,500 feet or greater and less than or equal to 4,300 feet. The FAA Safety Management System acceptable level of risk of 0.000000001 per operation was used as the success criteria. The results show that the risk is acceptable up to an RCLS of 3,600 feet when utilizing the final controller to mitigate final approach course deviations and to accommodate reduction of in-trail spacing at the Final Approach Fix.

Craft, T. J., Gerasimov, A. V., Launder, B. E. and Robinson, C. M. E.

"A COMPUTATIONAL STUDY OF THE NEAR-FIELD GENERATION AND DECAY OF WINGTIP VORTICES"

International Journal of Heat and Fluid Flow, Vol. 27, Issue 4, August 2006, pp. 684-695

The numerical prediction of the downstream trailing vortex shed from an aircraft wingtip is a particularly challenging CFD task because, besides predicting the development of the strong vortex itself, one needs to compute accurately the flow over the wing to resolve the boundary layer roll-up and shedding which provide the initial conditions for the free vortex. Computations are here reported of the flow over a NACA 0012 half-wing with rounded wing tip and the near-field wake as measured by Chow, J. S., Zilliac, G., Bradshaw, P., 1997. The aim is to assess the performance of two turbulence models which, in principle, might be seen as capable of resolving both the three-dimensional boundary layer on the wing and the generation and near-field decay of the strongly accelerated vortex that develops from the wingtip. Results using linear and non-linear eddy-viscosity models are presented, but these both exhibit a far too rapid decay of the vortex core. Only a stress-transport (or second-moment) model that satisfies the 'two-component limit' reproduces the principal features found in the experimental measurements.

Craft, T., Iacovides, H., Launder, B. and Zacharos, A.

"SOME SWIRLING-FLOW CHALLENGES FOR TURBULENT CFD"

Flow Turbulence Combustion, Vol. 80, 2008, pp. 419-434.

This paper examines some of the continuing challenges, within a RANS framework, of computing turbulent swirling flows such as are encountered in industry and the environment. The principal focus is on modeling turbulent transport processes but serious problems also arise in handling numerical issues, too. Recent researches of two of these types of flow by the authors and their colleagues are examined; namely, the confined flow within a rotor-stator disc cavity and the trailing wing-tip vortex. The former flow, while geometrically axisymmetric, has been found to create multiple rotating vortices necessitating a three-dimensional time-dependent analysis. The wing-tip vortex is extremely sensitive to the choice of turbulence model and only a second-moment closure that complies with constraints of two-component turbulence has been found capable of handling both the flow over the wing and the wake vortex. Moreover, because of the large distances downstream of the aircraft to which, for practical cases, computations need to be carried, the numerical strategy is brought into question. Finally, arising from these two test cases, outline remarks are made about a swirling flow that poses one of the major computational challenges of the twenty-first century.

"ANALYSIS OF AIRCRAFT LATERAL PATH TRACKING ACCURACY AND ITS IMPLICATIONS FOR SEPARATION STANDARDS"

2013 Integrated Communications Navigation and Surveillance (ICNS) Conference, April 2013, Herndon, VA.

Application of Area Navigation (RNAV) and Required Navigation Performance (RNP) to aircraft separation continues to be a point of difficulty which frequently centers on defining statistical models for Performance-Based Navigation (PBN). Given that questions of the statistics associated with position estimation error are fairly well known, and that path definition error is near zero in modern RNP avionics, this paper will focus on path steering error, which has not been studied using operational data. We propose analysis methods that can be applied to analyzing large volumes of recorded, in-service data to answer the questions of statistical modeling for the path following behavior of these systems. Preliminary analysis results derived from partner airlines' RNAV and RNP equipped aircraft flying in revenue service are presented.

"AN INVESTIGATION OF VORTEX BREAKDOWN AT MACH 2"

CoA Note Aero 158, November 1963, Cranfield University, Cranfield, Bedfordshire, UK.

Wind tunnel tests have been made at $M = 2$ on a 75 deg swept delta wing to study the progressive breakdown of the leading-edge vortices, which occurs at high incidence. The incidence at which vortex breakdown occurred at supersonic speeds was somewhat less than at low speeds, but the pattern of breakdown appeared to be similar, although the spiraling region of flow is much larger at supersonic speeds. Quite slender objects placed downstream of the wing had appreciable upstream effects,

causing vortex breakdown to move upstream by as much as 20% of the root chord for the same incidence.

Credeur, L.

"BASIC ANALYSIS OF TERMINAL OPERATION BENEFITS RESULTING FROM REDUCED VORTEX SEPARATION MINIMA"

NASA TM 78624, October 1977, NASA Langley Research Center, Hampton, VA

The impact of reducing the wake vortex minimum separation required behind heavy jets on terminal area operation rate was analyzed. The effect on arrival saturation and steady state average delay was determined for various percentages mix of heavy and large jet traffic samples operating under various precision of interarrival spacing. Benefits increase with percentage of heavy aircraft and with precision of control. These results demonstrate the payoff possible from research to reduce the severity of the trailing vortex by aerodynamic means.

"PROCEEDINGS OF THE NASA FIRST WAKE VORTEX DYNAMIC SPACING WORKSHOP"

NASA/CP-97-206235, November 1997, NASA Langley Research Center, Hampton, VA

A Government and Industry workshop on wake vortex dynamic spacing systems was conducted on May 13-15, 1997, at the NASA Langley Research Center. The purpose of the workshop was to disclose the status of ongoing NASA wake vortex R&D to the international community and to seek feedback on the direction of future work to assure an optimized research approach. Workshop sessions examined wake vortex characterization and physics, wake sensor technologies, aircraft/wake encounters, terminal area weather characterization and prediction, and wake vortex systems integration and implementation. A final workshop session surveyed the Government and Industry perspectives on the NASA research underway and related international wake vortex activities. This document contains the proceedings of the workshop including the presenters' slides, the discussion following each presentation, the wrap-up panel discussion, and the attendees' evaluation feedback.

"IN-FLIGHT MEASUREMENT SYSTEM FOR WAKE VORTEX VELOCITY FIELDS"

XXV General Assembly, European Geophysical Society, Nice, France, April 2000

The Research Aircraft DO 128-6 of the TU Braunschweig is capable of measuring pilot inputs, flight path and aircraft reactions while encountering wake vortices. The aircraft is equipped with flow direction probes on a nose boom, at the wing tips and the vertical fin for measurements of a wake vortex field. DGPS is used to determine the exact position behind the vortex generating aircraft. With

the measured vortex position and strength, it is possible to validate numeric models for wake vortices and wake vortex encounters.

Crescenti, G. H.

"THE DEGRADATION OF DOPPLER SODAR PERFORMANCE DUE TO NOISE: A REVIEW"

Atmospheric Environment, Vol. 32, No. 9, 1998, pp. 1499-1509

Ambient background noise is a common problem for poor Doppler sodar performance. This noise can be active or passive and broad-band or narrow-band. Active broad-band noise decreases the sounding range of the sodar by decreasing the signal-to-noise ratio. Active narrow-band noise can be interpreted as erroneous wind values. Passive noise sources are objects which reflect the transmitted acoustic pulse back to the sodar with zero Doppler shift. Use of acoustic shielding is discussed as a method of noise pollution control by isolating the side lobe energy of the transmitted acoustic pulse. At the same time, these acoustic shields are effective in blocking out active ambient background noise. Previous studies which experienced noise interference are shown as examples of problems that are frequently encountered.

Crick, P.

"EVALUATION OF TWO HAZARD IDENTIFICATION TECHNIQUES IN THE CONTEXT OF TIME BASED AIRCRAFT SEPARATIONS"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

Up to now, no research project at the Eurocontrol Experimental Centre (EEC) impacting Air Traffic Management (ATM) has been accompanied by a formal safety assessment. This is to change as in future all such projects must be ESARR4 compliant. The need arises therefore to find one or more suitable methodologies that can be used to demonstrate that a project is ESARR4 compliant. In essence, this requires that risks be identified and assessed and corresponding mitigating actions be defined. The EATM Safety Assessment Methodology (SAM) is one possible means to demonstrate that a project complies with ESARR4. It aims at recommending one or more suitable techniques depending on the nature and status of the project in question. A survey of over 600 safety methodologies has recently been carried out and several suitable candidate methodologies have been identified. Two of these methodologies were selected for an in-depth evaluation focusing on human factors (people and procedures) elements: HAZOP (HAZard and Operability study) and TRACEr (Technique for the Retrospective and Predictive Analysis of Cognitive Errors in ATM). These were applied to three current projects at the EEC. One of these projects was the Time-Based Separations project. Both methodologies were found to have their applications: HAZOP could be recommended to be used at an early stage of a project to refine the concept whereas TRACEr could be used to analyze core tasks and to identify critical, high level errors as well as to contribute towards refining operational procedures.

Crider, D. A.

"THE NEED FOR UPSET RECOVERY TRAINING"

AIAA Paper 2008-6864, August 2008, Honolulu, Hawaii.

Several aviation accidents have occurred over the years, many in this decade, which have involved upsets from normal flight. Sometimes these upsets occurred slowly without the pilot noticing the departure until reaching an unusual attitude. Others occurred abruptly, such as those caused by a stall, whether early due to icing or other environmental factors, or at the normal point due to human action or inaction. Other abrupt departures have been caused by mechanical factors or environmental factors, such as aircraft wakes. Given the potentially serious consequences of such upsets, the ability to recover is an important part of pilot training. Accordingly, a comprehensive, well-conceived training program will necessarily address the various types of upset scenarios that may lead to accidents, the need to avoid negative transfer of training and, for accidents involving stalls, the need to accommodate simulator model aerodynamic data envelope limitations. Many, if not most, upsets remain within the aerodynamic data envelope such that current aerodynamic model limits would not be exceeded when these scenarios are simulated. Motion cueing is another issue for many upset training scenarios. This paper will present short case studies of several upset aircraft accidents and incidents, classified to gain insight into the training requirement for each scenario. The history of related National Transportation Safety Board recommendations and actions to date will also be discussed.

"VORTEX PERTURBATION DYNAMICS"

ICASE Report No. 95-52, Hampton, VA, July 1995

An initial value approach is used to examine the dynamics of perturbations introduced into a vortex under strain. Both the basic vortex considered and the perturbations are taken as fully three-dimensional. An explicit solution for the time evolution of the vorticity perturbations is given for arbitrary initial vorticity. Analytical solutions for the resulting velocity components are found when the initial vorticity is assumed to be localized. For more general initial vorticity distributions, the velocity components are determined numerically. It is found that the variation in the radial direction of the initial vorticity disturbance is the most important factor influencing the qualitative behavior of the solutions. Transient growth in the magnitude of the velocity components is found to be directly attributable to the compactness of the initial vorticity.

Crisp, V. K.

"WAKE VORTEX SYSTEMS COST/BENEFITS ANALYSIS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 509-519

The goals of cost/benefit assessments are to provide quantitative and qualitative data to aid in the decision-making process. Benefits derived from increased throughput (or decreased delays) are used to balance life-cycle costs. Packaging technologies together may provide greater gains (demonstrate higher return on investment).

Critchley, J. B.

"WAKE VORTEX: THE PROGRAMME IN THE UNITED KINGDOM"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 6-1 - 6-13

The UK program of work can be divided into three broad subject areas. The first area is the monitoring of the existing criteria. This has been done through the UK wake vortex incident reporting scheme and the associated database. The second area covers techniques or devices which would make use of the existing basic theoretical and practical understanding of wake vortex behavior and parameters. Lasers and radar are being investigated to see if the controller can be provided with information on vortices to help decide whether criteria can or cannot be relaxed. The third area considers longer term objectives such as increasing the number of categories of aircraft and providing computer assistance to controllers.

Critchley, J. B. and Foot, P. B.

"UNITED KINGDOM CIVIL AVIATION AUTHORITY WAKE VORTEX DATABASE: ANALYSIS OF INCIDENTS REPORTED BETWEEN 1982 AND 1990"

CAA Paper 91015, August 1991, Civil Aviation Authority, London, UK.

The report analyses wake vortex incidents reported to the Civil Aviation Authority between 1982 and 1990, focusing on Heathrow approaches. The analysis covers incident rates related to month of the year, traffic levels, aircraft separations, periods of the day and wind conditions; the occurrence rates for various leader and follower aircraft types are given, and the need for a review of separation standards is identified.

Critchley, J. B. and Foot, P. B.

"UNITED KINGDOM CIVIL AVIATION AUTHORITY WAKE VORTEX DATABASE: ANALYSIS OF INCIDENTS REPORTED BETWEEN 1982 AND 1990"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 8-1 - 8-18

The objective of this paper is to report the results of an analysis of the UK Wake Vortex Incident Database. The United Kingdom Civil Aviation Authority (CAA) has been operating a scheme since 1972 for the reporting, monitoring, and analysis of wake vortex incidents. The data for each incident come

from several sources: initially from the pilots of the leader and follower aircraft involved in an incident, the UK Meteorological Office, digitally recorded radar data from Air Traffic Control Centers and, in some cases, from the flight data recorders of the aircraft involved. The wake vortex database was computerized in 1983 and the details of each incident were recorded on the database, which is currently maintained by the CAA's ATC Evaluation Unit. Since 1982, the UK has used 4 wake vortex weight categories instead of the 3 categories used by ICAO. Because the wake vortex separation criteria for use in the UK were last changed in 1982, the analysis has been confined to the period 1982 to 1990. In this period there were 515 incidents, 392 of which occurred on the approach to Heathrow.

"SWIRL MEASUREMENTS IN A MOTOR CYLINDER"

Experiments in Fluids, Vol. 26, 1999, pp. 542-548.

The present article analyzes different definitions of the swirl number and their application to control the mixing process in the cylinder of direct injection diesel engines. We first discuss the origins of the existing methods used to control swirl, which are usually based on the presence of a stirring device, or rotometer, in the cylinder head. A new possibility is then proposed for determining the swirl number, based on equivalent angular velocity, and a comparison made of results obtained using the different techniques available for measuring swirl in motor cylinders.

"EVALUATION OF FLIGHT SPOILERS FOR VORTEX ALLEVIATION"

Journal of Aircraft, Vol. 14, No. 8, August 1977, pp. 823-825

The strong vortex wakes generated by large transport aircraft are a potential hazard to smaller aircraft, and so NASA is involved in a program of model tests, flight tests, and theoretical studies to determine the feasibility of reducing this hazard by aerodynamic means. This note summarizes the wind tunnel and full-scale flight investigations of the flight spoilers that exist on the wide-bodied transport jet aircraft when used as trailing vortex hazard alleviation devices. Existing flight spoilers on the B-747 airplane were found to be effective as trailing vortex attenuators.

Croom, D. R.

"LOW-SPEED WIND-TUNNEL PARAMETRIC INVESTIGATION OF FLIGHT SPOILERS AS TRAILING-VORTEX-ALLEVIATION DEVICES ON A TRANSPORT AIRCRAFT MODEL"

NASA TP-1419, April 1979, NASA Langley Research Center, Hampton, VA

An investigation was made in the Langley V/STOL tunnel to determine, by the trailing-wing sensor technique, the effectiveness of 11 combinations of the existing flight-spoiler segments on a jumbo-jet transport aircraft model when they were deflected as trailing-vortex-alleviation devices. All 11 of the flight-spoiler configurations investigated were effective in reducing the induced rolling moment on the trailing model by as much as 18 to 67 percent at a distance of 7.8 transport wing spans behind the transport aircraft model. The present investigation is an extension of earlier wind-tunnel and flight tests which showed that the existing flight spoilers on the jumbo-jet aircraft can be used as effective trailing-vortex-alleviation devices. Essentially all the reduction in induced rolling moment on the trailing-wing model was realized at a spoiler deflection of 45 deg. for single-spoiler configurations, 30 deg. for two-spoiler configurations, and 15 deg. for both the three- and four-spoiler configurations. Of the 11 flight-spoiler configurations investigated, the most promising configuration for trailing-vortex abatement on the jumbo-jet aircraft appears to be the three inboard flight spoilers deflected 15 deg. This configuration reduced induced rolling moment on the trailing-wing model by 65 percent and increased drag coefficient on the transport aircraft model by about 0.012 at a trim lift coefficient of 1.2.

Croom, D. R.

"LOW-SPEED WIND-TUNNEL INVESTIGATION OF FORWARD-LOCATED SPOILERS AND TRAILING SPLINES AS TRAILING-VORTEX HAZARD-ALLEVIATION DEVICES ON AN ASPECT-RATIO-8 WING MODEL"

NASA TM X-3166, February 1975, NASA Langley Research Center, Langley Station, VA

An investigation was made in the Langley V/STOL tunnel to determine, by the trailing-wing sensor technique, the effectiveness of either a forward-mounted spoiler or a tip-mounted spline as trailing-vortex attenuation devices on an upswept aspect-ratio-8 wing model. The trailing-wing rolling-moment data taken in the tunnel diffuser section show good agreement with the data taken in the tunnel test section. This agreement indicates that reasonable results may be obtained in the Langley V/STOL tunnel in experimental investigations of the trailing-vortex hazard at relatively great distances behind aircraft models.

Croom, D. R.

"THE DEVELOPMENT AND USE OF SPOILERS AS VORTEX ATTENUATORS"

Proceedings Wake Vortex Minimization Symposium, NASA, SP-409, 1977, pp. 339-368

This paper presents the results of ground-based and flight investigations performed at NASA to develop spoilers as trailing vortex alleviation devices. Based on the results obtained in these investigations, it was found that the induced rolling moment on a trailing model can be reduced by

spoilers located near the mid-semispan of a vortex-generating wing. Substantial reductions in induced rolling moment occur when the spoiler vortex attenuator is located well forward on both unswept and swept wing models. In addition, it was found that existing flight spoilers on the jumbo-jet transport aircraft can be effective as trailing vortex attenuators.

Croom, D. R.

"DEVELOPMENT OF SPOILERS AS TRAILING-VORTEX HAZARD ALLEVIATION DEVICES"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 217-228

This paper presents the results of ground-based and flight investigations that have been performed at NASA for the purpose of development of spoilers as trailing-vortex hazard alleviation devices. Based on the results obtained in these investigations, it was found that the induced rolling moment on a trailing model can be reduced by spoilers located near the mid-semispan of a vortex-generating wing. Substantial reductions in induced rolling moment occur when the spoiler vortex attenuator is located well forward on both unswept and swept wing models. In addition, it was found by ground-based model tests and verified by full-scale flight tests that the existing flight spoilers on the B-747 aircraft are effective as trailing vortex attenuators. Based on the results of wind-tunnel investigations of the DC-10-30 and L-1011 airplane models, the existing flight spoilers on both the DC-10-30 and L-1011 airplanes may also be effective trailing vortex attenuators.

Croom, D. R. and Dunham, Jr., R. E.

"LOW-SPEED WIND-TUNNEL INVESTIGATION OF SPAN LOAD ALTERNATION, FORWARD-LOCATED SPOILERS, AND SPLINES AS TRAILING-VORTEX-HAZARD ALLEVIATION DEVICES ON A TRANSPORT AIRCRAFT MODEL"

NASA TN D-8133, December 1975, NASA Langley Research Center, Hampton, V.

An investigation was made in the Langley V/STOL tunnel to determine the effectiveness of a forward-located spoiler, a spline, and a span load alteration due to a flap configuration change as trailing-vortex-hazard alleviation methods. For the transport aircraft model in the normal approach configuration, the results indicate that either a forward-located spoiler or a spline is effective in reducing the trailing-vortex hazard. The results also indicate that large changes in span loading, due to retraction of the outboard flap, may be an effective method of reducing the trailing-vortex hazard.

Croom, D. R. and Holbrook, G. T.

"LOW-SPEED WIND-TUNNEL INVESTIGATION OF WING FINS AS TRAILING-VORTEX-ALLEVIATION DEVICES ON A TRANSPORT AIRPLANE MODEL"

NASA TP-1453, June 1979, NASA Langley Research Center, Hampton, VA

An investigation was made in the Langley V/STOL tunnel to determine, by the trailing-wing sensor technique, the trailing-vortex-alleviation effectiveness of both a one- and a two-fin configuration (semicircular with a radius of 0.043 semispan) on a jumbo-jet transport airplane model in its landing configuration. The fins were located on the upper surface of the transport model wing along the 30-percent-chord line. The fin configurations were effective in reducing the vortex-induced rolling moment, by amounts varying from 28 to 60 percent, on the trailing wing model located at a distance of 7.8 transport model wing spans downstream of the transport model. The flow over the fins and over the transport airplane model wing downstream of the fins was observed to be separated and turbulent. All fin configurations caused a reduction in maximum lift coefficient, a positive increment in drag coefficient, and an increment in nose-up pitching-moment coefficient on the transport airplane model.

Croom, D. R., Vogler, R. D. and Thelander, J. A.

"LOW-SPEED WIND-TUNNEL INVESTIGATION OF FLIGHT SPOILERS AS TRAILING-VORTEX-ALLEVIATION DEVICES ON AN EXTENDED-RANGE WIDE-BODY TRI-JET AIRPLANE MODEL"

NASA TN D-8373, December 1976, NASA Langley Research Center, Hampton, VA

An investigation was made in the Langley V/STOL tunnel to determine, by the trailing-wing sensor technique, the effectiveness of various segments of the existing flight spoilers on an extended-range wide-body tri-jet transport airplane model when they were deflected as trailing-vortex-alleviation devices. On the transport model with the approach flap configuration, the four combinations of flight-spoiler segments investigated were effective in reducing the induced rolling moment on the trailing wing model by as much as 25 to 45 percent at downstream distances behind the transport model of 9.2 and 18.4 transport wing spans. On the transport airplane model with the landing flap configuration, the four combinations of flight-spoiler segments investigated were effective in reducing the induced rolling moment on the trailing wing model by as much as 35 to 60 percent at distances behind the transport model of from 3.7 to 18.4 transport wing spans, 18.4 spans being the downstream limit of distances used in this investigation.

Croom, D. R., Vogler, R. D. and Williams, G. M.

"LOW-SPEED WIND-TUNNEL INVESTIGATION OF FLIGHT SPOILERS AS TRAILING-VORTEX-ALLEVIATION DEVICES ON A MEDIUM-RANGE WIDE-BODY TRI-JET AIRPLANE MODEL"

NASA TN D-8360, November 1976, NASA Langley Research Center, Hampton, VA

An investigation was made in the Langley V/STOL tunnel to determine, by the trailing-wing sensor technique, the effectiveness of various segments of the existing flight spoilers on a medium-range wide-body tri-jet transport airplane model when they were deflected as trailing-vortex-alleviation devices. The four combinations of flight-spoiler segments investigated were effective in reducing the induced rolling moment on the trailing wing model by as much as 15 to 60 percent at distances behind the transport model of from 3.9 to 19.6 transport wing spans, 19.6 spans being the downstream limit

of distances used in this investigation. Essentially all of the reduction in induced rolling moment on the trailing wing model was realized at a spoiler deflection of about 45 degrees.

Crouch, J.

"AIRPLANE TRAILING VORTICES AND THEIR CONTROL"

C. R. Physique, Vol. 6, 2005, pp. 487-499

Airplane trailing vortices are examined under natural and forced conditions. Control strategies are presented, which aim to reduce the potential for severe upsets resulting from encounters with the vortices. These range from passive control, using span-load modifications, up to active control, using control-surface oscillation. Flight-simulator results are used to judge the effectiveness of the different control strategies. Active control is shown to be effective for breaking up the trailing vortices, and for reducing the potential for severe vortex-encounter upsets. Stability theory is used to explain the mechanisms underlying this form of control.

Crouch, J. D.

"INSTABILITY AND TRANSIENT GROWTH FOR TWO TRAILING-VORTEX PAIRS"

J. Fluid Mech., Vol. 350, November 1997, pp. 311-330

The stability of two vortex pairs is analyzed as a model for the vortex system generated by an aircraft in flaps-down configuration. The co-rotating vortices on the starboard and port sides tumble about one another as they propagate downward. This results in a time-periodic basic state for the stability analysis. The dynamics and instability of the trailing vortices are modelled using thin vortex filaments. Stability equations are derived by matching the induced velocities from Biot-Savart integrals with kinematic equations obtained by temporal differentiation of the vortex position vectors. The stability equations are solved analytically as an eigenvalue problem, using Floquet Theory, and numerically as an initial value problem. The instabilities are periodic along the axes of the vortices with wavelengths that are large compared to the size of the vortex cores. The results show symmetric instabilities that are linked to the long-wavelength Crow instability. In addition, new symmetric and antisymmetric instabilities are observed at shorter wavelengths. These instabilities have growth rates 60-100% greater than the Crow instability. The system of two vortex pairs also exhibits transient growth which can lead to growth factors of 10 or 15 in one-fifth of the time required for the same growth due to instability.

Crouch, J. D.

"STABILITY OF MULTIPLE TRAILING-VORTEX PAIRS"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 17-1 to 17-8

The stability of two vortex pairs is analyzed as a model for the vortex system generated by an aircraft in flaps-down configuration. The co-rotating vortices on the starboard and port sides tumble about one another as they propagate downward. This results in a time-periodic basic state. The instabilities are periodic along the axes of the vortices with wavelengths that are large compared to the size of the vortex cores. The results show symmetric instabilities that are linked to the long-wavelength Crow instability. In addition, new symmetric and antisymmetric instabilities are observed at shorter wavelengths. These instabilities have growth rates 60-100% greater than the Crow instability. The system of two vortex pairs also exhibits transient growth which can lead to growth factors of 5 or 10 in one fourth of the time required for the same growth due to instability.

Crouch, J. D.

"INSTABILITY AND TRANSIENT GROWTH FOR TWO TRAILING-VORTEX PAIRS"

AIAA Paper No. 1997-0062, Reno, NV, January 1997

Two trailing-vortex pairs are studied as a model for the vortex system generated by an aircraft in a flaps-down high-lift configuration. The co-rotating vortices on the starboard and port sides tumble about one another as they propagate downward. This results in a time-periodic basic state for the stability analysis. The dynamics and instability of the trailing vortices are modeled using thin vortex filaments. Stability equations are derived by matching the induced velocities from Biot-Savart with kinematic equations obtained by temporal differentiation of the vortex position vectors. The stability equations are solved analytically as an eigenvalue problem, using Floquet theory, and numerically as an initial value problem. The instabilities are periodic along the axes of the vortices with wavelengths that are large compared to the size of the vortex cores. The results show symmetric instabilities that are linked to the long-wavelength Crow instability. In addition, new symmetric and antisymmetric instabilities are observed at shorter wavelengths. These instabilities have growth rates 60-100% greater than the Crow instability. The system of two vortex pairs also exhibits transient growth which can lead to growth factors of 5 or 10 in one-fourth of the time required for the same growth due to instability.

Crouch, J. D.

"FORCING THE BREAKUP OF AIRPLANE TRAILING VORTICES"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

Boeing is working to develop an active system to break up the trailing vortices within a prescribed distance that is less than some current airplane separation distances. Airplane control surfaces are used to force flaps-down vortex instabilities that lead to the breakup of the vortices into vortex rings. The concept has been tested in a towing tank using a simplified flaps-down model. Breakup into vortex rings was achieved with a moderate level of forcing at a distance of about 2.5 to 3 nmi. behind the airplane (when scaled to flight for a 747 airplane). The experimental results are in general agreement

with numerical simulations. The performance of the active system depends on details of the airplane configuration (e.g., the flap system and horizontal tail loading). Ongoing efforts are aimed at determining a simple set of parameters that can be used to predict the effectiveness of the system for a given configuration. Before such a system can be implemented, there are a number of issues that must be addressed. These issues can be grouped into active-airplane issues, following-airplane issues, and airport-environment issues. The most obvious issues for the active airplane are the potential impact on ride quality, dynamic-load effects on the structure, and the ability to maintain control authority during operation. In terms of the following airplane, the primary question is at what stage in the breakup can the vortices be considered benign. Airport-environment issues include determining how the breakup is affected when the vortices are near the ground, what are the effects of atmospheric stratification and shear winds, and how can the total system reliability be demonstrated to such a high level that rules can be changed.

Crouch, J. D. and Czech, M. J.

"ASSESSING WAKE TURBULENCE CHARACTERISTICS FOR COMMERCIAL AIRCRAFT"

AIAA Paper 2016-3133, June 2016, Washington, DC.

The strength of trailing vortices at distances of following aircraft has become a key metric for assessing safe separations between aircraft in the airport terminal area. Different methods for determining wake strength are discussed and compared. A computational fluid dynamics approach is described in detail, consisting of an initialization stage and an evolution stage. The initialization is based on a full-configuration analysis as would be done for assessing the airplane configuration performance. The wake evolution takes advantage of quad-three-dimensional approximations resulting in greater efficiency, which allows the simulation of the wake to times equivalent to several miles behind the aircraft. Both initialization and wake evolution results are shown to be in good agreement with wind-tunnel measurements in the near field. The far-field wake simulations are found to be in good agreement with flight data for some of the key metrics governing the far-field wake strength.

Crouch, J. D. and Spalart, P. R.

"ACTIVE SYSTEM FOR EARLY DESTRUCTION OF TRAILING VORTICES"

Patent 6,082,679, 4 July 2000, Boeing Company, Seattle, WA

An active control method and apparatus for encouraging the early destruction of trailing vortices formed by a lifting body having at least two control surfaces on each side and creating multiple vortex pairs is provided. The method includes actuating the control surfaces in a manner leading to the direct excitation of one or more of the Transient Growth Mechanism, the Short Wavelength Instability, the Long Wavelength Instability, and the Crow Instability to result in the accelerated breakup of the trailing vortices. A method of selecting control parameters in an active control system includes identifying the near-field vorticity distribution of the aircraft, selecting at least one amplification mechanism for

distorting the trailing vortices, determining amplitudes and wavelengths for imposed vortex perturbations, simulating trailing vortex evolutions, determining effectiveness of perturbations and amplification mechanisms, determining vortex positions as a function of control surface deflections, and determining control parameters to govern the movement of the wing control surfaces.

Crouch, J. D., Miller, G. D. and Spalart, P. R.

"ACTIVE-CONTROL SYSTEM FOR BREAKUP OF AIRPLANE TRAILING VORTICES"

AIAA Journal, Vol. 39, No. 12, December 2001, pp. 2374-2381

Wing control surfaces are used to trigger the breakup of trailing vortices behind aircraft in a flaps-down configuration. In the near field of the aircraft there are multiple pairs of vortices, which admit new instability mechanisms that do not exist on a single pair of vortices. A periodic motion of the control surfaces is used to introduce a unique form of perturbation that is amplified in the multiple vortex-pair system but conserves total circulation, lift, and rolling moment. Growth of the perturbations leads to the periodic pinching of the starboard and port vortices into a series of vortex rings. The concept is demonstrated using numerical simulations and towing-tank experiments. Results show that the system breaks up the trailing vortices more rapidly than a comparable excitation of the Crow instability on a single pair of vortices. The overall effectiveness of the system depends on the airplane configuration, namely, details of the flap system and the horizontal tail.

Crouch, J., Miller, G. and Spalart, P.

"DEVELOPMENT OF AN ACTIVE SYSTEM TO BREAK UP TRAILING VORTICES BEHIND COMMERCIAL AIRPLANES"

Boeing Aero, April 2001, pp. 24-31

Boeing is developing a system that shows promise for breaking up trailing vortices behind flaps-down commercial airplanes within distances less than some current approach separations. The system uses control surfaces to cyclically shift a small fraction of the lift between inboard and outboard sections of the wing to trigger wake instabilities that destroy the vortices. The system has been demonstrated in ground-based testing, but outstanding technical issues are still being addressed and the system must be validated in flight. Along with continued technical success, future development and use of the system will require broad industry and regulatory support.

Crow, S. C.

"STABILITY THEORY FOR A PAIR OF TRAILING VORTICES"

D1-82-0918, September 1969, Boeing Scientific Research Laboratories, Seattle, WA.

Trailing vortices do not decay by simple diffusion. Usually, they undergo a symmetric and nearly sinusoidal instability, until eventually they join at intervals to form a train of vortex rings. The theory

accounts for the instability during the early stages of its growth. The vortices are idealized as interacting lines; their core diameters are considered by a cut-off in the line integral representing self-induction. The equation relating induced velocity to vortex displacement gives rise to an eigenvalue problem for the growth rate of sinusoidal perturbations. Stability is found to depend on the products of vortex separation (b) and cut-off distance (d) times the perturbation wavenumber. Depending on those products, both symmetric and antisymmetric eigenmodes can be unstable, but only the symmetric mode involves strongly interacting long waves. An argument is presented that $d/b = 0.07$ for the vortices trailing from an elliptically loaded wing.

Crow, S. C.

"STABILITY THEORY FOR A PAIR OF TRAILING VORTICES"

AIAA Journal, Vol. 8, No. 12, December 1970, pp. 2172-2179

Trailing vortices do not decay by simple diffusion. Usually, they undergo a symmetric and nearly sinusoidal instability, until eventually they join at intervals to form a train of vortex rings. The present theory accounts for the instability during the early stages of its growth. The vortices are idealized as interacting lines; their core diameters are considered by a cutoff in the line integral representing self-induction. The equation relating induced velocity to vortex displacement gives rise to an eigenvalue problem for the growth rate of sinusoidal perturbations. Stability is found to depend on the products of vortex separation b and cutoff distance d times the perturbation wavenumber. Depending on those products, both symmetric and antisymmetric eigenmodes can be unstable, but only the symmetric mode involves strongly interacting long waves. An argument is presented that $d/b = 0.063$ for the vortices trailing from an elliptically loaded wing. In that case, the maximally unstable long wave has a length $8.6b$ and grows by a factor e in a time $9.4(AR/CL)$ times (b/V) , where AR is the aspect ratio, CL is the lift coefficient, and V is the speed of the aircraft. The vortex displacements are symmetric and are confined to fixed planes inclined at 48° to the horizontal.

Crow, S. C.

"MOTION OF A VORTEX PAIR IN A STABLY STRATIFIED FLUID"

Research Report No. 1, May 1974, Poseidon Research, Santa Monica, CA

A theory is developed for the descent of a vortex pair in a stably stratified fluid. The stratification is assumed to be weak, and the evolution of vorticity is traced without recourse to assumptions about turbulent mixing. The conclusion is that the vortices draw together and accelerate downward under the influence of stable stratification, contrary to the intuition that the recirculation cell might buoy upward. Fluid particles do rebound to their original levels, but in the form of a buoyant upwash above a diminishing cell. Eventually the vortex cores overlap, and their impulse radiates away on internal waves.

Crow, S. C.

"STABILITY THEORY FOR A PAIR OF TRAILING VORTICES"

AIAA Paper No. 1970-0053, NY, January 1970

Presents a theory to find the cause of the instability of the pair of contra-rotating vortices that trail behind an aircraft. The persistence of coherent flow depends mainly on the growth rate of the instability that precedes the formation of vortex rings. Investigates the growth rate of this instability.

Crow, S. C. and Bate, Jr., E. R.

"LIFESPAN OF TRAILING VORTICES IN A TURBULENT ATMOSPHERE"

Journal of Aircraft, Vol. 13, No. 7, July 1976, pp. 476-482

The lifespan of aircraft trailing vortices is controlled by a mutual induction instability excited by atmospheric turbulence. The instability itself is well understood. The purpose here is to incorporate the effects of turbulence and thereby predict wake lifespan as a function of meteorological conditions. Eddies of the relevant size are assumed to lie in the Kolmogorov inertial subrange. A statistical definition of lifespan is proposed. The paper concludes with a review of a practical method for actively exciting the mutual induction instability. The method would shorten the typical lifespan of a 747 wake by a factor of 3.

Crowder, J. P.

"SMOKE FLOW VISUALIZATION IN LARGE INDUSTRIAL WIND TUNNELS"

9th International Symposium on Flow Visualization, Paper No. 69, 2000, pp. 69-1 - 69-10

The use of smoke in visualizing features of an aerodynamic flow field is often regarded as one of the most prominent applications in the field of flow visualization. However, the use of smoke flow visualization in large industrial wind tunnels is problematical due to practical difficulties of producing the smoke in the required quantity and location. Furthermore, the utility of smoke flow visualization depends very much on the nature of the flow field under study. Flow fields that experience large vortex roll-up features tend to be much more receptive to useful smoke flow visualization applications than do situations with bluff-body-type separation. The Flying Strut traverser has proven to be an important element in the practical application of smoke flow visualization in such settings. The paper includes details of Flying Strut traverser systems, smoke generators and lighting requirements. Several examples of smoke images are examined and ambiguities discussed.

"ANALYTICAL SOLUTIONS FOR ROTATING VORTEX ARRAYS INVOLVING MULTIPLE VORTEX PATCHES"

J. Fluid Mech., Vol. 523, 2005, pp. 307-337

A continuous two-parameter family of analytical solutions to the Euler equations are presented representing a class of steadily rotating vortex arrays involving $N + 1$ interacting vortex patches where N is greater than or equal to 3 is an integer. The solutions consist of a central vortex patch surrounded by an N -fold symmetric alternating array of satellite point vortices and vortex patches. One of the parameters governs the size of the central patch, the other governs the size of the N satellite patches. In the limit where the areas of the satellite vortex patches tend to zero, the solutions degenerate to the exact solutions of Crowdy. Limiting states are found in which cusps form only on the central patch, only on the satellite patches, or simultaneously on both central and satellite patches. Contour dynamics simulations are used to check the mathematical solutions and test their robustness. The linear stability of a class of 'point-vortex models' (in which the patches are replaced by point vortices) are also studied to examine the stability of the distributed-vorticity configurations to pure-displacement modes. On the other hand, a desingularization of all point vortices to Rankine vortices leads to a class of 'quasi-equilibria' consisting purely of interacting vortex patches close to hydrodynamic equilibrium.

Crowdy, D. and Marshall, J.

"GROWING VORTEX PATCHES"

Physics of Fluids, Vol. 16, No. 8, August 2004, pp. 3122-3130

This paper demonstrates that two well-known equilibrium solutions of the Euler equations -- the corotating point vortex pair and the Rankine vortex -- are connected by a continuous branch of exact solutions. The central idea is to 'grow' new vortex patches at two stagnation points that exist in the frame of reference of the corotating point vortex pair. This is done by generalizing a mathematical technique for constructing vortex equilibria first presented by Crowdy [D. G. Crowdy, 'A class of exact multipolar vortices' Phys. Fluids 11, 2556 (1999)]. The solutions exhibit several interesting features, including the merging of two separate vortex patches via the development of touching cusps. Numerical contour dynamics methods are used to verify the mathematical solutions and reveal them to be robust structures. The general issue of how simple vortex equilibria can be continued continuously to more complicated ones with very different vortical topologies is discussed. The solutions are examples of exact solutions of the Euler equations involving multiple interacting vortex patches.

"NUMERICAL STUDY OF HELICOPTER ROTORS IN A SHIP AIRWAKE"

Journal of Aircraft, Vol. 51, No. 6, November-December 2014, pp. 1813-1832.

Operating helicopters in a naval environment is challenging because it imposes a pilot workload significantly higher than that during land-based operations. The aerodynamic interaction between the aircraft and the ship wake is known to play an important role in increasing the pilot workload, hence reducing the aircraft capability because of the need to maintain safety. As a further step toward numerical prediction of ship/helicopter operational limitations, computational-fluid-dynamics

simulations are conducted for the Canadian Patrol Frigate. The effect of the rotor is included in the simulation, first using an actuator-disc method together with steady calculations, then using rotor blades and the unsteady Reynolds-averaged Navier-Stokes equations. Results using the actuator-disc method demonstrate the importance of coupling effects on the wake and rotor inflow when the rotor is operating close to the ship and therefore the invalidity of superposition methods. The case of a Sea King helicopter main rotor hovering above the deck just before touchdown is reproduced to overcome the limitations of steady calculations and the actuator-disc method. Predictions of rotor thrust compare well with the experimental data available and give confidence in the results. The findings highlight the differences in rotor loading between forward flight and near-deck operation. The possibility of using such simulations for determining safe flight envelopes is discussed as part of the future work.

"ON MULTIPLE-PATH SONIC ANEMOMETER MEASUREMENT THEORY"

Experiments in Fluids, Vol. 34, 2003, pp. 345-357.

In this paper, a model of the measuring process of sonic anemometers with more than one measuring path is presented. The main hypothesis of the work is that the time variation of the turbulent speed field during the sequence of pulses that produces a measure of the wind speed vector affects the measurement. Therefore, the previously considered frozen flow, or instantaneous averaging, condition is relaxed. This time variation, quantified by the mean Mach number of the flow and the time delay between consecutive pulses firings, in combination with both the full geometry of sensors (acoustic path location and orientation) and the incident angles of the mean with speed vector, give rise to significant errors in the measurement of turbulence which are not considered by models based on the hypothesis of instantaneous line averaging. The additional corrections (relative to the ones proposed by instantaneous line-averaging models) are strongly dependent on the wave number component parallel to the mean wind speed, the time delay between consecutive pulses, the Mach number of the flow, the geometry of the sensor and the incidence angles of mean wind speed vector. Kaimals limit $k_{sub W1} = 1/l$ (where $k_{sub W1}$ is the wave number component parallel to mean wind speed and l is the path length) for the maximum wave numbers from which the sonic process affects the measurement of turbulence is here generalized as $k_{sub W1} = (C_{sub l})/l$, where $C_{sub l}$ is usually lesser than unity and depends on all the new parameters taken into account by the present model.

"AIRCRAFT DYNAMICS, WIND TUNNEL TESTING AND CFD FLOW VISUALIZATION OF TWO LINKED UAVS FLYING AT CLOSE PROXIMITY"

Proceedings SPIE, Vol. 7643, Active and Passive Smart Structures and Integrated Systems, April 2010, pp. 76432C-1 - 76432C-12.

This paper presents an analysis of close-proximity aerodynamics and aircraft dynamics of two Linked UAVs. As the UAVs approach each other for wingtip docking there will be strong aerodynamic coupling between their wing tips. Lifting line and Computational Fluid Dynamics (CFD) simulation as well as wind tunnel testing of close-proximity effects on lift, drag, roll, pitch and yaw moments for two UAV wings has been performed. The proximity aerodynamics effects between the UAVs wings were analyzed as a function of its relative position in all three directions. A look-up library of aerodynamic forces and moments for relative positions and angles of attack between the two UAVs has been developed. In this study we examined how the close-proximity aerodynamics affects the dynamics and stability of the UAVs. The aircraft dynamics analysis is done in Simulink, which will include the close-proximity aerodynamic look-up library. An aerodynamic disturbance intensity field will be generated, utilizing both simulation and wind tunnel data, to determine a trajectory for the two UAVs to approach each other for docking.

"DOWNWASH IN VORTEX REGION BEHIND RECTANGULAR HALF-WING AT MACH NUMBER 1.91"

NACA RM-E50H10, October 1950, Langley Aeronautical Lab., Langley Field, VA

The results of an experimental investigation to determine the downwash in the region of the trailing vortex system behind a rectangular half-wing in a supersonic stream are presented. The half-wing had an aspect ratio of 1.667, a 5-percent-thick symmetrical diamond cross section, and was beveled to a knife edge at the tip. The investigation was made at a Mach number of 1.91 and a Reynolds number of 1,560,000 based on the wing chord. A wake survey was also conducted. At small angles of attack, the experimental spanwise variation generally followed the trends indicated by linearized theory based on the assumption that the trailing vortex sheet was undistorted. At higher angles of attack, the downwash field was greatly influenced by the rolling up of the vortex sheet. At each chordwise station the downwash field progressively changed with increasing angle of attack from that induced by an undistorted vortex sheet toward that induced by a completely rolled-up vortex sheet. The form and the location of the vortex sheet was indicated by a wake survey.

"MEASUREMENT AND PREDICTION OF FREE FLIGHT WING-INDUCED VORTEX VELOCITY FIELDS"

AIAA Paper No. 1987-2497, Monterey, CA, August 1987

An experimental method was developed to measure the wing-induced vortex velocity field of a free flight aircraft. Radio-controlled airplane models were flown through a field of small particles and measurements of the particle velocities were made using various photographic techniques. A theoretical model of the motion of the particles was developed and used to determine the vortex strength and velocity field induced by the aircraft. The experimental method is considered for application to full-scale aircraft or for comparisons and analysis of various wingtip vortex alleviation devices.

Curran, P.

"WINGTIP TURBINES FOR VORTEX ALLEVIATION"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 52-1 - 52-19

It has been shown that the strength of a vortex can be alleviated by installing a vortex turbine at the trailing edge of a wingtip. The initial interest in the vortex turbine, however, was not in the area of vortex alleviation. The vortex turbine concept was first investigated as a potential means of producing power and reducing aircraft drag. Power can be generated by taking advantage of the high-speed rotational flow that is present near the core of the vortex. By properly placing a vortex turbine within the high intensity vortex core, rotational energy can be extracted for use in secondary power applications onboard the aircraft. The rotational energy can be converted to electrical, hydraulic, pneumatic, or a combination of these modes of power. The unique feature of the vortex turbine in generating power is that it extracts power from the rotational flow rather than from the free-stream velocity component; the free stream flow is not utilized and the drag penalties associated with extracting power from the free stream are avoided. It has been demonstrated in both wind tunnel tests and small-scale flight tests that the vortex turbine can reduce the induced drag of an aircraft by disrupting the formation of the vortex. During flight the vortex exerts an upward flow component outboard of the wing tips, and a downward component directly behind the wing. This downward component, or downwash, contributes to the induced drag of an aircraft, and can be reduced by locating the vortex turbine in the center of the vortex flow field where the rotational velocities are greatest. The vortex turbine hinders the formation of the vortex, and can reduce the induced drag of the wing by as much as 20 percent.

"DYNAMIC PRESCRIBED VORTEX WAKE MODEL FOR AERODYN"

AIAA Paper No. 2007-421, Reno, NV, January 2007

A new aerodynamic model has been developed for Horizontal Axis Wind Turbines. The prescribed vortex wake code HAWTDAWG, developed at the University of Glasgow, has been extended for dynamic flow conditions. The new model is built into the aerodynamic code AeroDyn and linked to the structural dynamics code FAST. The new model has been validated using Unsteady Aerodynamic Experiment Phase VI wind tunnel axial flow data. Comparisons are made to Blade Element Momentum and Generalized Dynamic Wake models.

Curry, R. E.

"UTILIZATION OF THE WING-BODY AERODYNAMIC ANALYSIS PROGRAM"

NASA-TM-72856, October 1978, NASA Dryden Flight Research Center, Edwards, CA

The analysis program was used to investigate several aircraft characteristics. The studies performed included vehicle stability analysis, determination of upwash angle, identification of nonpotential flow, launch dynamics, and wake vortex upset loads. The techniques are discussed and when possible, computed results are compared with experimental data.

"FURTHER STUDIES OF THE RESPONSE OF SINGLE ROTOR HELICOPTERS TO VORTEX ENCOUNTERS"

Technical Report MAE-1726, Sept. 1985, Princeton University, Princeton, NJ.

A simplified approach to the problem of controlling the response of a helicopter in an encounter with the trailing vortex of a large transport aircraft indicates the following: 1) The uncontrolled longitudinal motions of a helicopter induced by the vortex field are of large amplitude. The effectiveness of a simple attitude feedback tends to indicate that it should be relatively easy for the pilot to suppress the longitudinal motion. 2) The roll of the helicopter can be suppressed by lateral control feedback; however, this feedback does little to suppress the yawing motion. 3) Directional control feedback suppresses the yawing motion but on two of the helicopters tends to amplify the rolling motion. The effectiveness of the yaw suppression is sensitive to pilot lags. 4) The nature of these results indicating that suppression of the lateral-directional motion is clearly a multi-loop task and sensitive to pilot time lags indicates that pilot-in-the-loop simulation experiments are highly desirable.

"THE DYNAMIC RESPONSE OF HELICOPTERS TO FIXED WING AIRCRAFT WAKE ENCOUNTERS"

Proceedings of the Theoretical Basis of Helicopter Technology Seminar, American Helicopter Society, November 1985, Alexandria, VA.

Fixed wing aircraft may experience a severe upset if they encounter the trailing vortex of a large jet transport. Limited flight experiments using a teetering rotor helicopter indicate that the response of a helicopter to a trailing vortex encounter is considerably less severe. This paper considers the basic nature of the gust response of helicopters and presents a simplified analytical approach to the problem of predicting the response of a single rotor helicopter to trailing vortex encounter. Consideration is given to the estimation of main rotor flapping as well as the motion of the complete vehicle. The influence of helicopter configuration, main rotor type and helicopter size relative to the vortex on the response is discussed and illustrated by calculation of the dynamic response of various helicopters to an encounter with the trailing vortex of a large transport aircraft. Results are compared to flight test. Basic reasons for the difference in severity of the response of fixed wing aircraft compared to helicopters are discussed.

Curtiss, Jr., H. C. and Zhou, Z.

"THE RESPONSE OF HELICOPTERS TO FIXED WING AIRCRAFT WAKE ENCOUNTERS"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 14-1 - 14-23

Fixed wing aircraft may experience a severe upset if they encounter the trailing vortex of a large jet transport. Limited flight experiments with a teetering rotor helicopter indicate that the response of a helicopter to a trailing vortex encounter is considerably less severe. This paper considers the basic

nature of the gust response of helicopters and presents a simplified analytical approach to the problem of predicting the response of a single rotor helicopter to trailing vortex encounter. Consideration is given to the estimation of main rotor flapping as well as the motion of the complete vehicle. The influence of helicopter configuration, main rotor type and helicopter size is discussed and illustrated by calculation of the dynamic response of various helicopters to an encounter with the trailing vortex of a large transport aircraft. Results are compared to flight test. Basic reasons for the difference in severity of the response of fixed wing aircraft compared to helicopters are discussed.

"ROTOR AERODYNAMICS IN GROUND EFFECT AT LOW ADVANCE RATIOS"

ARO-16061.2-EG, Princeton University, Princeton, NJ, July 1982

The results of an experimental study of the aerodynamic characteristics of a helicopter rotor operating in ground effect at low advance ratios are presented. Flow visualization studies were conducted along with measurement of the forces and moments acting on the rotor as a function of advance ratio, height above ground and collection pitch. Steady state experiments as well as non-steady experiments involving translational acceleration were conducted. Three distinct flow regimes were noted from the flow visualization studies. At the low end of the advance ratio range a recirculating flow was present, at intermediate advance ratios a horseshoe shaped vortex formed under the rotor, and at the high end of the advance ratio range studied, the rotor wake flows entirely downstream. At test conditions where the recirculating flow or ground vortex is present there are marked departures from classical ground effect theory. Translational acceleration was found to have a significant effect on the rotor forces and moments indicating that some appreciable time is required for the establishment of the ground effect flow field when a recirculating flow or ground vortex exists in the steady state. The results indicate that magnitude of the ground effects experienced by a helicopter are sensitive to the flight path of the helicopter.

"VORTEX BREAKDOWN IN A SUPERSONIC JET"

AIAA Paper No. 1991-1815, June 1991, Honolulu, Hawaii.

There has been considerable study of vortex breakdown in low-speed flows, but very little is known about it at supersonic speeds. The phenomena is potentially of importance in scramjet fuel mixing applications. In the current study a supersonic vortical jet was created by tangential injection and acceleration through a convergent-divergent nozzle. Vortex circulation was varied and the jet was visualized using Rayleigh scattering from a laser light sheet and focusing schlieren. The results show that the vortical jet mixed much more rapidly with the ambient air than a comparable straight jet. When overexpanded, the vortical jet exhibited considerable unsteadiness and evidence was obtained which suggested vortex breakdown.

Cutler, A. D., Levey, B. S. and Kraus, D. K.

"AN EXPERIMENTAL INVESTIGATION OF SUPERSONIC SWIRLING JETS"

AIAA Paper No. 1993-2922, July 1993, Orlando, FL.

The addition of swirl to scramjet fuel jets has been proposed as a method of enhancing fuel mixing, but little of a fundamental nature is known about supersonic swirling flows. This is a study of mixing in supersonic swirling air jets created by tangential injection and acceleration through a convergent-divergent nozzle into stagnant air. Several cases with different vortex circulations were investigated using pitot, cone and total-temperature probes, and Rayleigh scattering from a laser light sheet. The results show that tangential injection is an efficient method for generating swirling jets; and that when overexpanded, considerable turbulence and increased mixing is created as a result of vortex breakdown.

"NEAR-FIELD EVOLUTION OF TRAILING VORTICES BEHIND AIRCRAFT WITH FLAPS DEPLOYED"

AIAA Paper No. 2004-2149, Portland, OR, June-July 2004

The near-field development of trailing vortices behind flaps-down airplane configurations is investigated experimentally and numerically. Wind-tunnel wake surveys are measured at the tail of the airplane, and are utilized to initialize the calculations. Downstream surveys (up to ten spans) and flow visualizations from a towing tank are used to characterize the mid-field vortex system. Computational Fluid Dynamics (CFD) results are based on the solution of quasi-3D Reynolds Averaged Navier-Stokes (RANS) equations with a one-equation turbulence model. The inclusion of turbulent-mixing effects is found to be essential to capturing the correct near-field development for realistic vortex systems including a body wake. Results show that wing loadings typical of commercial airplanes in a landing configuration can lead to multiple vortex pairs, or a single vortex pair, in the mid field at say, fifteen spans downstream. The CFD results are shown to be in very good agreement with experimental wake-survey results out to ten spans (the downstream limit for the survey results). The CFD approach is used to calculate mid-field parameters, such as circulation ratios and vortex separation distances, for use in assessing active schemes for breaking up the trailing vortices.

"LARGE-EDDY SIMULATION OF A TRAILING VORTEX SYSTEM BEHIND A CIVIL AIRCRAFT MODEL"

ICAS 1998 Paper 98-2.10.2, Sept. 1998, Melbourne, Australia.

In this paper we investigate Flap-Tip vortex pair interaction behind a civil aircraft model. We perform Large-Eddy Simulation of a pair of Burgers vortices, whose parameters were set according to wind tunnel measurements of a Flap-Tip vortex pair issuing from a civil aircraft model. The study of the isolated (Flap) vortex provides us significant insight about its turbulent structure. In the Flap-Tip vortex system we see how the interaction of the vortices modifies their mean and turbulent flow fields. The work ends with the study of the effect of initial separation distance on the vortex pair development.

"ESA WIND LIDAR MISSION AEOLUS"

19th Coherent Laser Radar Conference (CLRC), Paper Mo2, June 2018, Okinawa, Japan.

AEOLUS is a space-based wind lidar. Developed in the frame of the Earth Explorer program of the European Space Agency, it will be launched in late August 2018. Built by Airbus Defence and Space, it will be the first Doppler lidar in space. It will measure winds all over the globe from the surface to the low stratosphere, as well as the optical properties of clouds and aerosols. Its data shall be used for weather and air quality prediction and help better understand the climate of the Earth.

"FLUID ENTRAINMENT BY ISOLATED VORTEX RINGS"

Journal of Fluid Mechanics, Vol. 511, 2004, pp. 311-331.

Of particular importance to the development of models for isolated vortex ring dynamics in a real fluid is knowledge of ambient fluid entrainment by the ring. This time-dependent process dictates changes in the volume of fluid that must share impulse delivered by the vortex ring generator. Therefore, fluid entrainment is also of immediate significance to the unsteady forces that arise due to the presence of vortex rings in starting flows. Applications ranging from industrial and transportation, to animal locomotion and cardiac flows, are currently being investigated to understand the dynamical role of the observed vortex ring structures. Despite this growing interest, fully empirical measurements of fluid entrainment by isolated vortex rings have remained elusive. The primary difficulties arise in defining the unsteady boundary of the ring, as well as an inability to maintain the vortex ring in the test section sufficiently long to facilitate measurements. We present a new technique for entrainment measurement that utilizes a coaxial counter-flow to retard translation of vortex rings generated from a piston-cylinder apparatus, so that their growth due to fluid entrainment can be observed. Instantaneous streamlines of the flow are used to determine the unsteady vortex ring boundary and compute ambient fluid entrainment. Measurements indicate that the entrainment process does not promote self-similar vortex ring growth, but instead consists of a rapid convection-based entrainment phase during ring formation, followed by a slower diffusive mechanism that entrains ambient fluid into the isolated vortex ring. Entrained fluid typically constitutes 30% to 40% of the total volume of fluid

carried with the vortex ring. Various counter-flow protocols were used to substantially manipulate the diffusive entrainment process, producing rings with entrained fluid fractions up to 65%. Measurements of vortex ring growth rate and vorticity distribution during diffusive entrainment are used to explain those observed effects, and a model is developed to relate the governing parameters of isolated vortex ring evolution. Measurement results are compared with previous studies of the process, and implications for the dynamics of starting flows are suggested.

"EFFECT OF A WINGLET ON NORMAL BLADE-VORTEX INTERACTION"

Journal of Aircraft, Vol. 44, No. 1, January-February 2007, pp. 264-273

The flow field downstream of a blade interacted normally with a winglet-generated double vortex was investigated experimentally. Like the baseline (with no winglet) interaction, the passage of the double vortex over the blade significantly altered the blade circulation distribution, causing negative vorticity to be shed into its wake, which, together with the turbulent wake motions, acted to trigger the turbulent decay of the vortex core, resulting in an increase in its size and loss of circulation. For a junction vortex interacted directly with the blade leading edge, a pair of two counter-rotating vortices, similar to the baseline interaction case, was observed at 1.5 chords downstream of the blade trailing edge. Qualitatively, the variation in double vortex-blade separation distance produced large variations in the vortex core parameters associated with the junction vortex, whereas minor changes for the tip vortex.

"NUMERICAL STUDY OF TIP VORTEX FLOWS"

USGRDR0009, January 2000, University of California, Davis, CA

This paper presents an overview and summary of the many different research work related to tip vortex flows and wake/trailing vortices as applied to practical engineering problems. As a literature survey paper, it outlines the relevant analytical, theoretical, experimental, and computational study found in literature. It also discusses in brief some of the fundamental aspects of the physics and its complexities. An appendix is also included. The topics included in this paper are: 1) Analytical Vortices; 2) Experimental Studies; 3) Computational Studies; 4) Wake Vortex Control and Management; 5) Wake Modeling; 6) High-Lift Systems; 7) Issues in Numerical Studies; 8) Instabilities; 9) Related Topics; 10) Visualization Tools for Vertical Flows; 11) Further Work Needed; 12) Acknowledgements; 13) References; and 14) Appendix.

"INCOMPRESSIBLE NAVIER-STOKES SIMULATION PROCEDURE FOR A WINGTIP VORTEX FLOW ANALYSIS"

Proceedings of 6th International Symposium on Computational Fluid Mechanics, Lake Tahoe, September 1995, pp. 1-7

The near-field behavior of a wingtip vortex flow has been studied computationally and compared with existing experimental results. The computational approach involved using the method of artificial compressibility to solve the three-dimensional, incompressible, Navier-Stokes equations with experimentally determined boundary conditions. A single grid generation strategy for the wing-wind tunnel wall configuration is outlined. Further, grid density/distribution is given for the vortex core and wing surface requirements. The role of higher-order differencing scheme to approximate the convective terms of the Navier-Stokes equations is discussed. Two one-equation models (Baldwin-Barth turbulence model and Spalart-Allmaras turbulence model) have been used with the production term modified to account for the nearly solid-body rotation effect in the vortex core. Some observations and recommendations, for a simulation procedure will be discussed addressing the impact of solver accuracy, grid resolution/distribution and turbulence modeling on accurate tip vortex flow analysis. Finally, the computed results using 1.5 million grid points is compared with experiment.

"ACCURACY ASSESSMENT OF A WINGTIP VORTEX FLOWFIELD IN THE NEAR-FIELD REGION"

AIAA Paper No. 1996-0208, Reno, NV, January 1996

Flow prediction of the near-field behavior of a wingtip vortex flow field has been studied and compared extensively with experiment. The computational approach involved using the method of artificial compressibility to solve the three-dimensional, incompressible, Navier-Stokes equations. Two one-equation models (Baldwin-Barth turbulence model and Spalart-Allmaras turbulence model) have been used with the production term modified to account for the stabilizing effect of the nearly solid-body rotation in the vortex core. A grid refinement study using 0.6 million, 1.1 million, 1.5 million and 2.5 million grid points is also presented and discussed. An accuracy assessment study revealed that turbulence modeling errors and errors due to numerics are both important factors which influence the resolution of the tip vortex flow. This study attempts to quantify to what extent each of these two error sources affect the accuracy of tip vortex flow prediction in the near-field.

Dacles-Mariani, J., Hafez, M. and Kwak, D.

"PREDICTION OF WAKE-VORTEX FLOW IN THE NEAR- AND INTERMEDIATE-FIELDS BEHIND WINGS"

AIAA Paper No. 1997-0040, Reno, NV, January 1997

To date, most flow prediction of the wake-vortex flow field model the intermediate-wake where the vortex has been assumed to have completed its roll-up process and is well established. However, it is equally important to accurately predict the near-wake region for improved drag prediction. This study explores the validity of modeling the near- and intermediate wake region behind wings with a simplified Navier-Stokes equations. As possible candidates, the Navier-Stokes equations simplified by invoking the ideal-wake assumption, and using the velocity/vorticity formulation and the stream

function/vorticity formulation were studied. Several acceleration techniques were also investigated including the preconditioned conjugate gradient method. To serve as proof-of-concept, two analytical vortices, the perturbed vortex, and the 3D steady Burgers vortex were investigated. The efficiency and the accuracy of these methods are reported and discussed. Finally, comparison with some measured data are presented. Results of the model equations and of the full Navier-Stokes equations are presented and discussed.

"ON NUMERICAL ERRORS AND TURBULENCE MODELING IN TIP VORTEX FLOW PREDICTION"

International J. for Numerical Methods in Fluids, Vol. 30, May 1999, pp. 65-82

The accuracy of tip vortex flow prediction in the near-field region is investigated numerically by attempting to quantify the shortcomings of the turbulence models and the flow solver. In particular, some turbulence models can produce a 'numerical diffusion' that artificially smears the vortex core. Low-order finite differencing techniques of the convective and pressure terms of the Navier-Stokes equations and inadequate grid density and distribution can also produce the same adverse effect. The flow over a wing and the near-wake with the wind tunnel walls included was simulated using 2.5 million grid points. Two subset problems, one using a steady, three-dimensional analytical vortex, and the other, a vortex obtained from experiment and propagated downstream, were also devised in order to make the study of vortex preservation more tractable. The method of artificial compressibility is used to solve the steady, three-dimensional, incompressible Navier-Stokes equations. Two one-equation turbulence models (Baldwin-Barth and Spalart-Allmaras turbulence models), have been used with the production term modified to account for the stabilizing effect of the nearly solid body rotation in the vortex core. Finally, a comparison between the computed results and experiment is presented.

"A COMPUTATIONAL STUDY OF WINGTIP VORTEX FLOWFIELD"

AIAA Paper No. 1993-3010, Orlando, FL, July 1993

The near-field behavior of a wingtip vortex flow is studied computationally using an incompressible flow solver for the Navier-Stokes equations based on the artificial compressibility method. Inaccuracies in current computational studies are addressed, especially, the role of numerical errors and transition/turbulence modeling. A subset problem is devised to make the study of vortex preservation more tractable. As part of the numerical checks, the flow is first run laminar while performing a systematic grid refinement study for the subset problem. Further studies on the numerical errors are conducted with the measured Reynolds stresses introduced into the momentum equations as source terms. As a preliminary study of turbulent flows, the one-equation Baldwin-Barth turbulence model is implemented as well as the approximation of the production term. The full-geometry case is computed using 1.1 million grid points. The results are compared with experiment.

Dacles-Mariani, J., Zilliac, G. G., Chow, J. S. and Bradshaw, P.

"NUMERICAL/EXPERIMENTAL STUDY OF A WINGTIP VORTEX IN THE NEAR FIELD"

AIAA Journal, Vol. 33, No. 9, September 1995, pp. 1561-1568

The near-field behavior of a wingtip vortex flow has been studied computationally and experimentally in an interactive fashion. The computational approach involved using the method of artificial compressibility to solve the three-dimensional, incompressible, Navier-Stokes equations with experimentally determined boundary conditions and a modified Baldwin-Barth turbulence model. Inaccuracies caused by the finite difference technique, grid resolution, and turbulence modeling have been explored. The complete geometry case was computed using 1.5 million grid points and compared with mean velocity measurements on the suction side of the wing and in the near wake. Good agreement between the computed and measured flow fields has been obtained. The velocity distribution in the vortex core compares to within 3% of the experiment.

Dadone, L.

"ROTORCRAFT WAKES IN THE CONTEXT OF AIRPORT OPERATIONS"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

Helicopters and tiltrotor aircraft are designed for high performance, and low vibration characteristics. Low noise becomes a requirement for civil operation close to urban areas. Rotor wakes play a key role in the flow environment of rotorcraft. The modeling of the interaction between wake and blades is at the core of all rotor aerodynamics and aeroacoustics analysis methods - whether they involve explicit models of the rotor wake, or rely on harmonic representations of rotor inflow characteristics. Dealing with airport environments requires addressing conditions that fall outside of the wake modeling employed in rotor design. Typically, when more rigorous analytical modeling is not possible, empirical data are used to complement the analytical predictions. Progress continues to be made in the modeling of complex flow fields by means of Computational Fluid Dynamics (CFD). Advanced methods are also being investigated to couple flow field information with blade aerodynamics and dynamics effects. This includes, or can potentially include, rotor downwash, ground proximity effects, the interaction of rotorcraft with the wake of large structures and other aircraft, and even blade sailing effects during start-up/shut-down. This presentation will review current rotorcraft analysis methods with emphasis on rotor wake modeling, by both CFD and vortex element methods, addressing what has been done and could be done to deal with flow field issues relevant to airport operations when rotorcraft and fixed-wing aircraft share the space.

"LES CALCULATIONS OF SPATIALLY EVOLVING WAKES IN GROUND EFFECT"

AST4-CT-2005-012238, Catholic Univ. of Leuven, Leuven, Belgium, December 2006

The case of a longitudinally developing wake generated by an elliptic wing is investigated at a moderate yet significant Reynolds number, and using LES. The exact same vortex wake is also investigated in a longitudinally uniform configuration (i.e., a temporal simulation with periodic boundary conditions) using the same code and LES sub-grid scale model. Finally, the 2-D (thus necessarily time developing) DNS of the same case is also performed, as a reference. For the two LES, the simulations are performed up to fully developed turbulence. For each configuration, the averaged vorticity field, vorticity fluctuation field, and axial velocity field are presented and discussed. For the 3-D configurations, the flow topology evolution is also analyzed. Finally, the time evolution of diagnostics characterizing the wake dynamics are presented: trajectories, circulation, energy, etc. The results show that, in the initial phase, the flow is essentially two-dimensional. During that phase, the 3-D results match very well with the 2-D reference configuration. One important feature, that is not present in the longitudinally uniform configuration, is the fact that the longitudinally developing wake induces an axial velocity defect in the primary vortices. The longitudinally developing wake therefore exhibits an earlier and more violent transition to turbulence than the longitudinally uniform configuration. The longitudinally developing configuration further differs from the uniform case by the fact that the vortex tubes describe a spiraling motion (i.e., they are not parallel). This feature is suspected to trigger some kind of vortex meandering, only observed in the longitudinally developing configuration.

Daeninck, G., Desenfans, O. and Winckelmans, G.

"SPAN LOADING VARIATIONS AND WAKE ROLL-UP IN GROUND EFFECT"

AST4-CT-2005-012238, Catholic Univ. of Leuven, Leuven, Belgium, September 2006

When an aircraft is close to the ground, its wake is generated in ground effect (IGE). The presence of the ground affects the lift coefficient of the wing section, the span loading of the wing and thus the resulting wake vortex sheet. The roll-up of this vortex sheet is also affected by the presence of the ground. The importance of these effects is here analyzed to determine whether they need to be considered when performing 3-D simulations or when using simplified real-time models. This document addresses the evaluation of span loading and the 2-D numerical simulations of wake roll-up in ground effect. In Section 1, the span loading is evaluated out and in ground effect using a modified 'lifting line' theory. Three cases are considered: an elliptical chord distribution, a uniform chord distribution (rectangular wing) and a double elliptical chord distribution (simplified model of a wing in landing configuration). Four aspect ratios are investigated for each wing, each at five altitudes. Before performing roll-up simulations, the importance of the ground proximity on the lift coefficient of a 2-D airfoil section is studied (Section 2). The span loadings are used to determine the wake initial condition for 2-D roll-up simulations IGE, and the resulting wake vortex system dynamics (Section 3). The effect of the wake generation altitude and the Reynolds number effect are investigated. We essentially analyze the dynamics of a wake generated by an elliptic wing; the case of a double-elliptic wing is also presented.

"EFFICIENT VORTEX METHODS FOR THE SIMULATION OF THREE-DIMENSIONAL UNSTEADY VORTEX WAKES"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

Vortex wakes that emanate from lifting surfaces (aircraft wings, wind turbine blades, helicopter blades) correspond to trailing vorticity that is spatially compact (sheet-like). For incompressible flows, they can be efficiently simulated using three-dimensional 'vortex element methods'. These methods are Lagrangian (thus accurate for flows dominated by convection) and solve for the vorticity-velocity formulation of the incompressible Navier-Stokes equations. The velocity field (and its gradients) at any point and time is that induced by all vortex elements (particles for free vorticity and boundary elements for bound vorticity): the Biot-Savart law. The use of fast multipole methods and tree codes allows to evaluate those fields very efficiently.

Dafa'Alla, A. A.

"COMPUTATIONS OF THE WAKE VORTICES BEHIND A CIVIL AIRCRAFT HIGH LIFT MODEL"

AIAA Paper No. 2004-1235, Reno, NV, January 2004

FLITE3D was used to compute the flow past a typical high-lift civil aircraft model and the wake region behind it at a Mach number of 0.2. Two flap settings at 32 degrees and 26 degrees were considered, while the slat was deployed at 23 degrees. The computed results predicted the major flow characteristics very well. Comparisons with the experimental data showed good agreement of the locations of the wing tip and flap vortices for the measured lift value. As FLITE3D is an Euler code, the agreement with the vortex strengths was only qualitative. However, all the expected physical trends of the velocity and pressure fields were observed showing that the data could provide useful initialization near-field data to be used in conjunction with any future mid-to-far-field computations with any advanced CFD method. Furthermore, comparisons of the data for the two flap settings with the experimental data supported the approach that viscous effects should be considered as further decambering of the wing. The comparisons also showed that the tip vortex for the 26-degree flap configuration was stronger relative to the flap end one, persisted longer and probably revolved faster round it as compared to that obtained for the 32-degree flap setting. These findings were confirmed by flow animations for the two flap settings.

Daiutolo, H.

"DEVELOPMENT AND EVALUATION OF A WAKE VORTEX ADVISORY SYSTEM"

Proceedings 22nd Annual Meeting, Air Traffic Control Assoc., Las Vegas, NV, October 1977, pp. 155-170

A prototype wake vortex advisory system, presently being tested at Chicago O'Hare International Airport, is examined. The system utilizes a predictive algorithm described by an elliptical boundary drawn about the cross wind and head or tail wind. System testing procedures are outlined noting

simulated and on-site evaluations of procedural implications, capacity gains, delay decreases, reliability, and maintenance. Preliminary results are presented.

Dallmann, U.

"THREE-DIMENSIONAL VORTEX STRUCTURES AND VORTICITY TOPOLOGY"

Fluid Dynamics Research, Vol. 3, 1988, pp. 183-189.

In this paper we describe the formation of steady, three-dimensional flow structures as changes of flow topology. Possible changes are analyzed in the space of divergence-free Navier-Stokes vector fields. Changes occur at structurally unstable flow states, for instance at incipient separation, incipient vortex formation and vortex breakdown, etc. and whenever the flow around a nominally two-dimensional or axisymmetric body becomes three-dimensional. Vortices may be defined as helical flow of fluid particles around a common axis, but we must distinguish between the topological structure of the velocity field and the vorticity field of such vortices (vortical flows). At first, we review our results on near-wall velocity-field structures and then we discuss the topology of the associated vorticity fields. Finally, we develop a geometric description which allows to give a local definition for a three-dimensional vortex based on the invariants of the Jacobian matrix of such Navier-Stokes vector fields.

"THE VORTEX ROLLUP PROBLEM USING LAMB VORTICES FOR THE ELLIPTICALLY LOADED WING"

AIAA Paper No. 1988-3746, Cincinnati, OH, July 1988

The classical roll-up of the vortex sheet trailing the elliptically loaded wing is examined here. Three factors, each of which contributed in a different, yet influential, manner were included in the analysis: use of Lamb vortices as the discrete vortices, use of a variable time step, and a redistribution of the initial vortex discretization as a variant to the traditional equal-spacing or equal-strength models. A smooth spiral roll-up was obtained for dimensionless times which exceed those of all but one previous investigation by at least a factor of ten without an increase in computation time for similar computers. In addition, very good comparison with the results of previous investigators is obtained for similar parameters. The redistribution of the initial discretization was found to prevent an early concentration of vortices in the spiral as the integration occurs. The spiral was found to form with an equal number of turns as in other calculations, but with less tightness which we attribute to the fact that Lamb vortices were used. Double precision arithmetic was necessary to obtain meaningful results.

Dalton, C. and Wang, X.

"THE VORTEX ROLL-UP PROBLEM USING LAMB VORTICES FOR THE ELLIPTICALLY LOADED WING"

Computers & Fluids, Vol. 18, No. 1, 1990, pp.139-150

The classical roll-up of the vortex sheet trailing the elliptically loaded wing is examined. Three factors, each of which contributed in a different, yet influential, manner were included in the analysis: use of Lamb vortices as the discrete vortices, use of a variable time step, and a redistribution of the initial vortex discretization as a variant to the traditional equal-spacing or equal-strength models. The latter two factors are used in the analysis of this problem for the first time in this study. A smooth spiral roll-up was obtained for dimensionless times which exceed those of all but one previous investigator by at least a factor of ten without an increase in computation time for similar computers.

"A LIMITED ANALYSIS OF SOME NONACOUSTIC ANTISUBMARINE WARFARE SYSTEMS"

MS Thesis, March 1994, Naval Postgraduate School, Monterey, CA.

The problem of Anti-Submarine Warfare early in the next century is examined. Non-acoustic detection methods including magnetic anomaly detection, laser radar, and hydrodynamic detection are examined. A simple analysis of their relative effectiveness is made.

Damania, R. B.

"INVESTIGATION OF NEAR FIELD WAKES BEHIND HIGH-LIFT WINGS"

Ph.D. Thesis, 1973, Mississippi State Univ., State College, MS

An experimental study was made of the partially rolled up vortex behind a high lift wing. Specifically, the velocity vector behind a STOL airplane was measured in flight. The data were obtained at two measurement planes behind the wing in the range of 3.0 to 0.85 for flapped and unflapped conditions. Wing surface pressure distribution and wake vorticity were also measured. Results are presented in the form of contour plots of vorticity and velocity components.

Danaila, I.

"VORTEX DIPOLES IMPINGING ON FINITE ASPECT RATIO RECTANGULAR OBSTACLES"

Flow, Turbulence and Combustion, Vol. 72, 2004, pp. 391-406

Numerical simulations of a vortex dipole rebound from finite aspect ratio rectangular obstacles are presented. Compared to the dipole interaction with infinite flat walls studied by Orlandi (Phys. Fluids A2 (1990) 1429) new phenomena are observed. Secondary dipoles formed after the first rebound can undergo head-on collisions and partner exchange. A new lifting dipole is generated, moving in the opposite direction of the initial dipole. This phenomenon occurs for a ratio between the half-width of the obstacle and the dipole radius lower than a critical value depending on the Reynolds number of the flow. Scatter plots show a quasi-linear vorticity-stream function relationship for the lifting dipole. Some passive control strategies to inhibit the generation of lifting dipoles are also suggested.

Daniel, M.

"THE COMPLETE FIRST ORDER EXPANSION OF A SLENDER VORTEX RING"

Proceedings IUTAM Symposium on Dynamics of Slender Vortices, September 1997, Aachen, Germany.

Dynamic equations for the axisymmetric part of the velocity field and for the equation of motion of a slender vortex ring are given at first order. This is the correction to the known leading order given by Callegari and Ting. Note that equations to this order are able to describe the evolution of helicity.

"SURFACE-LAYER WIND AND TURBULENCE PROFILING FROM LIDAR: THEORY AND MEASUREMENTS"

EWEC 2006, February 2006, Athens, Greece.

As wind turbines become taller wind energy assessment and turbine control require knowledge of the detailed mean and turbulence wind profiles at bigger heights (150 meters and more). A major challenge for wind power meteorology is therefore to circumvent the traditional role of the tall met-towers by replacing them with equally accurate, but ground-based remote sensing equipment. Compared to wind data from calibrated cup anemometers in tall met-towers, wind data from remote-sensing instrumentation, such as SODARS and LIDARS, still lack precision and data availability compared to met data acquired from a met tower; this is true for use in connection with power curve reference and wind turbine certification purposes. However, recent progress with worldwide optical telecom technology and stable fiber lasers has led to realization of a new and small wind Lidar system named 'ZephIR' able to profile the surface layer up to ~200 meters height. In this paper we describe how improved signal processing has led to more accurate remote wind and turbulence profile measurements. Included in this study, we have furthermore, for the first time to our knowledge, investigated a method to extract turbulence quantities such as the surface friction velocity directly from the LIDARs radial wind measurements. Following a short description of the LIDAR and the applied data processing we compare the LIDAR-retrieved mean wind and friction velocities with corresponding measurements from tall meteorological towers equipped with calibrated cup anemometers and 3D sonic anemometers at heights ranging between 44 meters and 123 meters.

Daniels, T. S.

"SIMULATION OF WAKE VORTEX RADIOMETRIC DETECTION VIA JET EXHAUST PROXY"

Proceedings SPIE 9482, Next-Generation Spectroscopic Technologies VIII, June 2015.

This paper describes an analysis of the potential of an airborne hyperspectral imaging IR instrument to infer wake vortices via turbine jet exhaust as a proxy. The goal was to determine the requirements for an imaging spectrometer or radiometer to effectively detect the exhaust plume, and by inference, the location of the wake vortices. The effort examines the gas spectroscopy of the various major

constituents of turbine jet exhaust and their contributions to the modeled detectable radiance. Initially, a theoretical analysis of wake vortex proxy detection by thermal radiation was realized in a series of simulations. The first stage used the SLAB plume model to simulate turbine jet exhaust plume characteristics, including exhaust gas transport dynamics and concentrations. The second stage used these plume characteristics as input to the Line-By-Line Radiative Transfer Model (LBLRTM) to simulate responses from both an imaging IR hyperspectral spectrometer or radiometer. These numerical simulations generated thermal imagery that was compared with previously reported wake vortex temperature data. This research is a continuation of an effort to specify the requirements for an imaging IR spectrometer or radiometer to make wake vortex measurements. Results of the two-stage simulation will be reported, including instrument specifications for wake vortex thermal detection. These results will be compared with previously reported results for IR imaging spectrometer performance.

Daniels, T. S.

"COMPARISON OF VELOCITY ESTIMATORS FOR WAKE VORTEX DETECTION"

AIAA Paper No. 1999-0516, Reno, NV, January 1999

National Aeronautics and Space Administration researchers are investigating the use of Ka-Band pulsed Doppler radar to detect wing tip generated wake vortices in foul weather conditions. Numerical simulation studies have determined that signal to noise ratios for the radar hardware are expected in the range from 0 to -15 dB. Current methods for estimating Doppler velocity are based on autocorrelation and Fourier analysis. A wavelet-based method is described that relates signed wavelet scaling index to Doppler velocity. Results are derived from the Terminal Area Simulation System and a numerical Doppler radar model. Two schemes for estimating power spectral density coupled with two methods for estimating mean velocity (four different methods altogether) are compared with the wavelet-based method. This new algorithm computes an index and yields a subjective improvement of 6 dB SNR over the other four methods.

Daniels, T. S., Smith, W. L. and Kirev, S.

"RECENT DEVELOPMENTS ON AIRBORNE FORWARD LOOKING INTERFEROMETER FOR THE DETECTION OF WAKE VORTICES"

AIAA Paper No. 2012-2791, June 2012, New Orleans, LA.

A goal of these studies was development of the measurement methods and algorithms necessary to detect wake vortex hazards in real time from either an aircraft or ground-based hyperspectral Fourier Transform Spectrometer (FTS). This paper provides an update on research to model FTS detection of wake vortices. The Terminal Area Simulation System was used to generate wake vortex fields of 3-D winds, temperature, and absolute humidity. These fields were input to the Line-by-Line Radiative Transfer Model, a hyperspectral radiance model in the infrared, employed for the FTS numerical modeling. An initial set of cases has been analyzed to identify a wake vortex IR signature and signature

sensitivities to various state variables. Results from the numerical modeling case studies will be presented. Preliminary results indicated that an imaging IR instrument sensitive to five narrow bands within the 670 to 3150 1/cm spectral region would be sufficient for wake vortex detection. Noise floor estimates for a recommended instrument are a current research topic.

Daniels, T., Smith Sr, W. L. and Kireev, S.

"SIMULATION OF AIRBORNE RADIOMETRIC DETECTION OF WAKE VORTICES"

IEEE Transactions on Geoscience and Remote Sensing, Vol. 53, No. 12, December 2015, pp. 6336-6343.

This paper describes an analysis of the potential of using an airborne Fourier transform spectrometer (FTS) or radiometer to detect wake vortices. The goal was to determine the requirements for an infrared (IR) FTS to effectively detect wake vortices. Initially, a theoretical analysis of wake vortex detection by thermal radiation was realized in a series of simulations. The first stage used the Terminal Area Simulation System (TASS) dynamic model to simulate wake vortex temperature, moisture, and velocity fields. The second stage used these fields as input to the line-by-line radiative transfer model (LBLRTM) to simulate responses from both an imaging IR hyperspectral FTS and an IR imaging radiometer. These numerical simulations generated FTS and radiometer imagery that was compared with the original temperature data. This research supported an effort, using ground-based imaging FTS instruments, to make measurements of wake vortices of various landing aircraft. Results from two different field campaigns have been previously reported. Instrument specifications for wake vortex thermal detection are recommended for an imaging radiometer sensitive within the following two narrow spectral bands: 670-750 1/cm and 2200-2350 1/cm. The instrument must have at the very minimum a noise equivalent differential temperature less than 2 mK and a spectral resolution of at least 32 1/cm.

"AEROSOL PARTICLE EVOLUTION IN AN AIRCRAFT WAKE: IMPLICATIONS FOR THE HIGH-SPEED CIVIL TRANSPORT FLEET IMPACT ON OZONE"

Journal of Geophysical Research, Vol. 102, No. D17, September 1997, pp. 21,453-21,463

Previous calculations of the ozone impact from a fleet of high-speed civil transports (HSCTs) have been carried out by global two-dimensional (2-D) models which have not included explicit wake processing of sulfur species. This processing could be important for the global sulfate aerosol and ozone perturbations. For an HSCT scenario with emission indices of NO_x and sulfur equal to 5 and 0.4, respectively, and a cruise speed of Mach 2.4, the Atmospheric and Environmental Research (AER) 2-D model gives 0.50-1.1% as the range of the annually averaged O₃ column depletion at 40-50 degrees N. This range is determined by the extreme assumption that emitted SO₂ is diluted into the global model grid box either as gas or as 10 nm sulfate particles. A hierarchy of models is used here to investigate

the impact of processes in the wake on the calculated global ozone response to sulfur emissions by a proposed HSCT fleet.

"HIGH FIDELITY MOMENT OF INERTIA TESTING OF UNMANNED AIRCRAFT"

AIAA Paper 2018-4219, June 2018, Atlanta, GA.

Knowledge of moment of inertia data for an aircraft is critical for both aircraft analysis as well as model development for control. There have been a variety of different methods employed to measure moment of inertia including: physical pendulums, bifilar pendulums, compound pendulums, torsional pendulums, and torque. The accuracy of the moments of inertia determined using these methods depend upon a variety of factors, such as friction, drag, and vibrations. These contributions can be significant, as errors due to drag can increase quadratically with velocity and errors due to friction can increase as mass is added to the system. This paper seeks to build upon previous moment of inertia measurement techniques by considering the effects of drag on experimental measurements. A torque-based moment of inertia testing rig was fabricated in house, made up of a 4 x 6 x 6 ft steel framework and a pulley torque system. The testing rig allows for quick and reliable measurement with minimal error. Validation was performed using a series of bars to quantify how much error is expected and then using a flat plate to demonstrate that drag is negligible. Finally, the testing rig was used to measure the moment of inertia of two unmanned aircraft.

D'Appolito, J. A. and Whitney, D. A.

"LDV WAKE VORTEX DETECTION SYSTEM ASSESSMENT"

TR-6417-1, February 1992, TASC, Reading, MA

This report summarizes the methodology and findings of an engineering evaluation of the Laser Doppler Velocimeter (LDV). The purpose of this effort is to perform an independent technical review of the capability of the LDV to provide quantitative data concerning the location, velocity, size, and strength of aircraft wake vortices. The LDV was evaluated from two perspectives: basic hardware/signal processing capabilities and limitations and post-test data processing procedures. To understand the basic hardware/signal processing characteristics of the system, an analytic LDV simulation was developed and exercised. This simulation captures the major sensor characteristics and its operation, and provides an understanding of what LDV data collection limitations are.

Darmofal, D. L.

"ANALYSIS OF A CONSERVATION LAW MODEL FOR AXISYMMETRIC VORTICES IN PRESSURE GRADIENTS WITH APPLICATIONS TO VORTEX BREAKDOWN"

AIAA Paper No. 1996-0800, Reno, NV, January 1996

A simple hyperbolic conservation law has been analyzed for vortex cores in pressure gradients. In particular, an analogy with quasi one-dimensional compressible flow has been explored; in this analogy shock jumps in the vortex core model equations are assumed to represent axisymmetric vortex breakdown. Using these simple model equations a family of steady vortex core solutions are constructed; the behavior of the vortex cores is determined by the downstream core pressure. One downstream pressure exists for which the flow remains isentropic. Other downstream pressures can result in the formation of steady breakdowns within the domain. The model equations are also compared with axisymmetric Navier-Stokes simulations. For isentropic flows the model and Navier-Stokes results are in good agreement. The model also shows excellent predictive capabilities for the onset of vortex breakdown in the Navier-Stokes simulations.

Darmofal, D. L.

"THE ROLE OF VORTICITY DYNAMICS IN VORTEX BREAKDOWN"

AIAA Paper No. 1993-3036, Orlando, FL, July 1993

The role of vorticity dynamics in vortex breakdown is examined in a theoretical and computational study. Under the assumptions of steady incompressible axisymmetric inviscid flow, a theory is developed concerning the interaction of vortex tilting and stretching in the breakdown process. This analytic theory is then confirmed using an unsteady incompressible axisymmetric viscous flow solver. The theoretical and computational results are in excellent agreement. Both results point towards the importance of vortex tilting in initiating vortex breakdown. The agreement between the inviscid theory and viscous computations indicates that breakdown is primarily an inviscid process. A measure of the susceptibility to breakdown is developed from the inviscid theory which corresponds well with known experimental and numerical trends concerning the occurrence of vortex breakdown.

"VORTEX CORE BEHAVIOUR IN CONFINED AND UNCONFINED GEOMETRIES: A QUASI-ONE-DIMENSIONAL MODEL"

J. Fluid Mechanics, Vol. 449, 2001, pp. 61-84

Axisymmetric vortex core flows, in unconfined and confined geometries, are examined using a quasi-one-dimensional analysis. The goal is to provide a simple unified view of the topic which gives insight into the key physical features, and the overall parametric dependence of the core area evolution due to boundary geometry or far-field pressure variation. The analysis yields conditions under which waves on vortex cores propagate only downstream (supercritical flow) or both upstream and downstream (subcritical flow), delineates the conditions for a Kelvin-Helmholtz instability arising from the difference in core and outer flow axial velocities, and illustrates the basic mechanism for suppression of this instability due to the presence of swirl. Analytic solutions are derived for steady smoothly varying vortex cores in unconfined geometries with specified far-field pressure and in confined flows with specified bounding area variation. For unconfined vortex cores, a maximum far-field pressure rise

exists above which the vortex cannot remain smoothly varying; this coincides with locally critical conditions (axial velocity equal to wave speed) in terms of wave propagation.

"A CONSIDERATION OF CONSTRAINTS ON AIRCRAFT DEPARTURE OPERATIONS"

NASA/CR-2009-215763, January 2009, National Institute of Aerospace, Hampton, VA.

This paper presents a system-level perspective on the operational issues and constraints that limit departure capacity at large metropolitan airports in today's air transportation system. It examines the influence of constraints evident in en route airspace, in metroplex operations, and at individual airports from today's perspective and with a view toward future gate-to-cruise operations. Cross cutting organizational and technological challenges are discussed in relation to their importance in addressing the constraints.

Darracq, D. and Corjon, A.

"COMPUTATIONAL INVESTIGATION OF AIRCRAFT TRAILING-VORTEX EVOLUTION IN ATMOSPHERIC BOUNDARY LAYERS"

XXIII General Assembly, European Geophysical Society, Nice, France, April 1998

This paper presents three-dimensional large eddy simulations (LES) of civil-aircraft trailing vortices in different realistic atmospheric boundary layers (ABL) with a non-hydrostatic meteorological model. These calculations were performed in order to parametrize an operational model aiming at managing the separations between aircraft at take-off and landing. The problems considered here are taken from twelve selected cases corresponding to trials made at Idaho Falls sponsored by the Federal Aviation Administration (FAA) in 1990. During these trials there were two prevalent meteorological conditions: stable boundary layer and turbulent convective boundary layer. The three-dimensional behavior of the wake vortices (Crow instabilities) as well as the effects of the atmospheric parameters (turbulence, lateral wind, stratification) are discussed. The results of the simulations are compared to experimental data.

Darracq, D., Benkenida, A. and Laporte, F.

"NUMERICAL SIMULATIONS OF LARGE AIRCRAFT TYPE WAKES"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001.

Numerical simulations may be used for the characterization of aircraft wake vortices in the near to extended near field, i.e. covering downstream distances corresponding to the completion of the roll-up process. Complete aircraft computations enable us to predict the vortex generation mechanisms and the downstream evolution. On the one hand, such simulations appear as an alternative/complement

to wind-tunnel experiments. On the other hand, accurate results in terms of vortex dynamics imply strong numerical requirements, such as high quality meshes (true for both structured and unstructured meshes) and high-order numerical schemes, that allow for steady Euler or Reynolds-averaged Navier Stokes computations (RANS), but not for Large Eddy Simulations (LES) now. Therefore, numerical simulations may usefully benefit from near-field wind-tunnel experiments, used as inlet data for Euler, RANS or LES extended near-field computations. Both approaches corresponding to complete aircraft computations, and to the complementary experimental/numerical approach are presented. The first approach is detailed considering inviscid computations of the flow around a large aircraft type in high-lift configuration by a structured Navier-Stokes solver. Preservation and transport of vorticity being the major concern of the computations, the numerical treatment is described in detail. The second approach is devoted to steady and unsteady simulations of the extended near field of commercial aircraft type wakes from time-averaged experimental data. Steady RANS simulations and LES are compared, confirming the widely-spread assumption of laminar vortex cores surrounded by turbulent fluctuations. The method has been validated against wind-tunnel measurements in the extended near field. Some configuration effects have been investigated, demonstrating the sensitivity of the vortex dynamics in the extended near field with respect to minor configuration changes.

"THREE-DIMENSIONAL NUMERICAL SIMULATION OF WAKE VORTEX DETECTION WITH THE MFLAME 2 MICRON LIDAR"

AIAA Paper No. 1998-0666, Reno, NV, January 1998.

The aim of this paper is to demonstrate that trailing wake vortices can be reliably detected from an axial point of view using Doppler lidar. Three-dimensional large eddy simulations of wake vortices are performed to investigate the performance of an airborne Doppler Lidar based wake vortex detection system, known as the MFLAME system. Three test cases were investigated: i) Crow instabilities, ii) wake vortex decay in isotropic homogeneous turbulence and iii) wake vortex collapse in convective atmospheric boundary layer. In all cases, the axial velocity is not initialized. Once the appropriate flow field is computed, it is inputted into the MFLAME system simulator. The results indicate that a forward-looking Doppler Lidar system can detect wake vortex signatures from several ages of the applied vortices.

Darracq, D., Corjon, A., Ducros, F., Keane, M., Buckton, D. and Redfern, M.

"SIMULATION OF WAKE VORTEX DETECTION WITH AIRBORNE DOPPLER LIDAR"

Journal of Aircraft, Vol. 37, No. 6, November-December 2000, pp. 984-993.

A simulation approach is used to demonstrate that an airborne, forward-looking lidar can detect trailing wake vortices generated by a leading aircraft. Computational fluid dynamics techniques are used to generate flow fields containing wake vortices. These flow fields are applied to a Doppler lidar simulation model. The simulated geometry has the forward-looking lidar mounted on a following

aircraft, whereas the wake vortices are generated by a leading aircraft. In such a configuration, it is not possible to directly detect the strong rotational velocity components of a wake vortex with a Doppler system; detection relies on the presence of induced axial velocity signatures. We demonstrate that axial flows are induced as the vortices evolve, and that these axial flows can be detected with a Doppler lidar system.

Darracq, D., Moet, H. and Corjon, A.

"EFFECTS OF CROSSWIND SHEAR AND ATMOSPHERIC STRATIFICATION ON AIRCRAFT TRAILING VORTICES"

AIAA Paper No. 1999-0985, Reno, NV, January 1999.

This paper presents results of a numerical investigation of atmospheric stratification, crosswind shear and ground friction on aircraft trailing vortices. 2-D direct numerical simulations (DNS) and 3-D large eddy simulations (LES) are performed with, respectively, a high-order Navier-Stokes solver and a non-hydrostatic meteorological simulation system. The results of the simulations are compared to numerical data available in literature and to Idaho Falls experiments. Features of the wake-vortex/shear-layer interaction are evidenced by means of numerous numerical simulations of fundamental test cases. Realistic problems are also investigated demonstrating that, even in non-turbulent ambient field, the 3-D approach may be mandatory in some case in order to represent the collapse of a primary vortex with the secondary one created by ground-friction effect. We also observed that the primary-vortex/secondary-vortex collapse can be canceled by particular crosswind characteristics. Under these conditions the dynamics of the vortices is essentially 2-D preserving the vortex life and increasing hazardous effects for a following aircraft. These calculations were performed to contribute to the parameterization of an operational model aiming at managing the separations between aircraft at take-off and landing.

Das, A. and Wichmann, G.

"ON THE PHYSICS AND KINEMATICS OF VORTEX MOTION IN THE DOWNSTREAM OF A HIGH ASPECT RATIO WING WITH HIGH-LIFT DEVICES"

Aerospace Science and Tech., Vol. 8, 2004, pp. 489-498

Vortical flows, source flows and spiraling flows are very common phenomena in fluid dynamics, as are frequently observed in the field of aerodynamics or atmospheric disturbances. In the present study some analysis is taken up at first on the details of the flow quantities in the core region of the vortical flows, it being the essential part of the vortex, while the surrounding outer region, as accompanying field, retains its usual potential flow character. In case of lifting wings vortex formation at the wing- and flap-edges is a common feature. When high aspect ratio wings with high-lift devices in the landing phase are concerned, they give rise to strong multiple vortices. It is observed that the wing-tip vortex spirals around the stronger flap-edge vortex, with continual decrease of the radial distance between them. Hence, it is essential to analyze the physics and kinematics of such vortex motion. Both

experimental field data and numerical field solutions of such flows are available to compare with the theoretical findings. Based on the causalities of the vortex motion one can work out measures to attenuate such flows downstream of the wing.

"GENERATION AND CHARACTERISTICS OF VORTEX RINGS FREE OF PISTON VORTEX AND STOPPING VORTEX EFFECTS"

Journal of Fluid Mechanics, Vol. 811, 2017, pp. 138-167.

This paper presents a novel method for generating vortex rings that circumvents some of the drawbacks associated with existing methods in producing them. The predominant effects that occur in previously used methods are due to the presence of some of the other vortices such as the stopping vortex, piston vortex, image vortex and orifice lip generated vortices in the early stage of development. These disturbances influence the geometric, kinematic, and dynamic characteristics of a vortex ring and lead to mismatches with classical theoretical predictions. It is shown in the present study that the disturbance free vortex rings produced follow the classical theory. Flow visualization and particle image velocimetry experiments are carried out in the Reynolds number (defined as the ratio of circulation and kinematic viscosity) range, $2270 < Re < 6790$, to find the translational velocity, total and core circulation, core diameter, ring diameter and bubble diameter. In reference to the earlier studies, significant differences are noted in the variations of the vortex ring diameter and core diameter. A model for the core diameter during the formation stage is proposed. The translational velocity variation with time shows that the second-order accurate formula derived using Hamilton's equation by Fraenkel (J. Fluid Mech., vol. 51, 1972, pp. 119-135) predicts it best.

Dasey, T. J.

"A DEPARTURE WAKE VORTEX MONITORING SYSTEM: CONCEPT AND BENEFITS"

Second USA/Europe Air Traffic Management R&D Seminar, December 1-4, 1998, Orlando, FL

This paper highlights a concept for an automated departure wake vortex separation system. Wake vortex research has focused on reducing aircraft separations on arrival to airports, but in many cases, the departure queues for certain runways are more severely limiting to airport capacity than are arrival constraints. A departure system has the advantages that it could be used in all weather conditions and it is technically simpler because there is no longer a requirement for a 30-minute to several hour weather forecast in order to take advantage of the reduced spacings. This paper examines the technical requirements of such a system, and defines a concept for implementation of the system. An attempt is made to begin to quantify the dollar benefit from a departure system, and the obstacles to implementation of the system are discussed.

"AN ALGORITHM FOR THE RECOGNITION AND TRACKING OF AIRCRAFT WAKE VORTICES WITH A CONTINUOUS WAVE COHERENT LASER RADAR"

Conference on Coherent Laser Radar, OSA, Keystone, CO, July 1995

A real-time algorithm for localizing and actively following wake vortices is described. Results from an experiment at Memphis airport and from modeled data are discussed. This is the first such system to track vortices, resulting in a more efficient scan and allowing more frequent estimates of location and strength.

Dasey, T. J. and Hinton, D. A.

"NOWCASTING REQUIREMENTS FOR THE AIRCRAFT VORTEX SPACING SYSTEM (AVOSS)"

Proceedings of the 8th Conference on Aviation, Range, and Aerospace Meteorology, Dallas, TX, January 1999

This paper addresses the requirements for the weather portion of AVOSS. The operational decisions that need to be supported are addressed, which helps to define the necessary time scales of the nowcasts. An analysis is presented of meteorological conditions during which an AVOSS would provide capacity enhancement at major U.S. airports. Finally, a discussion of the current understanding of the meteorological variables that affect vortex behavior will be made, including expected accuracy and temporal and spatial resolution.

"A COMPREHENSIVE SYSTEM FOR MEASURING WAKE VORTEX BEHAVIOR AND RELATED ATMOSPHERIC CONDITIONS AT MEMPHIS, TENNESSEE"

Air Traffic Control Quarterly, Vol. 5, No. 1, 1997, pp. 49-6.

Models of vortex behavior as a function of atmospheric conditions are being developed to improve safety and minimize unnecessary airport capacity restrictions due to wake vortices. Direct measurements of vortices and the relevant meteorological conditions in an operational setting, which serve to improve the understanding of vortex behavior, are scarce and incomplete. A comprehensive vortex, meteorological, and aircraft measurement system has been constructed at Memphis International Airport and operated in two 1-month periods during 1994 and 1995. A 10.6 micron continuous-wave (CW) coherent lidar was used to measure vortex parameters with high fidelity. This lidar features a number of improvements over previous systems, including an automatic vortex detection and tracking algorithm to ensure efficient scanning. Meteorological data were collected from a 45 m instrumented tower, balloon soundings, a wind profiler/radio acoustic sounding system (RASS),

sonic detection and ranging (SODAR), and other sensors. This paper presents ensemble distributions of the conditions under which the over 500 aircraft were measured, and samples of vortex and atmospheric measurements. These data will be compared with theoretical predictions of vortex behavior as part of the development of an operational system designed to reduce aircraft spacings in the terminal area.

"METEOROLOGICAL MEASUREMENTS AND DATA FUSION FOR THE DALLAS/FT. WORTH (DFW) AIRCRAFT VORTEX SPACING SYSTEM (AVOSS)"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Quebec, Canada, December 1997, pp. 113-117

Since 1994, Lincoln Laboratory has been working under NASA Langley sponsorship to construct a field system for characterizing the atmospheric boundary layer conditions related to vortex behavior. The latest version of this system has been established at Dallas/Ft. Worth (DFW) Airport. The DFW continuous wind measuring instruments include an instrumented 45 m tower and several smaller towers, a radar profiler, two Doppler sodars and two Terminal Doppler Radars. An automated wind data fusion algorithm is used to provide a single headwind and crosswind profile every 5 minutes, with a current vertical resolution of 15 m below 50 m altitude and 50 m resolution from 50 - 600 m. This presentation will outline our view of the meteorological sensing requirements for an arrival vortex advisory system and describe the meteorological instrument layout, data distribution system and wind data fusion algorithm at DFW.

"AIRCRAFT VORTEX SPACING SYSTEM (AVOSS) INITIAL 1997 SYSTEM DEPLOYMENT AT DALLAS/FT. WORTH (DFW) AIRPORT"

NASA/L-3, July 1998, MIT Lincoln Laboratory, Lexington, MA

The potential hazard of aircraft encounters with the wake turbulence of preceding aircraft requires the use of minimum separations on landing that are a significant constraint on airport arrival capacity during instrument flight rules (IFR) conditions. The NASA Langley Research Center has been researching the development of the Aircraft Vortex Spacing System (AVOSS) which would dynamically change aircraft arrival separations based on the forecasted weather conditions and vortex behavior. An experimental AVOSS test system has been constructed at DFW airport and includes a large set of meteorological instruments, wake vortex sensors, and an aircraft data collection system. All of this data are relayed to a central processing center at DFW for processing by automated meteorological data fusion algorithms and by NASA vortex behavior prediction software. An initial deployment and test was conducted during a three-week period in September/October of 1997. This document describes the overall system, the Lincoln-deployed sensors, including the Continuous-Wave Coherent lidar, and the meteorological data collection and processing system. Algorithms that were used to process the data

for scientific use are described, as well as the conditions of the data collection and the data format, for potential users of this database.

"HOT JET/WAKE TURBULENT STRUCTURE AND LASER PROPAGATION: PART I JET/WAKE TURBULENCE MODELING"

21st JANNAF Exhaust Plume Technology Meeting, Vol. 1, Oct. 1994, pp. 59-78.

The prediction of laser propagation through the hot turbulent exhaust of an aircraft (or missile) requires knowledge of the detailed turbulent structure, and in particular, density/temperature fluctuations and inner/outer turbulent scales. The ability to predict the mean flow structure of round turbulent jets in an isolated environment has now become well established including hot jets and supersonic jets. However, the ability to predict density or temperature fluctuations and inner scales is poorly established, as is the ability to predict jet interactions with the aerodynamic vorticity (e.g. with the wing-tip vortex). A three-tier program of work has been in progress to enhance our understanding of the turbulent structure in hot jets and its influence on laser propagation. In Part I of this paper, the turbulence modeling activities will be described whose basis is the new data being generated at NASA LaRC, to be described in Part II of this paper. The k-epsilon turbulence model and 'g' scalar-fluctuation extension have been implemented in this work. The coefficients of the g-equation have been revised in accordance with new temperature fluctuation data for hot, subsonic jets into still air. Data is now being gathered for hot jets in a co-flow which interact with wing-tip vortices. The inclusion of the g-equation into a Navier-Stokes framework and its analysis of this complex jet data for which detailed turbulence statistics will be available will comprise the main part of this paper. The utility of direct numerical simulation (LES approach to be described in paper by Sinha and Dash) to provide additional insight into this complex problem will also be discussed. Part II of this paper discusses the new data, the measurement techniques, and the complexities entailed in data reduction. Part III discusses the military applications (laser countermeasures), new laser propagation data through hot jets (as well as new atmospheric turbulence data, and predictive methodology.

Dash, S. M. and Kenzakowski, D. C.

"TURBULENT ASPECTS OF PLUME AERODYNAMIC INTERACTIONS"

AIAA Paper 95-2373, July 1995, San Diego, CA.

Detailed data on the structure of hot turbulent jets obtained at NASA LaRC has been analyzed using a two-equation modeling approach with extensions. The calculations have been found to be dependent on core turbulence characteristics and the turbulent Prandtl number. Predictions of Mach .24 and Mach .85 hot jets are described and compared with measurements. For realistic aircraft problems, jets are immersed in an aerodynamic flow field and experience complex interactions. Experiments for the interaction of hot jets with wing wake/vortices indicate substantive deflection of the jet and distortion of the round profile which will impact noise emission due to modification of the turbulence

characteristics. Full NS simulations are described and compare quite well with the data. Recent work has entailed the development of specialized pressure-splitting methodology to permit the time-iterative spatial marching analysis of 3D jets with negligible streamwise pressure variations (the cross-plane analysis is fully elliptic). Unit problems for rectangular jets in a uniform stream have been performed and compare favorably with full Navier-Stokes predictions.

Daugherty, J. W.

"STUDY OF THE ELECTROSTATIC FIELD AND CHARGE DISTRIBUTION IN A VORTEX SEEDED WITH DUST"

Ph.D. Thesis, June 1973, Ohio State Univ., Columbus, OH

An experimental program was undertaken to investigate the vortex geometry, particle distribution and electric field distribution in a trailing vortex shed from an airfoil tip placed in a dust laden flow. A differential airfoil, positioned in a subsonic wind tunnel, generated the trailing vortex. Vortex geometry, particle distribution and electric field intensity were measured throughout the plane normal to the wind tunnel axis at several locations downstream from the airfoil.

Davenport, L. H. and Vitalle, R. F.

"A SIMPLIFIED METHODOLOGY FOR THE CATEGORIZATION OF UNMANNED AERIAL VEHICLES"

AIAA Paper 2017-4269, June 2017, Denver, CO.

In this work, a categorization methodology is proposed which allows a relative grouping of Unmanned Aerial Vehicles (UAV) according to sensitivity to wake turbulence using the parameters of operating speed, wing span and Rolling Moment Coefficient (RMC). Potential operating altitudes and corresponding airspeeds for UAV are examined and used as the basis for assigning input parameters used in the calculations. A short form adaptation of the RMC equation is developed that reduced the number of input parameters and simplified the calculation. The categorization of UAVs into three groups using these findings is proposed.

"WAKE TURBULENCE MITIGATION USING A STANDARDIZED LATERAL OFFSET PROCEDURE"

AIAA Paper 2018-3190, June 2018, Atlanta, GA.

In this preliminary study, the operation of a Standardized Lateral Offset is analyzed for its application as a wake avoidance procedure at separation distances equal or less than the current 5NM minimum. The procedure is wind dependent and is designed for use in high altitude cruise flight by a pair of aircraft on a defined trajectory which are equipped with a Flight Management Computer and for GNSS navigation. A minimum crosswind to transport wake turbulence is calculated based on aircraft navigation cross track error. The WakeWlse probabilistic modeling tool is also used to investigate if the wake turbulence from an aircraft performing the Standard Lateral Offset could affect a trailing aircraft

on the primary route. The use and content of aircraft derived MET data as a planning and monitoring tool for the flight crew is also discussed.

Davenport, L. H., Vitale, R. F. and Proctor, F. H.

"A PRELIMINARY ANALYSIS AND COMPARISON OF IN-FLIGHT WAKE TURBULENCE DATA"

AIAA Paper 2018-3021, June 2018, Atlanta, GA.

This paper presents an overview and preliminary analysis of wake turbulence data collected behind commercial airliners in high altitude cruise flight. The analysis presented in this research uses a subset of data comprised of four aircraft types in the Heavy and Super weight categories. The spatial location of vortex cores and the derivation of key parameters such as tangential velocity and circulation strength are discussed. Vortex core separation distances and descent profiles with respect to wake age and trail distance are determined by measurement of the lateral position of vortex core centers and the recorded altitudes of the vortex crossings. Estimates of vortex core radius are obtained using a combination of aircraft position and the velocity profiles of wind components measured during vortex crossings. A tangential velocity profile derived from these wind components is also compared in a series of velocity profiles from three idealized vortex models.

Davies, H.

"NATS VOLUNTARY WAKE INCIDENT REPORTING DATABASE: DESCRIPTION AND USES"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

This presentation describes the NATS Database of voluntarily reported wake vortex incidents. This will include outlining the process by which reports are captured for pilots and ATC, and also the information gained from other sources (met/radar data). Examples are given of how this data is analyzed and presented for an annual UK Wake Vortex performance report (although due to commercial sensitivity it is not possible to report numbers). The presentation will also suggest a potential methodology for calculating wake vortex separations for new spacing categories from historical data (i.e. for categories for which no current data exists.).

Davies, H.

"THE S-WAKE VORTEX INCIDENT DETECTION AND DATA COLLECTION"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

This presentation includes a summary of the work undertaken by NATS in the S-Wake Project. This includes: Validation of the NLR-Vortex Algorithm; Analysis of Preliminary Wake Vortex Encounters

detected from Flight Data Recorder (FDR) data by algorithm; and Analysis of Pilot reported Wake Vortex Encounters.

Davis, S. S.

"THEORY OF DISCRETE VORTEX NOISE"

AIAA Journal, Vol.13, No. 3, March 1975, pp. 375-380.

A solution is obtained for the noise induced by vortex shedding from the trailing edge of a semi-infinite flat plate. The solution for the potential flow is based on a procedure whereby an inner incompressible flow is matched to an outer acoustic field. Acoustic wave fronts are calculated and compared qualitatively with Schlieren photographs of similar flows. The acoustic directivity pattern is obtained, and the extreme sensitivity of this parameter to the incompressible flow near the trailing edge of the plate is investigated.

Davis, T.

"THE MEASUREMENT OF DOWNWASH AND SIDEWASH BEHIND A RECTANGULAR WING AT A MACH NUMBER OF 1.6"

Journal of the Aeronautical Sciences, Vol. 19, No. 5, May 1952, pp.329-332, 340.

Downwash and sidewash angles were measured with a conical probe in vertical planes 0.5, 1.0, and 1.5 chord lengths downstream of a rectangular wing of biconvex section. Finely spaced measurements were taken to determine the downwash field in the region of steepest gradients, with the result that the rolling up of the vortex sheet was well defined. The experimental results are compared with the theoretical solutions calculated from the measured wing loading. The Mach Number and dynamic pressure in the empty tunnel and behind the wing were also determined. The free-stream Mach Number was 1.60, and the Reynolds Number, based on wing chord, was 580,000.

Davis, T.

"EXPERIMENTAL INVESTIGATION OF DOWNWASH AND SIDEWASH BEHIND A RECTANGULAR WING AT A MACH NUMBER OF 1.60"

UAC Meteor Report UAC-45, Jan. 1950, United Aircraft Corp., Hartford, CT.

Downwash and sidewash angles in planes 0.5, 1.0 and 1.5 chord lengths behind a rectangular planform wing were experimentally determined. The wing had an aspect ratio of 2.7 and a 6 per cent thick biconvex airfoil section. Measurements were made with a Reynolds number of 580000 based on the wing chord. Mach number and dynamic pressure at the test points were also determined. The experimental results agreed with the linearized theory in the plane of the wing, but deviated above and below the wing.

"MODELING A SUPERSONIC FLOWFIELD IN THE CORE OF THE WINGTIP VORTEX AT MACH 6"

Mathematical Models and Computer Simulations, Vol. 5, No. 1, 2013, pp. 25-36.

In this paper numerical calculations of a wingtip vortex for various wing angles of attack are presented, and the resulting flow modes are compared with each other and with the experimental data. Numerical computations were performed at the Keldysh Institute of Applied Mathematics, making use of the Spalart-Allmaras turbulence model. Experiments were carried out at the Institute of Theoretical and Applied Mechanics, Siberian Branch (SB), Russian Academy of Sciences (RAS), Khristianovich, Russia.

Dazin, A., Dupont, P. and Stanislas, M.

"EXPERIMENTAL CHARACTERIZATION OF THE INSTABILITY OF THE VORTEX RING. PART I: LINEAR PHASE"

Experiments in Fluids, Vol. 40, 2006, pp. 383-399

The results of experiments performed to study the linear phase of the instability of vortex rings are presented. The experiments were performed in water. The vortex rings are generated by pushing water through the cylindrical nozzle of a pipe submerged in an aquarium. The experiments were made with the help of planar laser induced fluorescence as well as 2D2C and 2D3C particle image velocimetry. They show the straining field causing the instability, and for the first time experimentally the growth of a band of linear unstable modes. They also confirm previous studies concerning the shape of the instability and theories predicting the number of waves and the bandwidth of unstable modes. However, the measurement of the growth rate shows the influence of viscous damping, and consequently, the limit of the theories based on the hypothesis of an ideal fluid.

Dazin, A., Dupont, P. and Stanislas, M.

"EXPERIMENTAL STUDY OF THE NON-LINEAR PHASE OF THE VORTEX RING INSTABILITY"

12th International Symposium on Applications of Laser Techniques to Fluid Mechanics, July 2004, Lisbon, Portugal.

The first stage of the instability of a vortex ring is linear and characterized by the growth of an azimuthal stationary wave which develops around the ring. Its origin, shape, number of waves and growth rate are predicted by theoretical works. Experimental and numerical results in viscous fluids fit well with those predictions based on an ideal fluid hypothesis. On the other hand, the next stages of the development of the instability (which are non-linear) are not well known. Only few phenomena are described, in an isolated way, in various partial contributions. The aim of this paper is to report a

complete experimental investigation made on the non-linear phase of the instability of the vortex ring. The vortices were produced in water and their Reynolds number was varied from 2650 to 6100. Visualizations were performed using Planar Laser Induced Fluorescence and measurements with 2D2C and 2D3C Particle Image Velocimetry. Based on a Fourier analysis of the results, it appears that the non-linear phase begins by the development of the harmonics of the linear modes (first unstable mode). But the growth of those harmonics is rapidly stopped by the development of low order modes. Then appears a $m=0$ mode, which corresponds to a mean azimuthal velocity around the vortex. Simultaneously, secondary vortical structures develop all around the vortex in its peripheral zone. These vortical structures are linked with the ejection of vorticity in the wake of the vortex and they appear just before the transition towards turbulence. A tentative is made here to place chronologically all these phenomena to propose a scenario from the end of the linear phase to turbulence.

Dazin, A., Dupont, P. and Stanislas, M.

"EXPERIMENTAL CHARACTERIZATION OF THE INSTABILITY OF THE VORTEX RINGS. PART II: NON-LINEAR PHASE"

Experiments in Fluids, Vol. 41, 2006, pp. 401-413

The first stage of the instability of a vortex ring is linear and characterized by the growth of an azimuthal stationary wave which develops around the ring. Theoretical works predict its origin, shape, number of waves and growth rate. Apart for the growth rate, experimental and numerical results in viscous fluids fit well with the predictions based on an ideal fluid hypothesis. On the other hand, the next stages of the development of the instability (which are non-linear) are not well known. Only few phenomena are described, in an isolated way, in various partial contributions. The aim of this paper is to report on a complete experimental investigation of the non-linear phase of the instability of the vortex ring. The vortices were produced in water and their Reynolds number was varied from 2,650 to 6,100. Visualizations were performed using planar laser induced fluorescence and measurements with 2D2C and 2D3C particle image velocimetry. Based on a Fourier analysis of the results, it appears that the non-linear phase begins with the development of harmonics of the linear modes (first unstable modes). But the growth of those harmonics is rapidly stopped by the development of low order modes. Then appears an $m=0$ mode, which corresponds to a mean azimuthal velocity around the vortex. Simultaneously, secondary vortical structures develop all around the vortex in its peripheral zone. These vortical structures are linked with the ejection of vorticity in the wake of the ring and they appear just before the transition towards turbulence. A tentative is made here to place all these phenomena chronologically, in order to propose a scenario for the transition from the linear phase to turbulence.

de Bruin, A.

"A SUMMARY OF EXPLOITABLE RESULTS FOR ENHANCED SAFETY AND/OR AIRPORT CAPACITY, RESULTS FROM THE FAR-WAKE SYNTHESIS ACTIVITY"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 200.

Within the EU co-funded project FAR-Wake, fundamental aspects of airplane wake vortex formation and decay were studied. The project considered wake instability and decay, vortex interactions with jets and wakes and wake transport and decay in head and cross-wind conditions near the ground. Important advances were made in the understanding of the physical phenomena. Within the Synthesis task of the project, a thorough analysis of the results has been made to investigate the implications for real aircraft wakes with respect to wake vortex safety and airport capacity issues. The presentation will give an overview of these exploitable results including an assessment of their importance and additional research needed for their application.

"WAKE VORTEX EVOLUTION AND ENCOUNTER (WAVENC)"

Air and Space Europe, Vol. 2, Issue 5, September-October 2000, pp. 84-87

WAVENC was a short research project to improve understanding of the evolution of aircraft wake vortices and of their impact on the safety of flight of following aircraft. The work included numerical modelling of vortex behavior, flight simulation and analysis of measured encounter data. This article describes some of the main results.

de Bruin, A. C.

"WAVENC, WAKE VORTEX EVOLUTION AND WAKE VORTEX ENCOUNTER, PUBLISHABLE SYNTHESIS REPORT"

NLR TR-2000-079, April 2000, National Aerospace Lab., Amsterdam, The Netherlands.

The main short-term goal of the WAVENC project was to address wake vortex encounter safety aspects. This is achieved by developing realistic models for the wake vortex evolution and for computing the aerodynamic forces and moments on an aircraft flying through a given wake vortex disturbance flow field. These models are implemented in realistic flight simulation environments for studying wake vortex encounter at the glide path during final approach, either with auto-land control or with pilot control. The project includes theoretical, experimental, and computational work by eight partners. The main technical objectives of the WAVENC project have been achieved. The present report gives a summary of the main outcomes of the project. The results will be exploited and further extended in the new EU funded projects S-Wake and C-Wake.

"PROSPECTS FOR HEAD- AND CROSSWIND DEPENDENT AIRCRAFT SEPARATIONS IN THE CONTEXT OF WAKE VORTEX SAFETY AND AIRPORT CAPACITY, APPLICATION TO SCHIPHOL AIRPORT"

ICAS 2006, September 2006, Hamburg, Germany.

The current wake vortex separation rules are generally believed to be sufficiently safe, but rather conservative in certain weather conditions. The present report addresses the possibility of applying head- and/or crosswind depending reduced aircraft separations during the landing and departure phase. Taking the mean annual wind conditions for aircraft operations at Schiphol Airport as an example, an initial estimate is made of the potential landing and departure capacity benefits for different wind-dependent aircraft separation strategies. For steep approach procedures (as being considered for reduced noise emissions) the initial assessments indicate a large potential gain in airport capacity. However, further study will be needed to assess the practical limitations and safety aspects for the proposed modified aircraft separation strategies.

"ESTIMATION OF EXHAUST VELOCITIES AND TEMPERATURES FOR VARIOUS OPERATION PHASES OF A MODERN HIGH BY-PASS TURBOFAN"

NLR-CR-2005-641, Nov. 2005, National Aerospace Laboratory, Amsterdam, The Netherlands

Within the FAR-Wake project fundamental research is focused on the the precise role of vortex instabilities on aircraft wing wake decay (WPI), the effects of engine jets and fuselage wakes (WP2), and the influence of ground proximity on wake evolution, relevant to the airport environment (WP3). Experimental and numerical investigations as well as theoretical/analytical studies are made and, where appropriate, this is complemented with existing knowledge and data from previous projects. The activities conducted as described in the present report, will support the Work Package WP2, where the effect of jets interacting with wake vortices will be investigated.

"EXPERIMENTAL STUDY OF VORTEX MERGING IN THE WAKE OF A PART SPAN FLAP MODEL"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

As part of the European funded project Wake Vortex Characterization and Control (C-Wake), extensive wake surveys were made up to 30 wingspans behind a model with a simple straight wing and a wingspan of 0.6 m. Different model configurations (a full span flap configuration without- and a part-span flap configuration with and without spoiler elements) were tested near a lift coefficient of $CL=1.6$. The wake was measured in detail from the near wake up to the extended near wake (between 0.45 and 30 wingspans downstream of the wing). Two different measurement techniques are employed: a rake with five-hole probes and PIV techniques (both a standard and three component PIV (3C-PIV)). The experimental data allow a direct comparison between results at several downstream planes.

"WAKE VORTEX RESULTS FROM THE AWIATOR PROJECT"

Report NLR-TP-2007-527, December 2007, National Aerospace Laboratory, Marknesse, The Netherlands.

Within the wake vortex task of the AWIATOR project (2002-2007) wake alleviation concepts were tested in wind tunnels, water towing tanks and ONERA B-20 catapult facility. In addition, advanced numerical methods were applied. The aim of this work was to down-select promising configurations to be tested in flight on an A340 aircraft in landing configuration. NLR managed the wake vortex task of AWIATOR and participated in the technical work by prescribing a mandatory wake characterization methodology to be used by all partners, by measuring atmospheric turbulence conditions and performing flow visualizations during the flight tests and by performing safety assessment studies with the WAVIR methodology for the baseline and modified A340 wing configurations tested. The present report gives a summary of the total work performed in the wake vortex task of the AWIATOR project (2002-2007).

de Bruin, A. C. and Schrauf, G.

"WAKE VORTEX RESULTS FROM THE AWIATOR PROJECT"

1st CEAS European Air and Space Conference, Berlin, Germany, CEAS-2007-008, September 2007, pp. 1027-1035

Wake turbulence poses a potential hazard to following aircraft. Therefore, minimum aircraft separation distances, based on an aircraft weight classification scheme, are recommended by ICAO in order to assure proper safety during all flight phases. These pose a limiting factor for the capacity at congested airports. If modifications of the wing configuration can be shown to alleviate the strength and fasten the decay of the wake vortices, this potentially allows a mitigation of aircraft separation rules. The EU co-funded projects EURO-WAKE, C-Wake and the wake vortex task of AWIATOR form a

continuous line of research focused on the effects of wing modification on wake roll-up and decay. The EUROWAKE project (1996-1998) concentrated on wake formation and roll-up in the near wake. The C-Wake project (2000-2003) investigated wing span-loading concepts and other wing modifications up to the extended wake region using wind tunnel, towing tank, B10 catapult facility and a limited number of flight tests with the A340-300 in landing configuration, using ground-based LIDAR. The AWIATOR project (2002-2007) focused on the selection of wake alleviation concepts, to be tested in flight on the same aircraft, also in landing configuration. A down-selection of promising configurations was made from extensive CFD simulations, wind tunnel experiments, free-flying model tests and tests in a large towing tank facility. This paper gives an overview of the methods used for the selection process, the physical mechanisms exploited and the wake alleviation results obtained.

"FLOW FIELD SURVEY IN TRAILING VORTEX SYSTEM BEHIND A CIVIL AIRCRAFT MODEL AT HIGH LIFT"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 25-1 to 25-12

The roll-up of the trailing vortex system behind a generic civil aircraft wind tunnel model with extended flaps and slats is studied up to 5 wing spans downstream. A laser light sheet flow visualization technique is used and detailed flow field measurements are made with a spanwise traversable rake with five-hole probes. The measurement results are compared against calculations with the 2D vorticity transport equation.

"S-WAKE: ASSESSMENT OF WAKE VORTEX SAFETY"

NLR-TP-2003-243, May 2003, National Aerospace Laboratory, Amsterdam, The Netherlands

This report summarizes the work and outcomes of the multi-disciplinary European research project S-Wake. Fourteen partners collaborated in the project. The aim of the project was to develop and apply tools for the assessment of wake vortex safety. The work consisted of five inter-related Work Packages: Wake vortex behavior in the atmosphere; Aerodynamic models for wake vortex encounter (including wake encounter flight tests); Flight simulations; Probabilistic safety assessment; and Safety assessment from flight data recording data collection.

de Bruin, A. C., van Baren, G. and Speijker, L.

"AN ASSESSMENT OF WAKE VORTEX SAFETY ASPECTS WITH A PROBABILISTIC APPROACH, AS PART OF THE S-WAKE PROJECT"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 200.

The potential risk imposed by wake vortices can be an important constraining factor for airport capacity. To investigate the levels of flight safety under current ATM rules and guide possible new ATM procedures that may have improved safety and/or increased capacity, a European co-funded research project S-Wake has started. The S-Wake project aims to develop and apply tools for assessing appropriate (safe) wake vortex separation distances. The specific objectives of S-Wake are: to define suitable weather categories for wake vortex safety for aircraft on the approach glide path; to improve the physical understanding of wake vortex evolution and decay in the atmosphere; to establish realistic flight simulation environments for investigating wake vortex encounter safety aspects and pilot's response; to establish a validated probabilistic safety assessment method; to analyze the safety aspects for current practice by collecting and analyzing large amounts of flight data recordings and to define possible new concepts which allow a safe mitigation of current separation rules under certain conditions. A probabilistic approach is followed to evaluate wake vortex induced risk related to different separation distances between landing aircraft on a single runway.

"WAKE VORTEX CHARACTERISATION IN TOWING TANK FACILITIES USING PIV TECHNIQUE"

AIAA Paper No. 2003-0093, Reno, NV, January 2003

This paper summarizes two different experimental campaigns aimed to the wake vortex characterization. The experiments were performed, first at HSVA (Hamburg) small towing tank and after a period of six months at INSEAN (Rome) large towing tank using Particle Image Velocimetry (PIV) technique to detect the wake evolution and decay from the near field up to the mid/far field. A 1/48 scaled four engines commercial aircraft model was used, the model allowed to investigate different configurations simulating both cruise and landing configuration. For the last configurations different slat and flap deflection angles were tested, furthermore the influence of the under carriage as well as the influence of horizontal tail plane on the wake vortex behavior was investigated varying velocity and angle of attack. Different towing tank sizes were used for investigating the wall effect influence and the capability to reach the mid/far field condition. The adopted experimental set-ups, the velocity fields measured, the main magnitudes characterizing the vortex phenomenon, the wake vortex motion and persistence are presented.

de Haan, S.

"MEASURING ATMOSPHERIC STABILITY WITH GPS"

Journal of Applied Meteorology and Climatology, Vol. 45, March 2006, pp. 467-475.

Nowcasting of convective systems plays a crucial role in weather forecasting. The strength of convection depends on the (in)stability of the air column. The stability can be detected by radiosonde observations. However, these observations are not frequent (typically 2 times per day) and are expensive to deploy. In this article a method is presented to detect the stability of the atmosphere based on high-frequency global positioning system (GPS) path-delay observations. The convection

parameter derived from these observations is the power of the non-isotropic GPS path-delay signal. Comparisons with the convective available potential energy obtained from radiosonde observations show a correlation with the convective parameter obtained from GPS. This result implies that, because of the continuous availability of GPS estimates and the good land coverage, this method of detecting atmospheric stability may be beneficial to forecasters.

"QUALITY ASSESSMENT OF AUTOMATIC DEPENDENT SURVEILLANCE CONTRACT (ADS-C) WIND AND TEMPERATURE OBSERVATION FROM COMMERCIAL AIRCRAFT"

Atmospheric Measurement Techniques, Vol. 6, 2013, pp. 199-206.

Aircraft observations of wind and temperature are very important for upper air meteorology. In this article, the quality of the meteorological information of an Automatic Dependent Surveillance-Contract (ADS-C) message is assessed. The ADS-C messages broadcast by the aircraft are received at air traffic control centers for surveillance and airline control centers for general aircraft and dispatch management. A comparison is performed against a global numerical prediction (NWP) model and a wind and temperature observations derived from Enhanced Surveillance (EHS) air-traffic control radar which interrogates all aircraft in selective mode (Mode-S EHS). Almost 16000 ADS-C reports with meteorological information were compiled from the Royal Dutch Airlines (KLM) database. The length of the data set is 76 consecutive days and started on 1 January 2011. The wind and temperature observations are of good quality when compared to the global NWP forecast fields from the European Centre for Medium-Range Weather Forecasts (ECMWF). Comparison of ADS-C wind and temperature observations against Mode-S EHS derived observations in the vicinity of Amsterdam Airport Schiphol shows that the wind observations are of similar quality and the temperature observations of ADS-C are of better quality than those from Mode-S EHS. However, the current ADS-C data set has a lower vertical resolution than Mode-S EHS. High vertical resolution can be achieved by requesting more ADS-C when aircraft are ascending or descending, but could result in increased data communication costs.

"WIND-PROFILE ESTIMATION USING AIRBORNE SENSORS"

Journal of Aircraft, Vol. 51, No. 6, November-December 2014, pp. 1852-1863.

Wind is one of the major contributors to uncertainties while flying continuous-descent operations. When aircraft are issued a required time of arrival over the runway threshold, as is foreseen in some of the future air-traffic-system concepts, the onboard availability of both dependable and accurate wind estimates becomes a necessity for spacing. This paper presents a method for real-time estimation of a wind profile in the terminal maneuvering area, based on data transmitted by nearby aircraft. The algorithm produces high-resolution and real-time wind-profile estimates, usable for accurate trajectory prediction to improve continuous-descent operations and spacing performance. The wind estimation algorithm is tested with mode-S derived meteorological data from Amsterdam Airport Schiphol. It

combines multiple measurements from different aircraft to estimate the current wind profile using a Kalman filter. Using these wind-observation data, the algorithm showed an rms in the estimation error of 1.35 kt, which is lower than the observed rms measurement error of 1.94 kt, reducing the uncertainty when used in trajectory prediction. Another simulation study investigating aircraft spacing showed a clear benefit of using wind estimates along the own trajectory by reducing the spacing time error and improving control space.

de Jong, R. C. and Mulder, J. A.

"ACCURATE ESTIMATION OF AIRCRAFT INERTIA CHARACTERISTICS FROM A SINGLE SUSPENSION EXPERIMENT"

Journal of Aircraft, Vol. 24, No. 6, June-July 1987, pp. 362-370.

A novel method for the experimental determination of the aircraft center of gravity and the moments and products of inertia is presented and evaluated. The method is based on the application of statistical parameter estimation techniques to the analysis of multi-degree-of-freedom oscillations using a high-accuracy instrumentation system. An existing suspension rig, in which the aircraft can simultaneously rotate about the F and Z axes (pitch and yaw axes) and translate along the X (roll) and Y axes, is used to demonstrate the validity of the method. The inertia moments I_y and I_z , the inertia product I_{yz} , and the three coordinates of the center of gravity are simultaneously estimated from measurements of only one oscillation. The experiment is much less time-consuming compared to earlier methods, since no separate center-of-gravity measurements nor rig reconfigurations are needed. It is suggested that the remaining inertia characteristics (I_x , I_{xz} , and I_{xy}) can be simultaneously estimated after a slight modification in the suspension construction.

de Laat, T. W. G. and Coene, R.

"UNSTEADY FORCE ON SLENDER AIRCRAFT WITH FREE VORTICES IN INVISCID FLOW"

AIAA Journal, Vol. 40, No. 4, April 2002, pp. 610-618

Expressions are derived for the force on circular and wing-body contours induced by a vortex pair in a two-dimensional uniform unsteady inviscid flow, such as arise in the slender-body approximation of an aircraft. Zero-force curves for the classical vortex pair behind a circular cylinder in oncoming flow are found, and it is shown that the direction of the force can be upwind as well as downwind. A convenient expression for the force on a contour in a symmetric flow-field is obtained by conformal mapping, involving only the first- and second-order derivatives of the required transformation function. A result of practical interest for free vortices intended to enhance the lift force of an aircraft is that the force on the crossflow contour induced by vortices with a certain strength generally decreases when enlarging the width of the contour perpendicular to the direction of that force. So span reduction increases the lift generated by vortices above the wings. The position of the vortices in relation to the contour is critical, however, as there are areas that are shown, where the lift caused by the vortices is negative. The force caused by the symmetric vortex pair on the symmetric contour is independent of the speed

of the oncoming flow; the pressure distribution on the contour, however, does vary with changing speed of the oncoming flow.

de Leege, A. M. P., van Paassen, M. M. and Mulder, M.

"USING AUTOMATIC DEPENDENT SURVEILLANCE-BROADCAST FOR METEOROLOGICAL MONITORING"

Journal of Aircraft, Vol. 50, No. 1, January-February 2013, pp. 249-261.

The use of automatic surveillance-broadcast for meteorological monitoring is explored. Although originally developed for surveillance, the data that the system provides can be used to estimate wind, pressure, and temperature profiles. Two methods to estimate wind are presented. These make use of velocity vector information from a single aircraft or multiple aircraft, respectively. Air pressure is derived from the barometric altitude and height above the World Geodetic System 1984 ellipsoid. From this pressure estimate the temperature is estimated, using the hydrostatic equilibrium and the ideal gas law. To validate the methods, automatic dependent surveillance-broadcast data were collected over a 100-day period and the resulting estimates compared to Global Forecast System forecasts. Estimating wind using information from one aircraft resulted in a low number of estimates. When using data from multiple aircraft, more accurate wind estimates could be produced, at fixed time intervals and at altitude intervals. The mean absolute errors for wind speed and direction estimates were 9.2 kt and 29.0 deg, respectively. The mean errors for pressure and temperature estimates were -0.1 hPa and 0.8 K, respectively. The mean absolute errors for the pressure and temperature estimates were 0.8 hPa and 2.0 K, respectively.

"CONSIDERATIONS ABOUT WINGTIP DEVICES DESIGN OF TRANSPORT AIRPLANE"

AIAA Paper 2015-3437, June 2015, Dallas, TX.

From the start of aviation, designers have been searching for methods and technologies to reduce the required fuel burn of commercial aircraft. Wingtip devices in special winglets offer a way of significant drag reduction for transport airplanes. Winglets alongside with tip tanks, raked wingtips as well as fans belong to this class of wingtip devices. Although winglets are targeted to induced drag reduction, their effects can also be extended to wave and zero-lift drag. Induced drag alone is responsible for 30-40 percent of the overall drag of a transport airplane at long-range cruise condition and for considerably downgrading the climb performance of fixed-wing aircraft. Better investigation in this field employing CFD tools and extensive wind-tunnel testing has allowed the rise of efficient winglet designs in recent times. Several of newly designed aircraft configurations embody winglets and many of the older ones are being retrofitted. However, there are discussions concerning the best cost/benefit ratio of reducing induced drag of a transport plane with wingtip devices. Another big issue is the associated penalties to the configuration caused by winglets when compared to a simple wingtip extension. Two winglet optimization studies were carried-out for a 70-seat airliner. In the first simulation, wing and winglet were optimized for cruise and field performance. In the second study, optimization was carried out for

wings without winglet. The Pareto front for the configuration with winglets lies above the one obtained from the optimization for wing-body alone, justifying the adoption of winglets from the aerodynamic point of view.

de Mattos, B. S., Macedo, A. P. and da Silva Filho, D. H.

"CONSIDERATIONS ABOUT WINGLET DESIGN"

AIAA Paper 2003-3502, June 2003, Orlando, FL.

From the beginning of aviation designers are searching for methods and technologies for reducing the required fuel burn of commercial aircraft. Wingtip devices aim the reduction of induced drag, which is responsible for 30-40% of the total drag of a transport-aircraft at long-range cruise condition and for considerably downgrading the climb performance of an aircraft. Winglet alongside with tip tanks, raked wingtips, aligned fans belong to this class of devices. Better investigation in this field employing CFD tools and extensive wind-tunnel testing has allowed the rising of efficient winglet designs in recent times. Several of newly designed aircraft configurations embody winglets and many older ones are being retrofitted. However, there are discussions concerning the best cost/benefit of reducing induced drag of a transport plane with wingtip devices. Another big issue is the associated penalties to the configuration caused by winglets when compared to a simple wingtip extension. This paper addresses some of these issues based on the expertise obtained designing winglets for several aircraft configurations, ranging from a business jet and a twinjet airliner for 70 passengers to an AEW&C military airplane.

de Saint Victor, X.

"THE ACTIVITIES OF THE ONERA PROJECT-- WAKE VORTEX DYNAMICS"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

The ONERA federated research project 'Wake Vortex Dynamics' was established in 1997. The following tasks were defined: Understanding of the phenomenon of wake vortices by the means of the analysis of the near and far field, the study of the development of the turbulence, the study of the instabilities, the analysis of the different means to use to destruct the wake. Modelling by means of DNS and LES or RANS calculations to simulate the evolution of the wake, the merging, the ground-effect or the jet/wake vortex interaction. The problem of the wake vortex encounter is also tackled using a flight mechanics code. Development of new measurement techniques as PIV or LIDAR using various facilities as the free flight facility or the water tunnel THALES.

De Souza, F. and Faghani, D.

"STUDY OF NEAR-FIELD WING-TIP VORTICES USING PARTICLE IMAGE VELOCIMETRY AND HOT-WIRE ANEMOMETRY"

Proceedings of 9th International Symposium on Flow Visualization, Edinburgh, Scotland, August 2000, pp. 399-1-399-11

The near-field development of tip vortices generated by rectangular planform wings with symmetrical profiles and different end-cap geometries is investigated using both Particle Image Velocimetry (PIV) and hot-wire anemometry. PIV Measurements are obtained in several cross-flow planes at up to five chord lengths downstream of the trailing edge. These are complemented by hot-wire anemometry measurements using a four-sensor probe. Comparison between these two independent measurement techniques allows some observations to be made on their accuracy in the highly sensitive flow region in and around the vortex core. The study also provides some insight on the effects of the wing end-cap shape and angle of incidence on the near-field flow structure.

de Souza, F. and Lee, B. H. K.

"MEAN FLOW AND TURBULENCE MEASUREMENTS IN THE NEAR FIELD OF A FIGHTER AIRCRAFT WING-TIP VORTEX AT HIGH REYNOLDS NUMBER AND TRANSONIC FLOW CONDITIONS"

ESAIM: Proceedings, Vol. 7, 1999, pp. 120-129

Mean and turbulent flow characteristics of the wing-tip vortex generated by a 6% scale model of the F/A-18 fighter aircraft equipped with AIM-9 sidewinders were investigated experimentally. This particular configuration was studied as part of the NRC/IAR stores clearance and certification program. However, the present study focuses on the near field structure of the tip vortex, as the existing literature contains relatively little information on tip vortices generated at such high Reynolds numbers (4,400,000, based on wing chord), and even less on the tip vortices of fighter aircraft. The experiments were conducted in the transonic test section of the NRC/IAR 1.5m x 1.5m tri-sonic blowdown wind tunnel. The present paper documents results obtained in a single cross-flow plane located immediately downstream of the wing trailing edge, for two angles of attack, 4.5 degrees and 13 degrees, and at a single freestream Mach number of 0.75. Mean velocities and flow angularities were measured using a five-hole directional velocity probe as well as an x-array constant temperature hot-wire probe. The latter also provided estimates of the turbulence intensities, Reynolds stresses and turbulent kinetic energy in the measurement plane. The results shed some light on the fairly complex interaction, particularly at the higher angle of attack, of the wing-tip vortex and the wake of the AIM-9 tip missile.

de Souza, J. M. and Catalano, F. M.

"MULTI-DISCIPLINARY DESIGN OPTIMIZATION OF A BLENDED WINGLET"

31st Congress of the International Council of the Aeronautical Sciences (ICAS 2018), September 2018, Belo Horizonte, Brazil.

To reduce operating costs directly related to fuel burn, it is proposed the development of a blended winglet optimized for a commuter aircraft of 11 passengers. Initially a brief description of the problem is made, as well as the background of the wingtip devices evolution. The optimization method used to model the physical phenomena in question, the drag generated by lift was a Vortex Lattice Method

(VLM) code based on the Trefftz-Plane theory for counting induced drag. After the iterative process the results are analyzed, presenting the comparisons between the aircraft without / with the final winglet. These comparisons cover several areas of aeronautics, such as aerodynamics, loads and performance.

De Visscher, I., Bricteux, L. and Winckelmans, G.

"AIRCRAFT VORTICES IN STABLY STRATIFIED AND WEAKLY TURBULENT ATMOSPHERES: SIMULATION AND MODELING"

AIAA Journal, Vol. 51, No. 3, March 2013, pp. 551-566.

This study investigates the influence, on aircraft wake vortex behavior, of atmospheres that are stably stratified (neutral to very strong) and weakly turbulent, by means of large-eddy simulations at very high Reynolds number and on relatively fine grids. The atmospheric fields are first generated using large-eddy simulations of forced and stratified turbulence reaching a statistically stationary state. The obtained fields are shown to be realistic and consistent with the literature. A pair of counter-rotating vortices, with relatively tight cores, is then put in the obtained fields and evolved. The evolution of the wake vortex topology, transport, and decay is analyzed in depth by measuring the wake vortex characteristics in all cross planes. The vortex transport and deformation are related to the stratification and turbulence levels. Stratification combined with weak turbulence is seen to strongly affect the Crow instability development. Different decay mechanisms are identified, related to the interactions with the turbulence, the turbulent baroclinic vorticity, and/or between the vortices themselves. Finally, improved simplified models of vortex altitude evolution and of vortex decay (with two phases) are proposed and calibrated on the present results. They yield good agreement with the large-eddy simulation results and are usefully integrated in our operational models.

De Visscher, I., Bricteux, L. and Winckelmans, G.

"LES OF AIRCRAFT WAKE VORTICES EVOLVING IN A STABLY STRATIFIED AND WEAKLY TURBULENT ATMOSPHERE"

Fifth European Conference on Computational Fluid Dynamics, June 2010, Lisbon, Portugal.

The aim of this study is to investigate the influence of weakly turbulent stable stratification of the atmosphere on aircraft wake vortex behavior, by means of Large Eddy Simulations (LES). To best represent the atmospheric conditions, the stratified and weakly turbulent fields are here first generated, using LES of forced and stratified turbulence. The obtained fields are non-isotropic. LES of a pair of counter-rotating vortices, with relatively tight cores, evolving in the obtained fields are then performed. Different stratification levels are investigated, from low to very high, and all with weak turbulence. The simulations are performed at very high Reynolds number; much higher than in previous work, thus more realistic. The current investigation is performed using a pseudo-spectral code with various sub-grid scale models. The influence of the domain size is also investigated, with box sizes also allowing the Crow instability development. The chosen resolution ensures that the essential dynamics of the vortices is properly captured. The time evolution of the wake vortex characteristics

(positions and circulation) is studied as a function of the stratification level. They are also compared to those obtained from previous simulations performed with stratification but without turbulence. It also appears that the turbulence of the temperature field has a strong impact on the decay of the vortices. It enhances the development of 3-D instabilities in the baroclinic vorticity. Hence, this quickens its interaction with the primary vortices, leading to a fast decay. A simplified model of altitude evolution is also proposed and fitted on the present results. Such model can be used in operational models for predicting the wake vortex behavior (transport and decay).

"EDDF-2 DATABASE ANALYSIS AND PERFORMANCE ASSESSMENT OF THE WAKE VORTEX MODELS ON THE EDDF-1 AND EDDF-2 DATABASES"

CREDOS Report D2-5, June 2009, Universite catholique de Louvain, Louvain-la-Neuve, Belgium.

This deliverable includes the contributions of UCL, DLR and Airbus-D concerning the use of the two measurement campaign databases, EDDF-1 and EDDF-2. The deliverable includes a detailed analysis of the EDDF-2 database, and a performance assessment of the operational prediction models (DVM/PVM of UCL and D2P/P2P of DLR) as compared to the data of the two campaigns. The results of a benchmark of the two deterministic models (DVM and D2P) performed by Airbus using some selected cases of the EDDF-1 database, are also reported.

De Visscher, I., Lonfils, T. and Winckelmans, G.

"FAST-TIME MODELING OF GROUND EFFECTS ON WAKE VORTEX TRANSPORT AND DECAY"

Journal of Aircraft, Vol. 50, No. 5, September-October 2013, pp. 1514-1525.

A fast-time model for wake vortex behavior prediction in ground proximity is presented. This model considers the combined effects of ground proximity and wind (both crosswind and headwind components) on the wake vortex transport and decay. It aims to mimic the whole flow using a limited set of vortex particles to model both the primary two-vortex system and the ground-generated secondary vorticity. A redistribution of the vortex particles is also included in the model to limit the number of used particles and hence, guarantee a high computational efficiency. The model is integrated in the deterministic wake vortex model, which is a software that predicts, also in real-time, the temporal evolution of the wake vortices generated by a given aircraft evolving in given ambient meteorological conditions. The new ground effect model capacity is assessed using data from a measurement campaign and from large-eddy simulations. It is found that the model can reproduce the wake vortex behavior (both for transport and decay) for the most relevant times required for air traffic management applications.

De Visscher, I., Lonfils, T. and Winckelmans, G.

"IMPROVEMENT OF THE DETERMINISTIC/PROBABILISTIC WAKE VORTEX MODEL (DVM/PVM) FOR THE COMBINED EFFECTS OF GROUND AND METEOROLOGY"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

UCL has developed a real-time tool to predict the wake vortex transport and decay: the Deterministic/Probabilistic wake vortex model (DVM/PVM). The DVM, based on the Method of Discrete Vortices integrates, in time, various physical models to forecast in real-time the transport and decay of the wake vortices in one computational gate (i.e., one slice in space along the flight path) generated by a given aircraft in given meteorological conditions. It includes models of the two-phase decay, the Near-/In-ground Effects (NGE/IGE), the wind shear and the stratification effects. Because probabilistic modelling and assessment of wake vortices is what is operationally required, an upper software layer was also developed. For each probabilistic run, several deterministic runs are computed, with variations on the impact parameters (i.e., met. conditions, aircraft characteristics and related physical model coefficients). A statistical analysis (e.g., PDF, mean, variance, confidence interval) is then performed on the deterministic result samples. The IGE model employs secondary vortex particles close to the ground modelling the separation of the wall boundary layer induced by the primary wake vortices in the proximity of the ground. These secondary vortices interact with the primary ones and induce rebound as well as the highly enhanced decay of the primary vortices after rebound, using a new 'Particle Strength Exchange' approach.

"A SIMPLE WAKE VORTEX ENCOUNTER SEVERITY METRIC"

Eleventh USA/Europe Air Traffic Management Research and Development Seminar (ATM2015), June 2015, Lisbon, Portugal.

This paper presents a severity metric supporting the characterization of the effect of a wake vortex encounter on a follower aircraft. The proposed metric is the Rolling Moment Coefficient computed using various simplified assumptions that lead to a simple and usable metric. The metric can indeed be computed using available aircraft data. The paper also presents the assessment of the metric based on the results of a wake vortex encounter flight test performed by Airbus. The use of the proposed metric yields good agreement with the experimental data. Because it is simple, yet realistic compared to experimental data, the metric can be used in a relative safety analysis permitting a reduction of the wake turbulence separations compared to today's ICAO standard, as was done in the framework of the RECAT-EU project.

"CHARACTERIZATION OF AIRCRAFT WAKE VORTEX CIRCULATION DECAY IN REASONABLE WORST CASE CONDITIONS"

AIAA Paper 2016-1603, January 2016, San Diego, CA.

This paper presents a methodology allowing the characterization of aircraft wake vortex circulation decay in reasonable worst-case conditions. These reasonable worst-case conditions correspond to wake vortices evolving in ground proximity and in meteorological conditions that are unfavorable in terms of wake circulation decay. The decay characterization is based on the analysis of a large measurement database. From the data analysis, it is observed that the dimensionless decay curves of wake vortices generated by various Heavy aircraft types collapse on a single generic curve. This generic dimensionless decay curve is used to support the characterization of the wake vortex encounter severity on a follower aircraft. The proposed generic decay curve can indeed be used, when combined with initial vortex circulation and spacing, in a relative safety analysis permitting a reduction of the wake turbulence separations compared to today's ICAO standard, as was done in the framework of the RECAT-EU project.

"OVERVIEW OF UCL OPERATIONAL TOOLS FOR PREDICTING AIRCRAFT WAKE VORTEX TRANSPORT AND DECAY: THE DETERMINISTIC/PROBABILISTIC WAKE VORTEX MODELS (DVM/PVM) AND THE WAKE4D PLATFORM"

Report, July 2008, Universite catholique de Louvain, Louvain-la-Neuve, Belgium.

The three UCL operational tools: (1) The '3-D space + time' (thus 4-D) wake vortex prediction platform software, WAKE4D, handles the space and time discretization of the aircraft trajectory. It creates n computational gates (n 'slices of space along the flight path'); (2) In each of these gates, one probabilistic forecast of the wake vortex behavior is performed using the Probabilistic wake Vortex Model (PVM); and (3) The PVM performs N deterministic predictions with variations on the impact parameters, using the Deterministic wake Vortex Model (DVM) as a sub-tool, in a Monte-Carlo approach. The DVM thus forms the core of the entire tool. UCL has implemented, within this software, several physical models that forecast the wake vortex behavior. These models have been developed, calibrated, and assessed, for more than ten years. The WAKE4D, and its subcomponents PVM and DVM, constitutes a fairly mature and operational wake vortex predictor. It can simulate realistically complex wake vortex behaviors depending on atmospheric conditions and ground proximity conditions. Its real time capabilities also make it a usable wake vortex predictor for practical applications.

De Visscher, I., Winckelmans, G., Lonfils, T., Bricteux, L., Duponcheel, M. and Bourgeois, N.

"THE WAKE4D SIMULATION PLATFORM FOR PREDICTING AIRCRAFT WAKE VORTEX TRANSPORT AND DECAY: DESCRIPTION AND EXAMPLES OF APPLICATION"

AIAA Paper No. 2010-7994, Toronto, Canada, August 2010.

The WAKE4D is a '3-D space + time' wake vortex (WV) prediction platform software developed at UCL. It allows to handle complete flight scenarios in 3-D space, and with given met conditions. It simulates the transport and decay of the WV generated by an aircraft evolving along a given flight path and under those met conditions. It uses many 'computational gates' to discretize the flight path, and, in each gate,

it uses either the Deterministic wake Vortex Model (DVM) or the Probabilistic wake Vortex Model (PVM), depending on application. The DVM constitutes the core of the WAKE4D. The models used in the DVM are here briefly presented together with their assessment and use in the past. The PVM is also presented. It enables a statistical analysis of the WV behavior using the DVM as a sub-tool in a Monte-Carlo approach. The WAKE4D platform software (or any of its subcomponent model software, DVM and PVM) can be used for off-line studies or can be part of real-time operational systems. Some examples of use of the WAKE4D are presented: simulation of a detailed approach to Marseille airport with 3-D WV reconstruction, simulation in support to a time-based separation concept on approach to a generic airport, simulation of take-off with potential WV encounter analysis on a parallel arrival runway, 3-D velocity field evaluation using the WAKE4D results: case of a take-off, thus with phases of WV in ground effect, and case of a flight at high altitude taking into account the Crow instability development.

"TOWARD UNDERSTANDING WAKE VORTICES AND ATMOSPHERIC TURBULENCE INTERACTIONS USING LARGE-EDDY SIMULATION"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 109-130

As aircraft wake vortices descend, they are transported by the air mass in which they are embedded and are decayed by both internal and external processes. Near the airport, these external influences are usually due to planetary boundary layer (PBL) turbulence. Using large-eddy simulation (LES), one may simulate a variety of PBL conditions. In the LES method, turbulence is generated in the PBL as a response to surface heat flux, horizontal pressure gradient, wind shear, and/or stratification, and may produce convective or unstably stratified, neutral, or stably stratified PBL's. Each of these PBL types can occur during a typical diurnal cycle of the PBL. Thus, it is important to be able to characterize these conditions with the LES method. Once this turbulent environment has been generated, a vortex pair will be introduced and the interactions are observed. The objective is to be able to quantify the PBL turbulence vortex interaction and be able to draw some conclusions of vortex behavior from the various scale interactions.

"RESEARCHES OF INTERACTION OF AIRCRAFT WAKE VORTICES AND CONDENSATION TRAILS"

AIAA Paper 2013-2554, June 2013, San Diego, CA.

The report presented is devoted to aircraft wake vortices and condensation trails interaction. Condensation trails could affect heat exchanging processes in the atmosphere and deteriorate ecology by contribution to 'greenhouse effect.' With the aim of investigation of condensation trails formation and minimization of its negative effect on ecology there was developed in the PJSC 'Flight Research Institute named after M. M. Gromov' a complex methodology of quantitative assessment of condensation trails characteristics and its formation prognosis during cruise flights of aircraft with jet

engines of various types. During flight tests it was demonstrated the necessity of accounting of aircraft condensation trails and wake vortices interaction and it is implemented in the methodology. Mathematical model of condensation trails and wake vortices development and interaction was created for that purpose. Using the model developed there were performed the calculations of different aircraft condensation trails and wake vortices and there were carried out the researches of the influence of atmospheric conditions, presence of axial flows in the vortices nuclei and engines location on the wing on the process of condensation trail and wake vortex interaction. The description of this mathematical model and some research results are presented.

Dee, F. W. and Nicholas, O. P.

"FLIGHT MEASUREMENTS OF WING-TIP VORTEX MOTION NEAR THE GROUND"

ARC Paper CP-1065, January 1968, Royal Aircraft Establishment, Bedford, England.

Tests have been made to measure the movement of the wing tip vortices from a Hunter aircraft flying at 170 knots approximately 35 feet above a runway, in a variety of wind conditions. Measurements were limited to a maximum time of 20 seconds after vortex generation. During this period the theoretical predictions presented are in good general agreement with the observed motions; however significant differences did occur. There was no clear indication as to whether the vortices decayed more rapidly in the presence of the ground and atmospheric turbulence, than would have been expected from the ground in calm air. Limited tests were also made to study the vortex mutual interaction away from the ground.

Deierling, W. and Williams, J. K.

"RELATIONSHIPS BETWEEN LIGHTNING AND CONVECTIVE TURBULENCE"

In Aviation Turbulence, edited by R. Sharman and T. Lane, Chapter 8, 2016, Springer International Publishing Switzerland, pp. 179-192.

Total lightning has been shown to correlate well with thunderstorm dynamics. Thus, correlations may exist between in-cloud convective turbulence and total lightning activity. Over the continental United States, the NEXRAD Turbulence Detection Algorithm (NTDA) provides three-dimensional (3D) fields of in-cloud Eddy Dissipation Rate (EDR), which is a quantitative measure of turbulence. Comprehensive total lightning measurements are available in some regions of the United States such as in Northern Colorado and New Mexico. Herein, investigation of the temporal and spatial relationships of 3D total lightning and NTDA EDR measurements for non-severe single cell thunderstorms in New Mexico and severe storms in Colorado are described. Results suggest that the occurrence of moderate or greater turbulence at upper levels of storms is related to storm total lightning flash rate, though exact relationships depend on the storm type. Areas of moderate and greater turbulence are also observed to coincide with the footprint of horizontal lightning flash extents. Time series show that lighter turbulence begins to occur prior to lightning initiation in the storms and extends past the storm's lightning activity. Furthermore, trends of storm total moderate or greater turbulence are correlated to

storm total lightning flash rate and extent. These observations are consistent with other recent studies by the authors and others that suggest that total lightning may be useful in diagnosing areas of potentially hazardous atmospheric turbulence. With the expected advent of geostationary satellite-based lightning mapping in the next few years, possible relationships between lightning and turbulence characteristics might provide useful information to aviation users, particularly in oceanic or remote areas where ground-based Doppler weather radar observations are unavailable.

Deissler, R. G. and Boldman, D. R.

"TORNADOLIKE GRAVITY-DRIVEN VORTEX MODEL"

NASA TN D-7738, August 1974, Lewis Research Center, Cleveland, OH.

A study was made of the buoyancy-induced vorticity concentration produced as the fluid in a vortex accelerates vertically. The boiloff from liquid nitrogen, to which a small amount of initial vorticity was added, provided a source of cool, heavy gas in which a concentration of vorticity could take place. Condensation streamers made the flow visible. It was shown that the presence of a surface boundary layer is not necessary for an effective concentration of vorticity. A simple theoretical analysis of the phenomenon was also made. A radial contraction of the flow with vertical position and a characteristic hook shape in the top view of the streamlines were observed in both theory and experiment. The vorticity concentration observed herein may be similar to that which occurs in tornadoes.

Deissler, R. G. and Perlmutter, M.

"ANALYSIS OF THE FLOW AND ENERGY SEPARATION IN A TURBULENT VORTEX"

Journal of Heat Mass Transfer, Vol. 1, 1960, pp. 173-191.

An analysis is made of the velocity, temperature, and pressure distributions in a turbulent vortex with radial and axial flow. For making the calculations the vortex is divided into a core and an annular region, each with a different uniform axial mass velocity, although the equations obtained are applicable to an arbitrary axial mass velocity distribution. Tangential velocity, temperature, and pressure distributions, as well as curves for overall energy or temperature separation, are produced and compared with experiment. Using the analytical results, the causes of the energy separation are studied. It is concluded that the most important factor affecting the total temperature of a fluid element in a compressible vortex is the turbulent shear work done on or by the element.

"IN-FLIGHT FLOW VISUALIZATION AND PRESSURE MEASUREMENTS AT LOW SPEEDS ON THE NASA F-18 HIGH ALPHA RESEARCH VEHICLE"

Proceedings of Fluid Dynamic Panel Symposium, Vortex Flow Aerodynamics, AGARD, CP-494, Scheveningen, The Netherlands, October 1990, pp. 13-1 to 13-42

In-flight results from surface and off-surface flow visualizations and from extensive pressure distributions document the vortical flow on the leading-edge extensions (LEX s) and forebody of the NASA F-18 high alpha research vehicle (HARV) for low speeds and angles of attack up to 50 deg. Surface flow visualization data, obtained using the emitted fluid technique, were used to define separation lines and laminar separation bubbles (LSB). Off-surface flow visualization data, obtained by smoke injection, were used to document both the path of the vortex cores and the location of vortex core breakdown. The location of vortex core breakdown correlated well with the loss of suction pressure on the LEX and with the flow visualization results from ground facilities. Surface flow separation lines on the LEX and forebody corresponded well with the end of pressure recovery under the vortical flows. Correlation of the pressures with wind-tunnel results show fair to good correlation.

del Pino, C., Lopez-Alonso, J. M. and Fernandez-Feria, R.

"DYNAMICS OF THE WING-TIP VORTEX IN THE NEAR FIELD OF A NACA 0012 AEROFOIL"

The Aeronautical Journal, Vol. 115, No. 1166, April 2011, pp. 229-239.

The dynamics of the wing tip vortex in the near field of a NACA 0012 airfoil has been analyzed by means of flow visualizations in a water tunnel. Different axial distances near the wing up to four chords. Reynolds numbers up to 42,000 and three angles-of-attack are studied to characterize the behavior of the vortex meandering. The spatio-temporal vortex center positions show distorted elliptical shapes in a (x,y)-plane. The Reynolds number has no significant influence on the axial evolution of the meandering amplitude. In addition, the flow visualizations obtained with a low-speed camera are analyzed by the singular value or proper orthogonal decomposition. Thus, the most energetic displacement modes are obtained. The frequency associated to these modes is computed by FFT. In all the cases studied, our results show that the most unstable mode corresponds to the azimuthal wavenumber $n=1$ in the so-called Kelvin helical modes and the frequency is lower or close to 1 Hz.

del Pino, C., Parras, L., Felli, M. and Fernandez-Feria, R.

"STRUCTURE OF TRAILING VORTICES: COMPARISON BETWEEN PARTICLE IMAGE VELOCIMETRY MEASUREMENTS AND THEORETICAL MODELS"

Physics of Fluids, Vol. 23, 2011, pp. 013602-1 - 013602-12.

The velocity field of the trailing vortex behind a wing at different angles of attack has been measured through the stereo particle image velocimetry technique in a water tunnel for Reynolds numbers between 20000 and 40000 for several distances to the wing tip. After filtering out the vortex meandering, the radial profiles of the axial and the azimuthal velocity components and of the radial profiles of the vorticity were compared to the theoretical models for trailing vortices by Batchelor and by Moore and Saffman, whose main features are conveniently summarized. We consider the downstream evolution of these profiles from just a fraction of the wing chord to more than ten chords. The radial profiles of the vorticity and the azimuthal velocity are shown to fit quite well to Moore and Saffman's trailing vortex model, while Batchelor's model does not fit so well, especially in the tails of

the profiles. At the downstream distances considered, the radial profiles of the axial velocity do not adjust so well to Moore and Saffman's model as the azimuthal velocity profiles do, but the disagreement with Batchelor's model is quite manifested, especially at the axis. Thus, the details of the flow structure are in better agreement with the predictions of Moore and Saffman's model. The downstream evolution of several key features of the measured velocity profiles is also in agreement with the predictions of Moore and Saffman's model, within the dispersion of the experimental data, but up to the largest axial distance considered in this work we cannot decide if they follow the asymptotic behavior predicted by this model.

Delaney, B. T.

"AIRCRAFT VORTEX EFFECTS ON GROUND LEVEL POLLUTANT CONCENTRATION AND TRACKING OF VORTEX MOVEMENT IN THE AIRPORT ENVIRONMENT"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 264-282

The effect on ground level pollutant concentrations of including a mechanism to consider the transport of aircraft-generated pollutants captured in the trailing vortex system is examined by coupling a three-dimensional vortex transport program with a line source dispersion routine. It was found that not only would the ground level concentrations of oxides of nitrogen change but so would the spatial distribution. Echoes recorded by a FM-CW radar are shown to be the result of water vapor and pollutants trapped in a descending vortex system.

Delaney, B. T. and Ledbetter, J. O.

"AIRCRAFT VORTEX EFFECTS ON GROUND LEVEL POLLUTANT CONCENTRATION"

Air Pollution Control Assoc., Paper 77-41,5, Toronto, Canada, June 1977

The effect of aircraft wake vortex transport on airport air pollution models is assessed. In particular, the emission of nitrogen oxides by aircraft during one segment of the takeoff phase (i.e., during the first 943 m of climb) is not adequately simulated by models adopted by the U.S. Air Force and the Environmental Protection Agency. In a study conducted at a major airport, inclusion of the effects of a rolled up contrarotating vortex pair generated by aircraft in the takeoff phase is found to improve the nitrogen oxides prediction capability of a conventional airport air quality model.

Delaney, B. T., Noonkester, R. V. and Ledbetter, J. O.

"REMOTE SENSING OF AIRCRAFT WAKE VORTEX MOVEMENT IN THE AIRPORT ENVIRONMENT"

Air Pollution Control Assoc., Paper 77-41,4, Toronto, Canada, June 1977

The use of FM-CW radar to track aircraft wake vortices at airports is discussed; remote tracking of vortices may aid in studying ground level pollution dispersion and the effects of vortex trails on

encountering aircraft. Results are reported for a month-long test of a FM-CW radar system placed at the edge of a runway at Lindbergh Field, San Diego. V-echoes detected by the FM-CW radar appear to reflect the water and/or exhaust products trapped in the descending vortex trails of aircraft departing from the runway. Thus FM-CW radar detection seems a possible alternative to vortex sensing systems based on acoustic energy, anemometers, or laser backscatter.

Delaplace, F.

"METHOD AND DEVICE FOR REDUCING THE WAKE VORTICES OF AN AIRCRAFT IN THE APPROACH/LANDING PHASE"

US Patent Application 2007/0170313 A1, July 2007.

According to the invention, the spoilers are automatically ordered to deploy when the lift-augmenting aerodynamic surfaces are themselves ordered to deploy and are automatically ordered to retract when at least one of the following three conditions holds: the angle of incidence of the aircraft is equal to or greater than an incidence threshold; the speed of the aircraft is equal to or less than a speed threshold; and the aircraft is instigating a go-around maneuver.

Delbende, I. and Chomaz, J.-M.

"NONLINEAR CONVECTIVE/ABSOLUTE INSTABILITIES IN PARALLEL TWO-DIMENSIONAL WAKES"

Physics of Fluids, Vol. 10, No. 11, November 1998, pp. 2724-2736

The linear versus nonlinear convective/absolute instability of a family of plane wake profiles at low Reynolds number is investigated by numerically comparing the linearized and the fully nonlinear impulse responses. Through an analysis of the linear flow response obtained by direct numerical simulation (DNS), the linear temporal and spatiotemporal instability properties are retrieved, in excellent agreement with the properties obtained by Monkewitz (1994) from the study of the associated viscous dispersion relation. Nonlinear terms are then shown to limit the amplitude to a saturation level within the response wave packet, while leaving the trailing and leading edges unaffected. For this family of open shear flows, the velocities of the fronts, formed between the trailing or leading edge and the central saturated region, are thus selected according to the linear Dee and Langer criterion (1983), whereas the front solutions are fully nonlinear. This property may be of importance in justifying the use of linear instability properties to predict the onset and the frequency of the von Karman vortex street, as determined by Hammond and Redekopp (1997).

Delbende, I., Chomaz, J.-M. and Huerre, P.

"ABSOLUTE/CONVECTIVE INSTABILITIES IN THE BATCHELOR VORTEX: A NUMERICAL STUDY OF THE LINEAR IMPULSE RESPONSE"

J. Fluid Mechanics, Vol. 355, 1998, pp. 229-254

The absolute/convective instability properties of the Batchelor vortex are determined by direct numerical simulation of the linear impulse response. A novel decomposition procedure is applied to the computed wavepacket to retrieve the complex wavenumber and frequency prevailing along each spatio-temporal ray. In particular, the absolute wavenumber and frequency observed in the laboratory frame are determined as a function of swirl parameter and external flow. The introduction of a moderate amount of swirl is found to strongly promote absolute instability. In the case of wakes, the transitional helical mode that first undergoes a switch-over to absolute instability is found to be $m = -1$ without requiring any external counterflow. In the case of jets, the transitional helical mode is very sensitive to swirl and varies in the range $-5 \leq m \leq -1$. Only a slight amount of external counterflow (1.5% of centerline velocity) is then necessary to trigger absolute instability. The results of this numerical procedure are in good qualitative and quantitative agreement with those obtained by direct application of the Briggs-Bers criterion to the inviscid dispersion relation (Olendraru et al. 1996). Implications for the dynamics of swirling jets and wakes are discussed.

"VARIOUS ASPECTS OF FLUID VORTICES"

Comptes Rendus Mecanique, Vol. 332, Issue 9, September 2004, pp. 767-781

A general review of the current research in vortex dynamics is presented, based on contributions given during a workshop held in May 2003 at Porquerolles, France. This article aims at providing a picture of the work performed on this subject in the French community. Various cases are covered, from 2D vortex patches to 3D vortex tubes; from isolated vortices to shear flows. Different contexts are considered: pure Euler and Navier-Stokes flows as well as stratified, rotating and magnetic flows.

Delbende, I., Rossi, M. and Le Dizès, S.

"STRETCHING EFFECTS ON THE THREE-DIMENSIONAL STABILITY OF VORTICES WITH AXIAL FLOW"

J. Fluid Mech., Vol. 454, March 2002, pp. 419-442

The effect of stretching on the three-dimensional stability of a viscous unsteady vortex is addressed. The basic flow, which satisfies the Navier-Stokes equations, is a vortex with axial flow subjected to a time-dependent strain field oriented along its axis. The linear equations for the three-dimensional perturbations of the stretched vortex are first reduced by using successive changes of variables to equations which are almost identical to those of the unstretched vortex but with time-dependent parameters. These equations are then numerically solved in the particular case of the Batchelor vortex with a strain field which first compresses then stretches the vortex. Through this simulation, it is qualitatively demonstrated how the simultaneous action of stretching and azimuthal vorticity may destabilize a vortex. It is also argued that it provides a possible mechanism for the vortex bursts observed in turbulence experiments.

Delery, J. and Horowitz, E.

"INTERACTION BETWEEN A SHOCK-WAVE AND A VORTEX FLOW"

Fluid Dynamics Panel Symposium, AGARD-CP-342, April 1983, Rotterdam, Netherlands, pp. 5-1 - 5-9.

The interaction between a vortex and a shock-wave normal to the streamline axis of the vortex has been studied both experimentally and theoretically. Measurements have been made for four values of the upstream Mach number ranging from 1.6 to 2.28. They allowed the characterization of the shock effect on the vortical flow structure when breakdown does not occur. They also led to the definition of a breakdown limit function of the two parameters: normal shock strength - vortex swirl/ratio. Two flow configurations associated respectively with interaction without and with vortex bursting have been carefully probed by using a two-color LDV system. When breakdown occurs, the mean meridian motion comprises a 'recirculating bubble' near the axis of the structure. A flow model has been developed in the framework of the Euler equations. As long as the vortex does not burst, the calculations thus made give a faithful description of flow phenomena. They also predict a limit for vortex breakdown which agrees satisfactorily with experiment. [In French].

Delery, J. M.

"SEPARATION AND VORTEX FORMATION IN TURBULENT FLOWS"

2nd Caribbean Conf. on Fluid Dynamics, Jan. 1992, Trinidad, West Indies.

Separation in three-dimensional flows leads to the formation of vortical structures resulting from rolling up of the viscous flow 'sheet', initially contained in a thin boundary layer, which springs up from the surface into the outer perfect fluid flow. A clear physical understanding of this phenomenon must be based on a rational analysis of the flow field structure using the critical-point theory. With the help of this theory it is possible to correctly interpret the surface flow patterns which constitute the imprints of the outer flow and to give a rational and coherent description of the vortical system generated by separation. This kind of analysis is applied to separated flows forming on typical obstacles, the field of which has been thoroughly studied.

Delery, J. M.

"PHYSICS OF VORTICAL FLOWS"

Journal of Aircraft, Vol. 29, No. 5, Sept.-Oct. 1992, pp. 856-876.

Separation in three-dimensional flows leads to the formation of vortical structures resulting from rolling up of the viscous flow 'sheet' initially contained in a thin boundary layer, which springs up from the surface into the outer perfect fluid flow. A clear physical understanding of this phenomenon must be based on a rational analysis of the flow field structure using the critical-point theory. With the help of this theory, it is possible to interpret correctly the surface flow patterns that constitute the imprints of the outer flow and to give a rational and coherent description of the vortical system generated by separation. This kind of analysis is applied to separated flows forming on typical obstacles, the field of

which has been thoroughly studied by means of visualizations and probing using multi-hole pressure probes and laser velocimetry. Thus, the skin friction line patterns of a transonic channel flow and of a multibody launcher are interpreted. Then, the vortical systems of a delta wing and an afterbody at an incidence are considered. The last two configurations are a missile fuselage-type body and an oblate ellipsoid.

Delery, J. M.

"ASPECTS OF VORTEX BREAKDOWN"

Prog. Aerospace Sci., Vol. 30, No. 1, March 1994, pp. 1-59

Carefully executed visualizations and velocity measurements have allowed a clear description of the field associated with breakdown. These experiments executed in a vortex tube, where the vortex is confined, or in arrangements where it is free, show that the existence of a stagnation point forming on the centerline of the vortical structure is a distinctive feature of breakdown. Different types of break down (spiral and bubble types) seem to exist, however this point is subject to controversy. At the same time, the vortex undergoes a brutal dilatation with the generation of large-scale fluctuations.

Delery, J., Horowitz, E., Leuchter, O. and Solignac, J.-L.

"FUNDAMENTAL STUDIES ON VORTEX FLOWS"

La Recherche Aerospatiale, No. 2, 1984, pp. 1-24.

Subsonic and supersonic flows are investigated in a study concerning vortex flows subjected to the destabilizing effect of an adverse pressure gradient. For the subsonic condition, two modes of vortex generation are considered: a vortex created by the rolling up of two vertical sheets coming from the trailing edge of two vanes mounted on a cylindrical string, and a vortex which is produced by a delta wing with an angle of attack. During supersonic flow tests, much attention is focused on the interaction between a normal shock wave and vortex whose streamwise axis is perpendicular to the shock. The data obtained on flows in subsonic and supersonic conditions, using conventional pressure probes and two-color laser velocimetry, gives a description of the vortex's mean and turbulent properties which evolve toward breakdown. In both subsonic and supersonic tests, a limit on the vortex breakdown could be defined experimentally as a function of parameters measuring the intensity of the destabilizing pressure gradient, and the vortex strength. For the shock wave/vortex interaction, this limit can be predicted using a no-flow model in which the Euler equations are solved by a time-marching method.

Delisi, D.

"CROW INSTABILITY IN HIGH AND LOW REYNOLDS NUMBER LABORATORY EXPERIMENTS, DEPENDENCE ON THE ENVIRONMENT, AND COMPARISONS TO FULL-SCALE MEASUREMENTS"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008.

Crow instability transforms two-dimensional vortex wakes, such as those generated by aircraft wingtips and flaps, into three-dimensional vortex rings. It was commonly believed that these 3D vortex rings, once generated, rapidly decay and dissipate. Through a series of laboratory experiments, we will examine how this instability evolves with ambient stratification, turbulence, shear, and a combination of turbulence and shear. Whenever possible, we will compare these experiments to full-scale measurements obtained at Denver and elsewhere.

Delisi, D. P.

"LABORATORY MEASUREMENTS OF THE EFFECT OF AMBIENT TURBULENCE ON TRAILING VORTEX EVOLUTION"

AIAA Paper No. 2006-1078, Reno, NV, January 2006

We have repeated the laboratory experiments of Sarpkaya and Daly, using different wings and different flow visualization techniques. Our results show that, although our vortices link at the same nondimensional times as those of Sarpkaya and Daly, the vortices do not die, but, instead, continue migrating as vortex rings, much as they would in a flow with no ambient turbulence. We also measured the turbulence levels between the vortex cores of both laboratory vortices and behind a C-130 aircraft. These turbulence levels were larger than many atmospheric turbulence levels, with normalized turbulent velocity dissipation rates greater than 0.3 within nondimensional times. Our conclusion is that, for nondimensional turbulent velocity dissipation rates less than ~ 0.3 , ambient turbulence has a large effect on when vortices from a wing link into rings, but may have little effect on their decay.

Delisi, D. P.

"LABORATORY STUDIES OF MASS TRANSPORT BY AIRCRAFT WAKE VORTICES"

XXV General Assembly, European Geophysical Society, Nice, France, April 2000

Aircraft engine exhaust can be transported vertically from one altitude to another by the counter-rotating vortices generated by the wing. In this paper, we present vortex transport laboratory measurements made in a water-filled towing tank. The vortices were generated by towing a wing down the tank at a constant angle of attack and a constant depth below the surface. The wing was towed through a cloud of particles, some of which became entrained into the vortex system. As the vortices migrated vertically, many particles remained in the vortex cell while some of the particles detrained from the cell. By counting the number of particles detrained and the total number of particles in the system, we can calculate the percent of particles left in the ring as a function of the vertical distance from the generation point. Measurements of vortex transport in both non-stratified and stratified flows will be presented as well as comparisons to published flight data.

Delisi, D. P.

"LABORATORY MEASUREMENTS OF THE CIRCULATION DECAY OF VORTICES GENERATED FROM A LIFTING WING"

AIAA Paper 2011-3034, June 2011, Honolulu, Hawaii.

Circulation measurements of the vortices generated behind a wing are made in both unstratified and stratified water. The circulations are measured in both the two-dimensional line vortices which evolve immediately behind the wing and in the three-dimensional ring vortices which evolve from the line vortices. The measurements show that the circulation decay of the vortices is faster in a stratified fluid than in an unstratified fluid, as expected. The circulations of the line vortices were measured in a plane perpendicular to the direction of motion of the wing. The circulation of the ring vortices was initially measured in a plane parallel to the direction of motion of the wing. Because these two measurement planes are perpendicular to each other, the circulations of ring vortices in an unstratified fluid were also measured in the plane perpendicular to the motion of the wing, that is, in the same measurement plane as the line vortices. These two sets of circulations of the ring vortices, in a plane perpendicular to the motion of the wing and in a plane parallel to the motion of the wing, are shown to be similar. For all the measurements, the circulation decay of vortex rings is shown to be about three times slower than the circulation decay of the line vortices. Finally, the circulations of the line vortices in a stratified fluid, with a Froude number of around 6, are shown to be consistent with measurements of circulations of aircraft vortices out of ground effect in an atmosphere with the same Froude number. This consistency suggests that laboratory measurements of the vortices behind lifting wings may, at least in some cases, be applicable to full-scale aircraft vortices.

"MEASUREMENTS AND IMPLICATIONS OF VORTEX MOTIONS USING TWO FLOW-VISUALIZATION TECHNIQUES"

J. Aircraft, Vol. 27, No. 11, November 1990, pp. 968-971

The new, laboratory wake measurements presented here are significant in their own right; however, the authors believe these results and the implications of incorporating different visualization techniques may be of interest to researchers studying other aircraft vortex flows. The evolution and migration of vortices is applicable to a wide class of aerospace problems. The data presented here point out the deficiencies in our current understanding of vortex motions. The evolution is even less well understood if we include ground effect, wind, and other environmental factors.

"EXPERIMENTAL MEASUREMENTS OF THE EVOLUTION OF A VORTEX PAIR IN A NONSTRATIFIED FLUID, PART 1: MIGRATION AND PERSISTENCE"

AIAA Paper No. 2009-0345, January 2009, Orlando, FL.

Laboratory measurements of the evolution of a vortex pair from a lifting wing in a non-stratified, nonturbulent, and unsheared fluid are presented. The new aspect of these measurements is that we have been able to follow vortex evolution from generation through decay in three stages: (1) a two-dimensional line vortex pair, (2) transition from two-dimensional to three-dimensional vorticity, and (3) development, migration, and decay of vortex rings. In non-dimensional units of time, T , the first stage is shown to last until T about 5, the second stage from T about 5 to about 10, and the third stage from T about 10 to at least 60 or more. In non-dimensional units of migration distance, the vortices were observed to propagate up to or beyond $H = 20$. Measurements were initially obtained using model laboratory wings. These wings had an aspect ratio of around 2, chord Reynolds numbers ranging from 41,000 to 124,000, and lift coefficients of around 1.0. Because the laboratory results were significantly different from previously reported results, we conducted tests on a larger-scale wing in a lake to determine if facility effects or laboratory flow visualization methods were a significant factor in the laboratory observations. In the lake study, we used a multi-element airfoil with an aspect ratio of around 1.7, a chord Reynolds number of 2,600,000, and a lift coefficient of 1.38. Results from the lake tests are presented which confirm the non-dimensional migration results of the laboratory study. This paper presents migration and persistence results. A companion paper (Part 2) presents detailed measurements of the low Reynolds number wings used in this study and measurements of the near- and far-wake vortex evolution.

Delisi, D. P. and Greene, G. C.

"EXPERIMENTAL MEASUREMENTS OF THE EVOLUTION OF A VORTEX PAIR IN A NONSTRATIFIED FLUID, PART 2: LOW REYNOLDS NUMBER WINGS AND VORTEX WAKE CHARACTERISTICS"

AIAA Paper No. 2009-0346, Jan. 2009, Orlando, FL.

Laboratory measurements of low Reynolds number 3-D wings and vortex wakes generated by the wings were obtained in a water-filled towing tank. Detailed measurements follow the vortices from near generation through vortex reconnection and the evolution and migration of vortex rings. Studies were performed with the wings at various distances below the water surface. Measurements show that the magnitude of lift generated decreases as the wing is towed closer to the water surface. The lift approaches the lift at deep depths for trailing edge depths below the surface of three chords or more. Measurements of wing characteristics show that cambered plate wings are more efficient generators of lift than conventional airfoil shapes at the Reynolds numbers of the experiments, where the chord Reynolds numbers range from around 40,000 to around 164,000. Near-field vortex measurements show that the initial velocity of the vortex system is well predicted from measurements of lift and the initial vortex separation. Near-field axial velocity measurements behind the wings are also presented and show an initial jet velocity in the core followed by a velocity defect. Measurements of the sinusoidal, or Crow, instability show that the most unstable wavelength, on average, is shorter than that predicted by Crow. Measurements of the distance between vortex rings as well as vortex ring diameters are also presented. Far-field vortex measurements show that there is considerable variability in the angle vortex rings make to the vertical. Because of this variability, many vortex rings merge as they migrate, resulting in fewer rings with increasing vertical distance from the ring. It is suggested that the variability in the angle of migration is caused by variability in vortex reconnection.

"DETRAINMENT FROM A VORTEX PAIR IN A NONSTRATIFIED FLUID"

AIP Conference Proceedings, Vol. 1376, 2011, pp. 311-313.

Laboratory experiments of detrainment from a vortex pair are reported to better understand and numerically model the evolution of aircraft trailing wake vortices. The vortex pair was generated by towing a model wing down a water-filled, unstratified towing tank at an angle of attack. Nearly neutrally buoyant particles were introduced into the vortex cell or into the vortex core. The detrainment of fluid from the vortex cell is shown to be faster than the detrainment from the vortex core.

Delisi, D. P. and Pierce IV, W. P.

"CIRCULATION MEASUREMENTS OF MERGING VORTEX RINGS"

AIAA Paper No. 2011-3033, June 2011, Honolulu, Hawaii.

Circulation measurements of merging vortex rings were performed in an unstratified fluid to determine the circulation loss during vortex reconnection. The rings were generated by pistons, aligned with a 15-degree difference between the two propagation directions. Circulation measurements were made in two measurement planes. A front view plane, in the plane of the generators and the centers of the two vortex rings, was used to measure the circulations of the vortex rings before reconnection. A side view plane, oriented symmetrically between the generators and orthogonal to the front view plane, was used to measure the circulations of the vortex rings emerging from the reconnection. The circulations of both laminar and turbulent vortices were measured. The measurements show that over 90% of the circulation is conserved during the reconnection of both laminar and turbulent vortex rings. Thus, almost no circulation was lost (beyond natural single-ring decay) between the vortices that disappeared in the front view and reappeared in the side view for either laminar or turbulent vortex rings. These results suggest that, while the vortex cells may be laminar or turbulent, their cores are laminar and reconnection is essentially a laminar process. These results also suggest that when aircraft line vortices evolve into vortex rings, when the flow is unstratified, the circulations of these rings will be nearly the same as the circulations of the line vortices before reconnection.

"DEVELOPMENT OF WAKE VORTEX PREDICTION ALGORITHMS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 469-488

Wake vortex prediction algorithms are developed that model the essential physics; handle atmospheric parameters; handle out-of-ground effect, near ground effect, and in-ground effect; and

runs quickly on a PC or workstation. In this project the following tasks are performed: (1) Predictor algorithm results have been compared with data for vortices in and out of ground effect; (2) Algorithm works reasonably well but needs refinement; and (3) Current predictor algorithm will be used at DFW.

Delisi, D. P. and Robins, R. E.

"EFFECTS OF CROSSWIND SHEAR ON TRAILING VORTEX EVOLUTION"

AIAA Paper No. 2006-1075, Reno, NV, January 2006

Wake vortices from aircraft evolve in a local atmosphere that may contain stratification, and/or turbulence, and/or wind. Previous investigations have studied the effects of ambient stratification and turbulence on wake vortex evolution, but the effects of wind, and, more specifically, wind shear, defined as the vertical change of the horizontal wind, are less well understood. In this study, we used laboratory experiments and numerical simulations to examine the effects of shear on the evolution of wake vortices. It is found that the second derivative of the crosswind profile is the important parameter in determining the vertical position of the vortices and the angle of tilt of a line joining the vortex cores. A concave shear profile tilts the vortices in one direction while a convex profile tilts the vortices in the other direction. The stronger the shear gradient, the larger the vortex tilt, and the slower the vertical migration speed of the vortex pair through the shear gradient, the larger the vortex tilt. The tilt of the vortex cores begins when the vortex cell first enters the region where the shear gradient is non-zero, and the tilt stops changing when the vortex cell leaves the region where the shear gradient is non-zero. Thus, the shear gradient affects the entire vortex cell, not just the vortex cores. The numerical simulations predict quite well the observed vertical descent and the tilt of the vortex cores observed in the laboratory experiments.

"VORTEX EVOLUTION IN REALISTIC GEOPHYSICAL FLOWS"

NWRA-CR-93-R083, July 1996, Northwest Research Associates, Bellevue, WA.

Laboratory experiments and numerical simulations of vortex evolution in realistic geophysical flows are reported. Two laboratory experiments are discussed. The first experiment examined three-dimensional vortices produced from a wing in a non-stratified non-sheared flow. This study showed that vortices can migrate farther and last longer than previously reported. The second laboratory experiment investigated the evolution of two-dimensional vortices in a stratified flow shear flow. This experiment showed the evolution of a 'solitary' vortex when the background Richardson number was around four or less. Circulation estimates were also obtained for these vortices and showed a more rapid decay of circulation of the countersign vortex. Two numerical studies are also reported. In the first numerical study, we examined the evolution of a two-dimensional vortex pair in a stratified shear flow. This study showed that the vortex pair evolved into a solitary vortex when the ambient Richardson number was on the order of unity or less. A second numerical study used a k-e model to examine the evolution of a two-dimensional vortex pair. It was found that the standard k-e model did a

poor job of representing the turbulent dissipation in vortex flows. Good agreement with experimental results was obtained with this model with a reduction in the eddy viscosity coefficient.

"SMALL-SCALE INSTABILITIES IN TRAILING WAKE VORTICES IN A STRATIFIED FLUID"

AIAA Paper No. 1997-1784, Snowmass Village, CO, June 1997.

We have examined the behavior of wake vortices in density-stratified fluids, both in laboratory experiments and by using a three-dimensional numerical code. In an unstratified fluid, the primary instability is the Crow instability, which has a characteristic initial wavelength of around $8.6B$, where B is the initial separation distance between the vortices. In stratified fluids at late times, we have observed an instability with a shorter wavelength of around $1-2B$. This instability appears at a time in the evolution of the vortices when the vertical migration nearly has reached its maximum extent. For a commercial aircraft, the vertical peak-to-peak amplitude due to this instability could be greater than 75 ft.

"OBSERVATIONS AND PREDICTIONS OF TRAILING WAKE VORTEX EVOLUTION FOR AIRCRAFT AND LABORATORY MODELS"

Proceedings of the International Wake Vortex Meeting, TP 13166, edited by H. Posluns, Transport Canada, Montreal, Ottawa, Canada, December 1997, pp. 73-75

Wake vortex evolution is investigated using a wake vortex prediction algorithm, observations of aircraft wakes, and laboratory measurements behind model wings. The prediction algorithm in the out-of-ground effect (OGE) region is based on the original algorithm presented by Greene, with modifications for variable stratification and cross wind. The algorithm uses unrestrained point vortices for the near-ground effect and in-ground effect (IGE) regions. Countersign vorticity is modeled in the IGE region using multiple secondary vortices. The aircraft data were obtained under the NASA AVOSS Program at Memphis International Airport with the MIT/Lincoln Laboratory lidar sensor. The lidar measurements contain temporal information on both vortex location and circulation. The circulation estimates have been corrected to account for both vortex descent and drift. Laboratory data were obtained using model wings in a water-filled towing tank. Digital Particle Imaging Velocimetry was used to estimate vortex circulations and trajectories. Ensemble aircraft measurements from 25 Boeing-727 aircraft in the OGE region show circulation decay and a nearly constant vortex radius for more than 100 seconds after aircraft passage. The vortex trajectory and circulation estimates from the aircraft compare well to similar measurements from laboratory vortices with comparable Froude numbers. Both the aircraft and laboratory measurements are compared to estimates from the prediction algorithm.

"VORTEX EVOLUTION AND CHARACTERIZATION"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

A major concern with airport capacity issues is the characterization and evolution of trailing wake vortices. These vortices can be studied with laboratory models, numerical simulations, and aircraft measurements. An issue with using laboratory studies is how the difference in Reynolds number affects the results and the interpretations of those results. The danger is that effects that are observed in low-Reynolds number flows may not be observed in high-Reynolds number aircraft flows. Consequently, care must be used in interpreting low-Reynolds number studies and extrapolating those results to the high-Reynolds number aircraft case. For several years, we have been performing low-Reynolds number laboratory model studies and comparing those results to aircraft data and numerical simulations. Favorable comparisons of laboratory vortices with aircraft vortices and numerical simulations have included vortex migration, in both non-stratified and stratified environments, vortex core size with time after aircraft passage, vortex circulation as a function of time after aircraft passage, and the level of turbulence in the vortex cell. In addition, we have performed several laboratory studies with which we have no full-scale data for comparison. These studies include vortex separation with time and vortex lifetime in both quiescent and turbulent backgrounds.

"SHORT-SCALE INSTABILITIES IN TRAILING WAKE VORTICES IN A STRATIFIED FLUID"

AIAA Journal, Vol. 38, No. 10, October 2000, pp. 1916-1923

Measurements of the evolution of wingtip trailing wake vortices in nonturbulent and unsheared density-stratified fluids are reported, using both laboratory experiments and a three-dimensional numerical code. As is widely known, and as our laboratory and numerical results confirm, the primary instability for these vortices in an unstratified fluid is the Crow instability, which has a characteristic initial wavelength of around $8.6B$, where B is the initial separation distance between the vortices. In stratified fluids, however, our laboratory observations and numerical simulations show an instability with a shorter wavelength of around $B-2B$. This instability appears at a time in the evolution of the vortices when the vertical migration nearly has reached its maximum extent. The observed instability grows both in amplitude and wavelength with time. When the vortex Froude number is around one, the instability first becomes visible at a nondimensional time T of around 2 and reaches a maximum at T of around 4. For a commercial aircraft, the latter time corresponds to distances of around 10-25 km behind the aircraft. In flight, at $T \sim 4$, the vertical peak-to-peak amplitude oscillation of the vortex cores due to this instability could be up to 20 m with a horizontal wavelength around 100 m.

"COMPARISON OF LABORATORY WAKE VORTICES WITH AIRCRAFT VORTICES"

XXIII General Assembly, European Geophysical Society, Nice, France, April 1998

Measurements of wake vortices from both laboratory models and aircraft will be presented. The laboratory measurements were obtained in a water-filled towing tank using model wings. Vortex evolution in the laboratory is followed from generation through decay in three stages: (1) a 2-D line vortex pair, (2) transition from 2-D line vortices to 3-D vortex rings, and (3) development, migration, and decay of vortex rings. The laboratory experiments use both dye (for visualization) and neutrally-buoyant particles (for both visualization and DPIV measurements of circulation). We will present measurements in both non-stratified and stratified flows to show the effects of stratification. Measurements of aircraft vortices, obtained as part of NASA's AVOSS Wake Vortex Program, will also be presented. Simultaneous meteorological measurements will be used to interpret the aircraft wake vortices in terms of nondimensional parameters. We will compare vortex transport and decay from the laboratory and aircraft measurements both to each other and to a modified version of a wake vortex prediction algorithm originally reported by Greene (1986).

"GEM4D, A GENERAL VORTEX ENCOUNTER MODEL WITH 4 DEGREES OF FREEDOM: FORMATION, VALIDATION, AND USE"

AIAA Paper 2018-3020, June 2018, Atlanta, GA.

A fast, versatile, and easy to run wake vortex encounter model has been developed and tested. The model is called GEM4D for General vortex Encounter Model with 4 Degrees of Freedom. GEM4D uses a straight, unswept wing with a linear taper and classical aerodynamic strip theory. The model includes the X, Y, and Z directions and roll but does not include pitch or yaw effects. The results from GEM4D have been compared to results from both 6-Degree of Freedom Full Flight Simulators and from field data of wake vortex encounters. Four examples of these comparisons are shown, and include a range of aircraft size and vortex strength. In all the comparisons performed, using the results from the simulator tests and field encounters as 'truth' GEM4D reproduced the maximum roll (bank) angles from these encounters with differences from near zero to around 20 percent. Thus, GEM4D appears to contain all or most of the essential physics of a wake vortex encounter.

"RECENT LABORATORY AND NUMERICAL TRAILING VORTEX STUDIES"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 34-1 to 34-10.

Results from two laboratory studies and two numerical studies are presented. In the first laboratory study, measurements of the strength of vortices from a three-dimensional (3-D) model wing are presented. The measurements follow the vortices as they evolve in time from a two-dimensional (2-D) line vortex pair to the development and migration of 3-D vortex rings. It is shown that the resulting vortex rings can contain up to 40 percent of the initial vortex circulation. Thus, the formation of vortex

rings may not necessarily signal the end of the wake hazard to following aircraft. In the second laboratory study, we present the results of an experiment which shows how the spanwise drag distribution affects wake-vortex evolution. In the first numerical study results of 3-D numerical calculations are presented which show that the vortex Reynolds number has a significant influence on the evolution and migration of wake vortices. When the Reynolds number is large, 3-D vortex rings evolve from the initially 2-D line vortex pairs. These vortex rings then migrate vertically. When the Reynolds number is lower, the transition of vorticity from 2-D to 3-D is delayed. When the Reynolds number is very low, the vortices never transition to 3-D, and the vertical migration is significantly reduced. It is suggested that this effect may have been important in previous laboratory wake-evolution studies. A second numerical study shows the influence that vertical wind shear can have on trailing vortex evolution.

"AIRCRAFT WAKE VORTEX CORE SIZE MEASUREMENTS"

AIAA Paper No. 2003-3811, Orlando, FL, June 2003.

We have examined data from three aircraft field tests designed, in part, to measure the size of the vortex cores generated by the aircraft. The field tests were performed between 1990 and 1997 at Idaho Falls, ID, Wallops Island, VA, and John F. Kennedy International Airport (JFK) in NY. At Idaho Falls, an instrumented 200-foot tower was used to measure velocities in the wakes of Boeing 727, 757 and 767 aircraft flown upwind of the tower. In the Wallops Island test, velocities and smoke trails behind a Lockheed-Martin C-130 aircraft were measured by an instrumented North-American Rockwell OV-10 aircraft flown behind the C-130. For the JFK tests, the vortex wakes of landing aircraft were measured by a Continuous Wave lidar operated by MIT/Lincoln Laboratories. The results from all three field tests are quite consistent, and suggest that the size of the velocity cores in trailing vortices behind an aircraft is on the order of one percent of the wingspan of the aircraft, where core size is defined as the radial distance from the vortex center to the point of maximum tangential velocity. We note that numerical simulations of trailing vortex evolution typically use velocity vortex core sizes in the range from five to twelve percent of the wingspan of an aircraft. Thus, the values of velocity core size used in numerical models are significantly larger than the full-scale values reported here. We also show that a typical size of smoke trails, where smoke is used to visualize the vortices behind an aircraft, is approximately twice the size of the velocity core.

"FIRST RESULTS FROM THE NASA WAKE VORTEX MEASUREMENTS AT THE MEMPHIS INTERNATIONAL AIRPORT"

AIAA Paper 2014-2467, June 2014, Atlanta, GA.

New measurements of aircraft wake vortices and concurrent meteorological measurements are being made at the Memphis International Airport by NorthWest Research Associates, Inc., with the support

of Coherent Research Group, LLC, under the National Aeronautics and Space Administration Airspace Systems Program. The meteorological measurements began in March 2013 and are continuing today. These measurements consist of vertical temperature profiles, point wind and temperature measurements, and supporting meteorological measurements (rain, pressure, etc.). In addition, a Halo Photonics StreamLine lidar has been used since April, 2013 to provide vertical profiles of wind speed and direction. Finally, a Lockheed Martin Coherent Technology (LMCT) WindTracer lidar, owned and operated by Arizona State University, has been used since June, 2013. Both the LMCT lidar and the Halo Photonics lidar have been used to measure aircraft wake vortices and to provide additional wind information. These measurements are being used to characterize the evolution of aircraft wake vortices generated in ground effect and to correlate those measurements with atmospheric conditions. The first results from these measurements that show the dependence of wake evolution on atmospheric conditions are presented.

Delisi, D. P., Pruis, M. J., Wang, F. W. and Lai, D. Y.

"ESTIMATES OF THE INITIAL VORTEX SEPARATION DISTANCE, B-ZERO, OF COMMERCIAL AIRCRAFT FROM PULSED LIDAR DATA"

AIAA Paper 2013-0365, January 2013, Grapevine, TX.

An aircraft in flight generates multiple wake vortices, the largest of which are a result of the lift on the wings. These vortices rapidly roll up into a counter-rotating vortex pair behind the aircraft. The initial separation between the centroids of vorticity behind the aircraft, or the cores of the resulting vortex pair, is commonly denoted as b-zero. This separation distance is used to estimate the initial vortex strength (circulation) and to nondimensionalize both time and circulation behind the aircraft. Thus, b-zero is an important parameter in nondimensionalizing aircraft wake measurements. For an elliptically loaded wing, $b\text{-zero} = (\pi/4)s$, where s is the wingspan of the generating aircraft. The initial descent velocity of the vortex system behind the aircraft, $V\text{-zero}$, is proportional to $1/b\text{-zero}^2$. Thus, from estimates of $V\text{-zero}$ from lidar measurements, we can estimate b-zero. Estimates of $V\text{-zero}$ from lidar measurements of vortex altitude vs. time are presented in the Out of Ground Effect (OGE) region for aircraft arriving at Denver International Airport and San Francisco International Airport. Estimates of b-zero for these aircraft are then obtained. These measurements suggest that, while some estimates of b-zero from commercial aircraft are close to the value based on elliptical wing loading, some aircraft have distinctly nonelliptical values of b-zero.

"LABORATORY AND NUMERICAL STUDIES OF VORTEX EVOLUTION IN IDEAL AND REALISTIC ENVIRONMENTS"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 30-1 - 30-28

Laboratory and numerical results are presented for the evolution of aircraft vortices. The laboratory results, for vortices from a rectangular wing towed in a non-stratified, water-filled tank, show that organized vorticity migrates much farther and lasts significantly longer than shown in previous studies. The differences between our results and results from previous studies are attributed to differences in flow visualization techniques. Numerically, we use a 2-D code to simulate full-scale measurements from a Boeing-747 aircraft in ground effect and to investigate the vortex hazard generated by a Boeing-767 aircraft near touchdown on landing. Measured stratification and cross-track winds are included in both numerical simulations. The numerical results show that full-scale measurements can be simulated by numerical codes, and that vortices generated by aircraft in ground effect may last longer than previously thought. It is cautioned that additional research is needed before a credible wake vortex hazard can be estimated from these results.

Delisi, D. P., Robins, R. E. and Fraser, R. B.

"THE EFFECTS OF STRATIFICATION AND WIND SHEAR ON THE EVOLUTION OF AIRCRAFT WAKE VORTICES NEAR THE GROUND"

NWRA-87-R006, April 1987, Northwest Research Associates, Bellevue, WA

We have performed a feasibility study of how stratification and shear affect the evolution of aircraft trailing-tip vortices as they approach the ground and how they evolve when they are generated near the ground. The study incorporates both laboratory experiments and concurrent numerical modeling, matching model Froude numbers and shear parameters with their full-scale values. Our results indicate that stratification and shear can have significant effects on the evolution of the vortex system. In non-stratified, non-sheared flow, vortex evolution is symmetric, each vortex decaying at the same rate. Adding stratification maintains the symmetry but inhibits the vertical migration. In ground effect, stratification also inhibits horizontal migration and cancels the rebound effect (observed in the non-stratified, non-sheared case). In a non-stratified flow with shear, vortex evolution is asymmetric, and, in ground effect, the shear also acts to severely reduce the rebound effect. With stratification and shear (Richardson number equal to one), the flow is asymmetric, and two effects are observed. When the vortex pair is weak relative to the shear (strong crosswind condition), the weaker downwind vortex is closer to the ground than the stronger upwind vortex. (If the vortex pair is far from the ground, a solitary vortex develops in this case.) If the vortex is stronger relative to the shear (weak crosswind conditions), the weaker downwind vortex is further from the ground than the stronger upwind vortex. In either case, the vortices may migrate far from their initial generation position.

"INITIAL LABORATORY OBSERVATIONS OF THE EVOLUTION OF A VORTEX PAIR IN A STRATIFIED SHEAR FLOW"

Phys. Fluids A, Vol. 3, No. 11, November 1991, pp. 2489 - 2491

First results are presented for a laboratory experiment and a supporting numerical simulation of the evolution of a vortex pair in a stratified and sheared flow where the Richardson number is 1.0 and the vortex Reynolds number is 14,400. Both the laboratory experiment and the numerical model show that the vortex pair evolves into a single vortex. It is believed that these are the first reported experimental measurements on the evolution of a vortex pair in a stratified shear flow.

Delisi, D. P., Robins, R. E. and Pruis, M. J.

"APA3.8 FAST-TIME NUMERICAL WAKE MODEL DESCRIPTION AND FIRST RESULTS"

AIAA Paper 2016-3437, June 2016, Washington, DC.

Fast time, numerical wake vortex models are useful in examining a variety of problems, including determining an understanding of new procedures and exploring the evolution of aircraft wake vortices under a range of atmospheric conditions. Version 1 of the APA (AVOSS Wake Vortex Prediction Algorithm) fast time model was first completed in December, 1997. Since that version, development has continued, under funding from NASA. Version 3.8 is the latest version in this development, and includes (i) more realistic stratification effects, based on the use of laboratory experiments to describe entrainment and detrainment, (ii) better modeling of countersign vorticity, and (iii) more realistic vortex bouncing in crosswind flows.

Delisi, D. P., Robins, R. E., Switzer, G. F., Lai, D. Y. and Wang, F. Y.

"COMPARISON OF NUMERICAL MODEL SIMULATIONS AND SFO WAKE VORTEX WINDLINE MEASUREMENTS"

AIAA Paper No. 2003-3810, Orlando, FL, June 2003

To provide quantitative support for the Simultaneous Offset Instrument Approach (SOIA) procedure, an extensive data collection effort was undertaken at San Francisco International Airport by the Federal Aviation Administration (FAA, U.S. Department of Transportation). During the time period from March 2000 to October 2002, wake vortex data was measured for over 260,000 landing aircraft. The data set includes wake vortex measurements from Small, Large, and Heavy category aircraft. The measurements consist of cross-runway wind speed recorded every two seconds from three windlines, comprised of a series of propeller anemometers on three-foot poles near the threshold of runways 28L and 28R. The resulting data set is being used to demonstrate the feasibility of SOIA and to guide the improvement of the wake vortex model in the FAA airspace simulation tool ASAT (Airspace Simulation and Analysis for TERPS). We show that a slightly modified version of the AVOSS (Aircraft VORtex Spacing System) Prediction Algorithm (APA) produces lateral position predictions that agree well with the windline data. We also show that the data and the APA results agree with results produced by TASS (Terminal Area Simulation System), a numerical code developed by NASA. These comparisons between code and data provide an independent validation of the lateral transport estimates using windline sensors and give us increased confidence in both the data obtained from the windline sensors and our ability to predict vortex evolution using numerical simulations.

"SPEED STABILITY AND OBSTACLE CLEARANCE DURING ENGINE INOPERATIVE TAKEOFF"

AIAA Paper 2018-3502, June 2018, Atlanta, GA.

This second paper in a series describes the consequences of unstable dynamic climb maneuvers performed during takeoff with a critical engine inoperative. If a pilot inadvertently commands horizon attitudes commonly experienced during normal all-engines-operating takeoff, the aircraft with a failed engine may not settle in to a stable climb. Instead, it will climb while losing speed. The rate at which speed is lost is a function of flight weight and the magnitude of mis-trim. For an aircraft resembling an A320 operated at 160,000-lbm, an aircraft may lose airspeed at a rate more than 2 knots per second if flown to customary horizon attitude. Once the pilot corrects this error and stabilizes climb, the aircraft will be flying under its scheduled speed. The consequences of flying under the scheduled speed can lead to a significant decrease in climb gradient. This impacts obstacle clearance capability and results in longer third segment acceleration phases. If aircraft are flown far enough below their scheduled speed, the associated terrain hazard consequences may be dangerous.

Denery, D. G., White, K. C. and Drinkwater, III, F. J.

"STATUS AND BENEFITS OF INSTRUMENTED TWO-SEGMENT APPROACHES; AUGUST, 1974"

Journal of Aircraft, Vol. 12, No. 10, October 1975, pp. 791-79.

NASA, in cooperation with the FAA, is evaluating the two-segment approach as a routine procedure for reducing aircraft noise. The program calls for separate flight evaluations using a 727 and a DC-8, and an extrapolation of these results to determine the adaptability of the technique to the rest of the fleet. The total program will be reviewed. The profile and procedures developed and the noise reduction achievable will be presented. The vortex characteristics behind an aircraft on a two-segment path will be covered. Finally, cost estimates for retrofitting aircraft with two-segment avionics will be presented.

"EDDF-1 DATA COLLECTION CAMPAIGN REPORT"

CREDOS Report D2-1, February 2008, DLR, Munich, Germany.

This document describes the analysis of the EDDF-1 data set. It provides a detailed analysis of the meteorological situation and the wake vortex behavior gathered during the measurement campaign EDDF-1. In particular, a statistical analysis of the meteorological conditions is made, the crosswind conditions in combination with LIDAR measurements of wake vortices are analyzed, and finally a simple concept is proposed that could be useful to operations.

"CROSSWIND THRESHOLDS SUPPORTING WAKE-VORTEX-FREE CORRIDORS FOR DEPARTING AIRCRAFT"

Meteorological Applications, Vol. 19, 2012, pp. 289-301

During two field measurement campaigns aircraft wake vortex trajectory and wind measurement data have been collected at Frankfurt airport. Three different approaches have been used to analyze the data to estimate crosswind threshold values supporting vortex-free corridors for departing aircraft. Although several competing effects such as wake vortex transport in and out of ground effect, temporal and spatial wind variability, and the spreading of aircraft trajectories after take-off, complicate the analyses, all three approaches lead to similar crosswind thresholds. Employing standard instrumentation at 10 m, a minimum crosswind threshold of 3.5-4.6 m/s has been identified to clear a safety corridor of 150 m width from wake vortices with a 95 percent probability within 60 s. Alternative estimations of crosswind thresholds employing different instrumentation and different height ranges are reported. Crosswind thresholds can be reduced if the wind is measured close to the air mass in which the vortices evolve. A definite crosswind threshold for operational use cannot be deduced solely from this study since critical factors such as risk and safety assessment have not yet been taken into account.

"THE DOMINANT WAVE MODE WITHIN A TRAILING LINE VORTEX"

Physics of Fluids, Vol. 17, 2005, pp. 014101-1 - 014101-9

We identify the dominant, or most unstable, wave mode for the flow in a trailing line vortex. This dominant mode is found to reside in a wavenumber regime between that of inviscid wave modes and the viscous upper branch neutral wave modes. A reevaluation of the growth rate in the vicinity of the upper branch of the curve of neutral stability allows us to predict the neutral value of the azimuthal and axial wavenumber as a function of the imposed swirl within the trailing line vortex.

"EVOLUTION ANALYSIS OF THE MAIN MECHANISM OF THE JET/VORTEX INTERACTION"

International Journal for Numerical Methods in Fluids, Vol. 67, 2011, pp. 1024-1046.

A new analysis method of the jet/vortex interaction is presented to better understand the effect of each vortical structure on the others composing the jet and even on itself. Vortical structures are isolated from each other and the velocity field they produce is calculated by means of the Biot-Savart law. The structure influence on each another is then distinguished from the others by using its velocity field in the calculation of the vorticity momentum equations. Based on 3D-datafields provided by a large-eddy-simulation (LES) of the interaction between a Lamb-Oseen vortex and a turbulent round jet, a post-processing tool reduces the vortical structures and quantifies the different vorticity momentum equations terms. The study has been limited to the first steps of the interaction regime when there are still few vortical structures so that the subsequent analysis of the post-process results remains simple enough to be performed. The present method confirmed the intensification of azimuthal structures as they roll up around the main vortex. Core disturbance of the latter was found to be initially caused by those structures and not by core dynamic instabilities, which become dominant with the appearance of non-linear mechanisms.

"NASA/FRC WAKE TURBULENCE FLIGHT TEST PROGRAM: RIDE QUALITY ASPECTS"

NASA CR-145700, November 1975, Univ. of Virginia, Charlottesville, VA

To determine how much the ride quality of the Shuttle Carrier (Boeing 747) Aircraft is affected at various spoiler settings, the PEMS II (Portable Environmental Measuring System) was used to measure onboard motion during a test flight October 15, 1975. The PEMS II measures acceleration in the

vertical, transverse and longitudinal directions as well as angular rates of pitch, roll, and yaw. The data acquired by this instrument, combined with an airline passenger comfort model, gives an indication of how passengers would react to the motion induced by flying in a vortex alleviation configuration.

"DIRECT CIRCULATION MEASUREMENT OF A TIP VORTEX"

AIAA Journal, Vol. 38, No. 11, November 2000, pp. 2189-2191

The circulation of tip vortices has traditionally been calculated by performing integration over velocity or vorticity field. However, if vortex circulation is the primary parameter of interest, the direct measurement of circulation can be achieved via acoustic means, thus eliminating the need for detailed velocity measurements. The utilization of an ultrasonic technique is described, and the measured circulation values for a wing tip vortex are compared to those obtained with Particle Image Velocimetry. The authors concluded that the ultrasound method offers accurate circulation measurements as long as the flow scales are larger than the size of the sound pulse employed in the measurements.

Desabrais, K. J. and Johari, H.

"DIRECT CIRCULATION MEASUREMENT OF A WING TIP VORTEX USING ULTRASOUND"

AIAA Paper No. 1998-0609, Reno, NV, January 1998

The circulation distribution of a wing tip vortex as a function of the spanwise coordinate was measured directly by a novel ultrasound technique. This technique measures the total circulation enclosed by a rectangular path. To observe the effects of forcing on the vortex structure, blowing along the vortex core was employed. The wing tip vortex was generated by a blunt-ended, rectangular planform NACA 0012 wing with a chord of 10.5 cm and a half-wing aspect ratio of 2.1. The circulation distribution was measured at four chords downstream of the trailing edge of the wing. The circulation distribution behaved as expected achieving its highest level when the closed integration path surrounded the vortex. The circulation decreased rapidly through the vortex center before reaching nearly zero circulation outside the vortex. The ultrasound measurements agreed well with detailed circulation measurements derived from velocity field data generated by a similar tip vortex. The vortex was forced by both steady and pulsed injection and extraction of air into the core of the tip vortex. For blowing coefficients of 7.10×10^{-6} to 1.16×10^{-4} and a pulsing frequency range of 1-10 Hz, no appreciable changes were measured by the ultrasound method over the baseline flow at the four-chord station.

"WAKE SURVEY OF POWERED AND UNPOWERED C-5A AIRCRAFT MODELS"

AIAA Paper No. 1968-0931, El Centro, CA, 1968

As part of the development program to airdrop 50,000-pound unit loads from the C-5A aircraft, a wind tunnel study was initiated to investigate the flow characteristics in the wake of the aircraft during airdrop. Two models of the C-5A were used in the study, a 1/2 scale unpowered model and a 1/17 scale powered model. By using both the powered and unpowered models it was possible to completely determine the C-5A wake characteristics and to isolate the variations in the wake which were caused by the interaction of the engine discharge and the aircraft wake.

Deshpande, M. D.

"DECAY OF A THREE-DIMENSIONAL VORTEX IN AN ENCLOSURE"

Proceedings Royal Society of London, Series A, Vol. 457, No. 2011, July 2001, pp. 1533-1554.

Consider viscous, incompressible flow in a cubic container, generated by the uniform, linear motion of the top wall. Depending on the Reynolds number Re the flow could be laminar, transitional, or turbulent. If the motion of the top wall is now suddenly stopped, the fluid motion will begin to decay. Direct numerical simulations show that no matter what the initial conditions are, the final stages of decay follow an exponential law. To explain this interesting behavior of three-dimensional vortex motion, exact decaying, axisymmetric solutions of the Navier-Stokes equations were sought. It is shown that the field represents a swirling decaying vortex. These new exact solutions to the Navier-Stokes equations are used to identify and quantify the different regimes of vortex decay and scaling in the cubic cavity.

DeSouza, F. and Faghani, D.

"NEAR-FIELD WING TIP VORTEX MEASUREMENTS VIA PIV"

AIAA Paper No. 2001-2451, Anaheim, CA, June 2001

The paper presents some near-field properties of tip vortices generated by a rectangular NACA-0012 half-wing. Different end-cap geometries (flat, round, and elliptical), Reynolds numbers (0.5, 1.2 and 2×10^5 based on the chord) and angles of attack ($\alpha = 5$ degrees and 10 degrees) were considered in a low-speed wind tunnel. Measurements were performed by Particle Image Velocimetry (PIV) over a cross-flow plane at 2 chord lengths downstream of the trailing edge. Reynolds dependence of vortex properties such as vorticity or core size are investigated. Vortex wandering and its influence on high turbulence levels in the core region are analyzed. Finally, a Bi-Orthogonal Decomposition (Bi-POD) analysis of velocity fields is put forward. A Bi-POD-based entropy is defined in order to quantify the complexity of the vortex flow in each configuration.

DeSpirito, J.

"CFD VALIDATION OF INTERACTION OF FIN TRAILING VORTEX WITH DOWNSTREAM CONTROL SURFACE IN HIGH SUBSONIC FLOW"

AIAA Paper 2016-1546, January 2016, San Diego, CA.

Numerical simulations of the interaction of a fin trailing vortex with a downstream fin were performed to validate the numerical tools being used to characterize precision-guided munitions involving these type of vortex interactions. The predictions were validated against an existing experimental dataset involving the particle image velocimetry measurements of the mean and fluctuating velocities in the wake of a fin located on the wind tunnel floor. A grid resolution study concentrating on the mesh density in the wake region of the fin determined the adequate resolution: a minimum of 15-20 cells to define the vortex core. The predicted vortex characteristics compared reasonably well to the experimental data but had an initially higher intensity that was found to diffuse faster than the experimentally measured vortex. The predicted vortex trajectory was found to track closely to the experimental vortex trajectory. The predicted normal force coefficient on the downstream fin in the absence of interference from an upstream vortex agreed very well with the experimental data with a 3.1 percent difference at angle of attack of 10 degrees. The predicted bending moment slope was higher than the experimental, with a 15-degree difference in bending moment at angle of attack of 10 degrees. The predicted hinge (pitching) moment slope was much steeper than the experimental data, with a 100 percent difference in hinge moment at angle of attack of 10 degrees. However, the difference between the predicted and experimental center of pressure was 1.9 mm, only a 2.5 percent difference based on the fin root chord. The predicted aerodynamic coefficients on the downstream fin in the presence of vortex interference showed similar levels of agreement, with some exaggeration of the differences at the larger forward fin deflections.

deVelder, N. B.

"FREE WAKE POTENTIAL FLOW VORTEX WIND TURBINE MODELING: ADVANCES IN PARALLEL PROCESSING AND INTEGRATION OF GROUND EFFECTS"

MS Thesis, February 2014, University of Massachusetts, Amherst, MA.

Potential flow simulations are a great engineering type, middle-ground approach to modeling complex aerodynamic systems, but quickly become computationally unwieldy for large domains. An N-body problem with N-squared interactions to calculate, this free wake vortex model of a wind turbine is well suited to parallel computation. This thesis discusses general trends in wind turbine modeling, a potential flow model of the rotor of the NREL 5MW reference turbine, various forms of parallel computing, current GPU hardware, and the application of ground effects to the model. For approximately 200,000 points, current GPU hardware was found to be nearly 17 times faster than an OpenMP 12 core CPU parallel code, and over 280 times faster than serial MATLAB code. Convergence of the solution is found to be dependent on the direction in which the grid is refined. The 'no entry' condition at the ground plane is found to have a measurable but small impact on the model outputs with a periodicity driven by the blade proximity to the ground plane. The effect of the ground panel method was found to converge to that of the 'method of images' for increasing ground extent and number of panels.

"FAR-FIELD TURBULENCE STRUCTURE OF THE TIP VORTEX SHED BY A SINGLE RECTANGULAR WING"

Proceedings of the ASME 8th Symposium on Turbulent Shear Flows, Munich, September 9-11, 1991

The tip vortex shed by a single rectangular NACA 0012 wing is being studied. Helium bubble flow visualizations and extensive hot-wire velocity measurements have been performed over a wide range of conditions with the intent of revealing the far-field turbulence structure of this flow. At all conditions the vortex appears insensitive to probe interference and relatively stable. Some very low frequency ($f_c/U_{ref}=0.005$) lateral motions are present but these have an amplitude of less than $\pm 5\%$ of the wing chord. These motions dominate turbulence measurements made close to the vortex center. Away from the center the effect of the motions are much smaller, however, and the true turbulence structure is visible. This is dominated by the wing wake which forms a spiral around the core.

Devenport, W. J., Muthanna, C., Ma, R. and Glegg, S. A.

"TWO-POINT DESCRIPTIONS OF WAKE TURBULENCE WITH APPLICATION TO NOISE PREDICTION"

AIAA Journal, Vol. 39, No. 12, December 2001, pp. 2302-2307

Measurements of the four-dimensional two-point correlation tensor of a fully developed airfoil wake are presented. These data allow examination of the characteristic eddies of the turbulence through proper orthogonal decomposition and linear stochastic estimation. A simple generic technique has been developed to extrapolate the correlation tensor function from the Reynolds stress field based on the hypothesis that its form is largely determined by the constraints imposed by inhomogeneity and continuity. Estimates for the plane wake compare favorably with measurements, and, interestingly, proper orthogonal modes and characteristic eddy structures inferred from the estimates are like those obtained from measurements. This implies that these measures of the correlation function are largely determined by basic physical information, suggesting some simplification of the turbulence-modeling problem for applications such as aeroacoustics.

"TURBULENCE STRUCTURE AND SCALING IN TRAILING VORTICES, "

AIAA Paper No. 1995-0588, Reno, NV, 1995.

Experiments have been performed on the tip vortex trailing from a rectangular NACA 0012 half wing. Preliminary studies showed the vortex to be insensitive to the introduction of a probe and subject only to small wandering motions. Meaningful velocity measurements could therefore be made using hot-wire probes. Detailed analysis of the effects of wandering was performed to properly reveal the flow structure in the core region and to give confidence in measurements made outside the core. A theory has been developed to correct mean-velocity profiles for the effects of wandering and to provide complete quantitative estimates of its amplitude and contributions to Reynolds stress fields. Spectral

decomposition was found to be the most effective method of separating these contributions from velocity fluctuations due to turbulence. Outside the core the flow structure is dominated by the remainder of the wing wake which winds into an ever-increasing spiral. There is no large region of axisymmetric turbulence surrounding the core. Turbulence stress levels vary along the wake spiral in response to the varying rates of strain imposed by the vortex. Despite this complexity, the shape of the wake spiral and its turbulent structure reach an approximately self-similar form. Moving from the spiral wake to the core the overall level of velocity fluctuations greatly increases, but none of this increase is directly produced by turbulence. Velocity spectra measured at the core center scale in a manner that implies that the core generates no turbulence of its own. The core therefore appears to be laminar and velocity fluctuations here a consequence of inactive motion of the core as it is buffeted by turbulence of the surrounding wake. Mean velocity profiles through the core show evidence of a two-layered structure - an outer core possibly formed by roll up at the wing tip and an inner core that grows with distance downstream.

Devenport, W. J., Rife, M. C., Liapis, S. I. and Follin, G. J.

"THE STRUCTURE AND DEVELOPMENT OF A WING-TIP VORTEX"

J. Fluid Mech., Vol. 312, April 1996, pp. 67-106

Experiments have been performed on the tip vortex trailing from a rectangular NACA 0012 half-wing. Preliminary studies showed the vortex to be insensitive to the introduction of a probe and subject only to small wandering motions. Meaningful velocity measurements could therefore be made using hot-wire probes. Detailed analysis of the effects of wandering was performed to properly reveal the flow structure in the core region and to give confidence in measurements made outside the core. Outside the core the flow structure is dominated by the remainder of the wing wake which winds into an ever-increasing spiral. There is no large region of axisymmetric turbulence surrounding the core and little sign of turbulence generated by the rotational motion of the vortex. Velocity spectra measured at the vortex center scale in a manner that implies that the core is laminar and that velocity fluctuations here are a consequence of inactive motion produced as the core is buffeted by turbulence in the surrounding spiral wake.

Devenport, W. J., Rife, M. C., Liapis, S. I. and Miranda, J.

"TURBULENT TRAILING VORTICES"

AIAA Paper No. 1994-0404, Reno, NV, January 1994

Measurements were performed on the vortex shed from a rectangular NACA 0012 half wing over a range of conditions. These show the wing wake to dominate the turbulence structure both outside and inside the core. Peak turbulence levels in the wake decrease as the core is approached. Velocity spectra show the drop continuing into the core. Core-center spectra collapse well when they are scaled on wake velocity deficit and core radius but show no correlation when scaled using core parameters. It therefore appears that turbulence in the core is provided from the wake and that rates of strain

associated with the vortex core produce little if any turbulence of their own. A theory on the effects of vortex wandering on measurements is presented. The theory provides corrections for measured core parameters. It also shows that if sufficient wandering is present, the measurement of a q-vortex tangential velocity profile and a Gaussian axial velocity profile in the core is inevitable, regardless of the true flow field. A core similarity theory is also developed. This shows the growth of a vortex core to depend strongly on which parameters scale turbulence stresses at the core center. If they scale on peak tangential velocity, core growth rate rapidly becomes independent of Reynolds Number. If they scale on the wake velocity deficit (as evidenced by present measurements), growth rate is always a function of Reynolds Number, in qualitative agreement with established observations.

Devenport, W. J., Vogel, C. M. and Zsoldos, J. S.

"FLOW STRUCTURE PRODUCED BY THE INTERACTION AND MERGER OF A PAIR OF CO-ROTATING WING-TIP VORTICES"

J. Fluid Mech., Vol. 394, September 1999, pp. 357-377

Experiments have been performed to study the co-rotating wing-tip vortex pair produced by a pair of rectangular wings in a split-wing configuration. Detailed measurements made in cross-sections upstream and downstream of merger reveal, for the first time, the complex turbulence structure of this flow. The vortices spiral around each other and merge some 20 chord lengths downstream of the wings. As merger is approached the vortices lose their axisymmetry - their cores develop lopsided tangential velocity fields and the mean vorticity field is convected into filaments. The cores also become part of a single turbulence structure dominated by a braid of high turbulence levels that links them together. The braid, which quite closely resembles the structure formed between adjacent spanwise eddies of transitional mixing layers, grows in intensity with downstream distance and extends into the vortex cores. Unlike a single tip vortex, the unmerged cores appear turbulent. The merging of the vortices wraps the cores and the flow structure that surrounds them into a large turbulent region with an intricate double spiral structure. This structure then relaxes to a closely axisymmetric state. The merged core appears stable and develops a structure similar to the laminar core of a vortex shed from a single wing. However, the turbulent region formed around the vortex core during the merger process is much larger and more axisymmetric than that found around a single wing-tip vortex.

Devenport, W. J., Wenger, C. W., Glegg, S. A. L. and Miranda, J. A.

"WAVE NUMBER FREQUENCY SPECTRA OF A LIFTING WAKE FOR BROADBAND NOISE PREDICTION"

AIAA Journal, Vol. 36, No. 6, June 1998, pp. 881-887

Measurements of wave number frequency spectra of velocity fluctuations have been made using two three-component hot-wire probes in the wake of a rectangular NACA 0012 half-wing at a 5-deg angle of attack. Spectra were measured along spanwise lines in the near two-dimensional part of the wake, in the stretched region where the wake begins to wind around the vortex, directly above the vortex core, and radially from the core center. Dominated by the large-scale organized motions present in the wake,

the spectra show little similarity with the von Karman isotropic turbulence spectrum. Outside the core, upwash spectra contain a single maximum at the passage frequency of these large structures. Motions associated with this peak are highly anisotropic, both in terms of velocity components and length scales. Similar anisotropy is also seen at higher wave numbers, suggesting either that the smaller scale turbulent motions are organized by the large eddies or that the non-sinusoidal components of those eddies contribute significantly to the spectrum at higher wave numbers. The implications of these results for broadband noise prediction have been assessed by considering the sound radiation from this turbulent flow over a semi-infinite flat plate. The major conclusion is that the correlation length scales of the flow are small compared to the acoustic wavelength and so are well represented by their values at zero spanwise wave number. However, the blade response function has a variation with spanwise wave number that cannot be ignored and significantly influences the spanwise directionality.

Devenport, W. J., Zsoldos, J. S. and Vogel, C. M.

"THE STRUCTURE AND DEVELOPMENT OF A COUNTER-ROTATING WING-TIP VORTEX PAIR"

J. Fluid Mech., Vol. 332, February 1997, pp. 71-104

Experiments have been performed to examine the turbulence structure and development of a pair of counter-rotating wing-tip vortices. The vortices were generated by two rectangular NACA 0012 half wings placed tip to tip, separated by 0.25 chord lengths. Preliminary studies showed the vortices to be insensitive to the introduction of a probe and subject only to small wandering motions. Meaningful measurements could therefore be made using hot-wire probes. Three-component velocity measurements were made 10 and 30 chord lengths downstream of the wing leading edges for a chord Reynolds number of 260000. At 10 chord lengths the vortex cores are laminar. The turbulence that surrounds the cores is formed by the roll-up of and interaction of the wing wakes that spiral around them. This turbulence is stretched and organized but apparently not produced by the circulating mean velocity fields of the vortices. At 30 chord lengths the vortex cores have become turbulent. True turbulence levels within them are larger and increasing rapidly with radius. The turbulent region surrounding the cores has doubled in size and turbulence levels have not diminished, apparently being sustained by outward diffusion from the core regions. The distribution of the turbulence has also changed, the wake spirals having been replaced by a much more core-centered turbulence field. This change in flow structure contrasts sharply with what is seen in the equivalent isolated tip vortex, produced when one of the wings is removed. Here the vortex core remains laminar and the turbulence surrounding it decays rapidly with downstream distance. This implies that the transition to turbulence in the cores of the vortex pair is stimulated by interaction between the vortices. Spectral measurements at 10 chord lengths suggest that short-wave instability may be the cause.

Devenport, W., Zsoldos, J. and Vogel, C.

"TURBULENCE IN TRAILING VORTEX PAIRS"

20th Symposium, Naval Hydrodynamics, Santa Barbara, CA, August 1994, pp. 682-701

The turbulence structure associated with a pair of counter-rotating trailing vortices is examined through analysis of a large experimental database. The vortices were generated by two rectangular NACA 0012 half wings placed tip to tip, separated by 0.25 chord lengths. The database consists primarily of detailed 3-component hot-wire velocity records measured in planes 10 and 30 chord lengths downstream of the wing leading edges for a chord Reynolds number of 260,000. The data reveal much about the turbulence structure of the vortex cores, the surrounding spiral wakes, and their interaction. The wakes dominate turbulence structure outside the core regions. The drift of the vortex pair and the secondary flow they generate stretches and distorts the wakes, causes them to merge and separate again. While these events cause substantial changes in the organization and structure the wake-like character of the turbulence is never lost. The interaction between the vortex cores, in addition to producing Crow instability, appears to be a crucial player in their decay. Specifically, the interaction seems to stimulate turbulence production in the vicinity of the otherwise laminar cores, accelerating their growth. This previously unobserved mechanism provides a possible physical explanation of the two-stages of vortex decay seen in the far wakes of lifting vehicles.

"WAKE SENSING AND ESTIMATION FOR CONTROL OF AUTONOMOUS AIRCRAFT IN FORMATION FLIGHT"

Journal of Guidance, Control, and Dynamics, Vol. 39, No. 1, January 2016, pp. 32-41.

The continued development of sophisticated aircraft with high-fidelity control systems will enable autonomous execution of challenging tasks such as aerial refueling and close-formation flight. To achieve such tasks autonomously, an aircraft must sense other aircraft in close proximity and position itself relative to them. For example, formation-flying aircraft must position themselves strategically to realize benefits of aerodynamic efficiency; aerial refueling requires the follower aircraft to intercept the filling nozzle attached to the leader aircraft. This paper uses lifting-line theory to represent a two-aircraft formation and presents a grid-based, recursive Bayesian filter for estimating the wake parameters of the lead aircraft using noisy pressure measurements distributed along the trailing aircraft's wing; the estimator also uses a binary, relative-altitude measurement to break the vertical symmetry. The paper employs measures of observability to quantify spatial regions prone to degraded estimation performance. Optimal control strategies are presented to steer the follower aircraft to a desired lateral position relative to the leader while simultaneously optimizing the observability of the leader's relative position. The control algorithms guide the follower aircraft along trajectories that maintain adequate observability, thereby guaranteeing estimator performance. Theoretical results are illustrated using numerical examples of a two-aircraft formation.

Deyst, Jr., J. J. and Serben, S.

"AUTOMATIC TRACKING OF WAKE VORTICES USING GROUND-WIND SENSOR DATA"

FAA-RD-77-11, January 1977, Charles Stark Draper Lab., Cambridge, MA

Algorithms for automatic tracking of wake vortices using ground-wind anemometer data are developed. Methods of bad-data suppression, track initiation, and track termination are included. An effective sensor-failure detection-and-identification system is also documented. System performance is verified using actual sensor data. Computer requirements for implementing the system in the field are summarized, and a plan for developing a general-purpose vortex-tracking simulation is presented.

Dezhe, Z. J. and Dubin, D. H. E.

"POINT VORTEX DYNAMICS WITHIN A BACKGROUND VORTICITY PATCH"

Physics of Fluids, Vol. 13, No. 3, March 2001, pp. 677-691

Recent experiments and simulations have observed that the interaction of strong vortices with a low vorticity background can strongly affect the dynamics of both vortices and background. This paper considers an idealized model of this interaction. The background is treated as a patch of uniform vorticity with a nearly circular shape. The strong vortices are treated as point vortices, and their total circulation is assumed to be small compared to that of the background. It is found that Kelvin waves on the boundary of the background patch can be driven to large amplitude by the strong vortices, eventually resulting in wave breaking and filamentation.

"STEREOSCOPIC PIV INVESTIGATION OF THE EFFECT OF SYNTHETIC JET ACTUATION ON A WING TIP VORTEX"

AIAA Paper 2017-3038, June 2017, Denver, CO.

The structure and development of a wing tip vortex under the effect of synthetic jet (SJ) actuation were experimentally investigated using high resolution Stereoscopic PIV technique. The SJ was pushed through two different nozzle geometries namely a straight SJ (SSJ) and a directed SJ (DSJ) mounted at the wing tip. Measurements at multiple locations downstream the trailing edge of the wing showed an increased core radius and a decreased circumferential velocity when the vortex was subjected to SJ actuation. The DSJ was found to outperform the SSJ by further stretching the vortex and promoting turbulent mixing at its core.

Dghim, M., Ferchichi, M. and Fellouah, H.

"MEANDERING OF A WING TIP VORTEX UNDER THE EFFECT OF SYNTHETIC JET ACTUATION"

AIAA Paper 2018-3372, June 2018, Atlanta, GA.

The meandering of a wing tip vortex under the effect of synthetic jet (SJ) actuation was experimentally investigated using high resolution Stereoscopic PIV technique. The SJ was injected through two different nozzle geometries, namely a straight SJ (SSJ) and a curved SJ (CSJ), mounted at the wing tip. Measurements at multiple locations in the wake indicated increased meandering

amplitudes when the vortex was subjected to SJ actuation. The increased meandering introduced additional turbulence within the vortex core. When corrected for meandering, high turbulence levels were contained within the periphery of the vortex core. This suggests that, despite the removal of the meandering-induced turbulence, the SJ actuation of both SSJ and CSJ cases promoted turbulent mixing within the periphery of the vortex core, with the effect being more pronounced for the CSJ case.

Dhanak, M. R.

"INTERACTION BETWEEN A VORTEX FILAMENT AND AN APPROACHING RIGID SPHERE"

Journal of Fluid Mechanics, Vol. 110, 1981, pp. 129-147.

The evolution of an infinitely long straight vortex filament in the presence of an approaching rigid sphere is considered. The fluid is regarded as being inviscid and incompressible. The shape of the vortex filament when the sphere is sufficiently far away from the vortex is determined approximately using linear theory. The subsequent evolution is followed numerically by integrating the nonlinear equation of motion.

Dhanak, M. R. and Marshall, M. P.

"VORTEX DESTABILIZATION BY A HARMONIC STRAIN FIELD"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 16-1 - 16-16

A mechanism for vortex destabilization is presented. The mechanism is based on the recognition that a pair of vortices, such as in the vortex trail of an aircraft or a vortex in ground effect, impose a weak strain-field upon each other causing the shape of the vortex core to distort from a circle. The presence of a pressure gradient can also induce a strain on a vortex. In general, the strain fields are unsteady and three-dimensional. For plane steady strain-fields, equations of fluid motion suggest that a Rankin-type vortex core of uniform vorticity and elliptical shape can exist in a state in which it (a) is steady and stationary, (b) rotates about its axis or nutates about a fixed axis, or (c) elongates indefinitely smearing the core into a thin layer. In state (a), for sufficiently weak strain fields, a vortex of small enough aspect ratio of the ellipse persists under such a plane strain, being robust to small disturbances present in the flow field. It is shown that if, however, a small periodically varying strain-field is superimposed on the basic field, then at certain frequencies and their harmonics, a resonance phenomenon takes place which destabilizes the apparently stable stationary vortex in finite time, causing it to flip into states (b) or (c), in which action of instabilities associated with higher, non-elliptical, mode of deformation of the vortex boundary by disturbances in the flow field leads to disintegration of the vortex structure. For a vortex of given strength, the frequencies and amplitude required for destabilization vary with the size of the basic strain-field. The potential of the phenomena for the vortex hazard problem is discussed.

"THE INTERACTION BETWEEN AN INJECTED VORTEX AND A ROLLING UP VORTEX SHEET"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 6-1 to 6-7

The interaction between two symmetrically located finite Rankine vortices and an elliptically loaded vortex sheet is examined in the Trefftz plane for a range of flow parameters. The Rankine vortices, which are placed over the sheet, have vorticity of opposite sign to that of the adjacent section of the vortex sheet. They may be considered to represent, in the Trefftz plane, vortices 'injected' into the flow from an upstream location. It is shown that there are in general three types of interactions which significantly affect the rolling up process. Accordingly, an interaction can result in straightforward merging, formation of subsidiary structures or considerable inboard displacement of the rolling up tip vortex. In the last case, the process should help to enhance the onset of the Crow instability considerably.

"ENERGY SPECTRA IN A HELICAL VORTEX BREAKDOWN"

Physics of Fluids, Vol. 23, 2011, pp. 025104-1 - 025104-9.

Using spectrally accurate, direct numerical simulations, we show that vortices with axial flows (without an imposed strain) generate small scales, i.e., breakdown, when they are randomly perturbed. We show that the breakdown that occurs without the necessity of a stagnation point in the flow is nonlinear and that energy spectra of the breakdown present a range of a k to $-5/3$ power scaling (k being a wavenumber). These features are the same for centrifugally stable and unstable azimuthal velocities. However, centrifugally unstable azimuthal velocities promote mixing in vortices with an axial flow. We also find that vortex breakdown could be a physical mechanism against a finite time singularity in Navier-Stokes equations. Contrarily, we do not observe a breakdown using spectrally truncated Euler equations. For these equations we find a scaling of the energy spectra compatible with the existence of a finite time singularity.

"AN EVALUATION OF THE IMPACT OF WAKE VORTEX RE-CATEGORIZATION: THE CASE OF CHARLOTTE DOUGLAS INTERNATIONAL AIRPORT"

Transportation Research Part A, Vol. 109, 2018, pp. 41-49.

This study compared departures before and after wake recat implementation at CLT. In both periods, departure counts and departure demand loaded highly onto Factor 1, arrival demand and gate departure delays onto Factor 2, and taxi-out time onto Factor 3. A two-level negative binomial mixed-effects model considered the random effects of approach conditions on operations. Only gate departure delay was significant within and across both samples. NextGen capabilities including wake recat appeared to minimize the random effects of instrument approach conditions (IAC) on operations

in both samples. Wake recat increased departure throughputs in IAC and enabled multiple departure pushes throughout the day.

"THE RAKELET -- A WINGTIP MODIFICATION APPROACH TO IMPROVE ENDURANCE, RANGE AND FUEL SAVINGS"

AIAA Paper No. 2012-0669, January 2012, Nashville, TN.

Starting in 2008, the Air Force Research Laboratory and Air Mobility Command tasked the US Air Force Academy with examining the benefits of various wingtip devices using the KC-125 Stratotanker as a test bed. The investigation that this paper focuses on involved a new type of wingtip device which combines a winglet and a raked wingtip. This new device is called a Rakelet. An optimized Rakelet configuration was developed for the KC-135 by optimizing the size, cant angle, and toe out angle of the winglet component as well as the level of blending between the winglet and the raked wingtip components. Testing proved that the optimal configuration was 100 percent size, 15 degrees of cant and -2 degrees of toe, as well as 35 percent blending. An unblended but otherwise optimal configuration provided a best-case endurance and range potential improvement over the unmodified KC-135 wingtip of 9.85 percent and 7.51 percent respectively. A KC-135 mission analysis was performed, providing a rough estimate of \$34 million savings per year for the Air Force KC-135 fleet. Evaluation of Rakelet blending was accomplished using a second, larger scale model to improve resolution. The improvement potential of the 35 percent blended Rakelet over the unblended Rakelet was found to be an average 3.98 percent and 4.24 percent in endurance and range potentials respectively. Overall, the Rakelet concept was shown to provide a significant endurance, range and fuel savings potential over conventional wingtip, winglet and raked wingtip designs.

"WAKE-SURVEY TECHNIQUE FOR ICED SWEEP-WING AERODYNAMICS"

AIAA Journal, Vol. 53, No. 6, June 2015, pp. 1712-1715.

The value of the wake-survey technique for studying swept-wing icing is demonstrated. The drag decomposition demonstrated the physical mechanisms through which the ice altered the drag of the wing. The increase in profile drag from the separated flow field can be inferred from surface oil flow and force balance measurements, but the wake-survey method is able to quantify this change. More importantly, the wake survey can determine how an ice shape alters the performance of the wing along the span. For the particular ice shape and wing tested, the ice shape resulted in significant performance penalties over the outboard section of the wing. This information can be used to determine which sections along the span are most susceptible to ice.

Diebold, J. M. and Bragg, M. B.

"STUDY OF A SWEPT WING WITH LEADING-EDGE ICE USING A WAKE SURVEY TECHNIQUE"

AIAA Paper 2013-0245, January 2013, Grapevine, TX.

The aerodynamics of swept wings with leading-edge ice is very complex and not fully understood. Previous swept wing icing studies have only provided force balance measurements and/or qualitative flow visualization. To more fully understand the complex aerodynamics, it is necessary to understand how the ice influences the drag breakdown and the spanwise distributions of lift and drag. This paper utilizes 5-hole probe wake surveys and a far-field analysis to decompose the drag into profile and induced drag components and to determine the spanwise distributions of lift and drag. It is shown that the leading-edge ice primarily influences the profile drag and the induced drag is relatively unaltered. Features observed in the lift and drag distributions are related to features seen in the wake as well as in surface oil flow visualization.

Diederich, F. W.

"CHARTS AND TABLES FOR USE IN CALCULATIONS OF DOWNWASH OF WINGS OF ARBITRARY PLAN FORM"

NACA TN-2353, May 1951, Langley Aeronautical Laboratory, Langley Field, VA

Values of the downwash of a horseshoe vortex in incompressible flow are presented in the form of charts and tables. The use of the charts and tables in the calculations of the downwash of wings of arbitrary plan form is discussed. The results of a few calculations are compared with experimental results.

Dieterle, L., Ehrenfried, K., Stuff, R., Schneider, G., Coton, P., Monnier, J. C. and Lozier, J. F.

"QUANTITATIVE FLOW FIELD MEASUREMENTS IN A CATAPULT FACILITY USING PARTICLE IMAGE VELOCIMETRY"

18th International Congress on Instrumentation in Aerospace Simulation Facilities (ICIASF), June 1999

In order to investigate the long-term behavior of the wake vortex flow behind an aircraft, quantitative whole-field measurements have been carried out in a free flight analysis laboratory using the PIV (Particle Image Velocimetry) technique. Instantaneous velocity fields were measured in successive planes crosswise to the flight path of a free flying air-liner model, so that the evolution, interaction, and decay of vortices originating from the wing, flap and slat tips can be described. The optical measurement system consisting of two aerosol generators for seeding, a pulsed laser system for illumination, two CCD cameras for image recording and trigger electronics for synchronization had to be adapted to the test conditions of a catapult facility, where a long-lasting, unsteady 'single event' initiated by the model's launch is subject of the experimental study. The paper focuses on the technical aspects of interfacing a catapult facility and a digital PIV system.

Dieterle, L., Stuff, R., Vollmers, H. and Coton, P.

"WAKE VORTEX STUDIES IN THE ONERA CATAPULT FACILITY AND IN THE DNW WIND TUNNELS"

First ONERA-DLR Aerospace Symposium, June 1999, Paris, France.

As part of the European research programs WAVENC and EUROWAKE the wake vortex system behind (i) a free flying Airbus model and (ii) the DLR's ALVAST half model has been investigated experimentally in the ONERA catapult facility and in the DNW-LLF (large low-speed wind tunnel facility) respectively. Digital particle image velocimetry (PIV) was used for both testing campaigns. The two facilities offer different experimental access to the physical phenomena of vortex formation, evolution, and decay with one and the same measurement technique and require a particular adaptation of this measurement technique to the different test conditions each. In both cases tracer particles added to the flow were illuminated by a pulsed laser light sheet in a plane crosswise to the flight path of the model or to the main flow direction respectively. Two CCD cameras recorded neighboring areas of the flow field simultaneously. The PIV system operation was fitted to the facilities' requirements. Image data were evaluated utilizing the cross-correlation method. The resulting velocity and vorticity fields give quantitative information on the structure and motion of the trailing vortices in different frames of reference: a ground-based one for the catapult and a model's one for the wind tunnel.

Dietz, M., Kebler, M., Kramer, E. and Wagner, S.

"TIP VORTEX CONSERVATION ON A HELICOPTER MAIN ROTOR USING VORTEX-ADAPTED CHIMERA GRIDS"

AIAA Journal, Vol. 45, No. 8, August 2007, pp. 2062-2074

This paper presents a method to improve the tip vortex conservation in a computational fluid dynamics simulation of a helicopter main rotor. Our approach uses vortex-adapted Chimera child grids to achieve a local refinement of the grid in the vicinity of the vortex and thus reduce the numerical dissipation of the vortex. The method is applied to the higher-harmonic-control aero-acoustic rotor test case to evaluate its potential with respect to the prediction of blade-vortex interaction air-loads. To allow a meaningful comparison with the experimental data, the rotor is trimmed for thrust, as well as for longitudinal and lateral mast moments, using weak fluid-structure coupling with a flight mechanics code. We obtained a good overall agreement with the experimental data for both aerodynamics and blade dynamics. The effect of the improvement in tip vortex conservation is demonstrated by comparison with simulations without Chimera refinement and with the experimental results. It turned out that a very fine grid resolution in the vicinity of the vortex is necessary to capture the blade-vortex interaction air-loads. The required grid resolution was provided by a refinement of the vortex-adapted grids, allowing for a very good reproduction of the blade-vortex interaction air-loads, especially on the retreating blade side.

"AIRCRAFT WAKE VORTEX VELOCITY MEASUREMENTS USING A SCANNING CO₂ LASER DOPPLER VELOCIMETER"

Electro-Optics '75 International Laser Conf., Anaheim, CA, 1975, pp. 391-397

Aircraft wake vortex flow fields have been studied using a scanning laser Doppler velocimeter located adjacent to runway 31R at Kennedy International Airport in New York. Data has been obtained on vortex location, transport, and flow fields for a variety of aircraft. The data which has been analyzed was recorded with a one-dimensional laser Doppler system capable of measuring only the magnitude of a single velocity component. Although the optical range resolution determines the spatial resolution of the velocity profile in one direction, the laser system's excellent angular resolution makes it possible (assuming circular symmetry of the vortex) to obtain the tangential vortex velocity flow field. The resolution with which this function is obtained depends on the angular scan rate. With the present scan configurations, data points are obtained at approximately 1-degree intervals, corresponding to a resolution of 2 to 3 meters at ranges of 100 to 150 meters.

Dixit, H. N. and Govindarajan, R.

"VORTICES AND THE EFFECTS OF ATMOSPHERIC DENSITY STRATIFICATION"

Proceedings of the ICEAE, May 2009, Bangalore, India.

Our goal is to study the effects of atmospheric density stratification on the formation and longevity of aircraft trailing vortices. Towards this end, we study a series of model two-dimensional problems, two of which are presented here. The first is on the dynamics of a single vortex located at a density stratified layer. Due to the presence of the vortex, the density interface rolls up into a spiral. Centrifugal acceleration is shown to play a major role in reducing the life-span of the vortex. Due to the misalignment of the acceleration vector with the normal to the spiral interface, vorticity is created along the density interface, resulting in a spiral Kelvin-Helmholtz instability. At every interface where heavier fluid is closer to the vortex than lighter, the flow is also unstable due to a centrifugal Rayleigh-Taylor instability. In the second problem, centrifugal effects are neglected, i.e., the Boussinesq approximation is employed. Here gravity is shown to eat into the vortex and create small-scale structures, although the initial stratification is stable. In both cases, a turbulence-like state ensues. The relevance of the present work to aircraft trailing vortices is discussed in the introduction, and ongoing work addresses this problem more directly.

Dixit, H. N. and Govindarajan, R.

"STABILITY OF A VORTEX IN RADIAL DENSITY STRATIFICATION: ROLE OF WAVE INTERACTIONS"

Journal of Fluid Mechanics, Vol. 679, 2011, pp. 582-615.

We study the stability of a vortex in an axisymmetric density distribution. It is shown that a light-cored vortex can be unstable in spite of the 'stable stratification' of density. Using a model flow consisting of step jumps in vorticity and density, we show that a wave interaction mediated by shear is the

mechanism for the instability. The requirement is for the density gradient to be placed outside the vortex core but within the critical radius of the Kelvin mode. Conversely, a heavy-cored vortex, found in other studies to be unstable in the centrifugal Rayleigh-Taylor sense, is stabilized when the density jump is placed in this region. Asymptotic solutions at small Atwood number, At , show growth rates scaling as the cube root of At close to the critical radius, and the square root of At further away. By considering a family of vorticity and density profiles of progressively increasing smoothness, going from a step to a Gaussian, it is shown that sharp gradients are necessary for the instability of the light-cored vortex, consistent with recent work which found Gaussian profiles to be stable. For sharp gradients, it is argued that wave interaction can be supported due to the presence of quasi-modes. Probably for the first time, a quasi-mode which decays exponentially is shown to interact with a neutral wave to give exponential growth in the combined case. We finally study the nonlinear stages using viscous direct numerical simulations. The initial exponential instability of light-cored vortices is arrested due to a restoring centrifugal buoyancy force, leading to stable non-axisymmetric structures, such as a tripolar state for an azimuthal wavenumber of 2. The study is restricted to two dimensions, and neglects gravity.

Djojodihardjo, H.

"AIRCRAFT TRAILING VORTICES -- CIRRUS CLOUD INTERACTION AND GREEN AIRCRAFT TECHNOLOGY: AN OVERVIEW"

Proceedings of the 2013 IEEE International Conference on Space Science and Communication, July 2013, Melaka, Malaysia, pp. 318-323.

Anthropogenic solutions that can be offered by Aerospace Technology to address environmental changes known are known as green technology initiatives. Such initiatives, however, may only provide partial or temporary solutions, as learned from mankind experience through the ages. To this end, basic principles governing physical changes occurring in the earth's environment will be reviewed. In the efforts to intervene such process and thus maintaining the sustainability of the earth's environment, some scientific and technological guidelines to comprehend the natural phenomena and global changes are reviewed and discussed. In particular, efforts devoted to aircraft technology and aviation will be elaborated in view of the goal of maintaining the sustainability of the earth's environment. In addition to fuel burn, particular considerations are given to contrail and trailing vortices.

Djojodihardjo, H.

"REVIEW ON DEVELOPMENT AND RECENT PATENTS ON TRAILING VORTICES ALLEVIATION"

Recent Patents on Mechanical Engineering, Vol. 4, Issue 2, 2011, pp. 83-129.

Continuous research efforts have been devoted to the fundamental understanding of aircraft aerodynamics and the introduction of new concepts and innovations for the improvement of basic and fundamental aircraft aerodynamic performance, and hence economy, which leads to the enhancement

of lift and the reduction of drag. It is also well known that the trailing vortices which reflect the lift as well as drag characteristics of the aircraft could be optimized for better aircraft performance characteristics and reduction of environmental impact as well as hazardous interference to other flight vehicles and/or objects. Research in enhanced aerodynamic efficiency has led to geometrical modifications, novel devices and features on the aircraft wings, such as blended-wing-body configuration, airfoil profiles and winglet designs, introduction of and/or invention of sensors for identifying relevant physical phenomena or measuring devices, introduction of novel computational methods to assess the prevailing force system with better accuracy through meticulous modeling, and introduction of control system and procedures for wake vortices alleviation and aerodynamic configuration optimization. Typical winglets configuration can significantly reduce the induced drag (in the order of less than 10 percent) with a resulting increase in wing lift-drag ratio and near the design lift coefficient. The corresponding improvement in lift-drag ratio is more than twice as great as that achieved with the comparable wing-tip extension. As also observed in many aircrafts produced in the last decades, only winglets have demonstrated sufficient benefits to find application on modern airliners. Further enhanced aircraft aerodynamic performance are suggested by introduction of recent innovative designs and patents of winglets, sharklets, blended winglets, capped winglets, s-shaped winglets and spiroidal winglet. The review identifies stability of various configurations of vortices, vortex decay and means of reducing vortex hazard. Passive wake vortices alleviation systems utilize the natural evolution of the instability modes with the highest growth rates while active systems rely on accelerating selected modes of instability by imposing the vortices individually or as a system. The passive system is essentially a vortex wake, hence an aerodynamic surface design, while an active system is an actuator design effort, respectively.

Djojodihardjo, H.

"SIMULATION OF ROLLING MOMENT INDUCED BY VARIOUS AIRCRAFT TRAILING VORTICES VORTEX MODELS: REVIEW AND ANALYSIS"

Proceedings of 17th International Conference on Mathematical and Computational Methods in Science and Engineering, April 2015, Kuala Lumpur, Malaysia, pp, 224-233.

It is well known that the trailing vortices which reflect the lift as well as drag characteristics of the aircraft could be optimized for better aircraft performance characteristics and reduction of environmental impact as well as hazardous interference to other flight vehicles and/or objects. Attention is given to identify the stability of various configurations of vortices, vortex decay and means of reducing vortex hazard. Passive wake vortices alleviation systems utilize the natural evolution of the instability modes with the highest growth rates while active systems rely on accelerating selected modes of instability by imposing the vortices individually or as a system. The passive system is essentially a vortex wake, hence an aerodynamic surface design, while an active system is an actuator design effort, respectively. Within such frame of thought, various vortex Aircraft Trailing Vortices Vortex Models are reviewed and analyzed in view of their potentials Wake Hazard Alleviation, by simulating the rolling moment induced. The simulation of various vortex model chosen are judged by their expected characteristics that may reproduce actual state-of-affairs.

"A400M WAKE FLOW STUDIES BASED ON RANS CFD METHODS ON HYBRID MESHES"

RTO-MP-AVT-133, Proceedings Fluid Dynamics of Personnel and Equipment Precision Delivery from Military Platforms, Paper 7, 2006, Neuilly-sur-Seine, France, pp. 7-1 - 7-12.

Knowledge of flow conditions in the vicinity of the aft section of military transport aircraft is crucial to ensure the safe and precise deployment of personnel and material. CFD methods used by Airbus and DLR allow valuable predictions of these conditions, considering the influence of flow deflectors, sponsons, open cargo hold doors/ramps, as well as propulsion slip-streams. With the requirement of precisely delivering personnel and/or equipment into an area of limited size, while guaranteeing safe conditions for the airframe (as well as paratroops/dropped equipment), military transport aircraft pose unique challenges to aerodynamics. Among them: Guaranteeing the safety of parachutists, whose near aircraft trajectory is significantly influenced by the aircraft wake shedding substantial vorticity; and providing safe operational conditions within the aircraft while open doors strongly influence the internal air flow.

"BOW WAVE EFFECT IN AERIAL REFUELING: COMPUTATIONAL ANALYSIS AND MODELING"

Journal of Aircraft, Vol. 50, No. 6, November-December 2013, pp. 1856-1868.

Mechanisms contributing in the 'bow wave' effect of a receiver on a tanker are investigated, and a modeling method for dynamic simulation is developed. Vortex lattice and Cart3D codes are used to calculate the aerodynamic forces and moments for a C-141B behind a KC-135. The vortex lattice code significantly underpredicts the bow wave effect, whereas the Cart3D code shows good agreement with available flight data. The modeling method uses stream functions for inviscid flow around solid bodies. The flow field induced by the presence of aircraft bodies is superimposed on the flow field generated by horseshoe vortices. The resultant flow field is approximated by the effective uniform translational and rotational velocity components, which are used in the buildup equations for the aerodynamic force and moment coefficients of both tanker and receiver aircraft. This method applied to a flying wing behind a KC-135 shows good agreement with Cart3D results. It is concluded that the major contribution to the 'bow wave' effect is the effect of the displacement of air due to the volume of the receiver and not upwash from the bound vortex due to the lift of the receiver. This disagrees with earlier studies that did not have the benefit of flight data to use as a benchmark.

Dogan, A., Lewis, T. A. and Blake, W.

"FLIGHT DATA ANALYSIS AND SIMULATION OF WIND EFFECTS DURING AERIAL REFUELING"

J. Aircraft, Vol. 45, No. 6, November-December 2008, pp. 2036-2048

This paper presents the analysis of the data obtained in an automated aerial refueling test flight conducted with a KC-135 as the tanker and a Learjet 25 as the surrogate receiver unmanned aerial

vehicle. The purpose of the analysis is to identify the wind induced by the tanker wake and its effect on the receiver aircraft. From the available flight data, a direct computation of the winds experienced by the tanker and receiver is carried out. The mean variation of the receiver wind is compared with the tanker wind when the receiver is at the observation and contact positions. This results in the identification of the wake-induced wind. A spectrum analysis is conducted to characterize the turbulence and to identify the pilot effects. The paper also presents methods used to model 1) prevailing wind, 2) wake-vortex-induced wind, and 3) turbulence as the three sources of wind that the aircraft are exposed to and the approach used for incorporating the wind effect into the dynamic simulation of the aircraft. The test flight is simulated in various cases with different turbulence models and flight controllers. The simulation results are analyzed and compared with the flight data in terms of the power spectral densities and mean variations to validate the wind and turbulence modeling techniques.

Dogan, A., Lewis, T. A. and Blake, W.

"WAKE-VORTEX INDUCED WIND WITH TURBULENCE IN AERIAL REFUELING -- PART A: FLIGHT DATA ANALYSIS"

AIAA Paper 2008-6696, Honolulu, HI, August 2008.

This paper presents the analysis of the data obtained in an automated aerial refueling test flight conducted with a KC-135 as the tanker and a Learjet 25 as the surrogate receiver UAV. The purpose of the analysis is to identify the wind induced by the tanker wake and its effect on the receiver aircraft. From the available flight data, a direct computation of the winds experienced by the tanker and receiver is carried out. The mean variation of the receiver wind is compared with the tanker wind when the receiver is at the observation and contact positions. This results in the identification of the wake-induced wind. Further, a spectrum analysis is conducted to characterize the turbulence and to identify the pilot effects. This paper is the first of a series of two papers. In the second paper (Part B), the flight data analyzed herein are used to validate a modeling and simulation technique.

Dogan, A., Lewis, T. A. and Blake, W.

"WAKE-VORTEX INDUCED WIND WITH TURBULENCE IN AERIAL REFUELING -- PART B: MODEL AND SIMULATION VALIDATION"

AIAA Paper 2008-6697, Honolulu, HI, August 2008

This paper is the second of a series of two papers. The first paper (Part A) presents the analysis of the data obtained in an automated aerial refueling test flight conducted with a KC-135 as the tanker and a Learjet 25 as the receiver. The purpose of the analysis is to identify the turbulence and wind induced by the tanker wake and their effect on the receiver aircraft. This paper presents the methods used to model (i) prevailing wind, (ii) wake vortex induced wind and (iii) turbulence as the three sources of wind that the aircraft are exposed to and the approach used for incorporating the wind effect into the dynamic simulation of the aircraft. The test flight is simulated in various cases with different turbulence

models and flight controllers. The simulation results are analyzed and compared with the flight data in terms of the power spectral densities and mean variations in order to validate the wind and turbulence modeling techniques.

Dogan, A., Venkataramanan, S. and Blake, W.

"MODELING OF AERODYNAMIC COUPLING BETWEEN AIRCRAFT IN CLOSE PROXIMITY"

Journal of Aircraft, Vol. 42, No. 4, July-August 2005, pp. 941-955

A method is developed for modeling the aerodynamic coupling between aircraft flying in close proximity. Velocities induced on a trailing aircraft by vortices from an aircraft upstream are written as a function of the relative separation and relative orientation between the two aircraft. The nonuniform vortex-induced wind and wind gradients acting on the trail aircraft are approximated as effective uniform wind and wind gradients. In a dynamic simulation, the effective wind can be used directly in the equations of motion, whereas the wind gradient can be used in the standard buildup equations for the aerodynamic moments. This removes necessity to explicitly compute the induced forces and moments. Various vortex models for estimating induced velocities and averaging schemes for computing effective wind components and gradients are assessed. Results from the method are compared to wind-tunnel data for a formation of two similar aircraft. A good match is obtained between experimental data and the predicted incremental force and moment coefficients induced on the trail aircraft. It is briefly discussed how the effective wind components and gradients can be incorporated into equations of motion of aircraft flying in a vortex field.

Doggett, Jr., R. V., Rivera, Jr., J. A. and Stewart, E. C.

"FLUTTER CLEARANCE FLIGHT TESTS OF AN OV-10A AIRPLANE MODIFIED FOR WAKE VORTEX FLIGHT EXPERIMENTS"

NASA TM-109168, April 1995, NASA Langley Research Center, Hampton, VA

Envelope expansion, flight flutter tests of a modified OV-10A aircraft are described. For a wake vortex research program, the airplane was modified to incorporate three, forward-extending instrumentation booms, one extending forward from each wing tip and one from the right side of the fuselage. The booms are instrumented with sensors to measure the velocity and direction of local air flow. The flutter tests results show that the modified OV-10A aircraft is free from flutter at speeds up to 330 KEAS at 5000 feet altitude.

Doig, G., Barber, T. J. and Neely, A. J.

"AERODYNAMIC CHARACTERISTICS OF A SWEPT WING IN CLOSE GROUND PROXIMITY AT HIGH SUBSONIC MACH NUMBERS"

Journal of Aerospace Engineering, Vol. 25, No. 4, October 2012, pp. 600-612.

The potential positive influence of close ground proximity on the aerodynamic performance of a wing has long been established; however, flight at a Mach number that causes shock waves to form between the wing and the ground plane would have significant aerodynamic consequences. A numerical study to investigate the effects of extremely low-level flight at subsonic Mach numbers up to 0.9 was conducted involving the symmetric, swept ONERA M6 wing. The aerodynamic coefficients as well as the pressure distributions and tip vortex behavior were analyzed for cases involving the angle of incidence, ground clearance, and Mach number as variables. It was found that lift was augmented with decreasing ground clearance in most cases with the wing at positive incidence, although the critical Mach number for the wing, in particular for the lower surface, was reduced at very low clearances. The earlier emergence of a lower shock was accompanied by a considerable increase in drag, although this was offset in part by a marked decrease in the strength of the tip vortex when the wing was within one chord length of the ground plane. As a result of the more pronounced shock structures and separation regions that occur above a freestream Mach number of 0.8, there is no net aerodynamic efficiency to be gained from flight with this wing in close ground proximity compared with unbounded flight at altitude.

Dolfi-Bouteyre, A., Augere, B., Besson, C., Canat, G., Fleury, D., Gaudo, T., Goular, D., Lombard, L., Planchat, C., Valla, M., Cariou, J.-P., Petilon, O. and Lawson-Daku, J.

"1.5 MICRON ALL FIBER PULSED LIDAR FOR WAKE VORTEX MONITORING"

Conf. on Lasers and Electro-Optics, CLEO/QELS 2008, May 2008, pp. 1-2

A pulsed fiber lidar based on 1.5-micron fiber technology has been demonstrated for wake vortex monitoring on airport sites. The wake vortex cores position resolution is plus/minus 2 m, the error on circulation 10 percent.

Dolfi-Bouteyre, A., Augere, B., Bourdon, P., Canat, G., Cezard, N., Dobroc, A., Durecu, A., Fleury, D., Le Gouet, J., Goular, D., Lombard, L., Planchat, C., Renard, W., Valla, M. and Besson, C.

"NEW FIBER LASER AND COHERENT LIDAR DEVELOPMENTS AT ONERA"

17th Coherent Laser Radar Conference, June 2013, Barcelona, Spain.

Onera has been developing lidars for military, environmental, and aeronautical applications for more than 30 years. The main instrumental developments deal with wind/wake vortex lidar for airport and environmental applications, lidar vibrometer for identification purpose or seismology applications, dial and supercontinuum lidars for gas detection and identification, airborne lidar for navigation sensors. In parallel, the team has a strong involvement in fiber laser technology in order to develop laser sources suitable to lidar applications. The main objective are the power scaling of fiber laser sources to increase lidar range, measurements accuracy and/or measurement rate. This implies the development of new active fibers, new technologies to overcome the stimulated Brillouin threshold or architectures involving coherent combining of amplifiers. Other developments deal with new wavelengths narrow linewidth fiber lasers or supercontinuum lasers to address particular gas species detection. In this

paper, we focus on innovative fiber laser developments and their integration in lidar systems for wind or gas monitoring. We also present new developments for two lidar applications: lidar vibrometer for structural damage assessment, and supercontinuum lidar for remote spectroscopy. Two other topics (wake vortex detection and wind sensing using coherent combining), are presented in dedicated papers.

Dolfi-Bouteyre, A., Augere, B., Valla, M., Goular, D., Fleury, D., Canat, G., Planchat, C., Gaudo, T., Besson, C., Gilliot, A., Cariou, J.-P., Petilon, O., Lawson-Daku, J., Brousmiche, S., Lugan, S., Bricteux, L. and Macq, B.

"AIRCRAFT WAKE VORTEX STUDY AND CHARACTERIZATION WITH 1.5 MICRON FIBER DOPPLER LIDAR"

Onera AerospaceLab Journal, Issue 1, Dec. 2009, pp.1-12.

For 10 years now, Onera has been developing lidar tools for wake vortex detection and studies. Since 2003, new developments based on 1.5- micron fibered laser sources have been achieved in parallel with extensive research work on the laser sources themselves. Three innovative lidars have been developed and are presented in this paper: 1) A mini-lidar, based on a CW 2W/1.5-micron laser source, for aircraft model wake vortex characterization in a catapult facility. A self-triangulation technique allows the vortex core position to be found with 10 cm error, and the circulation error is 10 percent. 2) A pulsed 1.5-micron lidar, based on a 50 microjoule/15 kHz Master Power Oscillator Power Amplifier (MOPA) source, for lateral wake vortex monitoring at airports. The range is 400 m, the core position error is about +/- 2 m and the circulation error is about 10 percent. 3) A pulsed 1.5-micron lidar, based on a 120 microjoule/12 kHz MOPA source, for onboard axial wake vortex detection. Ground based lidar tests at Orly airport demonstrated wake vortex detection up to 1.2 km..

"PULSED 1.5-MICRON LIDAR FOR AXIAL AIRCRAFT WAKE VORTEX DETECTION BASED ON HIGH-BRIGHTNESS LARGE-CORE FIBER AMPLIFIER"

IEEE Journal of Selected Topics in Quantum Electronics, Vol. 15, No. 2, March/April 2009, pp. 441-450.

In this paper, we present the development of an axial aircraft wake vortex light detection and ranging (LIDAR) sensor, working in the Mie scattering range, based on pulsed 1.5-micron high-brightness large-core fiber amplifier. An end-to-end Doppler heterodyne LIDAR simulator is used for the LIDAR design. The simulation includes the observation geometry, the wake vortex velocity image, the scanning pattern, the LIDAR instrument, the wind turbulence outside the vortex, and the signal processing. An innovative high-brightness pulsed 1.5-micron laser source is described, based on a master oscillator power fiber amplifier (MOPFA) architecture with a large-core fiber. The obtained beam quality is excellent, and achieved pulsed energy is 120 micro-Joules with a pulse repetition frequency of 12 kHz and a pulse duration of 800 ns. A Doppler heterodyne LIDAR is developed based on this laser source with a high-isolation free-space circulator. The LIDAR includes a real-time display of the wind field.

Wind dispersion is postprocessed. Field tests carried out at Orly airport in April 2008 are reported. Axial aircraft wake vortex signatures have been successfully observed and acquired at a range of 1.2 km with axial resolution of 75 m for the first time with fiber laser source.

"MEASUREMENT OF AIRCRAFT WAKE VORTEX USING COHERENT LASER RADAR: COMPARISON BETWEEN CATAPULT AND AIRPORT MEASUREMENTS"

13th Coherent Laser Radar Conf., October 2005, Kamakura, Japan.

Coherent laser radar or lidar is a powerful technique for detection and study of aircraft wake vortices. The technique measures the Doppler shift of light scattered from atmospheric particles, and hence infers the line-of-sight flow velocity allowing a picture of vortex flow to be built up. CW lidar technique has been used in reduced scale studies in catapult facilities and for full-scale aircraft wakes measurements and is the link between both approaches. In ONERA's B20 new catapult facility, non-motorized scaled models are accelerated by means of a pneumatic catapult via a trolley and then released as a free-flying model. Smoke generators on the ground are used to seed the vortices. Measurements are obtained at high spectral and angular resolution. Using a self-triangulation technique, the position of the cores and their trajectories over time is determined with 15 cm accuracy. This new measurement instrumentation will be presented in detail. During the AWIATOR program, ONERA 10-micron continuous wave lidar was coupled with a DLR 2-micron pulsed lidar. The pulsed lidar monitored the seeded vortices of a large transport aircraft (vortex position and circulation) while detailed measurements of velocity profiles were obtained with ONERA's continuous-wave lidar. The lidar appears to be an essential tool to check the scale factor between model and true aircraft and to analyze external factors such as wind and atmospheric turbulence on vortex decay. Comparison of catapult and field test measurements will be presented.

"ALL-WEATHER SENSORS (LIDAR + RADAR) FOR WAKE-VORTEX HAZARDS MITIGATION ON AIRPORT"

17th Coherent Lidar Conference, June 2013, Barcelona, Spain.

RADAR and LIDAR sensors are complementary in terms of ambient weather conditions: X-band Radar performances are optimal under rainy conditions whereas Lidar performances are optimal in dry air. During SESAR XP0 and XP1 trials in CDG airport, a multi-function (wake-vortex, weather) electronic scanning X-band Radar (THALES), and a multifunction 1.5-micron Lidar with a 3D scanner (Leosphere with Onera signal processing) have been used together to detect and follow aircraft wake vortices. These sensors were associated in an all-weather conditions system. Trials configuration is presented and test results are analyzed.

Dolfi-Bouteyre, A., Valla, M., Augere, B., Cariou, J.-P., Goular, D., Fleury, D., Canat, G., Planchat, C., Gaudo, T., Lombard, L., Petilon, O. and Lawson-Daku, J.

"1.5 MICRON ALL FIBER PULSED LIDAR FOR WAKE VORTEX MONITORING"

14th Conference on Coherent Laser Radar, Snowmass, CO, July 2007

A new 1.5-micron pulsed lidar using an all-fiber laser source has been developed by ONERA in cooperation with Leosphere, for wake vortex and wind field measurements. This paper illustrates the good results obtained with a pulsed lidar based on MOPFA 1.5-micron laser, for detection and monitoring of wake vortices on airport fields. Operational ranges larger than 400m have been demonstrated with a 60 microjoule, 15kHz, 250ns pulse fiber doped Er laser. Wake profiles, positions and circulations can be derived from recorded data.

"VORTEX INTERACTIONS WITH WALLS"

Annual Review of Fluid Mechanics, Vol. 26, 1994, pp. 573-616

The response of a viscous boundary layer to vortex motion has been described in this article, with an emphasis on flows at high Reynolds number. In general, a boundary-layer eruption occurs in such circumstances in the form of a thin spire containing significant levels of vorticity, which usually rolls up into one or more secondary vortices. This regenerative process of vortex-induced separation is evidently a common phenomenon occurring in a wide variety of applications, some of which are described here. Because these eruptions develop and take place in moving reference frames and involve sharply focused eruptions that occur abruptly (at times and locations that are not easily predicted a priori), experimental and computational research on such phenomena is extremely challenging. It is evident that conventional experimental techniques, wherein measurements are taken at fixed points in space, are virtually useless in attempting to detect such phenomena. Progress can be made using combinations of innovative flow visualization and particle image velocimetry; however, a moving reference frame is often crucial to proper interpretation of vortex-induced events. It is also worth noting that a substantial increase in resolution may be required in current PIV methods in order to capture the abrupt narrow-band eruptions.

"VORTEX SIGNATURE RECOGNITION BY A DOPPLER RADAR"

J. Applied Meteorology, Vol. 9, August 1970, pp. 661-670

A scanning Doppler radar has capability for measurement of the tangential shear of radial velocity or gradient of the radial component of velocity in a direction normal to the radial vector. Tangential shear of sufficient magnitude in a horizontal direction reveals one term of the expression for vorticity in a horizontal plane. A vortex is reasonably well identified by Doppler radar if the shear is sufficiently steady during the time required for half a revolution of a vortex, and is further confirmed by extension of the shear pattern throughout a depth greater than its diameter, and by invariance of the character of the shear with respect to a change in viewing angle. A vortex in solid rotation has a characteristically uniform signature on a Doppler velocity display which may, however, be smoothed down according to the resolution limitations of the antenna beam. Sharp velocity peaks are rounded down to roughly half the magnitude of the velocity interval encompassed within the half-power antenna beamwidth.

"A BRIEF REVIEW OF THE AIRCRAFT TRAILING VORTEX PROBLEM"

AFOSR-TR-71-1910, May 1971, Aeronautical Research Assoc. of Princeton, Princeton, NJ

In this paper, an attempt will be made to review the simplest theory of the wake, as well as to bring to attention a more detailed description of vortex roll-up that has been available for many years. This more complete description of the wake is in far better agreement with experimental results than the conventional description and may be used to illustrate several problems that face the experimentalist in the interpretation of this data. Once the roll-up problem has been discussed, the ways in which trailing vortex systems may be dissipated are reviewed. Finally, a system for evaluating the danger potential of aircraft wakes is discussed and the wake characteristics of a representative selection of present-day aircraft are presented in terms of this method of classifying aircraft wakes.

Donaldson, C. duP.

"CALCULATION OF TURBULENT SHEAR FLOWS FOR ATMOSPHERIC AND VORTEX MOTIONS"

AIAA Journal, Vol. 10, No. 1, January 1972, pp. 4-14

The basic ideas behind methods for computing the transport properties of turbulent shear flows for the past several decades are reviewed. Their shortcomings, insofar as computing several problems that arise in nature, are discussed. Particular emphasis is given to the case of vortex flows and atmospheric motion. The results of several years' effort toward establishing a general method for computing turbulent shear flows which does not suffer from the shortcomings of the older methods are reviewed, and a new method for the calculation of turbulent shear flows is suggested. The new results obtained when this method is applied to the computation of simple atmospheric motions and to vortex flows are presented and discussed in some detail.

Donaldson, C. duP.

"VORTICES AND AIRCRAFT PERFORMANCE"

Proceedings of the AFFDL/NASA/FAA Wake Turbulence Work Shop, Air Force Flight Dynamics Laboratory, AFFDL-TM-75-16-FGC, 1974, pp. 11-17

A review is given on ARAP's work on the roll-up and initial organization of vorticity shed by the wing of an aircraft and on the aging effects in the far wake due to viscosity (molecular and turbulent). The modified Betz model was shown to be an effective approach to the roll-up problem; it includes the effect of distributed wing drag on vortex structure. In considering the far-field flow, a detailed second-order numerical closure model has been developed for the axisymmetric vortex under the usual assumptions of equilibrium between the production and convection of turbulent energy.

Donaldson, C. duP. and Bilanin, A. J.

"VORTEX WAKES OF CONVENTIONAL AIRCRAFT"

AGARDograph No. 204, May 1975, Aero. Research Assoc. of Princeton, Princeton, NJ

A review is made of the present state of our knowledge of the vortex wakes of conventional aircraft. Included are discussions of wake roll-up, geometry, instability, and turbulent aging. In the light of these discussions, a brief review is made of the persistence of vortices in the atmosphere and design techniques which might be used to minimize wake hazard are considered.

Donaldson, C. duP. and Sullivan, R. D.

"DECAY OF AN ISOLATED VORTEX"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 389-411

The effect of turbulent shear on the decay of a single vortex is considered. The ultimate aim of the program is the development of a method by which the effects of turbulence, whether introduced initially in the center of a vortex or contained in the fluid in which the vortex is formed, could be calculated.

Donaldson, C. duP., Bilanin, A. J. and Crow, S. C.

"VORTEX WAKES OF LARGE AIRCRAFT"

Notebook for AIAA Professional Study Seminar, June 1974, Aeronautical Research Assoc. of Princeton, Princeton, NJ

A compendium of lecture notes on the subject of vortex wakes of large aircraft. The notes include the following topics: rollup of shed vorticity, new roll-up models, comparison of rollup computations with experiments, interactive motion of shed vorticity, aging of vortices, vortex breakdown, mutually induced instabilities, atmospheric effects, and the impact on aircraft design.

Donaldson, C. duP., Snedeker, R. S. and Sullivan, R. D.

"A METHOD OF CALCULATING AIRCRAFT WAKE VELOCITY PROFILES AND COMPARISON WITH FULL-SCALE EXPERIMENTAL MEASUREMENTS"

AIAA Paper No. 1974-0039, Washington, DC, January 1974

A method is developed for the calculation of the initial inviscid form of rolled-up wake vortices behind a wing having arbitrary lift distribution. The method makes use of the Betz assumptions of conservation of wake vorticity and moments of vorticity. It is found that a simple relationship exists between the radial distribution of vorticity in the rolled-up wake and the spanwise lift distribution. Computed tangential velocity profiles for DC-7, DC-9, and C-141 aircraft are shown to compare favorably with profiles measured by the FAA during tower flyby tests of these aircraft in both flapped and unflapped configurations.

Donaldson, C. duP., Snedeker, R. S. and Sullivan, R. D.

"CALCULATION OF AIRCRAFT WAKE VELOCITY PROFILES AND COMPARISON WITH EXPERIMENTAL RESULTS"

Journal of Aircraft, Vol. 11, No. 9, September 1974, pp. 547-555

A method is developed for the circulation of the initial inviscid form of rolled-up wake vortices behind a wing having arbitrary lift distribution. The method makes use of the Betz assumptions of conservation of wake vorticity and moments of vorticity. It is found that a simple relationship exists between the radial distribution of vorticity in the rolled-up wake and the spanwise lift distribution. Computed tangential velocity profiles for DC-7, DC-9, and C-141 aircraft are shown to compare favorably with profiles measured by the FAA during tower flyby tests of these aircraft in both flapped and unflapped configurations.

Donaldson, C. duP., Snedeker, R. S. and Sullivan, R. D.

"CALCULATION OF THE WAKES OF THREE TRANSPORT AIRCRAFT IN HOLDING, TAKEOFF, AND LANDING CONFIGURATIONS AND COMPARISON WITH EXPERIMENTAL MEASUREMENTS"

FAA-RD-73-42, March 1973, Aeronautical Research Assoc. of Princeton, Princeton, N.

A method is described for the calculation of the initial form and location of the inviscid rolled-up wake vortices behind wings having both simple and complex load distributions such as those which occur when the wing is highly flapped. The method makes use of the Betz theorems of conservation of

vorticity and moments of vorticity in the wake. It is found that a simple relationship exists between the radial distribution of vorticity concentrated in the wake vortices and the spanwise distribution of vorticity shed from the wing. Velocity profiles computed for the vortices of several aircraft in holding, takeoff, and landing configurations are shown to compare favorably with those measured at times up to one minute after fly-by during full-scale experiments.

"STUDY OF THE FEASIBILITY OF CONDUCTING A WAKE-RIDING EXPERIMENT USING A T-2 AIRCRAFT BEHIND TWO P-3 AIRCRAFT"

ARAP-287, August 1976, Aeronautical Research Assoc. of Princeton, Princeton, NJ.

A study has been made of a T-2 aircraft attempting to establish a wake-riding position behind two P-3 aircraft. The major objectives were to estimate structural loads in the wake rider and to evaluate wake entry and station keeping control techniques. The results of the study indicate that the root-bending load on the tail of the T-2 aircraft would be of the order of the design load if the aircraft were to inadvertently pass directly through the center of a trailing vortex from one of the P-3's. Thus, the flight tests, as originally envisaged, must be considered as high-risk experiments unless the tail of the T-2 were to be strengthened. If wake riding experiments are carried out, approach to the wake-riding position should be made from above using a reduced-power, constant-airspeed approach. In calm air the piloting task appears reasonable if the trailing vortices are marked by smoke or condensation.

Dong, Y., Yang, Y. and Liu, C.

"DNS STUDY ON THREE VORTEX IDENTIFICATION METHODS"

AIAA Paper 2017-0137, January 2017, Grapevine, TX.

Vorticity, vorticity line and vorticity tube have rigorous definitions, but vortex has not been mathematically defined yet. It is realized that vortex is not vorticity tube and must be given a more rigorous definition, at least by some accurate identification methods. The current paper compares two popular vortex identification methods, Q-criterion and Λ^2 with the new Omega vortex identification method by visualization of several examples studied by direct numerical simulation (DNS) and large eddy simulation for flows with different speeds. The comparisons show the Omega method is much close to give vortex a mathematical definition and better visualization for vortical structures. The Omega method is quite universal and has no need to set up a threshold case by case. Additional advantages include easiness to perform, clear physical meaning, and high capability to capture both strong and weak vortices, which make Omega the most effective and efficient tool in vortex identification.

Donnadieu, C., Chomaz, J.-M. and Ortiz, S.

"INSTABILITIES AND TRANSIENT GROWTH OF TRAILING VORTICES IN STRATIFIED FLUID"

The wake, which forms behind an aircraft due to its lift, is a pair of horizontal counter-rotating vortices propagating downwards. Depending on the atmospheric conditions, such dipole can persist over a long time or be rapidly destroyed. This vortex pair, in homogeneous fluids, is unstable with respect to three-dimensional perturbations. Crow has discovered a long-wavelength instability, symmetric with respect to the plane separating the two vortices. The existence of a short-wavelength elliptic instability has been revealed by Tsai and Widnall. Moore and Saffman and numerous articles ever since have discussed both symmetric and antisymmetric modes. Recently Donnadieu et al observed a novel oscillatory instability, less unstable than Crow and elliptic modes, for large Reynolds numbers. However, in many atmospheric situations, as such dipoles propagate downwards, they evolve under the influence of the stable stratification of the atmosphere. The three-dimensional dynamics of this vortex pair in stratified flow, has received much less attention: still Robins and Delisi and Garten et al. have discussed persistence of the Crow instability and Nomura et al. of the short-wavelength instability.

Donnadieu, C., Ortiz, S., Chomaz, J.-M. and Billant, P.

"THREE-DIMENSIONAL INSTABILITIES AND TRANSIENT GROWTH OF A COUNTER-ROTATING VORTEX PAIR"

Physics of Fluids, Vol. 21, 2009, p. 094102-1 to 094102-16.

This paper investigates the three-dimensional instabilities and the transient growth of perturbations on a counter-rotating vortex pair. The two-dimensional base flow is obtained by a direct numerical simulation initialized by two Lamb-Oseen vortices that quickly adjust to a flow with elliptic vortices. In the present study, the Reynolds number is taken large enough for the quasi-steady assumption to be valid. Both the direct linearized Navier-Stokes equation and its adjoint are solved numerically and used to investigate transient and long-time dynamics. The transient dynamics is led by different regions of the flow, depending on the optimal time considered. At very small times compared to the advection time of the dipole, the dynamics is concentrated on the points of maximal strain of the base flow, located at the periphery of the vortex core. At intermediate times, depending on the symmetry of the perturbation, one of the hyperbolic stagnation points provides the optimal amplification by stretching of the perturbation vorticity as in the classical hyperbolic instability. The growth of both short time and intermediate time transient perturbations are non- or weakly dependent on the axial wavenumber whereas the long-time behavior strongly selects narrow bands of wavenumbers. We show that, for all unstable spanwise wavenumbers, the transient dynamics last until the nondimensional time $t=2$, during which the dipole has traveled twice the separation distance between vortices b . During that time, all the wavenumbers exhibit a transient growth of energy by a factor of 50, for the Reynolds number 2000. For time larger than $t=2$, energy starts growing at a rate given by the standard temporal stability theory. At large Reynolds number, the computed Crow and elliptic instability branches are in excellent agreement with the inviscid theory and numerical analysis.

Donnelly, M. J., Vlachos, P. and Telionis, D. T.

"A VORTEX PAIR IMPINGING ON A SOLID BOUNDARY"

AIAA Paper No. 1998-0690, Reno, NV, January 1998

An experimental investigation is conducted which considers the interaction of a vortex pair propagating towards a solid boundary. This problem holds significance in several engineering applications including investigations into trailing wing tip vortices and their interaction with the ground. Data are acquired with both a high-speed digital video camera and a laser Doppler velocimetry system (LDV). The digital video camera is used to capture the development and trajectory of one of the primary vortices for a variety of pitch rates. The flow field is assumed to be symmetric and only half of it is investigated. The LDV system measures two components of velocity in a plane at the center of the vortex generating flaps. Grids of data were acquired for three pitch rates and a variety of locations. It is determined that the initial vortex trajectory behaves very much like an inviscid analysis of this problem. Upon development of a secondary vortex, due to separation at the wall, the primary vortex is seen to meander and even stall.

Donohue, G. and Shortle, J.

"APPLICATION OF TOPAZ AND OTHER STATISTICAL METHODS TO PROPOSED USA CONOPS FOR REDUCED WAKE VORTEX SEPARATION"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

Wake turbulence is a major cause of terminal delays. This is particularly true during Instrument Meteorological Conditions (IMC). NASA and the FAA have recently proposed a research plan to improve airport capacity related to these standards. The plan includes near-term solutions (e.g., modification of the 2,500-foot separation standard for independent operations on closely spaced parallel runways during IMC), mid-term solutions (e.g., use of weather sensitive procedures to account for cross-winds), and far-term solutions (e.g., a dynamic wake-avoidance tool to optimize in-trail spacing based on weather conditions). This talk discussed plans to apply the TOPAZ (Traffic Organizer and Perturbation AnalyZer) safety modeling methodology to analyze proposed USA concepts of operations for reduced wake vortex separation. To motivate the methodology, we first present an application of statistical techniques used by the methodology in the analysis of simultaneous runway occupancy and runway collision probabilities at Atlanta Hartsfield Airport. We then discuss ways to extend the methodology to predict the probabilities of severe wake vortex encounters under the proposed reduced separations.

Donohue, G. L.

"THE EFFECT OF AIRCRAFT WAKE VORTEX SEPARATION ON AIR TRANSPORTATION CAPACITY"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

The wake vortex separation problem has been known for over 30 years. The current system of static restrictions and approach separation criteria reduces the air transportation system capacity under IFR conditions. In the US, these static restrictions are frequently ignored under VMC conditions by assigning aircraft separation responsibility to the pilot once he has the airport runway in sight. The current system leads to 1) frequently imposing excessive separation under IMC and 2) infrequently allowing inadequate separation under VMC. The recent NASA/FAA research on wake vortex separation has made significant progress on both theoretical understanding and empirical measurement of the aircraft wake vortex behavior interacting with the atmospheric boundary layer. The current state-of-the-art indicates that new sensors and vortex prediction and warning algorithms should be incorporated into FAA weather and ATM decision support system software to recover critical lost air transportation capacity while at the same time maintaining or increasing safety. Runway wind directional variability is intrinsic to the random nature of the atmospheric turbulent boundary layer. This inherent uncertainty in wind vector presents challenges to accurately predicting runway wind direction out to 30 minutes. The prediction time is required to begin the spacing of arriving aircraft approximately 200 miles from the airport due to the aircraft maneuver restrictions. The atmospheric turbulent boundary layer Turbulent Kinetic Energy (TKE) level or eddy dissipation level is a more stable scalar quantity and is more reliable in predicting the conditions for wake vortex breakup and accelerated circulation decay. Based upon both the experimental results observed in the NASA DFW experiments and theoretical considerations, it is recommended that the FAA Integrated Terminal Weather System (ITWS) be upgraded to initially provide a WARNING of wake vortex circulation intensity above background. It is suggested that this is a better criterion for any wake vortex ATC system, NOT a PREDICTION of wake vortex location relative to the runway centerline for initial system implementations. This system should work well under most windy conditions. Under low wind, stable IMC conditions, the wind conditions may be more predictable and wake centerline prediction may provide more additional capacity.

Donzier, A.

"WAKE VORTEX DETECTION USING A PHASED ARRAY SODAR"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 39-1 - 39-10

Following the study of windshear at Roissy International Airport, using a REMTECH PA3 phased array system tilted at low elevation angles, the system was used to investigate wake vortex intensity using acoustic techniques. The PA3 system was installed at Roissy/Charles de Gaulle Airport on April 22, 1991, with a revised software version allowing the emission of 5 frequencies in a single acoustic pulse. The sounding range was set from 50 m to 1 km. The averaging time was set to 5 minutes. The system is operating continuously and data are stored on the hard disk. Strong echo regions are observed, but need to be studied to determine the source of the scattering.

Doolan, C. J., Coton, F. N. and Galbraith, R. A. McD.

"MEASUREMENT OF THREE-DIMENSIONAL VORTICES USING A HOT WIRE ANEMOMETER"

AIAA Paper No. 1999-3810, Norfolk, VA, June 1999

A series of tests were performed using a new vortex generator rig in the 1.15 m x 0.85 m low speed wind tunnel at Glasgow University. Results were acquired with a hot wire anemometer system using single and cross wire probes. A strong vortex velocity field was measured which confirmed the success of the vortex generation techniques and provided information about features of the flow. An interaction occurred between the vortex core and the hot wire probe which manifested itself as variations in vortex core measurements which one would not expect without probe interference. While an interaction was present when measuring close to the viscous core region, in the inviscid external field the probe had little effect on vortex dynamics. This allowed analysis of vortex geometry and an estimation of the vortex wandering amplitude in the test section. The curvature of the vortex generator wake was also measured using differently spaced single and cross wire probes. The data were compared with a computational model and showed good agreement.

Doolan, C. J., Coton, F. N. and Galbraith, R. A. M.

"SURFACE PRESSURE MEASUREMENTS OF THE ORTHOGONAL VORTEX INTERACTION"

AIAA Journal, Vol. 39, No. 1, January 2001, pp. 88-95.

A unique vortex generator that simulates the trailing vortex produced by a helicopter main rotor in forward flight was used in a study of main rotor/tail rotor blade vortex interaction. Velocity measurements were performed using hot wire anemometry and particle image velocimetry, which showed the interacting vortices to be three dimensional and to contain a significant core axial flow. Surface pressure measurements during vortex collision with an instrumented, stationary blade were obtained at a variety of incidence settings. At the leading edge, a suction peak occurred where the core flow was directed away from the surface and, similarly, a pressure peak occurred where the core flow was directed toward the surface. This behavior can be explained in terms of the impulsively blocked vortex core axial flow. Also, the leading-edge suction and pressure peaks were amplified or attenuated by changing the incidence of the blade. However, the changes in surface pressure distribution were such that the peak normal force was approximately the same for each incidence setting.

Doran, P.

"STUDY OF INSTABILITY OF AIRCRAFT WAKE VORTICES IN GROUND EFFECT"

PhD Thesis, July 2017, University of Quebec, Montreal, Canada [In French].

With the increasing use of air transport for passengers, traffic increasingly dense near airports is formed. The wake of each aircraft represents a potential threat to the stability of a plane in the vicinity of this wake. This threat is even greater when the plane is near the ground, as in the case of an aircraft in landing and takeoff phase. To minimize risks, a safe distance must be imposed between the aircraft leader and follower aircraft. To increase air traffic, the distance should be minimized. To do this, a

study of the wakes' natural dissipation mechanisms in ground effect is achieved. This study is obtained by numerical simulations and linear stability analyses of a pair of counter-rotating vortices. DNS models the configuration of a pair of counter-rotating vortices in ground effect, while the analytical stability study models a pair of counter-rotating out of ground effect. It is noted for in ground effect configuration the main vortices of the pair mutually induce a downward velocity. At ground approach, boundary layers are formed and eventually separated to become secondary vortices whose circulations are less than the principal's. The study of the vortex perturbation field from the numerical results shows a typical bending mode instability in the secondary vortices and the beginning of the appearance of an elliptical instability in the main vortices. In addition, the study of the linear stability of the subsystem consists of a primary vortex and secondary vortex which corroborates the wave numbers identified using numerical simulations. Now, it is deduced that only the ratio of circulations and the radius of the secondary vortex are needed to predict the most unstable wave number from theoretical analysis of stability the vortex system. Subsequently, the effect of a side wind is considered. The effect of the wind is equivalent to adding a background vorticity. This background vorticity has the effect of making the vortex system asymmetric. The left and right vortex subsystems, each composed of a main vortex and a secondary vortex, interact differently depending on the vorticity resulting from the superposition of the background vorticity and that of the subsystem. In this in ground effect configuration with a crosswind, the ratio of circulation and the radius of the secondary vortex are evaluated. These two parameters are used to determine, with the same linear stability theory outlined above, the most unstable wave number leading to the dissipation of the aircraft wake vortices.

Dosanjh, D. S. and Weeks, T. M.

"INTERACTION OF A STARTING VORTEX AS WELL AS A VORTEX STREET WITH A TRAVELING SHOCK WAVE"

AIAA Journal, Vol. 3, No. 2, 1965, pp. 216-223.

The passage of a shock front and the associated drift flow over a two-dimensional airfoil, at an angle of attack mounted in a shock tube, generated a columnar spiral starting vortex that interacted with the normal reflected shock. Interferometric investigations of this interaction extended considerably earlier schlieren observations by Hollingsworth and Richards. The generation of a progressive cylindrical acoustic wave front centered on the transmitted vortex and its alternate compression-rarefaction nature, as predicted by linearized analyses by Hollingsworth and Richards and later by Ribner, was experimentally verified and deviations from the predicted pressure amplitude distribution were discovered. A semiempirical relation for the wave-front pressure-amplitude distribution (expressed as a linear combination of quadrupole, dipole, and monopole acoustic sources) was found to represent closely the experimental results. The time variation of the core density of the transmitted vortex was deduced. The spiral vortex decayed essentially as a circular, incompressible viscous vortex until a neighboring high-density region appeared and the vortex decayed at a faster rate. The interaction of the reflected shock with the vortex street generated behind a circular cylinder, resulted in an abrupt change in vortex spacing and rapid dissolution of the vortex street. No well-defined acoustic wave fronts were evident behind the reflected shock front.

Dosanjh, D. S., Gasparek, E. P. and Eskinazi, S.

"DECAY OF A VISCOUS TRAILING VORTEX"

Aero. Quarterly, Vol. 13, May 1962, pp. 167-188

An experimental investigation of the viscous decay of a steady three-dimensional helical vortex is presented. The vortex was generated by a rectangular, symmetrical half airfoil, cantilevered from the wall of the circular test section of a low-speed wind tunnel. Only the local total head and flow directions were measured with a five-hole pressure sensitive probe at one to eight chord lengths behind the trailing edge of the airfoil and the radial, tangential and axial velocity distributions in the trailing vortex were derived. The static pressure variation on the vortex flow and the difficulties in its accurate measurement are discussed.

Dougherty, R. P.

"EXTENSIONS OF DAMAS AND BENEFITS AND LIMITATIONS OF DECONVOLUTION IN BEAMFORMING"

AIAA Paper No. 2005-2961, Monterey, CA, May 2005

The DAMAS deconvolution algorithm represents a breakthrough in phased array imaging for aeroacoustics, potentially eliminating sidelobes and array resolution effects from beamform maps. DAMAS is an iterative non-negative least squares solver. The original algorithm is too slow and lacks an explicit regularization method to prevent noise amplification. Two extensions are proposed, DAMAS2 and DAMAS3. DAMAS2 provides a dramatic speedup of each iteration and adds regularization by a low pass filter. DAMAS3 also provides fast iterations, and additionally, reduces the required number of iterations. It uses a different regularization technique from DAMAS2, and is partially based on the Wiener filter. Both DAMAS2 and DAMAS3 restrict the point spread function to a translationally-invariant, convolutional, form. This is a common assumption in optics and radio astronomy, but may be a serious limitation in aero-acoustic beamforming. This limitation is addressed with a change of variables from (x,y,z) to a new set, (u,v,w) . The concepts taken together, along with appropriate array design, may permit practical 3D beamforming in aeroacoustics.

"AIRCRAFT WAKE VORTEX MEASUREMENTS AT DENVER INTERNATIONAL, AIRPORT"

AIAA Paper No. 2004-2880, Manchester, UK, May 2004.

Airport capacity is constrained, in part, by spacing requirements associated with the wake vortex hazard. NASA's Wake Vortex Avoidance Project has a goal to establish the feasibility of reducing this spacing while maintaining safety. Passive acoustic phased array sensors, if shown to have operational potential, may aid in this effort by detecting and tracking the vortices. During August/September 2003, NASA and the USDOT sponsored a wake acoustics test at the Denver International Airport. The central instrument of the test was a large microphone phased array. This paper describes the test in general terms and gives an overview of the array hardware. It outlines one of the analysis techniques that is

being applied to the data and gives sample results. The technique can clearly resolve the wake vortices of landing aircraft and measure their separation, height, and sinking rate. These observations permit an indirect estimate of the vortex circulation. The array also provides visualization of the vortex evolution, including the Crow instability.

Douxchamps, D.

"MULTIDIMENSIONAL PHOTOGRAMMETRY OF SHORT-LIVED EVENTS"

PhD Thesis, October 2004, Universite Catholique de Louvain, Louvain-la-Neuve, Belgium.

We have presented three photogrammetry techniques that successfully capture different short-lived events of increasing complexity. First, we have shown that the first simple unidimensional motion of vehicles on a highway can be analyzed with accuracy by a set of two line-scan cameras. This new technique also provides much other information about the traffic, making it a very good choice both for traffic management and law enforcement. The second theme developed shows how a close relationship between the fluid mechanics and the vision techniques can lead to a better confidence in the measurements compared to what would be obtained by each method individually. The recent advances in the theoretical formulation of the anti-dunes behavior will have to be compared with surfaces like the ones presented here, although the unstable and evolutive character of this phenomenon will make this task far from trivial. At last, a new model for the spectrum returned by an on-board lidar is compared with several other spectral estimation approaches. The higher performance of the model enables the detection of the aircraft wake vortices that were sought.

"ON-BOARD AXIAL DETECTION OF WAKE VORTICES USING A 2-MICRON LIDAR"

IEEE Transactions on Aerospace and Electronic Systems, Vol. 44, No. 4, Oct. 2008, pp. 1276-1290.

This paper describes the first successful attempt to detect wake vortices axially using an on-board infrared pulsed Doppler LiDAR. On-board axial detection is more complex than the classic ground-based tangential approach, because the axial air speed in vortices is low and the atmospheric particle density is reduced, yielding a poorer SNR. To provide meaningful results in such unfavorable conditions we have developed a new flexible signal processing method based on a two-primitive model fitting the spectrum of the Doppler return. This new spectral estimation successfully detects wake vortices with an admissible SNR that is lower than other on-board state-of-the-art approaches. It was validated through flight tests.

"NUMERICAL MODELING AND PREDICTABILITY OF MOUNTAIN WAVE-INDUCED TURBULENCE AND ROTORS"

In Aviation Turbulence, edited by R. Sharman and T. Lane, Chapter 18, 2016, Springer International Publishing Switzerland, pp. 357-384.

A survey is provided of a series of studies that demonstrate the capabilities of modern nonhydrostatic numerical models to simulate and predict the occurrence of mountain waves, wave-induced turbulence in the upper troposphere and stratosphere, and rotors in the lower troposphere generated by flow over topography. Field campaign measurement from research aircraft, turbulence reports from commercial aviation, and numerical simulations demonstrate that flow over larger-scale topography (e.g., Greenland) and three-dimensional complex terrain (e.g., Alps, Sierra Nevada Range) frequently generates upper-level wave breaking and turbulence in a variety of conditions including in the presence of environmental critical levels. In some situations, the boundary layer can strongly influence wave launching, and may limit wave amplitudes and impact the altitude and likelihood of wave breaking and turbulence. Near the surface, rotors occur when strong downslope flow in the boundary layer along the lee slopes separate from the surface as a turbulent vortex sheet, which is lifted aloft within the lee wave. Because of their strong turbulent flow, rotors are often significant aeronautical hazards. The predictive skill of numerical simulations of mountain wave-induced turbulence observed in nature is limited by errors in initial conditions, boundary conditions (e.g., for limited area models), and the models themselves (e.g., parameterizations, dynamical methods). Ultimately, high-resolution ensemble methods that are capable of explicitly resolving mountain waves should be used to provide probabilistic forecasts of turbulence needed for aviation hazard mitigation.

Draghicescu, C. I. and Draghicescu, M.

"A FAST ALGORITHM FOR VORTEX BLOB INTERACTIONS"

Journal of Computational Physics, Vol. 116, 1995, pp. 69-78

We introduce a new fast summation algorithm which, unlike previous methods, is not restricted to potential functions. Its asymptotic complexity is $O(nH, H \text{ to the } d+1 \text{ power})$, where n is the number of blobs, H is the level of refinement, and d is the domain dimension. For a nonsingular kernel the complexity reduces to $O(n)$. We present a complete error and complexity analysis of the algorithm and describe its implementation. As an example, we use the vortex blob method to simulate vortex sheet motion in incompressible flow.

Drasky, J.

"ON SOME PARTICULAR CASES OF THE SOLUTION OF LAPLACE'S EQUATION DESCRIBING THE PRINCIPAL PROPERTIES OF VORTEX FORMATIONS IN FLUIDS"

Zeitschrift fur Angewandte Mathematik und Mechanik, Vol. 46, No. 2, 1966, pp. 81-95.

Vortex formations represent a particular case of discontinuous flow of fluids. For the most, they are non-stationary formations with a pronounced whirling motion of intensity that is characterized by velocity circulation about the center, decreasing or increasing with time. They always contain a core with a marked component of rotational motion and one or two discontinuity surfaces or vortex layers

rolling up in the form of spirals. In addition to the intensive whirling motion, they also exhibit centripetal or centrifugal motions. For cases where in the first approximation the effect of viscosity may be neglected and the medium considered an incompressible fluid, the paper demonstrates that all basic features of vortex formations may be described by a solution of Laplace's equation constructed as a convenient combination of algebraic and logarithmic singularities. The solution thus obtained is dependent on time insofar that all conditions of compatibility of the flow must be satisfied at all times in every point (particularly on the discontinuity surface). Several plane models of vortex formations are considered and with their aid a model is constructed of a flow field with vortex pair behind a cylinder starting from rest. A comparison of theoretical and experimental results is presented for this case.

"OBSERVATIONS OF WIND SPEED PROFILES OVER GREATER LONDON, UK, USING A DOPPLER LIDAR"

Journal of Wind Engineering and Industrial Aerodynamics, Vol. 121, 2013, pp. 98-105.

To calculate the potential wind loading on a tall building in an urban area, an accurate representation of the wind speed profile is required. However, due to a lack of observations, wind engineers typically estimate the characteristics of the urban boundary layer by translating the measurements from a nearby reference rural site. This study presents wind speed profile data obtained from a Doppler lidar in central London, UK, during an 8-month observation period. Used in conjunction with wind speed data measured at a nearby airport, the data have been used to assess the accuracy of the predictions made by the wind engineering tools currently available. When applied to multiple changes in surface roughness identified from morphological parameters, the non-equilibrium wind speed profile model by Deaves provides a good representation of the urban wind speed profile. For heights below 500 m, the predicted wind speed remains within the 95 percent confidence interval of the measured data. However, when the surface roughness is estimated using land use as a proxy, the model tends to overestimate the wind speed, particularly for very high wind speed periods. These results highlight the importance of a detailed assessment of the nature of the surface when estimating the wind speed above an urban surface.

"ON THE COMPUTATION OF INSTABILITIES AND SYMMETRY-BREAKING IN FLUID MECHANICS"

Progress in Aerospace Sciences, Vol. 41, Issue 8, November 2005, pp. 609-641

A review on the implementation of modern computational fluid dynamics (CFD) methods for simulating low- and high-speed flows featuring turbulent mixing, instabilities and symmetry-breaking is presented. Results are reviewed for several complex flows including turbulent mixing associated with Richtmyer-Meshkov and Raleigh-Taylor instabilities, incompressible flows in suddenly expanded geometries, shock-induced instabilities, free-shear instabilities, and complex vortex dynamics. Many of the results presented in this review have been obtained by large eddy simulation (LES), monotone

integrated LES (MILES) in particular. The computational challenges associated with complex flow physics and nonlinear behaviour of the numerics are discussed.

Dritschel, D. G.

"ON THE PERSISTENCE OF NON-AXISYMMETRIC VORTICES IN INVISCID TWO-DIMENSIONAL FLOWS"

Journal of Fluid Mechanics, Vol. 371, 1998, pp. 141-155.

Previous research has suggested that isolated, initially non-axisymmetric vortices in two-dimensional flows tend to become axisymmetric, in a coarse-grained sense, by purely inviscid mechanisms. That research, however, considered only vortices with broadly distributed vorticity. In this paper, it is shown that vortices with sufficiently steep edge gradients behave in a radically different way; in particular, they can remain non-axisymmetric, apparently indefinitely. Such vortices, it is argued, are more typical in inviscid two-dimensional flows than the broadly distributed vortices previously considered, and hence the tendency for vortices to become axisymmetric is not generic to these flows.

Dritschel, D. G.

"A GENERAL THEORY FOR TWO-DIMENSIONAL VORTEX INTERACTIONS"

J. Fluid Mech., Vol. 293, June 1995, pp. 269-303

A general theory for two-dimensional vortex interactions is developed from the observation that, under slowly changing external influences, an individual vortex evolves through a series of equilibrium states until such a state proves unstable. Once an unstable equilibrium state is reached, a relatively fast unsteady evolution ensues, typically involving another nearby vortex. During this fast unsteady evolution, a fraction of the original coherent circulation is lost to filamentary debris, and, remarkably, the flow reorganizes into a set of quasi-steady stable vortices. The simplifying feature of the proposed theory is its use of adiabatic steadiness and marginal stability to determine the shapes and separation distances of vortices on the brink of an inelastic interaction. In the case of two vortex patches, which is the focus of the present work, inelastic interactions depend only on a single parameter: the area ratio of the two vortices (taking the vorticity magnitude inside each to be equal). Without invoking adiabatic steadiness and marginal stability, one would have to contend with the additional parameters of vortex separation and shapes and the latter is actually an infinitude of parameters.

Droandi, G., Zanotti, A., Gibertini, G., Grassi, D. and Campanardi, G.

"EXPERIMENTAL INVESTIGATION OF THE ROTOR-WING AERODYNAMIC INTERACTION IN A TILTWING AIRCRAFT IN HOVER"

The Aeronautical Journal, Vol. 119, No. 1215, May 2015, pp. 591-612.

The hovering performance and the lifting capability of tiltrotor aircraft are strongly affected by the aerodynamic interaction between wing and rotors. The tiltwing concept represents a promising

technology to increase the hover performance by reducing the wing-rotor interference. The present work describes an experimental activity carried out on a 1/4 scaled tiltwing aircraft half-model to achieve a detailed insight about the main issues characterizing the aerodynamic interaction between wing and rotor in hover. The results of the experimental campaign, including both force measurements and Particle Image Velocimetry surveys, enabled to evaluate both the aircraft performance for different configurations of the tilting wing and to achieve a detailed insight about the flow physics of the rotor wake in the interaction with the wing. The test activity provided a comprehensive experimental database that was obtained over a not confidential aircraft configuration.

Drue, C., Hauf, T. and Hoff, A.

"COMPARISON OF BOUNDARY-LAYER PROFILES AND LAYER DETECTION BY AMDAR AND WTR/RASS AT FRANKFURT AIRPORT"

Boundary-Layer Meteorology, Vol. 135, 2010, pp. 407-432.

At Frankfurt Airport vertical soundings of the lower atmosphere from two independent sources are available. One of them is a wind and temperature profiler (wind temperature radar and radio acoustic sounding system, WTR/RASS) located at the western end of the main pair of runways. The second source is aircraft meteorological data relay (AMDAR), i.e. measurements operationally collected by approaching and departing aircraft. Together, both offer a rare opportunity to compare the performance of these widely used systems. We use 1 year of continuous data to calculate systematic temperature and wind vector differences between both measurement systems. The differences show a clear season-dependent structure in conjunction with typical inversion heights. Possible causes for this behavior are discussed. Second, we compare the ability of both systems to identify inversion and wind-shear layers above the airport. AMDAR-detected layers are typically higher than wind profiler detections. The layer base is usually detected with more agreement than the top. The mutual probability of detection of inversions is found to be mostly between 40 and 60 percent.

Drummond, A. M., Onno, R. and Panneton, B.

"TRAJECTORIES AND STABILITY OF TRAILING VORTICES VERY NEAR THE GROUND"

IAR-AN-74, December 1991, Inst. Aerospace Research, Ottawa, Canada

The behavior of the trailing vortices of a Harvard aircraft used as the spraying vehicle during a set of experiments in aerial spraying over flat terrain for agricultural applications is discussed. The aircraft flew at a nominal altitude of 3 m (10 ft.) above ground at a speed of 56.7 m/s (110 knots). The stability and trajectory of a chosen element of the trailing vortices were measured by analyzing movie films taken by a ground-based camera and by a camera in a helicopter hovering at about 244 m (800 ft.) above the aircraft. The vortices decayed by core bursting in every case and the time to burst was usually in agreement with other published data for a light aircraft out of ground effect. The downwind vortex almost always burst before the upwind vortex and in most cases, both upwind and downwind vortices exhibited about the same amount of rebound even though the downwind vortex generally had

a shorter lifetime. The classical inviscid theory for vortex descent was not a good model for the current experiments but it was able to predict with some success the lateral separation between the vortices when the aircraft wing tip height was arbitrarily reduced by a factor of 0.85. It was concluded that vortex core bursting and rebound must be included in any procedure for calculating aerial spray deposit on the ground.

"HARDWARE-IN-LOOP SIMULATION PLATFORM FOR UAV AUTONOMOUS AERIAL REFUELING BASED ON COMPUTER VISION"

Journal of Beijing University of Aeronautics and Astronautics, Vol. 39, No. 11, November 2013, pp. 1491-1496.

A hardware-in-loop simulation platform of unmanned aerial vehicle (UAV) autonomous aerial refueling based on computer vision was developed. Point feature matching and LHM pose estimation algorithms were adopted to the recognition of light emitting diodes (LEDs) on the drogue. The models of atmospheric disturbances and wake vortex had been built, and the drogue model was also presented. Subsequently, a linear quadratic regulator (LQR) control law for UAV was designed. The hardware-in-loop simulation platform with airborne monocular camera for UAV autonomous aerial refueling had been developed in lab environment. Series of hardware-in-loop experimental results demonstrate the feasibility and effectiveness of our presented approaches in this simulation platform. [In Chinese.]

Duck, P. W.

"ON THE DOWNSTREAM DEVELOPMENT AND BREAKUP OF SYSTEMS OF TRAILING-LINE VORTICES"

Theoretical Computational Fluid Dynamics, Vol. 25, 2011, pp. 43-52.

The downstream evolution of two configurations of trailing-line vortex systems is considered and analyzed from the point of view of bi-global instability. The results lead to predictions for the breakup of the systems considered, based primarily on stability analysis. Throughout, the analysis is entirely rational from the theoretical (asymptotic, large Reynolds number) point of view, with a relatively long developmental length scale in the streamwise direction for the base flow, and a relatively short streamwise wavelength for the bi-global stability analysis. As such, the stability modes are inviscid in nature, and therefore likely to be one of the dominant instability mechanisms. The issue of adverse streamwise freestream pressure gradients is also addressed, and it is suggested that these can lead to a rapid breakdown/up of a vortex system, analogous to the axisymmetric case discussed by Hall (1972).

Duck, P. W. and Khorrami, M. R.

"A NOTE ON THE EFFECTS OF VISCOSITY ON THE STABILITY OF A TRAILING-LINE VORTEX"

J. Fluid Mech., Vol. 245, December 1992, pp. 175-189

The linear stability of the Batchelor vortex is investigated. Particular emphasis is placed on modes found recently in a numerical study by Khorrami. These modes have several features very distinct from those found previously for this vortex, including (i) exhibiting small growth rates at large Reynolds number and (ii) susceptibility to destabilization by viscosity. In this paper these modes are described using asymptotic techniques, producing results which compare very favorably with fully numerical results at large Reynolds numbers.

Duffy, R. E., Czajkowski, E. A. and Jaran, C.

"FINITE ELEMENT APPROXIMATION TO THEODORSEN'S SOLUTION FOR NON-STEADY AERODYNAMICS OF AN AIRFOIL SECTION"

AIAA Paper No. 1984-1640, Snowmass, CO, June 1984

The aerodynamic forces acting on a helicopter rotor blade have been calculated by several investigators using finite element methods and theories. All these results depend to some extent on the proper modeling of the wake behind the rotor blade. To evaluate the importance of proper modeling of the near wake behind a rotor blade, a simpler, but related, problem is addressed -- namely the modeling of the flow field about a two-dimensional, flat plate airfoil section which is undergoing simple harmonic motion in both vertical translation and pitch. An exact closed form solution of this problem has been obtained by Theodorsen. This study evaluates how the circulation on the airfoil and in the wake has to be modeled to predict the proper value of lift and pitching moment as determined by Theodorsen. The goal is to use the least number of elements in the model. It is shown that it is only necessary to follow the wake, at most, one cycle length downstream. The cycle length can be divided as coarsely as ten increments and as few as two and no more than ten wake vortex filaments must be considered. The accuracy of prediction decreases slightly as the number of bound vortex lifting lines increases.

Dufresne, L. and Winckelmans, G.

"PREVIOUS WORK AND PRESENT KNOWLEDGE ON WAKE VORTICES NEAR THE GROUND"

AST4-CT-2005-012238, Catholic Univ. of Leuven, Leuven, Belgium, July 2005

The understanding of the formation and decay of wake vortex systems has indeed greatly progressed over the years. The knowledge was mostly developed though for free vortex systems, i.e. far from any ground proximity (or 'out of ground effect' OGE). When considering wake vortex dynamics from the stand point of safety delays between aircrafts taking-off or landing, ground proximity will most certainly, sooner or later, affect the wake vortex behavior. Considering the research objectives for the wake vortex evolution near the ground, which constitute the Work-Package 3 of the FAR-Wake project, the present report aims at giving a synthesis of past work and present knowledge on this particular subject.

Duke, T.

"TRAINING TO BEAT WAKE TURBULENCE"

Air Line Pilot, Vol. 64, No. 8, September 1995, pp. 20-24.

Recently, a cooperative effort involving FAA, the Boeing Company, and a joint industry group (including ALPA) developed training materials. The training kit consists of a 430-page comprehensive, well-illustrated manual titled: 'Wake Turbulence Training Aid' in printed or CD ROM disc form and an accompanying videotape.

Dumitrescu, H. and Frunzulica, F.

"A FREE-WAKE AERODYNAMIC MODEL FOR HELICOPTER ROTORS"

Proceedings of the Romanian Academy, Series A, Vol. 5, No. 3, 2004, pp. 1-9.

The accurate computation of the induced velocity on helicopter rotor plane is a prerequisite for the precise evaluation of the angle of attack distribution along the rotor blades, which leads to improved air loads prediction for aerodynamics and aeroacoustics design and performance analysis. The Vortex Lattice Method provides a transparent investigation concerning the role of various physical parameters which influence the aerodynamic problem of rotor downwash calculation. This paper presents a method for the calculation of the nonuniform induced downwash of a helicopter rotor using the vortex ring model for a thin lifting surface coupled with a free-wake model.

Dunagan, S. E. and Norman, T. R.

"LIFT DISTRIBUTION OF VELOCITY FIELD MEASUREMENTS FOR A THREE-DIMENSIONAL, STEADY BLADE/VORTEX INTERACTION"

NASA TM-100013, November 1987, Ames Research Center, Moffett Field, CA.

A wind tunnel experiment simulating a steady three-dimensional helicopter rotor blade/vortex interaction is reported. The experimental configuration consisted of a vertical semispan vortex-generating wing, mounted upstream of a horizontal semispan rotor blade airfoil. A three-dimensional laser velocimeter was used to measure the velocity field in the region of the blade. Sectional lift coefficients were calculated by integrating the velocity field to obtain the bound vorticity. Total lift values, obtained by using an internal strain-gauge balance, verified the laser velocimeter data. Parametric variations of vortex strength, rotor blade angle of attack, and vortex position relative to the rotor blade were explored. These data are reported herein (with attention to experimental limitations) to provide a dataset for the validation of analytical work.

Duncan Jr., J. B., Hirth, B. D. and Schroeder, J. L.

"DOPPLER RADAR MEASUREMENTS OF SPATIAL TURBULENCE INTENSITY IN THE ATMOSPHERIC BOUNDARY LAYER"

Journal of Applied Meteorology and Climatology, Vol. 58, July 2019, pp. 1535-1555.

Remote sensing instruments that scan have the ability to provide high-resolution spatial measurements of atmospheric boundary layer winds across a region. However, the time required to collect the volume of measurements used to produce this spatial representation of atmospheric winds typically limits the extraction of atmospheric turbulence information using traditional temporal analysis techniques. To overcome this constraint, a spatial turbulence intensity (STI) metric was developed to quantify atmospheric turbulence intensity (TI) through analysis of spatial wind field variability. The methods used to determine STI can be applied throughout the measurement domain to transform the spatially distributed velocity fields to analogous measurement maps of STI. This method enables a comprehensive spatial characterization of atmospheric TI. STI efficacy was examined across a range of wind speeds and atmospheric stability regimes using both single- and dual-Doppler measurements. STI demonstrated the ability to capture rapid fluctuations in TI and was able to discern large-scale TI trends consistent with the early evening transition. The ability to spatially depict atmospheric TI could benefit a variety of research disciplines such as the wind energy industry, where an understanding of wind plant complex flow spatiotemporal variability is limited.

Dunham, J.

"THE STATIC PRESSURE IN A VORTEX CORE"

Aeronautical Journal, Vol. 83, October 1979, pp. 402-406.

An analysis and comparison with experimental data is given for the static core pressure of ground and wingtip vortices that might be ingested by turbine engine compressor intakes. Parameters considered include tangential velocity, turbulence, static pressure, core radius, stagnation pressure and axial velocity, along with test data from hot wire and laser velocimeters.

Dunham, Jr., R. E.

"VORTEX DISSIPATION TESTS CONDUCTED AT NASA LANGLEY RESEARCH CENTER"

Proceedings of the AFFDL/NASA/FAA Wake Turbulence Work Shop, Air Force Flight Dynamics Laboratory, AFFDL-TM-75-16-FGC, 1974, pp. 29-35

The major interest in vortices at Langley lies in the far wake aspect of the problem, and especially in the possibility of enhancing the rate of far wake dissipation. Three separate facilities are used to conduct tests on wake vortex behavior and possible dissipation devices: the Vortex Flow Facility (an 1800-foot track), the Langley V/STOL wind tunnel, and the Hydronautics water tank facility. An overall summary of NASA Langley experiments with hazard reduction techniques was presented; the manipulation of span loading appears to be the most promising hazard reduction technique.

Dunham, Jr., R. E.

"SUMMARY OF NASA WAKE-VORTEX MINIMIZATION RESEARCH"

Proceedings Aircraft Safety and Operating Problems, NASA, Washington, DC, 1976, pp. 303-318

NASA's efforts in the area of wake-vortex minimization are reviewed. The results presented at a NASA symposium on wake-vortex minimization are summarized and additional results obtained since the symposium are included. Theoretical and experimental techniques for assessing the effectiveness of various wake-vortex minimization techniques are described. Three methods of reducing the effect of aircraft trailing vortices and a preliminary assessment of the operational suitability of employing wake-vortex minimization techniques are discussed. The application of one wake-vortex minimization technique to DC-10 and L-1011 aircraft is presented.

Dunham, Jr., R. E.

"UNSUCCESSFUL CONCEPTS FOR AIRCRAFT WAKE VORTEX MINIMIZATION"

Proceedings Wake Vortex Minimization Symposium, NASA, SP-409, 1977, pp. 221-250.

Exploratory concepts are described which were investigated to achieve a reduction in the vortex induced rolling upsets produced by heavy aircraft trailing vortexes. The initial tests included the use of mass injection, oscillating devices, wingtip shape design, interacting multiple vortexes, and end plates. Although later refinements of some of these concepts were successful, initial test results did not indicate a capability of these concepts to significantly alter the vortex induced rolling upset on a following aircraft.

Dunham, Jr., R. E. and Morris, D. J.

"RECENT DEVELOPMENTS IN WAKE VORTEX MINIMIZATION"

SAE Paper No. 780524, Boston, MA, May 1978

Aircraft trailing vortices are one of the principal factors affecting aircraft arrival and departure rates at airports. Minimization of the trailed vortex strength would allow reduction of the present spacing requirements and full utilization of advances in automatically aided landing systems. For several years, NASA has been conducting an intensive in-house and contractual research effort involving theoretical and experimental studies of various wake vortex minimization techniques. The results of these studies are briefly described herein.

Dunham, Jr., R. E., Barber, M. R. and Croom, D. R.

"WAKE VORTEX TECHNOLOGY"

CTOL Transport Technology, 1978, pp. 757-771

A brief overview of the highlights of NASA's wake vortex minimization program is presented. The significant results of this program are summarized as follows: (1) it is technically feasible to reduce significantly the rolling upset created on a trailing aircraft; (2) the basic principles or methods by which reduction in the vortex strength can be achieved have been identified; and (3) an analytical capability for investigating aircraft vortex wakes has been developed.

Dunham, Jr., R. E., Holbrook, G. T., Mantay, W. R., Campbell, R. L. and Van Gunst, R. W.

"FLIGHT-TEST EXPERIENCE OF A HELICOPTER ENCOUNTERING AN AIRPLANE TRAILING VORTEX"

32nd Annual National V/STOL Forum, American Helicopter Society, Washington, DC, May 1976

This paper presents results of a flight-test experiment of a UH-1H helicopter encountering the vortex wake of a C-54 airplane. The helicopter was instrumented to record the pilot control inputs, determine the upset experienced, and measure critical loads within the rotor system. During the flight-test program 132 penetrations of the vortex wake were made by the helicopter at separation distances from 3/8 to 6-1/2 nautical miles. Test results indicated that the helicopter upsets and the vortex induced blade loads experienced were minimal and well within safe limits. The upsets were very mild when compared to a typical response of a small airplane to the vortex wake of the C-54 airplane.

Dunham, Jr., R. E., Stuever, R. A. and Vicroy, D. D.

"THE CHALLENGES OF SIMULATING WAKE VORTEX ENCOUNTERS AND ASSESSING SEPARATION CRITERIA"

AIAA Paper No. 1993-3568, Monterey, CA, August 1993.

During landings and take-offs, the longitudinal spacing between airplanes is in part determined by the safe separation required to avoid the trailing vortex wake of the preceding aircraft. Safe exploration of the feasibility of reducing longitudinal separation standards will require use of aircraft simulators. This paper discusses the approaches to vortex modeling, methods for modeling the aircraft/vortex interaction, some of the previous attempts of defining vortex hazard criteria, and current understanding of the development of vortex hazard criteria.

Dunham, Jr., R. E., Verstynen, H. A. and Banner, M. S.

"PROGRESS REPORT ON WING-TRAILING-VORTEX STUDIES"

NASA Aircraft Safety and Operating Problems, Vol. 1, NASA SP-270, 1971, pp. 101-113

The paper summarizes the activities of NASA in three major areas of vortex research. The first area is concerned with the measurement of the characteristics of full-scale aircraft vortices to obtain an understanding of the behavior of vortices at altitude and near the ground. Of particular interest are the velocities and their distributions, and the vortex persistence. The second area involves investigations of possible techniques to affect a more rapid breakdown or decay of vortices; the

deployment of wing flaps creates a vortex system which is less intense and decays more rapidly than vortices created in a flaps-up condition. The third area concerns an investigation of the feasibility of remotely detecting the presence of wing trailing vortices in the terminal area.

Dunham, Jr., R. E., Verstynen, H. A. and Banner, M. S.

"PRELIMINARY RESULTS OF A FLIGHT INVESTIGATION OF THE TRAILING VORTICES GENERATED BY A C-5A HEAVY JET TRANSPORT"

LWP-969, June 1971, NASA Langley Research Center, Hampton, VA

Some exploratory flight tests were conducted to investigate the strength and persistence characteristics of the vortices generated by a C-5A jet transport. The tests were conducted using an instrumented T-33 aircraft to probe the vortices of the C-5A while ranging information was provided by ground-based radars. The results are presented in terms of tabulated maximum measured tangential velocities and radii of maximum velocities, vortex positions as a function of distance behind the C-5A, and maximum recorded velocity as a function of vortex age.

Dunley, Jr., W. J. and Muldoon, J. P.

"EFFECT OF WAKE VORTEX INTERACTION ON DELAYS AT LAGUARDIA AIRPORT"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 28-1 - 28-11

One of the primary runway-use configurations at LaGuardia Airport (LGA) involves arrivals on Runway 22 and departures on Runway 31. The FAA requires a standard two-minute wake turbulence separation between a heavy jet departure on Runway 31 and an arrival on Runway 22. This wake-vortex interaction manifests itself mainly as large arrival delays, because controllers in the LGA Tower must ask the New York TRACON to create and maintain a 6 to 7 nautical mile gap between arrivals for each heavy jet departure. This interaction is one of the major causes of delays at LGA and is expected to worsen in the future with an expected increasing percentage of heavy jet aircraft in the mix.

"EVALUATION OF OPERATIONS ON AN AIRPORT WITH A CIRCULAR RUNWAY"

ICAS 2014, September 2014, St. Petersburg, Russia.

This paper presents an innovative concept for airport operations in the long-term future, based on a radically new airport design encompassing a circular circumventing runway. The Endless Runway project, mostly funded by the European Commission, during the Framework Programme 7, aims at evaluating the benefits and identifying the constraints associated to this kind of airport. The possibility to operate the airport whatever the wind direction and for every aircraft type, the optimization of air

and ground aircraft trajectories using the best runway section, as well as the compact airport footprint are part of the observed gains. Those must be balanced with the high runway construction cost, additional safety issues in gusty winds and the impossibility to extend the runway system if additional capacity is desired. A foreseen application could be a small airport dedicated to unmanned aircraft operations or a large hub airport with limited traffic mix and high reliability of operations.

"DPIV, HPTV AND VISUALIZATION STUDY OF A VORTEX RING-MOVING WALL INTERACTION"

Experiments in Fluids, Vol. 33, 2002, pp. 555-56.

This paper presents an experimental study of the interaction between a vortex ring and a moving wall. This type of flow can be considered as modeling, in a simplified way, the interaction between a 'typical eddy' and the viscous sublayer of a turbulent boundary layer. In the present study, the vortex ring is considered as a three-dimensional (3D) perturbation of a viscous Stokes layer. The interaction was first characterized by visualization. To obtain quantitative information, digital particle image velocimetry (DPIV) and holographic particle-tracking velocimetry (HPTV) were used. These different techniques led to a precise and detailed characterization of the vortex ring alone and of an interaction in which a hairpin vortex is generated in the Stokes layer. The results obtained show a good similarity between the observed vortex ring and the Oseen model. They also validate the Stokes layer model and show that in the present conditions, the hairpin vorticity is comparable to that of the Stokes layer. The holographic study, which was undertaken to obtain full 3D three-component (3D3C) velocity maps, showed the present limitations of HPTV.

"A HYBRID VORTEX-PARTICLE METHOD FOR ROTORCRAFT APPLICATIONS"

AIAA Paper No. 2012-2912, June 2012, New Orleans, LA.

A rotor wake simulation method based upon the Lagrangian vortex particle method (VPM) has been coupled with the OVERFLOW-2 grid-based CFD code to accurately predict the vortex dynamics in the wake of rotorcraft. Computational benchmarks are presented demonstrating the efficiency of the GPU-based tree algorithm for the Biot-Savart velocity induction. Numerical simulation results are compared to experimental wind-tunnel measurements of a rotor-fuselage assembly demonstrating the fidelity and efficiency of the hybrid particle-grid simulation strategy.

"STANDARDIZED POST-PROCESSING AND VISUALIZATION OF PARTICIPANTS' SIMULATIONS OF A ROTOR IN HOVER"

AIAA Paper 2017-1668, January 2017, Grapevine, TX.

For the AIAA Special Session for Rotors in Hover 2017 Computational Fluid Dynamics (CFD) simulations of two helicopter rotor in hover cases were studied -- the S-76 rotor and the proposed PSP rotor. Four participants uploaded their results to a remote 'cloud server' and then FieldView extract-based post-processing tools were used to automatically extract and present the resultant flow features such as tip vortices via velocity contours and iso-surfaces. This automated system enabled researchers to concentrate on understanding the flow physics and perform unbiased comparisons. The paper herein presents the results for four of the participants.

"NUMERICAL SIMULATION OF THE EFFECTS OF SPANWISE BLOWING ON WING-TIP VORTEX FORMATION AND EVOLUTION"

AIAA Paper No. 2005-4726, Toronto, Canada, June 2005

A high-resolution computational methodology is developed for the solution of the Compressible Reynolds Averaged Navier Stokes (RANS) equations. This methodology is used to study the formation and control of tip vortices from fixed wings. The numerical error is reduced by using high order accurate schemes on appropriately refined meshes. For vortex evolution problems, the equations are solved on multiple overset grids that ensure adequate resolution in an efficient manner. Reliable validations of the mean flow field are obtained by adding a simple correction to the production term in the Spalart-Allmaras turbulence model in order to account for the stabilizing effects of rotation in the core of the tip vortex. The fidelity of the approach allows for a detailed study of the underlying physics of vortex formation and evolution. The effect of spanwise blowing on the vortex structure is investigated with some experimental validation.

Duraisamy, K. and Baeder, J. D.

"NUMERICAL SIMULATION OF THE EFFECTS OF SPANWISE BLOWING ON TIP VORTEX FORMATION"

Journal of Aircraft, Vol. 43, No. 4, July-August 2006, pp. 996-1006

A high-resolution computational methodology is developed for the solution of the compressible Reynolds-averaged Navier-Stokes equations. This methodology is used to study the effect of spanwise blowing as a method of tip vortex control. The numerical error is reduced by using high order accurate schemes on appropriately refined meshes. For vortex evolution problems, the equations are solved on multiple overset grids that ensure adequate resolution in an efficient manner. Reliable validation of the mean flow field for the baseline and control configurations is obtained by adding a simple correction to the production term in the Spalart-Allmaras turbulence model. A detailed study of the underlying physics of the effects of spanwise blowing is presented.

"HIGH RESOLUTION WAKE CAPTURING METHODOLOGY FOR HOVERING ROTORS"

Journal of the American Helicopter Society, Vol. 52, No. 2, April 2007, pp. 110-122.

A high-resolution Reynolds-averaged Navier-Stokes (RANS) solver is applied to study the evolution of tip vortices from rotary blades. The numerical error is reduced by using high-order accurate schemes on appropriately refined meshes. To better resolve the vortex evolution, the equations were solved on multiple overset grids that ensured adequate resolution in an efficient manner. For the RANS closure, a one equation wall-based turbulence model was used with a correction to the production term to account for the stabilizing effects of rotation in the core of the tip vortex. While experimental comparison of the computed vortex structure beyond a few chord lengths downstream of the trailing edge is lacking in the literature, reasonable validation of the vortex velocity profiles is demonstrated up to a distance of 50 chord lengths of evolution for a single-bladed rotor. For the two-bladed rotor case, the tip vortex could be tracked up to two rotor revolutions with minimal diffusion. The accuracy of the computed blade pressures and vortex trajectories confirm that the inflow distribution and blade-vortex interaction are represented correctly. The accuracy achieved in the validation studies establishes the viability of the methodology as a reliable tool that can be used to predict vortex evolution and the aerodynamic performance of hovering rotors.

"EVOLUTION OF ISOLATED TURBULENT TRAILING VORTICES"

Physics of Fluids, Vol. 20, 2008, pp. 035102-1 - 035102-11.

In this work, the temporal evolution of a low swirl-number turbulent Batchelor vortex is studied using pseudo-spectral direct numerical simulations. The solution of the governing equations in the vorticity-velocity form allows for accurate application of boundary conditions. The physics of the evolution is investigated with an emphasis on the mechanisms that influence the transport of axial and angular momentum. Excitation of normal mode instabilities gives rise to coherent large scale helical structures inside the vortical core. The radial growth of these helical structures and the action of axial shear and differential rotation results in the creation of a polarized vortex layer. This vortex layer evolves into a series of hairpin-shaped structures that subsequently breakdown into elongated fine scale vortices. Ultimately, the radially outward propagation of these structures results in the relaxation of the flow towards a stable high-swirl configuration. Two conserved quantities, based on the deviation from the laminar solution, are derived and these prove to be useful in characterizing the polarized vortex layer and enhancing the understanding of the transport process. The generation and evaluation of the Reynolds stresses is also addressed.

Duraisamy, K. and Lele, S. K.

"DNS OF TEMPORAL EVOLUTION OF ISOLATED TURBULENT VORTICES"

Proceedings of the Summer Program 2006, Center for Turbulence Research, pp. 35-47

The temporal evolution of isolated turbulent Batchelor vortices is investigated using pseudo-spectral direct numerical simulations (DNS) of the vorticity transport equations. Analytic treatment of the

velocity at the domain boundaries (Rennich et al. (1997)) effectively isolates the vortex. The flow dynamics is examined over a range of swirl numbers. (The swirl number is a measure of the ratio of the azimuthal and axial velocities). For the cases in which the mean flow is unstable to normal mode perturbations, helical instabilities are seen to grow and advect radially. The local stretching and tilting of vortex lines by these instabilities is seen to generate mean counter-signed axial vorticity, and consequently, a circulation overshoot. The velocity field introduced by the distorted vortex tries to concentrate the axial vorticity away from the centerline. For low swirl cases, the axial vorticity is briefly shifted almost entirely to helical lobes near the edge of the vortical core. Ultimately, the coherence of the helical structures is lost and the flow progresses toward equilibrium. Angular momentum transport to the exterior potential flow is seen to be enhanced by the radial advection of streamwise oriented vorticity. During the return to equilibrium, azimuthal vorticity is present in the exterior of the core in the form of highly stretched spirals. While there is very little turbulent mixing in the inner part of the core, the turbulent kinetic energy and dissipation are seen to peak at the core centerline.

"HIGH-RESOLUTION COMPUTATIONAL AND EXPERIMENTAL STUDY OF ROTARY-WING TIP VORTEX FORMATION"

AIAA Journal, Vol. 45, No. 11, November 2007, pp. 2593-2602

The formation and rollup of a tip vortex trailed from a hovering helicopter rotor blade is studied in detail using both computations and measurements. The compressible Reynolds-averaged Navier-Stokes equations are computationally solved on an overset mesh system. The flow measurements are made using stereoscopic particle image velocimetry. The high resolution of both the numerics and the measurements reveal multiple coherent structures in the evolving rotor tip vortex flow field. Secondary and tertiary vortices that result from crossflow separations near the blade tip are identified. These vortices, along with a part of the trailed wake, are ultimately entrained into the tip vortex that is formed downstream of the blade's trailing edge. The simulations clearly demonstrate the resolution required to accurately represent the complex three-dimensional flow field. The advantage of particle image velocimetry, which can make planar measurements at a given instant of time, has been fully used to validate the computational fluid dynamics predictions. Even though linear eddy viscosity models are expected to inadequately represent the details of the turbulent quantities, good agreement is seen to be achieved with the particle image velocimetry measurements of the mean flow field. The various sources of computational and measurement uncertainties are discussed.

Durgin, F. H., Pastrone, C. J. and Marenzi, O. B.

"COMPARISON OF MEASURED WIND VELOCITIES FROM THE TOP OF AN 800 FOOT TOWER IN BOSTON AND LOGAN AIRPORT BOSTON"

Journal of Wind Engineering and Industrial Aerodynamics, Vol. 36, 1990, pp. 403-413.

The existence of five years of wind speed and direction data from the top of a 100-foot tower mounted at the top of an 800-foot-tall building in Boston has been noted. Preliminary analysis of the data shows that the presence of the building affects both the indicated wind direction and speed. An initial calculation of the ratio of uncorrected fastest hourly wind speed each day at the tower to the fastest mile data measured at Logan Airport produced an average ratio of 1.50. That compares reasonably with the value of 1.52 normally used at the MIT Wright Brothers Facility, but much additional analysis is needed to confirm that result.

Durgin, W. W. and Karlsson, S. K. F.

"ON THE PHENOMENON OF VORTEX STREET BREAKDOWN"

J. Fluid Mech., Vol. 48, No. 3, August 1971, pp. 507-527

A von Karman vortex street generated in the usual way was subjected to a deceleration, thereby changing the ratio of longitudinal to lateral spacing between the vortices. Distortion of the individual vortices followed which resulted in annihilation of concentrated vortex regions and creation of a stationary wake flow. This wake flow was itself dynamically unstable and developed into a new vortex street of a different frequency from the initial one. The breakdown of the initial vortex street is qualitatively explained by considering the convection of a concentrated vortex region due to the motion imposed by all the other vortices. In ground effect, stratification also inhibits horizontal migration and cancels the rebound effect (observed in the non-stratified, non-sheared case). In a non-stratified flow with shear, vortex evolution is asymmetric, and, in ground effect, the shear also acts to severely reduce the rebound effect. With stratification and shear (Richardson number equal to one), the flow is asymmetric, and two effects are observed. When the vortex pair is weak relative to the shear (strong crosswind condition), the weaker downwind vortex is closer to the ground than the stronger upwind vortex. (If the vortex pair is far from the ground, a solitary vortex develops in this case.) If the vortex is stronger relative to the shear (weak crosswind conditions), the weaker downwind vortex is further from the ground than the stronger upwind vortex. In either case, the vortices may migrate far from their initial generation position.

"WAKE-VORTEX ALLEVIATION FLOWFIELD STUDIES"

Journal of Aircraft, Vol. 42, No. 4, July-August 2005, pp. 894-907

Wake-vortex-alleviation research was conducted in the far-field vortex wake of a generic wing-tail aircraft model. The goals were to achieve accelerated vortex strength reduction and to map the conditions at which this reduction would occur. The wing-tail model was run in a water tow tank to generate a pair of unequal-strength counter-rotating vortices on each side of centerline. Dye flow visualization provided physical insight into the nature of the vortex interactions, and three-component particle image velocimetry allowed quantification of key characteristics of the flow field, including circulation, vorticity, vortex trajectory, and induced rolling moments. Experiments were conducted for

a variety of model angles of attack, tail incidence angles, and tail spans. The results showed that with high tail/wing circulation ratios (high tail downloads) the tail and wing vortices interacted strongly, leaving substantially weakened vortices after a distance of about 60 to 70 spans downstream of the model. A longitudinal static stability analysis identified the moderate-to-high static margins required to achieve such circulation ratios.

Durston, D. A., Walker, S. M., Driver, D. M., Smith, S. C. and Savas, O.

"WAKE VORTEX ALLEVIATION FLOW FIELD STUDIES"

AIAA Paper No. 2004-1073, Reno, NV, January 2004

Wake vortex alleviation research was conducted in a water tow-tank investigation of the far-field wake from a generic wing-tail aircraft model. The goals of the research were to achieve accelerated vortex breakdown and to map the conditions - the relative vortex strengths and locations - for which this breakdown would occur. The wing-tail model was used to generate a pair of unequal-strength counter-rotating vortices on each side of centerline. Both qualitative and quantitative data were recorded from the model runs: dye flow visualization and particle-image velocimetry (PIV). The flow visualization provided physical insight into the nature of the vortex interactions, and the three-component PIV velocity measurements allowed calculation of key characteristics of the flow field, including circulation, vorticity, and other parameters. Data were obtained for a variety of model angles of attack, tail incidence angles, and tail spans. The results showed that with high tail/wing circulation ratios (high tail downloads), the tail and wing vortices interacted so as to leave very little recognizable vortex structure after a distance of about 60 to 70 spans downstream of the model. A longitudinal static stability analysis identified the moderate-to-high static margins required to achieve such circulation ratios.

Duwaldt, F. A.

"WAKES AND LIFTING PROPELLERS (ROTORS) IN GROUND EFFECT"

CAL-BB-1665-S-3, November 1966, Cornell Aeronautical Lab., Buffalo, NY

The report presents the development of a wake model for a lifting propeller (rotor) in ground effect and the computation procedure used to determine the special distribution of wake vorticity and the induced velocity field accompanying that vorticity distribution. Sample calculations for a two-bladed rotor were carried out. Locations of wake vortical elements and the associated induced velocities at selected field points are presented for various advance ratios for a H/R ratio of rotor height above ground to rotor radius of 1.0. A few results for a hovering case with $H/R = 0.5$ are presented. A calculated root-mean-square velocity map is compared with measured hovering data and good agreement is obtained in the outer half of the slipstream.

Dvorak, R.

"AERODYNAMICS OF BIRD FLIGHT"

EPJ Web of Conferences, Vol. 114, 2016, pp. 01001-1 to 01001-8.

Unlike airplanes birds must have either flapping or oscillating wings (the hummingbird). Only such wings can produce both lift and thrust -- two sine qua non attributes of flying. The bird wings have several possibilities how to obtain the same functions as airplane wings. All are realized by the system of flight feathers. Birds have also the capabilities of adjusting the shape of the wing according to what the immediate flight situation demands, as well as of responding almost immediately to conditions the flow environment dictates, such as wind gusts, object avoidance, target tracking, etc. In bird aerodynamics also the tail plays an important role. To fly, wings impart downward momentum to the surrounding air and obtain lift by reaction. How this is achieved under various flight situations (cruise flight, hovering, landing, etc.), and what the role is of the wing-generated vortices in producing lift and thrust is discussed. The issue of studying bird flight experimentally from in vivo or in vitro experiments is also briefly discussed.

Dyachevsky, A. P., Glushkov, N. N. and Kozachenko, A. V.

"TRANSFORMATION OF EXTERNAL DISTURBANCES BY THE WING VORTEX SYSTEMS OF AN AIRCRAFT FLYING THROUGH A NON-UNIFORM MEDIUM"

In: Flight Safety, Aircraft Wake Vortex and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 223-225

The problem on computing the aerodynamic effect of the vortex wake generated by an aircraft on other aircraft at low subsonic speeds is considered in the linear formulation. The velocity field of an arbitrary structure is shown to be transformed by free vortices into a field uniform in chordwise direction and varying in the spanwise direction. The field thus transformed is perceived by the wing bound vortices which induce corresponding aerodynamic loads. The transformation of the non-uniform velocity field to the uniform one by the free vortices is the primary reason why the solution in quasi-steady approximation differs from that of the unsteady problem.

Dyachevsky, A. P., Glushkov, N. N. and Mikhailov, Y. S.

"MODIFICATION OF A PANEL METHOD FOR CALCULATION OF THE AIRCRAFT AERODYNAMIC LOADING UNDER VORTEX WAKE ENVIRONMENT"

In: Flight Safety, Aircraft Vortex Wake and Airport Operation Capacity - Collection of Papers, Trudy TsAGI, Vol. 2641, Publishing Dept. of TsAGI, Moscow, Russia, 1999, pp. 214-222

In the framework of the hypothesis of a 'frozen' external velocity field, a panel method is modified for calculation of the vortex wake effect on the aircraft flying along a path close to the centerline of one of the wake vortices generated by a leading aircraft. The non-symmetry inherent in the nonuniform velocity field around the aircraft components is considered by representing the fuselage geometry with wing panels and introducing additional information about the velocity field in the control points of the

aircraft surface. The verification of the numerical method against the results of testing the aircraft model in the nonuniform wind tunnel flow has shown a satisfactory accuracy of prediction of aerodynamic characteristics over a range of linear variations of the wing lifting capacity.

Dynnikov, A. A.

"DEVELOPMENT OF VORTEX WAKE INSTABILITY UNDER THE ACTION OF ATMOSPHERIC TURBULENCE"

In: Investigation of Vortex Wake Evolution and Flight Safety - Collection of Papers, Trudy TsAGI, Vol. 2622, Publishing Dept. of TsAGI, Moscow, Russia, 1996, pp. 119-128

The sinuous instability known as Crow's instability is one of substantial factors influencing the vortex decay behind an aircraft. It is usually assumed that the vortex wake can be considered as destroyed when the amplitude of vortex core deviations from their initial positions becomes equal to the initial distance between them. It is evident that these deviations vary as some random process whose parameter distributions were the subjects of this study. Air turbulence was assumed to be the source of disturbances provoking the development of Crow's instability. On this assumption, in this work the expression for the spectral density function of vortex deviations has been obtained and various turbulence models have been compared. The results obtained can be used both for calculating the probability of vortex to decay at a time specified as well as for statistical simulation purposes. [In Russian.]

Dynnikov, A. A.

"THE INFLUENCE OF ATMOSPHERIC TURBULENCE ON CROW INSTABILITY INITIATION"

XXIII General Assembly, European Geophysical Society, Nice, France, April 1998

The sinusoidal instability known as the Crow instability is an essential factor affecting the disintegration of the vortex wakes. This instability should be considered in the wake vortex decay model intended for the investigation of the second airplane dynamics. The initiation of the Crow instability due to atmospheric turbulence and variable wing loads is considered in some publications in which the lifespan of a vortex time is estimated. In this investigation it is supported that the wake vortices disappear when the amplitude of vortex line deviations from an initial position becomes equal to the initial distance between them. There are several experimental works in which the vortex lifespan is estimated at different turbulence levels. To investigate the second airplane dynamics, it is necessary to know not only the lifespan of a trace, but also a spatial position of vortex lines. This position is a random process, the characteristics of which depend on many factors, mainly on atmospheric turbulence. The purpose of this paper is to determine the characteristics of this process. These characteristics can be used to construct an algorithm which generates random realizations of the wake vortex position in space. Such an algorithm can be used for the investigation of the second airplane dynamics.

Dynnikova, G. Ya.

"VORTEX MOTION IN TWO-DIMENSIONAL VISCOUS FLUID FLOWS"

Fluid Dynamics, Vol. 38, No. 5, 2003, pp. 670-678

The diffusion and annihilation of vortices in axisymmetric and plane incompressible viscous fluid flows are considered. A formula relating the pressure with the velocity of the vortices in the viscous fluid is obtained.

Dziedzic, M. and Leutheusser, H. J.

"AN EXPERIMENTAL STUDY OF VISCOUS VORTEX RINGS"

Experiments in Fluids, Vol. 21, 1996, pp. 315-324

The work focuses on the problem of stability and viscous decay of single vortex rings. A tentative classification scheme is proposed for vortex rings which is based on extensive hot-wire measurements of velocity in the ring core and wake, and flow visualization, viz. laminar, wavy, turbulence-producing, and turbulent. Prediction of vortex ring type is shown to be possible, at least approximately, based on the vortex ring Reynolds number alone. Linear growth rates of ring diameter with time are observed for all types of vortex rings, with different growth rates occurring for laminar and turbulent vortex rings. Data on the viscous decay of vortex rings are used to provide experimental confirmation of the accuracy of Saffman's equation for the velocity of propagation of a vortex ring.

"PHENOMENA OBSERVED DURING THE ORTHOGONAL BLADE-VORTEX INTERACTION"

4th International Symposium on Particle Image Velocimetry, Paper 1180, September 2001, Gottingen, Germany.

Through the application of a Particle Image Velocimetry (PIV) technique, the flow field associated with the Orthogonal Blade-Vortex Interaction (BVI) has been examined. The use of the PIV technique has allowed quantitative measurement of the orthogonal BVI to be carried out, examining in detail the progression of the interacting vortex from the leading edge to the trailing edge region of the blade, and the effect of the interaction on the vortex core axial flow. The PIV system has also been successfully utilized in conjunction with a pressure data acquisition system, allowing simultaneous pressure data capture and analysis of the position of the interacting vortex in relation to the pressure transducers. This paper will outline the experimental techniques employed, and highlight the salient features observed within this investigation.

Earnshaw, P. B.

"PRELIMINARY RESULTS USING A RAPID PHOTOGRAPHIC WAKE TRAVERSE SYSTEM"

RAE-TM-AERO-1987, November 1983, Royal Aircraft Establishment, Farnborough, England

A rapid photographic wake traverse system was constructed for a 4 ft x 3 ft wind tunnel to assess the feasibility of, and design requirements for, a similar equipment to suit a 5 m wind tunnel. Sample photographs using a gothic wing and a Harrier model with and without stores show the ease with which useful information can be acquired.

Earnshaw, P. B.

"MEASUREMENTS OF VORTEX-BREAKDOWN POSITION AT LOW SPEED ON A SERIES OF SHARP-EDGED SYMMETRICAL MODELS"

ARC Paper CP-828, November 1964, Royal Aircraft Establishment, Farnborough, England

Measurements have been made at low speed of vortex-breakdown positions on a series of five, symmetrical wings, using a schlieren system to detect the position of breakdown. The results suggest that the modification of a delta planform to incorporate streamwise tips has little effect on breakdown position when this is forward of the modified tip. Examination of the large differences between these measurements and those from other sources suggests that the influence of cross-sectional shape even on nominally thin wings may be larger than expected and merits further investigation.

Easterbrook, C. C. and Joss, W. W.

"THE UTILITY OF DOPPLER RADAR IN THE STUDY OF AIRCRAFT WING-TIP VORTICES"

Aircraft Wake Turbulence and Its Detection, 1st ed., Plenum Press, New York, 1971, pp. 97-112

The feasibility of utilizing a special purpose Doppler radar to investigate air motions in aircraft wakes is explored and tested. One method involves the injection of radar reflecting chaff into the wing-tip vortex of an aircraft in flight, and subsequently recording the Doppler spectrum of the return from the chaff packet as obtained by the radar looking normal to the flight path. The second method consists of Doppler measurements in the wake behind aircraft on the approach to an airport during snow conditions, where natural snow crystals and flakes assume the role of radar reflecting tracers of air motion. The power spectra derived from both techniques reflect the distribution of velocities of scatterers in the direction of the radar, weighted by the spatial distribution of the scatterers contained in the radar sensitive volume.

Easterbrook, C. C., Joss, W. W. and Prinsen, H. W.

"AN EXPERIMENTAL INVESTIGATION AND EVALUATION OF A DOPPLER RADAR TECHNIQUE FOR THE MEASUREMENT OF THE FLOW GENERATED BY WING TIP VORTICES"

CAL-AF-3015-1, January 1971, Cornell Aeronautical Lab., Buffalo, NY

Results are described of tests conducted to determine if radar reflective chaff injected at the wing tip of an aircraft would be ingested into the vortex structure and sufficiently distributed to allow velocity profiles to be measured by a Doppler radar. The results are presented in the form of flow field visualization results and an analysis of radar returns. The data show that individual chaff filaments dispensed at the wing tips of an Aztec aircraft are entrained by the wing tip vortices. An examination of the radar returns reveals the presence of large Doppler spreads in relatively small regions of the vortices. It was also found that a substantial percentage of the chaff tended to form clumps which hampered the determination of the detailed velocity profiles.

Eaton, J. A. and O'Flaherty, M. P.

"FLOWFIELD PREDICTION OF THREE-DIMENSIONAL WING TRAILING VORTICES USING ADVANCED TURBULENCE MODELS, "

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 7-1 to 7-.

The feasibility of employing a general-purpose Navier-Stokes code, in conjunction with a Reynolds stress transport turbulence model, for predicting wake vortex flow fields is investigated. Two test cases are considered, each employing two different turbulence models, a model, which is isotropic, and an anisotropic, differential Reynolds stress model. First the flow field around a low aspect ratio wing in a wind tunnel is computed to assess the influence of the turbulence model on the solution. Pressure distributions on the surface and velocity distributions in the wake, particularly the streamwise component, are compared with measurements. Although the grids used are suboptimal, predictions indicate a qualitative improvement for the anisotropic model, in particular where the swirl component of the flow is greater, such as in the vortex core. Next, wind tunnel data are used as a starting point for an axisymmetric model of a free vortex with axial flow. These computations allow the effects of choice of turbulence model on the aging and decay of a vortex in the far field to be observed. The k-epsilon model predicts a rapid growth of the vortex, whereas the differential Reynolds stress model results in a more realistic, almost uniform evolution of the core radius.

Eaton, J. K. and Matalanis, C.

"TRANSLATING ACTIVE GURNEY FLAP TO ALLEVIATE AIRCRAFT WAKE VORTEX HAZARD"

US Patent Application 2009/0321582 A1, December 2009.

A wake vortex alleviator is provided. The wake vortex alleviator produces rapid variations in the position of vortices emanating from aerodynamic surfaces by using an active flap that moves span-wise back and forth along the outboard section of the surface. Rapidly moving the flap back and forth in a slot at an appropriate frequency will cause the vortex to oscillate, resulting in interaction between other vortices and subsequent destruction much earlier than it would occur naturally. The slot is positioned near the aerodynamic surface trailing edge and generally transverse to a chord line of the aerodynamic surface. The flap can be moved using a variety of actuators to position, translate and stow

the flap. The oscillation frequency and position are guided by information feedback according variations in lift in the aerodynamic surface, such as wind gusts. The flaps can control yaw, roll and pitch of the aerodynamic surface.

Eberle, W. R.

"PILOT RESPONSE TO WAKE TURBULENCE ENCOUNTERS AT NEW YORK'S LAGUARDIA AIRPORT"

LMSC-HSV TR-P038105, October 1993, Lockheed Missiles & Space Corp., Huntsville, AL

This effort was initiated to develop a rationale for decreasing the aircraft spacing required for vortex consideration at LaGuardia Airport in New York. During the winter months, the primary runway configuration is takeoff on Runway 31 and landing on Runway 22. FAA procedures require an increase in the distance a landing aircraft must be from the runway intersection when a heavy takeoff aircraft crosses the intersection. The extra distance is required to permit demise of the vortices from the heavy takeoff aircraft before the next aircraft lands on Runway 22. This report examined normal pilot response to cross-vortex encounters to see if such response would create a hazardous condition. B-727 and DHC-7 simulators were used. Pilots reported that any cross-vortex encounters could be handled safely with training and warning of a heavy aircraft takeoff; the encounter could be dangerous if it were conducted without training and/or warning.

Eberle, W. R. and Dillard, A. E.

"WAKE VORTEX PROGRAM FOR CROSS-VORTEX ENCOUNTERS AT LAGUARDIA AIRPORT"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.2, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 54-1 - 54-28

One of the primary runway configurations for LaGuardia Airport is departure on Runway 31 and landing on Runway 22. Because of wake vortex considerations, the FAA enforces the standard 3/4/5/6 n.mi. vortex separations between a heavy aircraft departing on Runway 31 and a landing aircraft on Runway 22. When aircraft separations are established by IFR control, if a heavy take-off aircraft on Runway 31 crosses the intersection, any large aircraft landing on Runway 22 must be five miles from the intersection. The capacity of LaGuardia Airport is significantly degraded by this spacing requirement. A study was initiated to determine if a rationale for eliminating the additional spacing imposed by wake vortex considerations of Runway 31 aircraft could be developed. If such a rationale were developed, aircraft performing IFR landings on Runway 22 would maintain normal separations for landing aircraft without consideration of the type of aircraft departing on Runway 31. The initial approach to developing such a rationale was to analyze vortex transport and demise to determine if vortex encounters could be avoided. The initial study showed that vortex encounters would be very rare, but could not be completely avoided. The second approach was to demonstrate that aircraft response to a cross-encounter is significantly different from aircraft response to an in-trail encounter and to demonstrate that a cross-vortex encounter is innocuous for transport category aircraft.

Eberle, W. R., Brashears, M. R., Zalay, A. D., Shrider, K. R. and Love, D. A.

"AIRCRAFT WAKE VORTEX CHARACTERISTICS FROM DATA MEASURED AT JOHN F. KENNEDY INTERNATIONAL AIRPORT"

FAA-RD-78-47, March 1978, Lockheed Missiles & Space Co., Huntsville, AL

Data from 1320 aircraft flybys at Kennedy International Airport, Jamaica, New York, in 1975 were processed and stored in a computerized vortex data management system. The data were selectively recalled to determine vortex characteristics pertinent to the design of an effective wake vortex avoidance system. Vortex and meteorological characteristics which are relevant to the design of an effective wake vortex avoidance system are discussed from an analytical viewpoint as well as from an analysis of the data. Several formulations for feedback of vortex sensor information to provide vortex prediction are presented. Several wake vortex avoidance system designs are shown.

"WAKE TURBULENCE INVESTIGATION AT NEW YORK'S LA GUARDIA AIRPORT"

LMSC-HEC TR F225747-B, December 1988, Lockheed Missiles & Space Co., Huntsville, AL

The intent of the study was the development of a rationale for increased airport capacity by eliminating the extra space required for aircraft landing behind heavy takeoff aircraft at La Guardia airport. The study considered two approaches: (1) demonstration that a vortex encounter would not occur for the runway configuration of interest (takeoff on runway 31 and landing on runway 22), and (2) demonstration that if a vortex encounter occurred where the flight path of the following aircraft is perpendicular to the flight path of the generating aircraft, it would not be hazardous to the landing aircraft.

"AN EXPERIMENTAL STUDY ON THE FREE SURFACE VERTICAL VORTEX"

Experiments in Fluids, Vol. 33, 2002, pp. 414-421

An experimental investigation of the three-dimensional configuration of a vertical vortex flow, showing the importance of separating the radial and axial components of the total outflow, is presented. The relative magnitudes of the axial and radial flow components are measured and the depth of the air core is shown to be highly sensitive to the axial flow component. A representation of the flow in the core zone is also presented which may indicate internal boundary conditions that may be of interest to those developing theoretical models.

Economou, T.

"EFFECTS OF WAKE VORTICES ON COMMERCIAL AIRCRAFT"

The strength of a wake vortex can be modeled and quantified by the coefficient of roll which a penetrating aircraft will experience when passing through a vortex. In this study, the coefficient was computed by a closed-form method and by using strip theory to analyze the effects of the vortex on the penetrating aircraft and determine the risk involved. Results showed that a penetrating aircraft with an equivalent span to the wake generating aircraft will experience a much lower coefficient of roll than when the penetrating aircraft has a smaller span. Further, the coefficient of roll induced by a trailing vortex with a small core radius will be stronger than that of a vortex with a larger radius. In all cases, at least one scenario existed where the penetrating aircraft could not produce a control power coefficient of roll of the same magnitude as the induced coefficient from the vortex. Also, the taper ratio of the penetrating wing affects the strength of the induced coefficient of roll. A more rectangular wing will experience a stronger induced roll coefficient than a wing with taper. Lastly, the effect of the spanwise vortex location of the vortex on the penetrating wing was examined. The induced roll coefficient was found to be the largest when the aircraft penetrates along the vortex axis and the vortex axis coincides with the centerline of the airplane.

"A PARALLEL STABILITY ANALYSIS OF A TRAILING VORTEX WAKE"

Journal of Fluid Mechanics, Vol. 837, 2018, pp. 858-895.

Trailing vortices are generated in aeronautical and maritime applications and produce a variety of adverse effects that remain difficult to control. A stability analysis can direct flow control designers towards pertinent frequencies, wavelengths and locations that may lead to the excitation of instabilities, resulting in the eventual breakup of the vortex. Most models for trailing vortices, however, are far-field models, making implementation of the findings from stability analyses challenging. As such, we perform a stability analysis in the formative region where the numerically computed base flow contains both a two-dimensional wake and a tip vortex generated from a NACA0012 at a 5- degree angle of attack and a chord-based Reynolds number of $Re=1000$. The parallel temporal and spatial analyses show that at three chord lengths downstream of the trailing edge, seven unstable modes are present: three stemming from the temporal analysis and four arising in the spatial analysis. The three temporal instabilities are analogues to three unstable modes in the spatial analysis, with the wake instability dominating in both analyses. The helical mode localized to the vortex co-rotates with the base flow, which is converse with the counter-rotating $m=-1$ instabilities of a Batchelor vortex model, which may be a result of the formative nature of the base-flow vortex. The fourth spatial mode is localized to the tip vortex region. The continuous part of the spectrum contains oscillatory and wavepacket solutions prompting the utilization of a wavepacket analysis to analyze the flow field and group velocity. The structure and details of the full bi-global spectrum will help navigate the design space of effective control strategies to hasten decay of persistent wingtip vortices.

"FEASIBILITY ANALYSES FOR PAIRED APPROACH PROCEDURES FOR CLOSELY SPACED PARALLEL RUNWAYS"

Integrated Communications, Navigation and Surveillance (ICNS) Conference, May 2011, Herndon, VA.

In current air traffic operations in the U.S., closely spaced parallel runways (CSPRs) separated by less than 2500 feet can be used to conduct simultaneous parallel operations using visual separation. Once below visual approach minima, such dual runway operations are no longer possible. To address this loss of throughput, several concepts are currently under consideration. This paper discusses a 'paired approach' concept which enables use of CSPRs down to Category I and II approach minima. The paper documents Monte Carlo analyses on the feasibility and trade-offs of paired approach procedure variants with and without an escape maneuver. It concludes that both procedure variations require echelon staggering for most airports with runway centerline separations below 2500 ft and provides window parameters required for an acceptable Target Level of Safety. It shows that a value of up to 4000 ft for this echelon spacing is adequate for most CSPRs for an adverse wind threshold of 10 knots; the specific value depending on the concept variation and geometry. Other findings include the ability to achieve abeam positioning with an escape procedure for several runway configurations. Many procedural combinations examined are capable of pairing 95 to 100 percent of aircraft. Additionally, this paper presents an analysis of wake encounter risk during blunders. The analysis results suggest the non-escape procedure variant has a high probability of wake vortex encounter during blunder. On the other hand, the escape procedure variant with a delay in breakout of 8 seconds or less appears to provide protection from wake encounters even during a blunder.

Egolf, T. A.

"AN ANALYTICAL AND EXPERIMENTAL STUDY OF FARFIELD ROTOR WAKE GEOMETRY AND VELOCITY"

MS Thesis, August 1973, Pennsylvania State University, University Park, PA.

All fixed wing aircraft generate trailing vortex wakes whose circulatory strength is dependent on flight conditions and aircraft geometry. A rotor also generates a vortex wake. A vortex sheet is shed from each blade. Each sheet rolls up rapidly outboard to form a tip vortex. The purpose of the study here is to estimate the rotor wake geometry and velocity field downstream of the rotor for the particular case where the rotor wake exhibits strong similarities to the fixed wing wake. A method is developed by

which the helicopter far field wake can be readily compared to the far field wake generated by an equivalent wing.

Egolf, T. A.

"AN ANALYTICAL AND EXPERIMENTAL STUDY OF FARFIELD ROTOR WAKE GEOMETRY AND VELOCITY"

PSU Aersp. 73-7, August 1973, Pennsylvania State Univ., University Park, PA

From the analyses and empirical measurements performed in this study, it appears that the far field wake of a rotor can be adequately described by treating the rotor as a circular wing.

Egolf, T. A. and Landgrebe, A. J.

"GENERALIZED WAKE GEOMETRY FOR A HELICOPTER ROTOR IN FORWARD FLIGHT AND EFFECT OF WAKE DEFORMATION ON AIRLOADS"

40th Annual Forum of the American Helicopter Society, May 1984, Arlington, VA.

An analytical investigation was conducted to develop a first level generalization of the predicted distorted wake geometry of a helicopter rotor in level steady forward flight and to demonstrate the influence of wake deformation on the prediction of rotor airloads. Distortions of the tip vortex relative to the classical undistorted geometry are generalized in terms of vortex age, blade azimuth, advance ratio, thrust coefficient, and number of blades for a representative rotor. A computer module and charts were developed for approximating wake geometry and identifying wake boundaries and locations of blade-vortex passage. Predicted H-34 airloads for several inflow/wake models are compared with data for selected flight conditions. The occurrence of close blade-vortex passages and the high sensitivity of predicted airloads to small deviations of blade to tip vortex distance demonstrate the requirement for improved blade-vortex interaction models. The airload correlations indicate that refined distorted wake methodology has the potential to provide more accurate airload prediction.

Egolf, T. A. and Landgrebe, A. J.

"HELICOPTER ROTOR WAKE GEOMETRY AND ITS INFLUENCE IN FORWARD FLIGHT. VOLUME 1: GENERALIZED WAKE GEOMETRY AND WAKE EFFECT ON ROTOR AIRLOADS AND PERFORMANCE"

NASA/CR-3726, October 1983, United Technologies Research Center, East Hartford, CT

An analytic investigation to generalize wake geometry of a helicopter rotor in steady level forward flight and to demonstrate the influence of wake deformation in the prediction of rotor airloads and performance is described. Volume 1 presents a first level generalized wake model based on theoretically predicted tip vortex geometries for a selected representative blade design. The tip vortex distortions are generalized in equation form as displacements from the classical undistorted tip vortex geometry in terms of vortex age, blade azimuth, rotor advance ratio, thrust coefficient, and number of blades. These equations were programmed to provide distorted wake coordinates at very low cost for

use in rotor airflow and airloads prediction analyses. The sensitivity of predicted rotor airloads, performance, and blade bending moments to the modeling of the tip vortex distortion are demonstrated for low to moderately high advance ratios for a representative rotor and the H-34 rotor. Comparisons with H-34 rotor test data demonstrate the effects of the classical, predicted distorted, and the newly developed generalized wake models on airloads and blade bending moments. Use of distorted wake models results in the occurrence of numerous blade-vortex interactions on the forward and lateral sides of the rotor disk. The significance of these interactions is related to the number and degree of proximity to the blades of the tip vortices. The correlation obtained with the distorted wake models (generalized and predicted) is encouraging.

"OVERVIEW AND PERSPECTIVES OF VORTEX ELEMENT WAKE MODELING AT SIKORSKY"

Proceedings of the ARO Rotorcraft Wake Prediction Basic Research Workshop, March 2009, Georgia Institute of Technology, Atlanta, GA, pp. 4-29.

This paper presents several Sikorsky engineer's perspective on vortex- element based wake modeling for rotors, including a final emphasis on hybrid CFD/Vortex Element methodology. It briefly reviews some basic aspects of these models, their strengths and weaknesses, modeling issues, and what is needed to improve current hybrid CFD/Vortex Element methodology to support the aerodynamic design and analysis of isolated rotors. It directly or indirectly provides some insight into future research areas for this type of rotor wake modeling.

Egolf, T. A., Wake, B. E. and Berezin, C.

"RECENT ROTOR WAKE SIMULATION AND MODELING STUDIES AT UNITED TECHNOLOGIES CORPORATION"

AIAA Paper No. 2000-0115, Reno, NV, January 2000

The accurate prediction of the rotor wake and its influence on the rotorcraft continues to be a major obstacle for the rotorcraft community. Traditional vortex lattice methods are very useful, but cannot predict the details of the tip vortex formation. They are relatively efficient for tip vortex convection calculations, but are very sensitive to modeling assumptions. Traditional Computational Fluid Dynamics (CFD) applied to problems requiring accurate tip vortex convection is still too time consuming, primarily because of the very fine grid resolution required to avoid significant numerical diffusion. This paper is a summary of recent unpublished work at United Technologies Corporation (UTC) by engineers at Sikorsky Aircraft (SA) and United Technologies Research Center (UTRC) to improve the modeling assumptions and resolve some of the limitations of both vortex lattice and CFD methods. Two areas are addressed: tip vortex roll-up modeling in vortex lattice methods and ways to improve the calculation of the convection of the tip vortex in traditional CFD codes.

Ehert, T.

"STABILITY THEORY FOR TWO WINGTIP VORTICES BEHIND CRUISING AIRCRAFT"

Proceedings of 78th Fluid Dynamics Panel Symposium, Characterization and Modification of Wakes from Lift: Vehicles in Fluids, AGARD, CP-584, Trondheim, Norway, May 1996, pp. 20-1 to 20-9

To perform a stability analysis on an interesting flow field, an undisturbed quasi steady basic velocity profile of the concerned flow field must be provided. In case of wake vortices behind cruising aircraft, the velocity distribution within the vortices must be evaluated as a function of the height coordinate z and the spanwise coordinate y . A three-dimensional vortex filament method was used to calculate the velocity field of the wake flow, because it is an efficient tool for flows consisting of large regions of vorticity. Vortex filament methods simulate such a flow field by discretizing the regions behind the aircraft wing which contain vorticity, and tracking this discretization in a Lagrangian reference frame. The velocity field behind the aircraft is determined kinematically from the given vorticity field and computed by an application of the Biot-Savart-law. Small perturbations are then superimposed on the given quasi steady base flow and this sum is then substituted into the governing equations. After a linearization process, two fourth order perturbation differential equations are found. They give rise to an eigenvalue problem with a complex eigenvalue w and eigenfunctions for the amplitudes of the disturbances.

"AIRBORNE DOPPLER LIDAR SENSOR PARAMETER ANALYSIS FOR WAKE VORTEX IMPACT ALLEVIATION PURPOSES"

Advances in Aerospace Guidance, Navigation and Control, edited by J. Bordeneuve-Guibe, A. Drouin and C. Ross, Springer International Publishing, Switzerland, 2015, pp. 433-453.

This paper presents a sensitivity study of a wake vortex impact alleviation system based on an airborne forward-looking Doppler LiDAR sensor. The basic principle of the system is to use this sensor to measure the wind remotely ahead of the aircraft. Based on these measurements the system estimates whether a wake vortex is in front of the aircraft. If this is the case, the wake vortex characteristics are identified and the control deflections countervailing the wake-induced aircraft response are computed and applied. An integrated simulation environment comprising a full nonlinear 6-DoF A320 model (with control laws), wake vortex models, and the wake impact alleviation algorithms was developed. The LiDAR sensor subsystem has many design parameters that influence the overall performance in a complex way, which makes it difficult to derive adequate requirements. The presented parameter study provides first insights into the role of each parameter as well as some adequate parameter combinations.

Ehlers, J., Fischenberg, D. and Niedermeier, D.

"WAKE IMPACT ALLEVIATION CONTROL BASED ON WAKE IDENTIFICATION"

Journal of Aircraft, Vol. 52, No. 6, November-December 2015, pp. 2077-2089.

During a wake vortex encounter, an aircraft can experience significant attitude and flight-path changes, which can represent a severe safety risk. The application of a wake impact alleviation control system can considerably decrease the aircraft's response during the wake encounter and hence diminish the pilot workload while reducing the potential risk to the passengers, crew, and aircraft. The realization of a wake impact alleviation controller presented here is based on a forward-looking light detection and ranging (LIDAR) sensor. The information about the disturbance velocities in front of the aircraft is used to determine the control-surface deflections that compensate the wake-induced disturbance moments. The novel approach of this concept is the combination of the wake impact alleviation system with a wake identification algorithm. Because of the integration of the identification algorithm, it is possible to apply the wake impact alleviation with LIDAR sensors restricted to line-of-sight measurements only. The wake-identification-based wake impact alleviation is assessed in numerical aircraft simulations for different encounter scenarios, and a sensitivity study is performed for the parameters of the wake identification. It is shown that the alleviation system significantly reduces the wake-induced attitude change of the aircraft and thus represents a promising concept to increase safety during wake-vortex encounters.

Ehlers, J., Fischenberg, D. and Niedermeier, D.

"WAKE IDENTIFICATION BASED WAKE IMPACT ALLEVIATION CONTROL"

AIAA Paper 2014-2591, June 2014, Atlanta, GA.

During a wake vortex encounter an aircraft is exposed to strong unsteady disturbance velocities which can lead to significant changes in the aircraft attitude and flight path. This can present a severe safety risk and can result in injuries to the passengers and crew as well as damages to the aircraft. The application of a wake impact alleviation control system can considerably decrease the aircraft's response during the wake encounter, and hence diminish the pilot workload while reducing the potential risk to the passengers, crew, and aircraft. The realization of a wake impact alleviation controller presented here is based on a forward-looking LiDAR sensor. The information about the disturbance velocities in front of the aircraft is used to determine the control surface deflections that compensate the wake-induced disturbance moments. The novel approach of this concept is the combination of the wake impact alleviation system with a wake identification algorithm. Due to the integration of the identification algorithm, it is possible to apply the wake impact alleviation with LiDAR sensors restricted to line-of-sight measurements only. In this case the LiDAR sensor only detects the flow velocity in the direction of the measurement beam. A measurement of the full velocity vector of the flow field upstream of the aircraft, which LiDAR sensors of the foreseeable future will most likely be unable to provide, is not necessary for this approach. The wake identification-based wake impact alleviation is assessed for different encounter scenarios and a brief sensitivity study is performed for the most important parameters of the wake identification. It is shown that the wake impact alleviation control system significantly reduces the wake-induced attitude change of the aircraft and thus represents a promising concept to increase safety during wake vortex encounters.

Ehrenstein, U. and Le Dizes, S.

"RELATIONSHIP BETWEEN COROTATING VORTEX-PAIR EQUILIBRIA AND A SINGLE VORTEX IN AN EXTERNAL DEFORMATION FIELD"

Physics of Fluids, Vol. 17, No. 7, July 2005, 074103-1-074103-7

Two-dimensional corotating vortex pairs are computed as equilibrium solutions of the Euler equations and the influence of one vortex on the other is characterized in terms of a deformation field acting on an isolated vortex region. It is shown, by computing equilibrium states for a single vortex within an equivalent strain field, that the external rotating strain accounts for the elliptic deformation of the streamlines near the center of each vortex. Critical states, as a function of the strain rate, are reached when stagnation points start to penetrate the vortex regions at the outer boundary. While critical states for a single vortex within a uniform external rotating strain field consist of elliptical corner solutions, the vortex shapes lose the elliptical symmetry in the corotating case. We show that these asymmetric equilibrium states can be captured by a single vortex model if we consider higher order terms in the deformation field. We also demonstrate that the critical strain rates are of the same order of magnitude for both the single-vortex model and the interacting vortex pair.

Ehrenstein, U. and Rossi, M.

"COMPUTATION OF EQUILIBRIA BETWEEN TWO COROTATING NONUNIFORM VORTICES"

Lecture Notes in Physics, Issue 555, 2000, pp. 147-153

Understanding decaying two-dimensional turbulence has important consequences for geophysics, meteorology, and astrophysics. Various aspects appear in a recurrent way: from an initially unorganized two-dimensional flow, vorticity rapidly concentrates in localized regions called coherent structures and in vorticity filaments. In this framework, the computation of a nonlinear equilibrium between the vortices and its stability becomes an essential ingredient. Focusing on vorticity patches, equilibria of two unequal-area vortices have been computed for instance by Dritschel. However, vortices of two-dimensional turbulence are not vorticity patches. Our purpose is thus to verify how previous results obtained in the context of uniform vorticity are modified when nonuniform vortex pairs are considered.

Ehret, T. and Oertel, Jr., H.

"CALCULATION OF WAKE VORTEX STRUCTURES IN THE NEAR-FIELD WAKE BEHIND CRUISING AIRCRAFT"

Atmospheric Environment, Vol. 32, No. 18, September 1998, pp. 3089-3095

Wake flows behind cruising aircraft influence the distribution of the exhaust gases. A three-dimensional vortex filament method was developed to calculate the vortex structures and the velocity field of the vorticity dominated wake flows as an integration of the Biot-Savart law. For three-dimensional vortex filament calculations, self-induction singularities were prevented using a finite vortex core for each vortex filament. Numerical simulations show the vortex structures and the

velocity field in the wake behind a cruising Boeing 747 because of the integration of the Biot-Savart law. It is further shown how the structures of the fully rolled-up trailing vortices depend on the wing span loading, i.e. the circulation distribution.

Ehret, T. and Oertel, Jr., H.

"NUMERICAL SIMULATION OF THE DYNAMICS AND DECAY OF TRAILING VORTICES INCLUDING POLLUTANTS FROM AIR TRAFFIC"

In: Impact of Emissions from Aircraft and Spacecraft Upon the Atmosphere, Proceedings of International Scientific Colloquium, Cologne, Germany, 1992, pp. 268-273

Recent results from numerical simulations concerning the wake of an aircraft, including the pollutants, are presented. The computation of the rolling up of the trailing vortices and their effect on the jet emissions was performed using a 3D vortex filament method. Furthermore, a velocity profile of the trailing vortex, which serves as the starting point for a primary stability theory, is shown and the perturbation differential equations describing the vortex decay are derived.

Eisenhuth, J. J., McCormick, B. W., Nelson, R. C. and Garodz, L. J.

"ANALYSIS OF EXPERIMENTAL MEASUREMENTS OF TRAILING VORTEX SYSTEMS OF LARGE JET TRANSPORT AIRCRAFT"

Proceedings of the National Aerospace Electronics Conf., IEEE, 1971, pp. 28-35

This paper presents an analysis of data obtained by the Federal Aviation Administration related to the characteristics of trailing vortex systems generated by large jet aircraft. Difficulty was experienced in analyzing the data because of the comparatively large spacing of sensors, but some significant information and conclusions can be derived from the analysis. It was found that the velocity field around a vortex produced by a large jet aircraft is defined by a logarithmic variation of circulation with radius. For a lift coefficient of unity, the core diameter was found to be approximately 5% of the mid-span chord while the maximum tangential velocity at the edge of the core was about 70% of the aircraft velocity. Both the diameter and core appear to change in proportion to the lift coefficient. Expressions are developed for predicting the velocity field produced by the trailing vortices from large aircraft. These should be used with caution, however, until additional and more precise data are obtained.

El Hassan, M., Assoum, H. H., Sobolik, V., Vetel, J., Abed-Meraim, K., Garon, A. and Sakout, A.

"EXPERIMENTAL INVESTIGATION OF THE WALL SHEAR STRESS AND THE VORTEX DYNAMICS IN A CIRCULAR IMPINGING JET"

Experimental Fluids, Vol. 52, 2012, pp. 1475-1489.

The wall shear stress and the vortex dynamics in a circular impinging jet are investigated experimentally for $Re = 1,260$ and $2,450$. The wall shear stress is obtained at different radial locations from the stagnation point using the polarographic method. The velocity field is given from the time resolved particle image velocimetry (TR-PIV) technique in both the free jet region and near the wall in the impinging region. The distribution of the momentum thickness is also inspected from the jet exit toward the impinged wall. It is found that the wall shear stress is correlated with the large-scale vortex passing. Both the primary vortices and the secondary structures strongly affect the variation of the wall shear stress. The maximum mean wall shear stress is obtained just upstream from the secondary vortex generation where the primary structures impinge the wall. Spectral analysis and cross-correlations between the wall shear stress fluctuations show that the vortex passing influences the wall shear stress at different locations simultaneously. Analysis of cross-correlations between temporal fluctuations of the wall shear stress and the transverse vorticity brings out the role of different vortical structures on the wall shear distribution for the two Reynolds numbers..

"A VORTEX PARTICLE METHOD FOR TWO-DIMENSIONAL COMPRESSIBLE FLOW"

Journal of Computational Physics, Vol. 179, 2002, pp. 371-399

A vortex particle method is developed for simulating two-dimensional, unsteady compressible flow. The method uses the Helmholtz decomposition of the velocity field to separately treat the irrotational and solenoidal portions of the flow, and the particles are allowed to change volume to conserve mass. In addition to having vorticity and dilatation properties, the particles also carry density, enthalpy, and entropy. The resulting evolution equations contain terms that are computed with techniques used in some incompressible methods. Truncation of unbounded domains via a nonreflecting boundary condition is also considered. The fast multipole method is adapted to compressible particles in order to make the method computationally efficient. The new method is applied to several problems, including sound generation by corotating vortices and generation of vorticity by baroclinic torque.

Eldredge, J. D., Colonius, T. and Leonard, A.

"A DILATING VORTEX PARTICLE METHOD FOR COMPRESSIBLE FLOW"

Journal of Turbulence, Vol. 3, Paper 036, October 2002, pp. 1-10

Vortex methods have become useful tools for the computation of incompressible fluid flow. In this work, a vortex particle method for the simulation of unsteady two-dimensional compressible flow is developed. By decomposing the velocity into irrotational and solenoidal parts, and using particles that can change volume and that carry vorticity, dilatation, enthalpy, entropy and density, the equations of motion are satisfied. Spatial derivatives are treated using the method of particle strength exchange with high-order-accurate, non-dissipative kernels. The new vortex method is applied to co-rotating and leapfrogging vortices in compressible flow, with the far acoustic field computed using a two-dimensional Kirchhoff surface.

Eldredge, J., Colonius, T. and Leonard, A.

"A VORTEX PARTICLE METHOD FOR COMPRESSIBLE FLOW"

AIAA Paper No. 2001-2641, Anaheim, CA, June 2001

A vortex particle method for the simulation of two-dimensional compressible flows is developed. The computational elements are Lagrangian particles that carry vorticity, dilatation, enthalpy, entropy, and density. The velocity field is decomposed into irrotational and solenoidal parts, which allows its calculation in terms of the particles' vorticity and dilatation. The particle coverage is truncated and incident acoustic waves are absorbed using a suitable boundary treatment. A Kirchhoff surface formulation is developed for computing the far-field sound. The method is applied to a co-rotating vortex pair and the results are discussed.

Eliason, B. G., Gartshore, I. S. and Parkinson, G. V.

"WIND TUNNEL INVESTIGATION OF CROW INSTABILITY"

Journal of Aircraft, Vol. 12, No. 12, December 1975, pp. 985-988

The mutual instability of a trailing vortex pair has been studied in a large wind tunnel. The vortices were visualized using helium-filled soap bubbles and the cores probed with a hot-wire anemometer. Measurements were made to permit calculation of the wing lift, the circulation of the trailing vortices, the diameter of the vortex cores, and the wavelength and plane of oscillation of the unstable vortices. The results show that the linear theories of either Crow or Parks closely predict the characteristics of the instability, the agreement depending on the definition of the vortex core diameter.

Elkhoury, M. and Rockwell, D.

"VISUALIZED VORTICES ON UNMANNED COMBAT AIR VEHICLE PLANFORM: EFFECT OF REYNOLDS NUMBER"

Journal of Aircraft, Vol. 41, No. 5, September-October 2004, pp. 1244-1247.

This Reynolds number dependence of the vortex patterns on a representative UCAV planform, which is distinguished by small sweep angles, can be defined in terms of the onset of pronounced instability/abrupt breakdown of the vortices from the apex of the main body, the effective sweep angle of the vortices from the wing root, and the degree of interaction of the vortices from the apex and the wing root. At relatively low angle of attack, the onset of pronounced instability/breakdown is highly sensitive to Reynolds number, whereas at relatively high angle of attack, it is much less sensitive. The effective sweep angle of the wing root vortex is only a mild function of angle of attack; it is predominantly a function of Reynolds number and tends toward an asymptotic value at high Reynolds number. The Reynolds number at which the vortices from the apex and the wing root cease to interact decreases substantially with a decrease in angle of attack.

Elkinton, C. N., Rogers, A. L. and Ellis, A. F.

"LONG-TERM SITE WIND DATA REPORT, BISHOP AND CLERKS"

Report, March 2006, Renewable Energy Research Laboratory, University of Massachusetts, Amherst, MA.

All the work presented in this Wind Data Report including installation and decommissioning of the meteorological tower and instrumentation, and the data analysis and reporting was performed by the Renewable Energy Research Laboratory (RERL) at the University of Massachusetts, Amherst. This wind measurement station is installed on the Bishop & Clerks US Coast Guard (USCG) automated lighthouse, almost 3 miles south-southeast of Pt. Gammon on Cape Cod, MA. Installed in November of 2000, the wind monitoring station has been in continuous operation to this day. The two anemometers and wind vanes are mounted 15 m (49 ft) above the Mean Low Water Level. This annual report covers the period January 1, 2005 - December 21, 2005. However, the data and graphs presented here only show data from January 1 -- June 23. On June 23, the system at Bishops and Clerks lost the ability to transmit data due to lack of battery charge. This problem was compounded by the inaccessibility of the site, so the problem persisted through the end of 2005. Between January 1 and June 23, the mean recorded wind speed at 15 m was 7.38 m/s (16.5 mph) and the prevailing wind direction was from the north-northeast. The average turbulence intensity at 15 m was 0.11, which is typical for this site. Over the entire year of 2005, the gross data recovery percentage (the actual percentage of expected data received) was 47.6% and the net data recovery percentage (the percentage of expected data which passed all of the quality assurance tests) was 46.9%. For the period when the system was reporting (January 1 - June 23), the gross data recovery percentage was 100.0% and the net data recovery percentage was 98.7%. These indicate that, before the battery failed, the system was working well.

"TECHNICAL FEASIBILITY AND IMPACTS OF REDUCING STANDARD SEPARATION MINIMA IN FINAL APPROACH"

18th Integrated Communications Navigation and Surveillance (ICNS) Conference, April 2018, Herndon, VA.

The Single European Sky ATM Research program (SESAR2020) project for Enhanced Runway Throughput (EARTH), is focused on developing and validating SESAR solutions to increase Runway Throughput. In particular, the project addresses the reduction of the Minimum Radar Separation (MRS) to 2.0NM. The reduction of MRS minima down to 2.0NM on final approach is subject to Required Surveillance Performance (RSP) and is constrained by factors such as satisfying Runway Occupancy Time (ROT). The project studies different technical and operational options to identify cost benefit technical and performance requirements covering safety, capacity, efficiency, resilience, environment and noise, access and equity as well as human performance to facilitate deployment decisions. In this paper we review the need for reducing separation minima on final approach, we provide technical study results covering technology readiness to cope with the operational requirements and the

required surveillance performance, we propose a set of Required Surveillance Performance and we provide the results of a first validation of the concept using real time simulation, we conclude with some recommendation on future steps to evaluate the concept.

Ellis, C. W.

"RECOMMENDATIONS FOR FUTURE AERODYNAMIC RESEARCH"

Proceedings of Third CAL/AVLABS Symposium, Aerodynamics of Rotor, Wing and V/STOL Aircraft, Vol. III, June 1969

The discussion outlines those areas of rotary wing aerodynamics which currently pose the most perplexing problems to the designer and the operator of such aircraft and those areas where aerodynamic improvements are likely to have the largest payoff in either the development of a new vehicle or in the performance of such a vehicle once it has been developed. Limited data is shown to demonstrate the magnitude and nature of the problem (when that data is available). No attempt has been made to correlate this statement of problems with any list of research currently under way, although it is recognized that in many cases such activities are in fact proceeding. The problems are discussed under six general topics: rotor systems, noise, downwash, rotary wing wake, flying qualities, and wind tunnel test techniques.

"THE INTERACTION OF A SHOCK WITH A VORTEX: SHOCK DISTORTION AND THE PRODUCTION OF ACOUSTIC WAVES"

Physics of Fluids, Vol. 7, No. 1, January 1995, pp. 172-184.

Numerical simulations of a shock interacting with a compressible vortex are presented for shocks and vortices of various relative strengths. The simulations show the effects of the vortex on the shock structure and the structure of the acoustic field generated by the shock-vortex interaction. A relatively weak vortex perturbs the transmitted shock only slightly, whereas a strong vortex leaves the transmitted shock with a structure corresponding to either a regular or Mach reflection. The acoustic wave generated by the interaction consists of two components: a 'quadrupolar' component produced by the initial shock-vortex interaction and the complex reflected shock system. When these waves merge, they form the asymmetric structure seen in experiments.

"INTERACTION OF A SHOCK WITH A COMPRESSIBLE VORTEX"

Proceedings of the International Symposium on Shock Waves and Shock Tubes, July 1989, Bethlehem, PA, pp. 928-933.

This paper presents a time-dependent two-dimensional numerical simulation of a shock propagating through a compressible vortex. A weak shock, with the fluid velocity behind the shock front very much less than the maximum velocity in the vortex, passes over a shock. The vortex breaks the initial planar shock into four curved shocks that eventually merge.

Elnitsky II, J.

"INTERACTION OF A VORTEX PAIR WITH A FREE SURFACE"

MS Thesis, September 1987, Naval Postgraduate School, Monterey, CA.

The trailing vortices generated by the control planes of submarines give rise to surface signatures in the form of scars and striations. Two counter-rotating vortices were generated in a novel experimental system and their interaction with the free surface was investigated. In addition, the governing equations have been solved using the boundary-element method for a representative Froude number. The results have been expressed in terms of the depth of submergence of the vortices, their mutual induction velocity, and the initial vortex separation. It has been shown that the free surface begins to deform when the vortices are at a distance of about one initial vortex separation from the free surface. The height of the maximum deformation is attained at a normalized time of about 0.1, when the vortices are at a distance of about 0.5 b -zero from the free surface. The elevated part of the surface is bounded by two scars, whose motion is connected to that of the vortices.

El-Ramly, Z.

"INVESTIGATION OF THE DEVELOPMENT OF THE TRAILING VORTEX SYSTEM BEHIND A SWEEPED-BACK WING"

ME/A 75-3, Carleton University, Ottawa, Canada, October 1975

Measurements of the trailing vortex system behind a 35-degree sweptback wing have been made in a low-speed wind tunnel at a mean chord Reynolds number R , of about 500,000 with vortex Reynolds numbers, r/v , up to about 250,000. Spanwise and chordwise loading on the main wing as obtained from pressure distributions, and the character of the boundary layer flow was explored using oil-dot flow visualization and limited hot wire measurements. Mean flow properties of the vortex field have been measured, using a non-nulling 5-hole probe, at two stations 2-1/2 and 5 main wing spans downstream (17.5 and 35 chords respectively). Using a simple strain-gauged balance, the induced rolling moment on two trailing wings (of representative relative scale and aircraft geometry), which intercepted the main wing vortex system, was also measured. Maximum induced rolling moments as well as variation with lateral and vertical position was found.

El-Ramly, Z.

"INDUCED ROLLING MOMENT ON TRAILING WINGS"

AIAA Paper No. 1977-0663, Albuquerque, NM, June 1977

An experimental wind tunnel test program has been conducted to investigate possible scaling parameters for the prediction of the maximum induced rolling moment on a trailing wing. Detailed variation of the induced rolling moment on a following wing in the wake of a generating wing is measured for several lead/trailing combinations. With five wings used ten different combinations were possible covering the trailing/generating span ratio of 0.24 to 1.22. The wings include both straight and swept configurations and the aspect ratio varies between 4 and 8.5. The results show that the maximum induced rolling coefficient depends on the trailing wing aspect ratio and is proportional to both the lift coefficient of the generating aircraft divided by its aspect ratio and to the square root of generating/trailing span ratio. The effect of trailing wing incidence is also examined.

El-Ramly, Z.

"AIRCRAFT TRAILING VORTICES - A SURVEY OF THE PROBLEM"

ME/A 72-1, November 1972, Carleton University, Ottawa, Canada

A survey of the trailing vortices problem is presented. In this report only the work related to vortices shed from high aspect ratio straight or sweptback wings is considered. The survey covers the initial formation and roll-up of trailing vortices, their steady motion and decay, the stability of a trailing vortex pair, atmospheric and ground effects, and vortex breakdown. Experimental results, both full scale and subscale are also reviewed and a survey of the work describing the hazards to aircraft encountering a trailing vortex system is included.

El-Ramly, Z. and Rainbird, W. J.

"WIND TUNNEL MEASUREMENTS OF THE TRAILING VORTEX DEVELOPMENT BEHIND A SWEEPED BACK WING: EFFECT OF SIMULATED JET ENGINES ON THE FLOW FIELD"

AIAA Paper No. 1976-0063, January 1976, Washington, DC.

Measurements of the trailing vortex system behind a semi-span model of a 35-degree sweptback wing of aspect ratio 7 and taper ratio 1/3 have been made in a low-speed wind tunnel at a mean chord Reynolds number of about 500000. Measurements were made for the clean wing configuration (no engines mounted), with two simulated engines mounted but no air injection, and with cold high pressure air injection simulating the jet exhausts. Wing chordwise and spanwise loadings were obtained from pressure distributions. Some mean flow properties of the vortex field have been measured at two stations 2.5 and 5 wing spans downstream using a non-nulling 5-hole probe and a single pitot pressure tube. An overall measure of the vortex field was also obtained by measuring the induced rolling moment on a trailing wing that intercepted the main wing vortex system. Mounting of the two engines on the wing lower surface at representative spanwise locations, but with no exhaust jet simulation, did not greatly affect the rolled-up part of the flow field. However, the still unrolled connecting shear layer was considerably distorted and seemed to be spiraling around the vortex core at a slower rate when compared to the clean wing case. The measured maximum induced rolling moment

on the trailing wing is not significantly changed and is consistent with the observed changes in main wing loading and in the vortex core. With the addition of air injection through the simulated engines no appreciable change in induced rolling moment was measured. The injection has however resulted in small changes in the vortex core position and in the position of the spiraling shear layer relative to it.

"EFFECT OF WING-MOUNTED DEVICES ON THE TRAILING VORTEX SYSTEM IN THE NEAR FIELD"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 194-206

The paper examines the results of an extensive wind tunnel test program aimed at evaluating the effect of several different devices mounted on a wing on the near field trailing vortex system. The devices used include different wing tip modifications, several spoilers, simulated flap-track fairings, as well as two simulated engines with and without air injection. Only practical tip modifications and spoilers have been incorporated, i.e., only those that appear to be structurally possible with reasonable drag penalties. The devices have been tried first individually and then in combination to see if the reduction in rolling moment is cumulative. Assessment of the effectiveness of the devices, in reducing vortex hazard, is measured as a reduction in the maximum induced rolling-moment coefficient on a following wing of fixed span ratio of 0.24, representative of a light aircraft. All devices tested have resulted in decreases of the vortex hazard. However, no single device by itself produced a substantial decrease in maximum induced rolling moment.

El-Ramly, Z. and Rainbird, W. J.

"FLOW SURVEY OF THE VORTEX WAKE BEHIND WINGS"

Journal of Aircraft, Vol. 14, No. 11, November 1977, pp. 1102-1108

Flow-field surveys of the wake behind three different wings have been carried out in a low-speed wind tunnel. The mean flow properties have been measured using a small non-nulling five-hole probe. The results include the three mean velocity components, complete definition of the viscous wake, and detailed loading on one of the wings. The three components of vorticity were calculated and the vortical wake completely defined. It was found that the vortical wake always is contained within the viscous wake (region of total pressure loss). The vortex system is never fully rolled up, in the traditional sense, within the reasonably large downstream distance tested of 13 wing spans. The overall lift coefficient calculated from the distribution of streamwise component of vorticity is found to be smaller (87-100%) than that measured directly on the wing. The total circulation accounted for, at any streamwise station, decreases slightly with downstream distance. Comparison was made between the measured tangential velocity profiles and circulation distribution and those calculated using Betz theory, based on measured spanwise loading. Agreement is reasonable over a radius more or less equal to that of the vortex viscous core ($<0.25 b/2$). Outside of this region, the Betz model assumes

that roll-up is complete when, in fact, it is not. Agreement is also poor very near the vortex center because of the strong viscous effects there.

"COMPUTER-CONTROLLED SYSTEM FOR THE INVESTIGATION OF THE FLOW BEHIND WINGS"

Journal of Aircraft, Vol. 14, No. 7, July 1977, pp. 668-674

A completely computer-controlled wind-tunnel test facility for measurements of the vortical flow field behind a lifting swept-back wing is described. The vortex generator model is a pressure-plotted root-mounted half-wing. Flow field measurements were made using a pre-calibrated non-nulling blunted conical five-hole probe. The program developed can calculate and plot, on-line, the three components of velocity and vorticity, the total pressure loss coefficient, and the circulation distribution. As a result of these automated flow field measurements, it was possible to account for almost all the vorticity shed from the wing.

El-Ramly, Z. and Rainbird, W. J.

"EFFECT OF SIMULATED JET ENGINES ON THE FLOWFIELD BEHIND A SWEPT-BACK WING"

Journal of Aircraft, Vol. 14, No. 4, April 1977, pp. 343-349

Measurements of the vortex behind a swept-back wing have been made in a low-speed wing tunnel. Results have been taken with a clean wing, with engines mounted in representative positions, and with and without jet exhaust simulation. Only cruising flight conditions are simulated. Loading on the wing has been obtained from pressure distribution measurements. Flow field properties and the rolling moment on a trailing wing have been measured at 2-1/2 and 5 wing spans downstream. The concentrated tip vortex structure is essentially unaffected by the engines but the remaining shear layers are considerably distorted by the pylon-nacelles. The maximum induced rolling moment on the trailing wing is only slightly reduced by the present engine installation or the simulated jet exhaust.

El-Ramly, Z., Rainbird, W. J. and Earl, D. G.

"WIND TUNNEL MEASUREMENTS OF ROLLING MOMENT IN A SWEPT-WING VORTEX WAKE"

Journal of Aircraft, Vol. 13, No. 12, December 1976, pp. 962-967

Some measurement of the trailing vortex system behind a 350 sweptback, tapered wing have been made in a low-speed tunnel at a chord Reynolds number of 0.5×10^6 . Detailed wing loading was obtained from pressure distributions. Mean flow properties have been measured, using a non-nulling 5-hole probe, at two stations: 2-1/2 and 5 main wing spans downstream. Induced rolling moment on two trailing wings, which intercepted the main wing vortex system was also measured. Judged by the circulation around the core, the shear layers had not fully rolled up at the 2-1/2 station. Also, no

further appreciable roll-up occurred at the 5b station. Furthermore, there was very little difference between the induced rolling moments measured at the two stations.

"EVOLUTION OF NACA23012 WAKE VORTICES STRUCTURE USING PIV"

Journal of Aerospace Engineering, Vol. 25, Issue 1, January 2012, pp. 10-20.

The formation and development of a wing-tip vortex in a near and extended near field were studied experimentally. A swept-back tapered wing with a NACA230112 cross-section was used as a vortex generator. Particle image velocimetry (PIV) as a whole field velocity measurement technique was used in a low-speed wind tunnel to measure and characterize the wing-tip vortex. Wake structures at successive downstream planes crosswise to the axis of the wake vortices were evaluated in internal and external core radius, maximum tangential velocities, vorticity, and circulation distributions. The effect of angle of attack on vortex parameters was examined at one downstream location. Internal core radius and circulation distributions were nearly constant along the downstream direction. A direct dependence of the circulation and tangential velocity distribution on the angle of attack was evident. The centers of the wing-tip vortices scatter in a circle of radius nearly equal to 1 percent of the mean wing chord. Meandering amplitudes showed no direct dependence on the vortex strength but increase along the downstream direction. Good agreement was obtained between the theoretical exponential vortex model and the measured data. Computed induced rolling moment coefficients generated by the wing are within the full roll control capability of a follower aircraft.

Elsayed, O. A., Asrar, W., Omar, A. A. and Kwon, K.

"INFLUENCE OF DIFFERENTIAL SPOILER SETTINGS ON THE WAKE VORTEX CHARACTERIZATION AND ALLEVIATION"

Journal of Aircraft, Vol. 47, No. 5, Sept.-Oct. 2010, pp. 1728-1738.

Experimental investigations using particle image velocimetry technique have been carried out for the evolution of the differential spoiler setting capabilities in modifying the span-wise wing load and further reduce the wake vortex hazard. The aircraft half model (at high lift configuration) was investigated for two differential spoiler settings. Results reveal a noticeable inboard shift of spanwise wing loading. Implementation of a differential spoiler setting results in a substantial redistribution of the flap tip vortex circulation with an increase in the diameter of the merged vortex by a factor of up to 2.72 relative to the undisturbed flap tip vortex. Inspection of the cross-stream distribution of axial vorticity shows a reduction by a factor of up to 2.33 in the peak vorticity value. A 44 percent decrease of the maximum crossflow velocity relative to the undisturbed flap tip vortex crossflow velocity was recorded for the case of deployed spoilers. Finally, assessment of the differential spoiler capabilities as a wake vortex attenuation device reveals that, while position of the maximum induced rolling moments in the flap tip area is little influenced by the differential spoiler setting, the maximum induced rolling

moments in the flap tip area is little influenced by the differential spoiler setting, the maximum induced rolling moment coefficient was reduced to nearly one third of the undisturbed flap tip vortex value.

"EXPERIMENTAL INVESTIGATION OF PLAIN- AND FLAPPED-WING TIP VORTICES"

J. Aircraft, Vol. 46, No. 1, Jan.-Feb. 2009, pp. 254-262

Particle image velocimetry was used in a low-speed wind tunnel to investigate and characterize wing tip vortex structure. A rectangular wing of a subsonic wall interference model was used as a vortex generator in two different configurations: (1) plain wing and (2) flapped wing with the trailing-edge flap extended at 20 degrees. Vortex flow quantities and their dependence on angle of attack at Reynolds numbers of 32800 and 43800 were evaluated. Assessment of measured data reveals that the peak values of tangential velocities, vortex strength, and vorticities are directly proportional to the angle of attack. The vortex core radius grows slowly as the angle of attack is increased. Both plain and flapped configurations showed similar trends. The peak tangential velocities and circulation almost doubled when the flapped configuration was used instead of the plain wing.

Elsayed, O. A., Kwon, K., Asrar, W. and Omar, A. A.

"INDUCED ROLLING MOMENT FOR NACA4412 PLAIN AND FLAPPED WING"

Aircraft Engineering and Aerospace Technology: An International Journal, Vol. 82, No. 1, 2010, pp. 23-31.

This paper describes the detailed variation of the induced rolling moment generated by a plain and flapped NACA4412 wing on a follower aircraft wing derived from a particle image velocimetry velocity field measurement. A rectangular wing of a subsonic wall interference model is used as a vortex generator in two different configurations: plane wing of NACA4412 cross-section profile; and flapped wing with trailing edge flap of NACA0012 cross-section profile extended at 20 degrees. Results obtained showed that the maximum induced rolling moment coefficient depends on the strength of the vortex produced by the generating aircraft wing and increases linearly with the increment of the angle of attack. The paper provides an insight on the effects of different angles of attack for plain and flapped wings on the induced rolling moment coefficient and therefore, the hazard imposed on the following aircraft can be estimated.

"EFFECT OF DIFFERENTIAL SPOILER SETTINGS ON THE WAKE VORTICES OF A WING AT HIGH-LIFT CONFIGURATION"

Aerospace Science and Technology, Vol. 15, 2011, pp. 555-566.

An experimental investigation has been carried out to evaluate the capabilities of differential spoiler setting (DSS) in modifying the wingspan loading. The particle image velocimetry (PIV) technique was used in a low-speed wind tunnel facility to measure wake velocities at four locations downstream of the half model in the near wake field. The model was investigated at a high lift configuration (called base-line configuration) and at two different DDSs believed to modify the baseline wingspan loading. Those settings were obtained by deflecting spoiler number 1 at 10 degrees (outboard loading case 1) and spoiler numbers 2, 3, 4, 5 and 6 at 5 degrees (outboard loading case 2). Results reveal that, introducing a highly turbulent oscillatory wake due to a spoiler in the flow field increases the flap tip vortex meandering amplitude by up to 2.17 times the flap tip vortex core radius value. This result emphasizes the importance of using spatially corrected data in extracting mean vortex parameters values. Moreover, meandering can lead to accelerated vortex breakdown especially when the vortex motion intensifies further downstream contributing favorably to wake vortex alleviation. Integration of the streamwise vorticity shows a mild outboard wing loading shift for outboard loading case 1, while the outboard loading case 2 leads to a reduction in the span-wise circulation with no change in the spanwise load distribution.

Elsenaar, A.

"VORTEX FORMATION AND FLOW SEPARATION: THE BEAUTY AND THE BEAST IN AERODYNAMICS"

NLR-TP-2000-421, August 2000, National Aerospace Laboratory, Amsterdam, The Netherlands.

Flow separation and vorticity generation are closely connected. When the flow leaves the trailing edge of a wing, a vorticity layer is formed, directly related to the lift of the wing and carrying streamwise vorticity. Boundary layers, in which the viscous flow very close to the wing surface is confined, carry vorticity in crosswise direction, perpendicular to the local flow direction at the boundary layer edge. Streamwise and crosswise vorticity are carried downstream in the wake. When boundary layers separate from the surface ahead of the trailing edge, the flow characteristics are essentially similar though more complex. Vortex sheet separations of a more conical nature can be found on the upper surface of delta wing configurations or slender bodies of revolution. They can be regarded as a skeleton of vortex lines again with a strength related to lift and induced drag. These separations might be induced by sharp edges, as is the case for the sharp-edged delta wing, or on smooth bodies, by boundary layer separation. Vortex sheet separations are not confined to conical geometries but can be found in all kinds of flow. Other separations on the wing will have a more bubble-like nature, confined to a region close to the surface, and contributing to the viscous drag. The distinction between streamwise and crosswise vorticity is preserved in the development of the wake downstream resulting finally, most often, in a pair of counter-rotating vortices that are of great concern from a safety point of view for landing aircraft. A simplified relation based on lift and induced drag can be used to estimate the strength of the vortices. They persist very long until the vortex pair breaks up through a basic instability very far downstream. A review is presented of these various types of separations and related vortex development, partly based on concepts as can be found in the literature. This is illustrated with practical examples of separations both from experiments and from CFD calculations.

Elsenaar, A.

"OPTIMIZATION OF THE (INVISCID) UPPER LIMIT OF THE ROLLING MOMENT INDUCED BY A VORTEX PAIR"

Conference on Capacity and Wake Vortices, Imperial College of Science, Technology and Medicine, London, England, September 2001

The vortex center is assumed to be surrounded by a viscous and a vorticity core. Outside the vorticity core the flow is irrotational. All vorticity (for a fully rolled-up vortex) is thought to be concentrated within the vorticity core. For the high Reynolds numbers of actual aircraft, the viscosity core is so small that it can be neglected: the vortex flow field is basically inviscid. The (vorticity) core radius follows then directly from the induced drag relation when a family of velocity distributions is assumed to apply inside the vorticity core. The velocity distributions that can be calculated from these assumptions can be regarded as a high Reynolds number upper limit for the vortex flow field. There is some experimental evidence that this upper limit is approached when roll-up is complete and in the absence of vortex decay (no external turbulence). This velocity distribution can subsequently be used to calculate the induced rolling moment for a follower A/C that flies right into the vortex center. The two parameters, vortex distance s and induced drag factor e can (within limits) be selected such that an optimum induced rolling moment results. Some examples will be given. The analysis suggests that the best compromise from the point of view of separation distances is obtained for an inboard loaded wing with a low induced drag. In practice decay due to external turbulence cannot be neglected. Other limitations, also from the point of view of vortex development (like multiple vortices) restrict the load distributions that can actually be achieved. But the present model might give some feeling for the possibilities to reduce wake vortex strength by design.

Elsenaar, A.

"VORTEX FORMATION AND FLOW SEPARATION: THE BEAUTY AND THE BEAST IN AERODYNAMICS"

Aeronautical Journal, December 2000, pp. 615-633

I have tried in this lecture to present a phenomenological view of separation and vortex formation. I have shown some examples of the complicated flow field on wings and slender bodies, a flow field that can be split into a field with streamwise and cross wise vorticity as clearly noticeable behind the wing. From there on this complex flow field simplifies, resulting in one or sometimes two vortex pairs. And this simplified flow field finally breaks up through vortex decay or instabilities into chaotic motion at smaller scales.

Elsenaar, B.

"COMPUTER SIMULATIONS OF AIRCRAFT WAKE VORTICES: GOOD ENOUGH TO QUANTIFY SAFETY?"

Proceedings ECCOMAS Computational Fluid Dynamics Conference, September 2006, Egmond aan Zee, The Netherlands.

To see if capacity can be increased without loss of safety, computer simulations are made of the air traffic situation, the generation and the decay of wake vortices and the flight mechanical effects on the follower aircraft when a vortex is encountered. The aim is to quantify both the capacity change (e.g. expressed as the number of landings per hour) and the safety (e.g. expressed as a target level of safety). The prediction of the weather dependent decay of wake vortices is a critical issue here. Large eddy simulations that include the specific features of the weather can describe the decay of vortices in a physically correct way. These calculations can be imbedded in a probabilistic safety assessment to calculate with Monte Carlo simulations the level of safety.

Elsenaar, B., Sulejmanovic, B. and Lentjes, V.

"THE VORTEX LIFE TIME FROM THE MEMPHIS DATA AND SOME IMPLICATIONS"

Second Workshop WakeNet2-Europe, 'Capacity Gains as Function of Weather and Weather Prediction Capabilities', Langen, November 2004.

The ability to predict the wake vortex position and strength as a function of the weather conditions is of paramount importance for any (probabilistic) safety analysis or wake vortex advisory system. Advection by wind and the decay of the vortex strength up till its final stage as a broken-up vortex, are the critical processes here. The talk will focus on the question how the time that the vortex breaks-up (the vortex demise time, VDT) can be correlated with weather conditions. The analysis is restricted to the 'out of ground effect' data collected at Memphis. It is widely accepted that the VDT, when made dimensionless with the corresponding length (distance between the two vortices) and velocity (descent speed of the vortex pair), can be expressed as a function of the atmospheric turbulence, preferably the eddy dissipation rate (EDR). Moreover, theoretical work has indicated strong effects of stratification. The available experimental evidence shows considerable scatter that makes it difficult to validate these relations for realistic weather conditions. EDR is usually measured near the ground (typically at 40 m) and the available measurements indicate very large fluctuations with time. One can argue if these values are sufficiently representative for an indication of the VDT at greater heights. To clarify this, the group of Thomas Gerz (DLR) has defined specific weather classes (so called Wake Vortex Behavior Classes) to correlate the weather conditions with the more readily available measurements of wind shear S and stratification N (expressed as the Brunt Vaisala frequency). It is only a small step further to treat S and N as truly independent variables, what makes sense from a physical point of view: the effect of external turbulence and of stratification are distinct physical mechanisms. It will be shown that the correlation can be improved in this way. The question will finally be raised how relevant these findings are if one wants to increase capacity without affecting safety e.g. by using a Wake Vortex Advisory System. This will of course depend on the local weather conditions (in a statistical sense) but an order of magnitude analysis can be made both for arriving and departing aircraft for weather statistics as follows from the Memphis recordings. The study is limited in the sense that only wakes out of ground effects are considered, whereas for landing situation the behavior near the ground is the most critical phase. However, for departing aircraft, where the departing tracks are distributed over a much wider area, the VDT is expected to be an important parameter. In future work ground effects are to be included as well as an application to other data sets, notably with a larger variety in wingspan to better assess the usual assumptions to non-dimensionalize the data.

"PRELIMINARY FINDINGS OF IN SITU EDR RESEARCH"

AMS Fourth Aviation, Range, and Aerospace Meteorology Special Symposium, February 2014, Atlanta, GA.

The preliminary findings of the project found that all existing in situ EDR implementations calculate mean EDR accurately and consistently for homogeneous turbulence. However, all existing in situ EDR implementations employ different data sampling window lengths, parameter settings, and methodologies, yielding inconsistent peak EDR values in very sudden intense turbulence. To reduce these inconsistencies between implementations, the project is performing a sensitivity analysis as continuing research with the goal of reducing inconsistencies across algorithms. The findings of the sensitivity analysis, along with a more in-depth narrative of the project's discovery, process, findings, and performance recommendations can be found in the project's FAA EDR Standards Report, scheduled for delivery to the FAA in July, 2014.

Emanuel, M., Sherry, J., Catapano, S., Cornman, L. and Robinson, P.

"IN SITU PERFORMANCE STANDARD FOR EDDY DISSIPATION RATE"

AMS 16th Conf. of Aviation, Range, and Aerospace Meteorology, 2013, Austin, TX.

The EDR Standards Project has been initiated by the FAA to perform the research required to develop performance standard recommendations for in situ EDR. Equally essential will be the project's recommendations for in situ EDR data encoding and label definitions. The project is leveraging information learned through the EDR literature search and collaboration outreach with key stakeholders. The knowledge gained will assist the team in development of a standardization process, which provides the artifacts required to support recommendations for in situ EDR performance standards. The standardization of in situ EDR will support the greater aviation community through the increase in fidelity and accuracy of in situ turbulence information. EDR performance standards will facilitate greater real time turbulence situational awareness and drive enhancements in safety, capacity, and operational efficiencies.

"ATMOSPHERIC BOUNDARY-LAYER STRUCTURE FROM SIMULTANEOUS SODAR, RASS, AND CEILOMETER MEASUREMENTS"

Atmospheric Environment, Vol. 38, 2004, pp. 273-286.

A comparison of the determination of boundary-layer structures by a SODAR, by a RASS, and by a ceilometer is presented. One important structure is the mixing-layer height (MLH). The comparison is

focused on 3 days with an evolution of a convective boundary layer over a larger city in Germany. The three instruments give information that partly agree and partly complement each other. By this, a picture of the diurnal evolution of the vertical structure of this urban boundary layer is presented. The ceilometer gives information on the aerosol content of the air and the RASS provides a direct measurement of the vertical temperature distribution in the boundary layer. The RASS and the ceilometer add information on the moisture structure of the boundary layer that is not detected by the SODAR. On the other hand, this comparison validates known techniques by which the MLH is derived from SODAR data. Especially the temperature information from the RASS agrees well with lifted inversions derived from the analysis of the SODAR data. The ceilometer, being the smallest instrument, has a potential to be used in future MLH studies.

"EXPLORING THE WAKES OF LARGE OFFSHORE WIND FARMS"

The Science of Making Torque from Wind (TORQUE 2016), published in IOP Journal of Physics: Conference Series, Vol. 753, 2016, pp. 092014-1 to 092014-11.

Offshore meteorological characteristics set specific conditions for the operation of offshore wind farms. One specific feature is low turbulence intensity which on the one hand reduces loads on turbines but on the other hand is the reason for much longer turbine and farm wakes than over land. The German Government is presently funding a research project called WIPAFF (WInd PARK Far Field) which heads for the analysis of properties and impacts of offshore wind park far fields. The focus is on the analysis of wind farm wakes, their interaction among each other and their regional climate impact. This is done by in-situ, extensive aircraft and satellite measurements and by operating meso-scale wind field models and an analytical wind farm model.

Emmer, D. S.

"EXPERIMENTAL STUDIES OF TRANSONIC AIRFOIL TRAILING EDGE AND WAKE FLOWFIELD PROPERTIES"

Ph.D. Thesis, 1984, Ohio State University, Columbus, OH

An experimental investigation of several of the trailing edge and wake turbulence properties for a NACA 84A010 airfoil section was completed. The experiment was conducted at The Ohio State University Aeronautical and Astronautical Research Laboratory in the 6-inch x 22 inch transonic flow facility. For both angles of attack, the turbulence intensities and turbulence kinetic energy were observed to decay in the streamwise direction. In the fair wake, the turbulence intensities were nearly isotropic for the non-lifting case. For the two-degree case, the horizontal component of the turbulence intensity was observed to be substantially higher than the vertical component. For each survey, the data demonstrated excellent repeatability with a high degree of spatial resolution. The results of this research should provide guidance for the development, verification, and improvement of turbulence modeling.

Engel, M. A. and Devenport, W. J.

"A WIND TUNNEL INVESTIGATION OF A WING-TIP TRAILING VORTEX"

VPI-AOE-218, May 1995, Virginia Polytechnic Inst. and State Univ., Blacksburg, VA

The 3'x2' Subsonic Wind Tunnel was used to study a wing-tip trailing vortex during its development at the wingtip and at 10 chord lengths downstream. The vortex was found to be well developed by 10 chord lengths. Helium bubble flow-visualization was used to study the development of the vortex in the near-tip regions. Hot wire anemometry was used to study the vortex at 10 chord lengths. Two vortices were found in the tip-flow studies, a primary vortex formed on the suction side surface of the wingtip and a weaker secondary vortex formed on the endcap. The primary vortex lifts from the surface of the wingtip as it proceeds along the chord. The vortex core radius, peak tangential velocity, and core circulation increase with increasing angle of attack. The tangential velocity profiles and axial vorticity profiles indicate the development of inner and outer core regions by 5.0 degrees angle of attack. The regions become increasingly differentiated with increasing angle of attack. The inner and outer regions appear to be associated with the primary and secondary tip vortices, respectively.

"FIRST RESULTS OF MEASUREMENTS WITH A NEWLY-DESIGNED PHASED-ARRAY SODAR WITH RASS"

Meteorology and Atmospheric Physics, Vol. 71, 1999, pp. 61-68.

At a special measuring site for boundary-layer studies as well as land-surface processes the Meteorological Observatory Lindenberg of the German Weather Service (DWD) has recently put into operation a newly-designed phased-array SODAR/RASS, which has been developed by METEK on behalf of the DWD. This system provides the vertical profiles of the three-dimensional wind vector in the boundary layer on an operational basis and is furthermore suitable for getting information on the profile of virtual temperature up to about 400 m in height based on the addition of RASS components. The following paper describes both the technique of this SODAR/RASS and the various modes of operation as well as the different options in managing the system. First evaluations on the data availability concerning the maximum height coverage will give an impression on the system's capabilities. Finally, the accuracy of the derived profiles of winds and temperature will be investigated by means of comparisons of the SODAR/RASS data with measurements of a six-sonde tethered-balloon system as well as meteorological data of a 99 m tower in the vicinity of the system.

"EXAMINATION OF MODE S EHS WIND OBSERVATIONS FOR USE IN WAKE VORTEX MITIGATION APPLICATIONS"

AIAA Paper 2018-3353, June 2018, Atlanta, GA.

Air transport continues to be an important part of our transportation system. As demand grows, increasing throughput becomes a challenge, driven partly by the need to maintain a safe distance between planes in order to mitigate the effects of wakes generated by leading aircraft. Wake vortex trajectories and strength are impacted by the winds, a fact which can be leveraged to safely decrease spacing between aircraft and thereby increase throughput when wind characteristics reduce the likelihood of wake encounters. Procedures to reduce spacing require reliable forecasts of wind to ensure that winds remain suitable for the entire duration the procedure. The major challenges these forecasts face are a lack of real-time wind information in the region of interest and lack of high fidelity, high-resolution observations to provide a validation source for development. Aircraft systems that report wind conditions are a logical solution to the problem and are routinely available through the Meteorological Data Collection and Reporting System (MDCRS). Unfortunately, in many regions of interest, the low spatial and temporal resolution and high latency of these reports limit their utility for wind forecasts and/or validation sources for wake applications. Aircraft derived Observations (AdOs) of meteorological conditions from Mode S Enhanced Surveillance (EHS) data have the advantages of other aircraft reports but also have much higher spatial and temporal resolution and lower latency compared to MDCRS. Therefore, they are under consideration to address both wind forecast challenges. Toward this end, simultaneous LIDAR and Mode S EHS derived observations were collected over an extended period in the proximity to Boston Logan International Airport (KBOS). Archived MDCRS data were also available for comparison. This paper presents a comparison of these observation sets that will speak to the applicability of the Mode S EHS data as a validation source. Further, an examination will be made of how current wind forecasts for use in wake vortex mitigation systems might be improved by access to these data. While in this paper we leverage the growing equipage of Mode S EHS technologies to gain access to AdOs and begin to understand their potential utility in current and future applications, results are applicable to other AdO sources which may be available in the future.

"DEFINING APPROPRIATE INTER-AIRCRAFT SEPARATION REQUIREMENTS"

AIAA Paper No. 2004-6203, Chicago, IL, September 2004

To maintain minimum separation standards between two aircraft, proper avoidance maneuvers must be initiated before their relative separation reaches the minimum separation due to aircraft dynamics, controller and pilot response delays, and other delays. This paper presents the concept and a systematic procedure for the calculation of required action thresholds, which is the time or distance when the conflict resolution process must begin to maintain minimum separation requirements. It sets an upper boundary or latest alert time for the conflict detection and resolution process. In this paper, 5 main segments in the process of conflict resolution are identified and modeled: state information acquisition, comprehension and decision, communication, pilot response, and aircraft maneuver. Then, the models of the five segments are brought together in a simulation where a robust aircraft maneuver time can be calculated through extensive simulations. The models and simulation are then used to determine the required action threshold. Three example scenarios are studied to illustrate the determinations of appropriate required action thresholds.

Ennis, R. L. and Zhao, Y. J.

"A FORMAL APPROACH TO THE ANALYSIS OF AIRCRAFT PROTECTED ZONE"

Air Traffic Control Quarterly, Vol. 12, No. 1, 2004, pp. 75-102

The protected zone represents a region around a given aircraft that no other aircraft should penetrate for the safety of both aircraft, and defines the minimum separation requirements. In this paper, three major components of the protected zone and their interplays are identified: a vortex region, a safety buffer region, and a state-uncertainty region. A systematic procedure is devised for the analysis of the state-uncertainty region. In particular, models of trajectory controls are developed that can be used to represent different modes of pilot and/or autopilot controls, such as path feedback and non-path feedback. Composite protected zones under various conditions are estimated, and effective ways to reduce sizes of protected zones for advanced air traffic management are examined.

Eppler, R.

"INDUCED DRAG AND WINGLETS"

Technical Soaring, Vol. XX, No. 2, 1996, pp. 89-96.

A simple method has been presented which allows consideration of an important second order term in the theory of induced drag. This term is the induced lift, which probably is the most important effect of the wake rollup. The new theory explains the difference between positive and negative dihedral which has been demonstrated by model experiments. Many more results can be expected from this theory.

Epps, B. P.

"REVIEW OF VORTEX IDENTIFICATION METHODS"

AIAA Paper 2017-0989, January 2017, Grapevine, TX.

While vortex identification is a problem of broad interest in fluid mechanics, the fluid mechanics community has not yet converged on a universally-accepted definition of a vortex. The goal of this paper is to provide a comprehensive review of the state of the art, to bring the community one step closer to answering the deceptively complicated question: What is a vortex.

Epstein, R. J. and Bliss, D. B.

"FREE VORTEX CALCULATIONS USING ANALYTIC/NUMERICAL MATCHING WITH SOLUTION PYRAMIDING"

AIAA Journal, Vol. 33, No. 5, May 1995, pp. 894-903

The motion of a free vortex system is predicted using a novel method called analytical/numerical matching (ANM). Analytical/numerical matching is a hybrid mathematical and numerical technique that results in a new problem formulation with high accuracy and increased computational efficiency. The approach capitalizes on the disparity of characteristic length scales that occur in many fluid dynamics problems. Accordingly, many problems can be decomposed into two distinct problems involving a local high-resolution near field, often solvable analytically, and a global, low-resolution far field, solved numerically. The ANM technique breaks the free vortex problem into these local and global problems, each of which being easier and more efficient to solve than the traditional problem formulation. In addition, the ANM decomposition can be repeated to form a hierarchy of nested problems of increasing resolution using a method called pyramiding. The ANM method with pyramiding, called ANM/P, is studied to assess its accuracy and computational efficiency for two-dimensional and three-dimensional vortex dynamics problems. In calculations of vortex sheet rollup and vortex ring motion and interactions, this method was found to be relatively easy to implement and exhibited reductions in computational time from a factor of three to more than an order of magnitude.

Epstein, R. J. and Bliss, D. B.

"WAKE GENERATION AND COMPRESSIBILITY EFFECTS IN UNSTEADY AERODYNAMICS"

AIAA Journal, Vol. 37, No. 3, March 1999, pp. 393-396

The necessity for modeling unsteady compressible wake effects in compressible unsteady aerodynamics is addressed. The role of compressibility during the initial stages of wake formation is determined. It is shown that a compact portion of the wake, that which is closest to the trailing edge, is most important regarding wake compressibility for many subsonic flows. A simple approximation is derived that determines the relative magnitude of the compressible wake length that must be used in a calculation.

"EXPERIMENTAL INVESTIGATION OF THE FLOWFIELD ABOUT AN UNSWEPT AFTERBODY"

Journal of Aircraft, Vol. 31, No. 6, November-December 1994, pp. 1281-1290.

In general, the flow field about the aft portion of an aircraft fuselage employing an un-swept afterbody is complex, and can have a detailed vortex structure. Directional pressure probe measurements show that the afterbody wake evolution is weakly dependent on the Reynolds number. Pressure taps are used to investigate the effect of base slant on the base pressure distribution. The base pressure distribution is found to increase along the upswept ramp in the freestream direction. Using oil flow visualizations general conclusions are drawn about the surface flow topology. Two distinct regions of flow separation are identified. An analytical model of the crossflow wake structure is developed from the experimental data. This model allows for conclusions to be drawn about the crossflow vortex structure and provides simple analytical expressions for the vorticity and swirl velocity distributions in the crossflow plane.

"WATER FACILITIES IN RETROSPECT AND PROSPECT -- AN ILLUMINATING TOOL FOR VEHICLE DESIGN"

Aerodynamic and Related Hydrodynamic Studies Using Water Facilities, AGARD-CP-413, Oct. 1986, pp. 1-1 to 1-28.

Water facilities play a fundamental role in the design of air, ground, and marine vehicles by providing a qualitative, and sometimes quantitative, description of complex flow phenomena. Water tunnels, channels, and tow tanks used as flow-diagnostic tools have experienced a renaissance in recent years in response to the increased complexity of designs suitable for advanced technology vehicles. These vehicles are frequently characterized by large regions of steady and unsteady three-dimensional flow separation and ensuing vortical flows. The visualization and interpretation of the complicated fluid motions about isolated vehicle components and complex configurations in a time- and cost-effective manner in hydrodynamic test facilities is a key element in the development of flow control concepts and, hence, improved vehicle designs. This paper presents a historical perspective of the role of water facilities in the vehicle design process. The application of water facilities to specific aerodynamic and hydrodynamic flow problems is discussed, and the strengths and limitations of these important experimental tools are emphasized.

Eriksson, S., Svard, M. and Nordstrom, J.

"SIMULATIONS OF GROUND EFFECTS ON WAKE VORTICES AT RUNWAYS"

Center of Turbulence Research, Annual Research Briefs, 2007, pp. 379-388.

In this paper the interaction between two counter-rotating vortices is examined, and the performance of a newly developed finite difference code is discussed. The Reynolds numbers considered are low to medium, and the flow is compressible. Most of the computations are performed in a two- dimensional domain, with different grid sizes, Reynolds number and order of accuracy of the scheme. Finally, a three-dimensional computation is made to examine the relevance of the two dimensional model.

Eriksson, S., Svard, M. and Nordstrom, J.

"SIMULATIONS OF GROUND EFFECTS ON WAKE VORTICES AT RUNWAYS"

Report 2007-019, June 2007, Uppsala University, Uppsala, Sweden

In this paper the interaction between two counter-rotating vortices is examined, and the performance of a newly developed finite difference code is discussed. The Reynolds numbers considered are low to medium, and the flow is compressible. Most of the computations are performed in a two- dimensional domain, with different grid sizes, Reynolds number and order of accuracy of the scheme. Finally, a three-dimensional computation is made to examine the relevance of the two dimensional model.

"INTERACTION OF A SHOCK WITH A LONGITUDINAL VORTEX"

ICASE Report No. 96-31 (NASA CR-198332), May 1996, Institute for Computer Applications in Science and Engineering, NASA Langley Research Center, Hampton, VA.

In this paper we study the shock/longitudinal vortex interaction problem in axisymmetric geometry. Linearized analysis for small vortex strength is performed, and compared with results from a high order axisymmetric shock-fitted Euler solution obtained for this purpose. It is confirmed that for weak vortices, predictions from linear theory agree well with results from nonlinear numerical simulations at the shock location. To handle very strong longitudinal vortices, which may ultimately break the shock, we use an axisymmetric high order essentially non-oscillatory shock capturing scheme. Comparison of shock-captured and shock-fitted results are performed in their regions of common validity. We also study the vortex breakdown as a function of Mach number ranging from 1.3 to 10, thus extending the range of existing results. For vortex strengths above a critical value, a triple point forms on the shock, and a secondary shock forms to provide the necessary deceleration so that the fluid velocity can adjust to downstream conditions at the shock.

"FAR-FIELD DRAG EXTRACTION FROM NUMERICAL SOLUTIONS AND WAKE SURVEYS"

7th ONERA-DLR Aerospace Symposium, Toulouse, France, October 4-6, 2006

This paper focuses on ONERA drag extraction methods from numerical simulations and flow field wake surveys. A new far-field drag extraction software (FFD72) allows, thanks to its face-based data structure, to extract drag as well from structured (elsA cell-centered) as from unstructured (TAU cell-vertex) RANS solutions. By field analysis, this approach provides a drag breakdown into its physical components i.e. viscous drag, wave drag and lift-induced drag. To carry out such a drag breakdown from wind tunnel tests another method has been developed and allows the evaluation of these physical components from flow field wake measurements.

Estes, M. J.

"DETECTION OF HIGH ALTITUDE AIRCRAFT WAKE VORTICES USING INFRARED DOPPLER LIDAR: AN ASSESSMENT"

AFIT/GEO/ENP/90D-1 [MS Thesis], December 1990, Air Force Inst. of Tech., Wright-Patterson AFB, OH

The feasibility is studied of air-to-air detection of high-altitude aircraft wake vortices at long ranges using infrared Doppler lidar. The purpose of this technique is to detect otherwise stealthy aircraft. Three laser wavelengths were analyzed: 1.064, 2.091, and 9.115 microns. Analysis revealed that the spectral width of the return signal from an aircraft wake presented a good signature for detection. Based on the analysis, a minimum signal-to-noise ratio of 0 dB was established. Detection performance was then analyzed using signal-to-noise ratio calculations for backscatter by ambient atmospheric

aerosols, jet engine exhaust soot particles, and condensation trail ice particles. Results indicated that atmospheric aerosols alone were not sufficient for detection in clean atmospheric regions. Backscatter enhancement by soot particles did appear to be sufficient for detection out to 80 km. Enhancement by condensed ice particles in wake contrails provided detection well beyond 100 km in range. The shorter wavelength lidars did not perform as well as the 9.115-micron lidar due to degradations from shot noise, wavefront mismatch, refractive turbulence, and atmospheric extinction.

"WAKE TURBULENCE AVOIDANCE AUTOMATION: EVALUATION OF FEASIBILITY AND IMPACT"

IEEE/AIAA 30th Digital Avionic Systems Conference, Paper 6A6, October 2011, Seattle,WA.

Wake turbulence encounters are a significant concern to pilots flying in the National Airspace System. By increasing efficiency and capacity, there will be a corresponding reduction in required separations that exist in operations today. As operations are optimized and these separations are reduced, it is important that there is not an increase in wake encounter rates that would tend to limit the acceptance of the FAA's Next Generation Air Transportation System (NextGen). NextGen technology, however, may enable the community to provide better tools to pilots and controllers for avoiding wake, thereby bounding the wake encounter rate at no more than today's operationally acceptable level. In this paper, arrival and departure procedures that take advantage of Automatic Dependent Surveillance-Broadcast and Cockpit Display of Traffic Information technology in the cockpit are reviewed and their performance during a human-in-the-loop evaluation discussed.

Evans, J. E.

"GETTING TO OPERATIONAL DEPLOYMENT: LESSONS FROM TDWR AND ITWS"

Proceedings of the NASA First Wake Vortex Dynamic Spacing Workshop, NASA/CP-97-206235, edited by L. Credeur and R. Perry, NASA Langley Research Center, Hampton, VA, November 1997, pp. 520-532

Achieving an operationally useful reliable production system at major airports will be a significant challenge for the AVOSS developers. The FAA experience at developing fully automated aviation weather information systems such as TDWR and the Integrated Terminal Weather System (ITWS) is quite applicable given the many similarities between the systems. A key factor in the FAA aviation system developments has been the operational use of functional 'rapid prototypes' to clarify user needs, quantify and improve benefits, build operational users support and reduce the production system schedule, cost and risk. The AVOSS also needs to get entrained into the FAA acquisition process in the relatively near future if the potential benefits are to be achieved by 2005.

Evans, J. E. and Welch, J. D.

"ROLE OF FAA/NWS TERMINAL WEATHER SENSORS AND TERMINAL AIR TRAFFIC AUTOMATION IN PROVIDING A VORTEX ADVISORY SERVICE"

Proceedings of the Aircraft Wake Vortices Conf., DOT/FAA/SD-92/1.1, DOT Volpe National Transportation Systems Center, Cambridge, June 1992, pp. 24-1 - 24-22

Existing and planned FAA/NWS terminal weather sensors and weather information systems are expected to provide an adequate sensory basis for a useful wake vortex advisory service (WVAS). These meteorological sensors, which provide broad terminal area coverage, should make it possible to reliably estimate and forecast when wake vortex advection characteristics make it possible to reduce the spacings between aircraft on final approach. Effective operational use of such a weather adaptive WVAS would be very difficult without computerized scheduling and spacing aids for terminal air traffic controllers. The developmental Terminal Air Traffic Control Automation (TATCA) program will provide precisely the planning and spacing tools necessary to help controllers take advantage of wake vortex advisories and forecasts to improve terminal throughput and efficiency.

"WEATHER SENSING AND DATA FUSION TO IMPROVE SAFETY AND REDUCE DELAYS AT MAJOR WEST COAST AIRPORTS"

Project Report ATC-290, November 1999, Lincoln Laboratory, Lexington, MA.

The objective of this study was to analyze the weather sensing and data fusion required to improve safety and reduce delays at several west coast airports that are not currently scheduled to receive an Integrated Terminal Weather System (ITWS). This report considers the Los Angeles (LAX), San Francisco (SFO), Seattle (SEA) and Portland, OR (PDX) international airports. Several visits were made to the various ATC facilities to better understand their weather decision support operational needs. Analyses were made of an incident of lightning strikes to two aircraft at SEA in February 1999, and a prototype terminal winds product was developed for LAX that uses profilers as well as plane reports to update the National Weather Service (NWS) Rapid Update Cycle (RUC) winds estimates. We found that an augmented ITWS could potentially address concerns for triggered lightning strikes and vertical wind shear in winter storms at Portland and Seattle. An augmented ITWS terminal winds product (that uses wind profiler data in addition to the current ITWS sensors) could provide very large delay reductions for LAX and SFO during winter storms as a component of a wake vortex advisory system. This augmented product also could provide significant delay reduction benefits at SEA. The sensors required to obtain the projected benefits at SFO do not exist currently. Portland may warrant additional sensors to address the vertical wind shear problems, and LAX would require additional sensors for a wake vortex advisory system. We recommend near-term experimental measurements at PDX to determine the optimum sensor mix and that an operational evaluation of the prototype ITWS terminal winds product be carried out at LAX to determine if the current sensor mix can meet operational needs. Lightning strike data at SEA and PDX should be analyzed to determine if a proposed triggered lightning predicant is accurate.

Evans, P. F. and Hackett, J. E.

"NUMERICAL STUDIES OF THREE-DIMENSIONAL BREAKDOWN IN TRAILING VORTEX WAKES"

NASA CR-137888, June 1976, Lockheed-Georgia Co., Marietta, GA

Finite element, three-dimensional relaxation methods are used to calculate the development of vortex wakes behind aircraft for a considerable downstream distance. The inclusion of a self-induction term in the solution, dependent upon local curvature and vortex core radius, permits calculation of finite lifetimes for systems for which infinite life would be predicted two-dimensionally. The present report describes the associated computer program together with single-pair, twin-pair, and multiple-pair studies carried out using it. It is found, in single-pair studies, that there is a lower limit to the wavelengths at which the 'Crow'-type of instability can occur. Below this limit, self-induction effects cause the plane of the disturbance waves to rotate counter to the vortex direction. Self-induction in two dimensionally generated twin spiral waves causes an increase in axial length which becomes more marked with decreasing initial wavelength. The time taken for vortex convergence toward the center plane is correspondingly increased. The limited parametric twin-pair study performed suggests that time-to-converge increases with increasing flap span. Limited studies of Boeing 747 configurations show correct qualitative response to removal of the outer flap and to gear deployment, as compared with wind tunnel and flight test experience.

"SIGNAL PROCESSING AND DISPLAY INTERFACE STUDIES"

NAS-8-29822, September 1975, Raytheon Company, Sudbury, MA

The report discusses the principles of operation and the design and testing of a digital signal processor to be used with a laser system in the detection and tracking of vortices. The processor is basically a spectrum analyzer with thresholding, frequency and time integration, and outputs to recorders and computer interfaces.

Extance, L. J., Byres, R., Kilner, C. and McAleese, P.

"AN ANALYSIS OF WAKE VORTEX ENCOUNTERS REPORTED DURING 1996"

R&D Report 9738, September 1997, National Air Traffic Services Ltd., London, England

This report provides a statistical review of the wake vortex encounters which were reported to the Department of ATM Systems Research in the period 1st January 1996 to 31st December 1996. This review provides information to support research and development activity being undertaken to ensure that Air Traffic Control procedures afford protection against the hazard of wake vortices, without unduly constraining airport capacity. There were 151 suspected wake vortex encounters reported. This is 36% higher than the average number of encounters reported for the previous four-year period. The trend indicates an increasing frequency of reported wake vortex encounters for inbound traffic at Heathrow and Gatwick. Analysis of the 151 suspected wake vortex encounters revealed that 12 were probably not due to wake vortex. Of the remaining 139 probable wake vortex encounters, 113 occurred at Heathrow.

Eyink, G. L.

"TURBULENT CASCADE OF CIRCULATIONS"

Comptes Rendus Physique, Vol. 7, Issue 3-4, April-May 2006, pp. 449-455

The circulation around any closed loop is a Lagrangian invariant for classical, smooth solutions of the incompressible Euler equations in any number of space dimensions. However, singular solutions relevant to turbulent flows need not preserve the classical integrals of motion. Here we generalize the Kelvin theorem on conservation of circulations to distributional solutions of Euler and give necessary conditions for the anomalous dissipation of circulations. We discuss the important role of Kelvin's theorem in turbulent vortex-stretching dynamics and conjecture a version of the theorem which may apply to suitable singular solutions.

Fabre, D. and Jacquin, L.

"STABILITY OF A FOUR-VORTEX AIRCRAFT WAKE MODEL"

Physics of Fluids, Vol. 12, No. 10, October 2000, pp. 2438-2443

The stability of an aircraft wake model composed of an external vortex pair (modeling the wing tip vortices) and an internal vortex pair rotating in the opposite direction (modeling the vortices generated by the fuselage and the horizontal tail) in a stationary configuration is investigated with the vortex filament stability method used by Crow [AIAA J., 8, 2172 (1970)] and Crouch [J. Fluid Mech., 350, 311 (1997)]. It is shown that this configuration is unstable with respect to two-dimensional and three-dimensional disturbances. For long wavelength three-dimensional symmetric perturbations, the rapid growth observed in the numerical simulations of Rennich and Lele [J. Aircraft, 36, 398 (1999)] is found. Moreover, the analysis allows one to show that without an excitation of the long-wave mode, the system will naturally develop short wavelength instabilities localized within the inner vortices which do not affect the outer vortices. Inspection of the initial value problem shows that the long-wave modes can be efficiently initiated by the introduction of perturbations on the internal vortices.

Fabre, D. and Jacquin, L.

"SHORT-WAVE COOPERATIVE INSTABILITIES IN REPRESENTATIVE AIRCRAFT VORTICES"

Physics of Fluids, Vol. 16, No. 5, May 2004, pp. 1366-1378

This paper considers the short-wave cooperative instabilities in a family of vortices representative of aircraft wakes. These vortices are characterized by two core scales, an internal core scale and an external core scale and their azimuthal velocity follows a power law in the intermediate zone. The results are compared to the cases of the Rankine (constant) and Lamb-Oseen (Gaussian) vortices, and to the elliptic instability theory. The unstable wavelengths and the structure of the unstable modes are characterized as functions of the base flow parameters. The wavelength of the instability is of the

order of the internal scale and the unstable modes only affect the internal core. In this case the growth rate of the instability is in accordance with the predictions of the elliptical instability theory and is a growing function of the ratio of the core scales.

Fabre, D. and Jacquin, L.

"VISCOUS INSTABILITIES IN TRAILING VORTICES AT LARGE SWIRL NUMBERS"

J. Fluid Mech., Vol. 500, 2004, pp. 239-262

This paper deals with the temporal stability of the q -vortex trailing line vortex model. We describe a family of viscous instabilities existing in a range of parameters which is usually assumed to be stable, namely large swirl parameters ($q > 1.5$) and large Reynolds numbers. These instabilities affect negative azimuthal wavenumbers ($m < 0$) and take the form of center-modes (i.e. with a structure concentrated along the vortex centerline). They are related to a family of viscous modes described by Stewartson, Ng and Brown (1988) in swirling Poiseuille flow, and are the temporal counterparts of weakly amplified spatial modes recently computed by Olendraru and Sellier (2002). These instabilities are studied numerically using an original and highly accurate Chebyshev collocation method, which allows a mapping of the unstable regions up to Re about 1,000,000 and q about 7. Our results indicate that in the limit of very large Reynolds numbers, trailing vortices are affected by this kind of instability whatever the value of the swirl number.

Fabre, D. and Le Dizes, S.

"VISCOUS AND INVISCID CENTRE MODES IN THE LINEAR STABILITY OF VORTICES: THE VICINITY OF THE NEUTRAL CURVES"

Journal of Fluid Mechanics, Vol. 603, 2008, pp. 1-38.

In a previous paper, we have demonstrated that if the Reynolds number is sufficiently large, all trailing vortices with non-zero rotation rate and non-constant axial velocity become linearly unstable with respect to a class of viscous center modes. We provided an asymptotic description of these modes which applies away from the neutral curves in the (q,k) -plane, where q is the swirl number which compares the azimuthal and axial velocities, and k is the axial wavenumber. In this paper, we complete the asymptotic description of these modes for general vortex flows by considering the vicinity of the neutral curves. Five different regions of the neutral curves are successively considered. In each region, the stability equations are reduced to a generic form which is solved numerically. The study permits us to predict the location of all branches of the neutral curve (except for a portion of the upper neutral curve where it is shown that near-neutral modes are not center modes). We also show that four other families of center modes exist in the vicinity of the neutral curves. Two of them are viscous damped modes and were also previously described. The third family corresponds to stable modes of an inviscid nature which exist outside of the unstable region. The modes of the fourth family are also of an inviscid nature, but their structure is singular owing to the presence of a critical point. These modes are unstable, but much less amplified than unstable viscous center modes. It is observed that in all the

regions of the neutral curve, the five families of center modes exchange their identity in a very intricate way. For the q vortex model, the asymptotic results are compared to numerical results, and a good agreement is demonstrated for all the regions of the neutral curve. Finally, the case of 'pure vortices' without axial flow is also considered in a similar way. In this case, center modes exist only in the long-wave limit, and are always stable. A comparison with numerical results is performed for the Lamb-Oseen vortex.

Fabre, D., Cossu, C. and Jacquin, L.

"ABSOLUTE/CONVECTIVE INSTABILITIES AND SPATIAL GROWTH IN A VORTEX PAIR"

Lecture Notes in Physics, Vol. 555, 2000, pp. 162-172

Airplane trailing vortices have a destabilizing effect on ensuing aircraft. Security spacings, related to the trailing vortices 'lifetime' are enforced between take-offs and landings. This spacing limits the maximum takeoff and landing frequency in saturated airports. A number of studies have been devoted to the understanding of vortex wake dynamics, usually modeled by a pair of counter-rotating vortices. Two types of vortex pair three-dimensional instabilities have been identified in the past: a long-wave instability (of the order of the spacing b between the two vortices) and a short-wave instability (of the order of the vortex core radius a). These two mechanisms, which are thought to participate in the vortex wake dissipation, have been observed in recent experiments. One possible technique to accelerate the dissipation of aircraft wakes is to force these instabilities by on-board control devices. Until now only temporal vortex pair instability analyses are available. If one wants to force these instabilities, however, it would be more appropriate to analyze their spatial stability in the airplane reference frame. As the spatial analysis makes sense only when the instabilities are convective, an absolute/convective stability analysis is required. The results presented consist of the absolute/convective and spatial stability analyses of both long- and short-wave instabilities.

Fabre, D., Cossu, C. and Jacquin, L.

"SPATIO-TEMPORAL DEVELOPMENT OF THE LONG AND THE SHORT-WAVE VORTEX-PAIR INSTABILITIES"

Physics of Fluids, Vol. 12, No. 5, May 2000, pp. 1247-1250

We consider the spatio-temporal development of the long-wave and short-wave instabilities in a pair of counter-rotating vortices in the presence of a uniform axial advection velocity. The stability properties depend upon the aspect ratio a/b of the vortex pair, where a is the core radius of the vortices and b their separation, and upon W_o/U_o the ratio between the self-induced velocity of the pair and the axial advection velocity. For sufficiently small W_o/U_o , the instabilities are convective, but an increase of W_o/U_o may lead to an absolute instability. Near the absolute instability threshold, spatial growth rates are larger than those predicted by temporal stability theory. Considering aeronautical applications, it is shown that instabilities of the type considered in this communication cannot become absolute in far field wakes of high aspect ratio wings.

Fabre, D., Jacquin, L. and Loof, A.

"OPTIMAL PERTURBATIONS IN AN AIRCRAFT WAKE COMPOSED OF FOUR VORTICES"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

We consider the instability properties of a system composed of two vortex pairs, which gives a simple model of the wake of an aircraft in landing or take-off configuration. Such a work may hopefully provide indications about possible strategies for designing wing planforms so as to favor faster decay of the wake. We consider counter-rotating configurations for a wide range of parameters which comprises periodic, divergent and stationary configurations, and compute optimal growths of the perturbations at a fixed distance from the generating aircraft.

Fabre, D., Jacquin, L. and Loof, A.

"OPTIMAL PERTURBATIONS IN A FOUR-VORTEX AIRCRAFT WAKE IN COUNTER-ROTATING CONFIGURATION"

J. Fluid Mechanics, Vol. 451, 2002, pp. 319-328

We consider the instability of two vortex pairs in a counter-rotating configuration. Such configurations model vortex wakes observed behind aircraft with inboard vortices produced at the inboard flap edges and at the tips of the horizontal tail. The instability potential is characterized by an optimal perturbation analysis. This extends the analysis of Fabre & Jacquin (2000) which was restricted to particular stationary configurations, and that of Crouch (1997) which considered co-rotating configurations. A complete mapping of the optimal perturbations is presented. The optimal perturbations grow faster than the Crow (1970) instability. However, they correspond to short-wavelength perturbations mainly affecting the weaker inboard vortices. A possible strategy which consists of forcing a long wavelength is then investigated. Application of both the optimal and the long-wave optimal perturbations to reduction of vortex wake danger is discussed.

"KELVIN WAVES AND THE SINGULAR MODES OF THE LAMB-OSEEN VORTEX"

J. Fluid Mech., Vol. 551, 2006, pp. 235-274

Columnar vortices are known to support a family of waves initially discovered by Lord Kelvin (1880) in the case of the Rankine vortex model. This paper presents an exhaustive cartography of the eigenmodes of a more realistic vortex model, the Lamb-Oseen vortex. Some modes are Kelvin waves related to those existing in the Rankine vortex, while some others are singular damped modes with a completely different nature. Several families are identified and are successively described. For each family, the underlying physical mechanism is explained, and the effect of viscosity is detailed. In the axisymmetric case (with azimuthal wavenumber $m = 0$), all modes are Kelvin waves and weakly affected by viscosity. For helical modes ($m = 1$), four families are identified. The first family, denoted D, corresponds to a particular wave called the displacement wave. The modes of the second family,

denoted C, are called cograde waves, except in the long-wave range where they become center modes and are strongly affected by viscosity. The modes of the third family, denoted V, are retrograde, singular modes which are always strongly damped and do not exist in the inviscid limit. The modes of the last family, denoted L, are regular, counter-rotating waves for short wavelengths, but they become singular damped modes for long wavelengths.

"PLASMA-HYDRODYNAMIC ANALOGY FOR WAVES AND VORTICES IN SHEAR FLOWS"

Lecture Notes in Physics, Vol. 586, 2002, pp. 192-209

A physical analogy between resonant wave-particle interactions in plasma and in fluid mechanics is considered in details. Numerous examples show that the plasma-hydrodynamical analogy is a powerful tool for classification of known phenomena, clarifying their physical nature, discovering new unexpected effects and inventing new devices. The analogy shows up both in plane parallel and in circular shear flows.

Fabry, E. P.

"3D HOLOGRAPHIC PIV WITH A FORWARD-SCATTERING LASER SHEET AND STEREOSCOPIC ANALYSIS"

Experiments in Fluids, Vol. 24, 1998, pp. 39-46

A new 3D PIV system combining holography and stereoscopic PIV is presented. The double pulsed holographic recording relies on the forward scattering of particles in the laser sheet. The holographic images of the particles are used for a stereoscopic PIV analysis. An imaging system with a right-angle prism is used to acquire a stereoscopic pair of images. The application of the system to the vortex flow from an inclined delta wing shows the prospects and limitations of the technique.

Faddy, J. M.

"FLOW STRUCTURE IN A MODEL OF AIRCRAFT TRAILING VORTICES"

PhD Thesis, April 2005, California Institute of Technology, Pasadena, CA.

We consider a model of incompressible trailing vortices consisting of an array of counter-rotating structures in a doubly periodic domain, infinite in the vertical direction. The two-dimensional vortex array of Mallier and Maslowe is combined with an axial velocity profile chosen proportional to the initial axial vorticity to provide an initial condition for the vortex wake. This base flow is a weak solution of the three component steady Euler equations in two dimensions thus allowing its linear stability properties to be investigated. These are used to interpret several stages in the development of vortex structure observed in fully three-dimensional DNS at Reynolds numbers $(\gamma/2\pi\nu) = O(1000)$. For sufficiently high axial velocity, its effect can be seen, in that each vortex in the linear array first develops helical structures before undergoing a period of relaminarization. At later times the more

slowly growing co-operative elliptical instabilities become apparent; however, the helical structure persists and the observed vortical structures remain coherent for longer periods than in the absence of axial velocity. Using the stretched vortex sub-grid model, large-eddy simulation runs are performed at higher Reynolds numbers and a mixing transition identified at about $Re = 10,000-20,000$. Similar phenomena are observed in these simulations as are seen in the DNS. Next the spatial nature of the true aircraft wake is compared to the temporal approximation commonly employed to simplify the computational complexity of the problem. A model is formulated to account for the average axial pressure gradients that develops in the spatial wake but is absent from the temporal simulation. The model enables jet- and wake-like axial flows to be distinguished and the subtle differences in the ensuing turbulent states investigated. Finally, the model is used to investigate co-rotating vortex merger, the new thrust term providing a mechanism to enhance the axial flow further destabilizing the base flow.

"EVOLUTION OF VORTEX STRUCTURES IN A MODEL OF THE TURBULENT TRAILING VORTEX"

In IUTAM Symposium on Elementary Vortices and Coherent Structures: Significance in Turbulence Dynamics, edited by S. Kida, Springer, The Netherlands, 2006, pp. 259-264.

We present results obtained from a direct numerical simulation for a model of incompressible trailing vortices consisting of an array of counter-rotating vortices and a superposed axial velocity in a doubly-

periodic domain, infinite in the vertical direction. The Reynolds number based on vortex circulation is 1000. It is found that for sufficiently strong axial flow, helical instability modes develop on each vortex. This leads to a decrease in the magnitude of the axial flow and subsequent relaminarization of each vortex. At later times, modes corresponding to the more slowly growing co-operative instability become dominant. These produce their own helical structures followed by the rapid growth of small scales, then vorticity cancellation and decay of the vortex array. In the presence of strong axial flow the helical structure persists and the vortices appear more resistant to the breakdown phenomena than for arrays with no axial flow.

"EFFECT OF WHITCOMB WINGLETS AND OTHER WINGTIP MODIFICATIONS ON WAKE VORTICES"

Proceedings of the Aircraft Wake Vortices Conf., DOT Transportation Systems Center, FAA-RD-77-68, June 1977, pp. 207-216

Experimental studies of the wake vortices generated behind six different wingtip configurations are presented. It is shown that the Whitcomb winglet configuration produces two distinct wingtip vortices, each of approximately 65% less swirl velocity than that produced by a simple rounded-tip configuration. Strong axial velocity deficits are shown to be characteristic of these vortices with reduced maximum swirl velocities.

Faery, Jr., H. F.

"THE EFFECT OF WHITCOMB WINGLETS AND OTHER WINGTIP MODIFICATIONS ON WAKE VORTICES"

Ph.D. Thesis, 1975, Virginia Polytechnic Inst. and State Univ., Blacksburg, VA

Wind tunnel experiments were conducted on six wingtip configurations to determine their wake vortex characteristics. The trailing wingtip vortex was probed by a 1/8-inch diameter five-hole yaw head pressure probe. The vortex tangential and axial velocity profiles are compared at five and twenty chord lengths downstream. The Whitcomb winglet and the upper winglet configuration both produce two distinct vortices of the same rotation. The maximum tangential velocity in each is about 64 percent less than that produced by a conventional wingtip configuration. The lift and drag characteristics of the wingtip configurations are compared. The aerodynamic force effects of the wing on the winglet and the winglet on the wing. The downwash distribution on the wing both with and without winglets, and the effect of different winglet dihedral angles on the wing downwash pattern are discussed.

Fage, A. and Simmons, L. F.

"AN INVESTIGATION OF THE AIR-FLOW PATTERN IN THE WAKE OF AN AEROFOIL OF FINITE SPAN"

Proc. Royal Soc. (London), Vol. 225, No. A632, December 1925, pp. 303-330

By means of precise measurements of the wind speed and direction, a picture of the disturbance behind an airfoil of finite span is presented. Changes in the extent and distribution of the vorticity in the wake as it passes downstream are mapped out. The measured vorticity is considered in relation to the circulation around the airfoil. The work provides an experimental verification of the theoretical relation that the total strength of the vorticity leaving a semi-span of an airfoil, as obtained by integration over a transverse plane close behind the airfoil, is equal to the circulation around the median section. It also shows that the distribution of vorticity behind the airfoil is closely connected with the distribution of lift along the span.

"A HISTORY OF WEATHER REPORTING FROM AIRCRAFT AND TURBULENCE FORECASTING FOR COMMERCIAL AVIATION"

In *Aviation Turbulence*, edited by R. Sharman and T. Lane, Chapter 2, 2016, Springer International Publishing Switzerland, pp. 31-58.

Manual pilot reporting of weather conditions, including turbulence, has been standard procedure during most of the Twentieth century. By the late 1940s, the International Civil Aviation Organization (ICAO) had developed standards which included aircraft-based weather observations by pilots and subsequent government distribution. In the USA, commercial airlines developed their own collection and distribution methods. This was in response to Federal Aviation Administration (FAA) requirements that pilots should report hazardous weather, and airlines should have the ability to monitor the progress of every flight. By the 1980s, flight location as well as wind and temperature were being automatically reported in some areas of the world. But automated turbulence report capability was mainly a research effort with some operational capability during the 1990s and 2000s. Aviation

weather forecasting has seen many government as well as airline efforts over the last 80-100 years. By World War II, military aircraft such as the B-17 were able to reach altitudes of over 30,000 ft. This initiated the need for weather forecasting in the upper troposphere and lower stratosphere. Turbulence and mountain wave forecasting emphasis increased significantly with the transition from propeller to jet powered commercial passenger aircraft in the 1950s and 1960s. By the 2000s, government developed forecasting tools such as the Graphical Turbulence Guidance (GTG) had begun to mature, and airlines continued to focus on minimizing turbulence exposure for passenger and flight attendant safety as well as comfort. Many US airlines have come and gone, likewise for airline meteorology offices. A brief history of Northwest (NWA), Delta, and Western meteorology; turbulence forecasting, including mountain wave; and the NWA/Delta Turbulence Plot system provide added perspective. Still today, manual and automated aircraft-based weather observations as well as government and airline produced turbulence forecasts are very valuable.

"DISRUPTED STATES OF VORTEX FLOW AND VORTEX BREAKDOWN"

Phys. Fluids, Vol. 20, No. 9, September 1977, pp. 1385-1400

Flow visualization studies and laser Doppler anemometer measurements on swirling water flows reveal six distinct types of very large amplitude disturbance modes of the vortex core. Three, the 'axisymmetric' and spiral vortex breakdowns and the 'double helix' have been described by others. A definite order of evolution in parameter space (Reynolds number and circulations) occurs, and is described. Puzzling responses of the axisymmetric and spiral vortex breakdowns to imposed flow transients reported previously are confirmed here, and are traced to the shedding of starting and stopping vortices from swirl vanes. Conclusions bearing upon the validity of some theories of vortex breakdown are possible from the data.

"VORTICITY PRESERVING SCHEME FOR UNSTEADY COMPRESSIBLE FLOWS"

4th International Conference on CFD (ICCFD), July 10-14, 2006, Ghent, Belgium

Taking advantage of the notion of vorticity preserving schemes introduced by Morton and Roe for acoustics, and on the residual-based schemes family proposed by Lerat and Corre, an implicit second order accurate residual-based vorticity preserving scheme is presented and applied to blade vortex interaction.

Falkner, V. M.

"THE SCOPE AND ACCURACY OF VORTEX LATTICE THEORY"

ARC Technical Report R&M 2740, 1952, Aeronautical Research Council, Great Britain

The report gives an outline of the development of the principles on which potential problems in lifting-plane theory are solved using a vortex lattice for the purpose of computing downwash. The conditions of convergence necessary for an accurate solution are defined, and the main purpose of the report is to show that those connected with the lattice have been, or can easily be satisfied. Published solutions by this method have been mainly concerned with spanwise load grading and local aerodynamic center and examples are given here of earlier checks on accuracy for rectangular and triangular wings, and a yawed infinite wing, based either on an alteration of the lattice spacing or on comparison with downwash obtained by surface integrals. The study of accuracy is now advanced by a comparison based on exact values calculated from surface integrals given by W. P. Jones, and applied to a rectangular and a sweptback wing. The downwashes obtained from the lattice are shown to converge to the exact values, but by a comparison of two solutions for the sweptback wing it is shown that the beneficial coupling effect of the lattice makes it unnecessary to obtain individual downwash values to great accuracy, at least for spanwise load grading and aerodynamic center calculations. Trial calculations reveal that there would be no difficulty in extending the convergence to detailed pressure distribution or other properties of any thin wing, but it is desirable to give prior attention to the main effects of wing thickness and viscosity.

Fan, M. and Steinhoff, J.

"COMPUTATION OF BLUNT BODY WAKE FLOW BY VORTICITY CONFINEMENT"

AIAA Paper No. 2004-0592, Reno, NV, January 2004

A new, fully conservative version of a method, 'Vorticity Confinement' (VC), is used to treat flow over blunt bodies, including attached and separating boundary layers, and resulting turbulent wakes. The method has been developed independently. However, in terms of current computational schemes, it can be described as a rotationally invariant generalization to multiple dimensions of current 1-D discontinuity confinement schemes. The method allows small (order of grid cell) vortical structures to be simulated which would ordinarily be lost due to diffusive and dispersive numerical effects in conventional pde-based finite difference approximations. In addition to small scales, this method is also efficient for large scales since it approximates conventional CFD for them. The basic idea is that an intrinsically discrete, nonlinear term is used to create what are, effectively, solitary wave-like vortical

features at the smallest scales (1-2 cells) that 'live' on the grid lattice, convecting over arbitrary distances with no numerical spreading. The method has been shown to be very effective at treating isolated, thin convecting vortex filaments and bound vortical layers (boundary layers on surfaces) 'immersed' in coarse, uniform Cartesian grids. These boundary layers are automatically captured, or 'immersed' with the method without complex logic, while maintaining no-slip conditions at the surface to allow separation. Results in 3-D are shown for circular cylinder, a sphere, and a half-sphere shell, as well as comparisons with available data.

Fan, Z.

"A COMPUTER MODEL TO PREDICT POTENTIAL WAKE TURBULENCE ENCOUNTERS IN THE NATIONAL AIRSPACE SYSTEM"

PhD Thesis, December 2014, Virginia Polytechnic Institute and State University, Blacksburg, VA.

With an increasing population of super heavy aircraft operating in the National Airspace System and with the introduction of NextGen technologies, the wake vortex problem has become more important for airport capacity and the en-route air traffic operations. The vortices generated by heavy and super heavy aircraft can generate potential hazards to other aircraft on nearby flight paths. Moreover, the design of new airport procedures needs to consider the interactions between aircraft in closer paths. New methods and models are required to examine these effects before new operations are conducted in the National Airspace System (NAS). Reducing wake vortex separations to safe levels between successive aircraft is essential for NextGen operations. One approach taken recently by ICAO and the FAA is to introduce a re-categorization (ReCat) of wake vortex separations to six groups from the existing five groups employed by the FAA in the United States. Reduced aircraft separations can increase capacity in the NAS with corresponding savings in delay times at busy airports. Future NextGen operations are likely to introduce smaller aircraft separations in the en-route and in the terminal area. Such operations would require better methods to identify potential wake hazards from reduced separation operations. This dissertation describes a model to identify potential wake encounters in the future NAS. The goal of the dissertation is to describe the Enhanced Wake Encounter Model (EWEM), a model that employs a detailed NASA-developed wake model to generate wake zones for different aircraft categories under different flight conditions that can be used with aircraft flight path data to identify potential wake encounters. The main contribution of this model is to gain an understanding of potential wake encounters under future NAS operations.

"WAKE VORTEX COLLECTION AT THE DUBAI INTERNATIONAL AIRPORT AND SAMPLE RESULTS"

AIAA Paper 2016-3436, June 2016, Washington, DC.

The Dubai Air Navigation Services (DANS) has an on-going field experiment at the Dubai International Airport (DXB) to measure wake turbulence generated by aircraft in the In Ground Effect and Out of Ground Effect regions. The data are collected using three Lockheed Martin Coherent Technologies (LMCT) WTX WindTracer pulsed Doppler lidars. The data have been collected from August, 2013, and the data collection is still ongoing. These data are being used to determine vortex circulation decay and vortex position under a variety of atmospheric conditions. The ultimate goal is to safely reduce aircraft separations and to safely increase the capacity of the Dubai International Airport. This paper will outline the strategy behind the lidar placement and the data that are being collected, and will provide a first look at results from the data collection.

Fanucci, A. L. and Jimenez, J. J.

"A NEAR-FIELD COMPARISON OF THE VORTEX-WAKE CHARACTERISTICS OF A TRAPEZOIDAL WING AND A CRANK-ARROW WING"

Report, Aero 16.622 Spring 2003, May 2003, MIT, Cambridge, MA.

Large commercial aircraft produce dangerous wake-vortices. If a trailing aircraft encounters such a vortex before its strength is sufficiently dissipated, the aircraft can experience loss of control authority. The FAA has issued separation standards for all aircraft classes in order to avoid the effects of these wake-vortices. However, these standards are based on the wake-vortex characteristics of conventional, subsonic-cruise aircraft that have trapezoidal wings. The current standards have no mention of crank-arrow wing geometry. In addition, studies have not been done on the wake-vortices of crank-arrow wings.

Fares, E., Huppertz, G., Abstiens, R. and Schroder, W.

"NUMERICAL AND EXPERIMENTAL INVESTIGATION OF THE INTERACTION OF WINGTIP VORTICES AND ENGINE JETS IN THE NEAR FIELD"

AIAA Paper No. 2002-0403, Reno, NV, January 2002

The near wake of a rectangular wing/engine configuration is investigated using numerical simulations and PIV measurements. The analysis is focused on the interaction of the engine jet and the wing-tip vortex in the near wake. The essential details of the solution technique such as turbulence modeling, boundary conditions, and the experimental setup are presented first. The engine jet is experimentally generated by a jet apparatus and simulated numerically using artificial boundaries within the engine. The paper concentrates on the influence of the engine jet on the development of the wing-tip vortex at varying thrust and engine positions. Finally, physical aspects of the flow in the near field behind the wing are discussed and compared with experimental data.

Fares, E., Meinke, M. and Schroeder, W.

"NUMERICAL SIMULATION OF THE INTERACTION OF WINGTIP VORTICES AND ENGINE JETS IN THE NEAR FIELD"

AIAA Paper No. 2000-2222, Denver, CO, June 2000

The near wake of a wing/engine configuration is investigated with the help of numerical simulations. The focus is put on the interaction of the engine jet and the wingtip vortex in the near wake. The essential details of the solution technique such as grid generation, turbulence modeling, boundary conditions, and their implementation are presented first. A modification of the Spalart-Allmaras one-equation model is proposed including a determination of the wall distance with a partial differential equation. The methods are validated with solutions for an isolated analytical vortex and a near wake of a flapped wing based on experimentally determined inflow boundary conditions. Finally, physical aspects of the flow in the near wake of the wing are discussed.

"MEASUREMENTS OF SUPERSONIC JET AIRCRAFT WAKES IN THE STRATOSPHERE"

International Conference on the Environmental Impact of Aerospace Operations in the High Atmosphere, American Meteorological Society, July 1974, pp. 53-58

Progress is reported in an experimental program consisting of making supersonic aircraft wakes visible in the stratosphere so that photographs can be taken which yield wake dimensions vs time, and so that aircraft equipped with instruments which measure key exhaust species can find and penetrate the wakes. The object is to provide verification of fluid dynamic and chemical models. Three available models are summarized, and the experimental methods used are described. The Lockheed model predictions correspond in general most closely to experimental wake cross-sectional area. NO data are in reasonable agreement with NO predictions, but chemical models are relatively undeveloped, and

additional measurements of exhaust products are needed before verification of chemical models becomes possible. However, the overall feasibility of wake visualization for model verification is substantiated. It is emphasized that significant model differences exist that must be resolved before reliable predictions can be made in the wake regimes studied.

"MODELING THE FAR-FIELD ACOUSTIC EMISSION OF ROTATING TURBULENCE"

Journal of Turbulence, Vol. 9, No. 30, 2008, pp. 1-21.

This paper focuses on the evaluation of the acoustic emission of anisotropic homogeneous turbulence. We propose a synthetic model that contains the main features of turbulence submitted to rotation: the velocity fluctuations are a mix of random Fourier modes and inertial waves, with variable respective intensities. The acoustic analogy introduced by Lighthill is applied to these sources to estimate the acoustic emission properties of the incompressible anisotropic field, such as the acoustic spectrum and the sound directivity. These quantities are compared to those obtained in the isotropic case, and discussed in view of the available analytical laws for sound emission by isotropic turbulence. An approach based on turbulent sources computed by direct numerical simulations, computationally more expensive than the kinematic sources, is also used for comparison.

"VORTICITY METER CALIBRATION USING A CROSS-WIRES SURVEY"

Experimenta in Fluids, Vol. 2, 1984, pp. 105-111.

A vorticity meter of the vane-type has been used in this study for direct and quantitative measurements of vortical flows. The vane calibration procedure is carried out by using measurements deduced from a preliminary cross-wires survey of the flow field generated in the wake of a half wing set at incidence in the wind tunnel. Emphasis is placed on the resulting calibration law which relates the vane rotational speed to the fluid angular velocity. Specially it is shown that this calibration law can be obtained as a linear expression by considering the minimum threshold rotational speed necessary for vane rotation. When comparing vorticity distributions obtained through the vortical wing wake by the indirect cross-wires technique, good agreements are found with the corresponding vorticity distributions as deduced from the so calibrated vorticity meter.

"VORTEX INFLUENCE ON OSCILLATING AIRFOILS AT HIGH ANGLE OF ATTACK"

J. Aircraft, Vol. 24, No. 7, July 1987, pp. 424-432

The influence of a streamwise vortical flow on an oscillating airfoil is investigated in a low subsonic wind tunnel. It constitutes a limiting case of more complex practical flow configurations encountered,

for instance, on a rotating helicopter blade section interacting with the vortical wakes generated upstream by the blade tips. The present experimental simulation is realized by means of a semispan airfoil generating a tip vortex convected downstream and nearby the lower side of a second airfoil, which spans the entire test section and oscillates in force-and-aft motion. Steady and unsteady behavior is obtained from lift, drag, and pitching-moment measurements, and chordwise pressure and skin-friction distributions are performed on the oscillating airfoil. Particular attention is given to the interaction effect of the lifting surface on the path and strength of the impinging vortex.

Fay, J. A.

"BUOYANT PLUMES AND WAKES"

Annual Review Fluid Mechanics, Vol. 5, Annual Reviews Inc., Palo Alto, CA, 1973, pp. 151-160

A review is given of the theories of the motion of buoyant plumes and the dispersion of exhaust gases in vehicular and aircraft wakes. Models for estimating the effects of downwash on the growth of buoyant aircraft trails are presented.

Fedorchenko, A. T.

"ON SOME FUNDAMENTAL FLAWS IN PRESENT AEROACOUSTIC THEORY"

Journal of Sound and Vibration, Vol. 232, No. 4, 2000, pp. 719-782.

A critical analysis of the main theoretical approaches to the theory of aerodynamic sound is presented for the case of inviscid gas flow. Various systems of acoustic equations are considered, with and without externally assigned source terms. Decomposition of flow variables into acoustic and non-acoustic components is discussed as a complex problem which is crucial for studying many aeroacoustic phenomena, and a new concept is suggested for this problem. A time-averaging procedure, which is usually applied for such a decomposition, is examined, and its essential flaws are revealed. The general formulation of Lighthill's acoustic analogy is analyzed as well as various subsequent approaches to the theory of sound generation. This analysis shows that in all these the definitions of aerodynamic sound sources are featured by evident defects, and so these models cannot be adopted as physically or mathematically accurate. The relevant problems of experimental and computational research are considered in connection with the theoretical models under discussion.

"STATISTICAL DETERMINATION OF VERTICAL RESOLUTION REQUIREMENTS FOR REAL-TIME WAKE-VORTEX PREDICTION"

Journal of Aircraft, Vol. 49, No. 3, May-June 2012, pp. 822-835.

Wake-vortex interaction is one of the primary drivers for aircraft separation minimums. Real-time wake-vortex prediction algorithms could enable following distances to be reduced, improving the

efficiency of the air transport system. This study uses statistical analysis to determine the necessary vertical resolution of meteorological parameters required to enable real-time wake-vortex models to predict wake-vortex position and strength using two separate analyses. The first analysis sought to characterize the accuracy of the predictions of real-time wake-vortex models for 1 m (highest) and 100 m (lowest) resolution by comparing the predictions to measured wake vortices. Using NASA's AVOSS Prediction Algorithm Suite v4.19 and two data sets collected at Memphis and Dallas-Fort Worth, the results indicate that the range of vortex circulation root-mean-square (RMS) error is [1.5-32.6] m²/s, the range of vortex Y-position RMS error is [0.7-134.5] m, and the range of vortex Z-position error is [1.2-10.1] m. The Y-position error had the largest variation with the maximum deviation exceeding 25 m. The second analysis sought to characterize the precision of the real-time wake-vortex model predictions as the resolution of the input meteorological files was reduced from 1 m to 100 m. Normalized RMS values (by 1 m resolution) were calculated for resolutions of 5, 15, 20, 25, 30, 40, and 100 m averaged over the first 60 s of data available. For predicted circulation, differences were found between medians at input resolutions 5-20 m vs 25-100 m; for Y- and Z-positions, differences were found between medians 100 m and all others.

"APA SUITE SENSITIVITY STUDY AND MODEL SCORING METHODOLOGIES"

Report DTFWA-09-A-8000, December 2010, Georgia Institute of Technology, Atlanta, GA.

Three methods for scoring wake vortex models have been presented: a residual method, a corridor exit time method, and a cross-correlation method. Each method can provide insight into specific areas of strength and weakness of wake models. The residual method provides the most thorough scoring of model accuracy, as it compares model output point by point with experimental data. Both the APA and TDP methods perform similarly under this method, agreeing with results observed in the sensitivity study performed in Task 1. The corridor exit method also shows very little difference between the methods. Both models produce a very conservative estimate of the vortex exit time from the defined corridor. At a smaller corridor size however, the TDP method significantly under-predicts corridor exit time for heavy aircraft. The cross-correlation method provides a measure of the uncertainty between the measured and predicted data with time. It can be used to align measured and predicted data by finding the lag time with the highest correlation. Under this methodology, the TDP method retained correlation better than the APA method did with time, suggesting that the TDP method is more resistant to changes in circulation and vortex position than the APA method as time goes on.

"SPANWISE LOADING DISTRIBUTION AND WAKE VELOCITY SURVEYS OF A SEMI-SPAN WING"

NASA Tech. Memorandum 84213, Feb. 1982, US Army Aviation Research and Development Command, Moffett Field, CA (also, USAVRADCOM TR 82-A-1)

The spanwise distribution of bound circulation on a semi-span wing and the flow velocities in its wake were measured in a wind tunnel. Particular attention was given to documenting the flow velocities in and around the developing tip vortex. A two-component laser velocimeter was used to make the velocity measurements. This report presents, without discussion, the spanwise distribution of bound circulation, three components of the time-averaged velocities throughout the near wake and their standard deviations, and the integrated forces and moments on a metric tip as measured by an internal strain gage balance.

"NUMERICAL SIMULATION OF PARALLEL AIRFOIL/VORTEX INTERACTION USING A ZONAL HYBRID RANS/LES METHOD"

AIAA Paper No. 2005-5127, Toronto, Canada, June 2005

Helicopter Blade-Vortex Interaction (BVI) generally occurs under certain conditions of powered descent or during extreme maneuvering. The vibration and acoustic problems associated with the interaction of rotor tip vortices and the following blades is a major aerodynamic concern for the helicopter community. Numerous experimental and computational studies have been performed over the last two decades in order to gain a better understanding of the physical mechanisms involved in BVI. The most severe interaction, in term of generated noise, happens when the vortex filament is parallel to the blade, thus affecting a great portion of it. Most of the previous numerical studies of parallel BVI fall within a potential flow framework therefore precluding vortex-induced flow separation. Some Navier-Stokes approaches using dissipative numerical methods in conjunction with RANS-type turbulence models have also been attempted, but with limited success. In this work, the situation is improved by increasing the fidelity of both the numerical method and the turbulence model. A kinetic energy conserving finite-volume scheme using a collocated-mesh arrangement, specially designed for simulation of turbulence in complex geometries, was implemented. For the turbulence model, a cost-effective zonal hybrid RANS/LES technique is used. The concentrated tip vortex is not attenuated as it is convected downstream and over a NACA-0012 airfoil. The lift, drag, moment coefficients induced by the passage of the vortex are monitored in time and compared with available experimental data.

"EMPIRICAL WAKE TURBULENCE MODEL OF TILTROTOR AIRCRAFT"

SAE Paper No. 2005-01-3182, Oct. 2005, Grapevine, TX.

This paper describes the methods used to collect and reduce wake turbulence data behind two distinct types of tiltrotor aircraft using a Light Detection and Ranging (LIDAR) measurement system, which uses laser velocimetry to measure the velocity of dust particles in air that has been disturbed by the passage of an aircraft. The test aircraft flew at various combinations of weight, rotor speed, airspeed, and configuration. The MIT LL LIDAR system measured the wake vortices with minimal pre-test preparation; we obtained a large quantity of high-quality data in only a few days of testing. The

data shows tiltrotor and fixed-wing wake characteristics are very similar. Data reduction methods used a classical horseshoe vortex system as a template, and employed a vortex that had a rotational core and an irrotational outer field. Intersecting polynomials that are linear in downstream distance and bi-linear in downstream distance and mast angle adequately modeled vortex strength. A bi-quadratic polynomial function of downstream distance and mast angle adequately modeled core size.

"ANALYSIS AND RECOMMENDATION OF SEPARATION REQUIREMENTS FOR ROTORCRAFT OPERATION AT AIRPORTS AND HELIPORTS"

TR-1224-1, September 1986, Systems Technology Inc., Mountain View, CA.

Low-speed rotorcraft operations at airports and heliports are investigated to better understand and quantify the potential hazards associated with various types of rotor-wash flow fields. Mathematical models for various types of rotor-induced flow fields are developed. These models are utilized in conjunction with hazard analysis models to evaluate the potential for rotor-wash related accidents in various operational scenarios. Correlation with available flight test and laboratory experimental data is provided wherever possible. The result from the analysis effort is a recommendation of separation requirements for rotorcraft operations at airports and heliports. Recommendations are also provided for future research that would aid in the elimination of safety factors used in the development of recommended separation criteria.

Ferguson, S. W. and Kocurek, J. D.

"ROTORWASH COMPUTER MODEL -- USER'S GUIDE"

DOT/FAA/RD-90/25, November 1991, Computational Methodology Associates, Hurst, TX.

The user's guide for the Rotorwash (ROTWASH) Analysis program is documented in this report. This computer program is used to analyze the rotor wash flow field characteristics and their effect on the environment for rotorcraft in hovering and low speed flight in close proximity to the ground. The documentation provides step-by-step descriptions on the use of each analysis option and a listing of the IBM PC/PC-compatible based FORTRAN-77 software. A brief introductory section to the report describes the history of the ROTWASH analysis software. References for the mathematical models used in the analysis modules are included in the report.

Fernandez, F. L. and Lubard, S. C.

"TURBULENT VORTEX WAKES AND JETS"

AIAA Paper No. 1971-0615, Palo Alto, CA, 1971

The turbulent viscous core of a potential vortex with axial velocity excess or defect is considered. An integral method is used with quasi-cylindrical flow approximations to describe the flow in the core of

the vortex. Models are postulated for both axial and swirl mixing. The resulting equations are shown to possess both regular wake-like and jet-like solutions and solutions which become singular indicating vortex breakdown. The singular solutions are found only for single vortex cores with a net axial momentum deficiency which implies a net drag for the vortex generator.

Fernandez-Feria, R., del Pino, C. and Parras, L.

"VISCOUS INSTABILITIES OF BATCHELOR'S VORTEX FOR HIGH SWIRL NUMBERS; THE ONSET OF ABSOLUTE INSTABILITIES AND NON-PARALLEL EFFECTS"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

Batchelor's vortex has been commonly used in the past as a model for trailing vortices. Using a temporal stability analysis, Fabre and Jacquin have recently found new viscous unstable modes for the high swirl numbers of interest in actual large-aircraft vortices. More recently, these instabilities were characterized asymptotically by Le Dizès and Febre and by Heaton. We look here for these unstable viscous modes occurring at large swirl numbers (q greater than 1.5), and large Reynolds numbers (Re greater than 1000), using a spatial stability analysis, thus characterizing the frequencies at which these modes become convectively unstable for different values of q , Re , and for different intensities of the uniform axial flow. We consider both jet-like and wake-like Batchelor's vortices, and can analyze the stability for Re as high as 100,000,000. We also characterize the frequencies and the swirl numbers for the onset of absolute instabilities of these unstable viscous modes for large q . One of the main conclusions is that these frequencies are not related to those observed experimentally for the vortex meandering phenomenon in trailing vortices. On the other hand, we also analyze the spatial stability of Batchelor's vortex considering non-parallel effects associated to the axial variation of this self-similar vortex that models the far downstream behavior of trailing vortices.

"VORTEX STRUCTURES IN GEOPHYSICAL CONVECTION"

Eur. J. Mech. B - Fluids, Vol. 20, 2001, pp. 437-470

An intriguing variety of vortex structures arise during buoyant convection, especially in the presence of background stratification and rotation. These vortices play an important role in environmental fluid motions, bearing upon small-scale turbulence to planetary-scale circulation. A brief review of vortex motions associated with buoyant convection is presented in this paper, emphasizing the sources of vorticity, evolution of vortex structures and their role in oceanic and atmospheric dynamics. The genesis of a variety of vortices, for example, mushroom vortices, geostrophic and ageostrophic vortices, dipolar structures and hetons in buoyant convection flows is described, and parameterizations to represent their properties are discussed. New laboratory and numerical simulation results on vortex-related phenomena in stratified and rotating fluids and their implications in geophysical convective flows are also presented.

"REYNOLDS NUMBER DEPENDENCE OF TWO-DIMENSIONAL LAMINAR CO-ROTATING VORTEX MERGING"

Theoretical and Computational Fluid Dynamics, Vol. 19, 2005, pp. 65-75

The paper reports unsteady Navier-Stokes calculations of laminar two-dimensional co-rotating vortex merging for various Reynolds numbers. The unsteady, incompressible two-dimensional Navier-Stokes equations were solved with fourth-order Runge-Kutta temporal discretization and fourth-order symmetric compact schemes for spatial discretization. Calculations of the unsteady Taylor vortex benchmark showed that fourth-order accurate solutions for all primitive variables were indeed achieved. Calculations for a pair of equal-strength co-rotating vortices show good agreement with reported direct numerical simulation and experiments for the evolution of the separation distance and core radius. It is found that the time required for merging is inversely proportional to the square root of the Reynolds number. According to previous experimental research, it was also found that complete merging in laminar regime undergoes four stages with physical meaning. The physical mechanism responsible for the merging process is investigated and it is found that the antisymmetric vorticity dynamics plays an important role until full merging.

Ferreira de Sousa, P. J. S. A. and Pereira, J. C. F.

"LAMINAR CO-ROTATING BATCHELOR VORTEX MERGING"

Theoretical Computational Fluid Dynamics, Vol. 23, 2009, pp. 1-14.

The dynamics of laminar co-rotating vortex pairs without axial flow have been recently thoroughly studied through theoretical, experimental, and numerical studies, which revealed different instabilities contributing to the decay of the vortices. In this paper, the objective is to extend the analysis to the case of co-rotating vortices with axial flow at low Reynolds numbers. A high-order incompressible Navier-Stokes flow solver is used. The momentum equations are spatially discretized on a staggered mesh by finite differences and all derivatives are evaluated with 10th order compact finite difference schemes with RK-4 temporal discretization. The initial condition is a linear superposition of two co-rotating circular Batchelor vortices with $q = 1$. It is found that there is an initial evolution that resembles the evolution that single $q = 1$ vortices go through. Azimuthal disturbances grow and result in the appearance of large-scale helical sheets of vorticity. With the development of these instability waves, the axial velocity deficit is weakened. The redistribution of both angular and axial momentum between the core and the surroundings drives the vortex core to a more stable configuration, with a higher q value. After these processes, the evolution is somewhat similar to a pair of co-rotating Lamb-Oseen vortices. A three-dimensional instability develops, with a large band of unstable modes, with the most amplified mode corresponding scaling with the vortex initial separation distance.

Ferri, A.

"PRELIMINARY INVESTIGATION OF DOWNWASH FLUCTUATIONS OF A HIGH-ASPECT-RATIO WING IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL"

NACA RM No. L6H28b, August 1946, Memorial Aeronautical Laboratory, Langley Field, VA.

A series of tests have been made in the wake of a high-speed wing of high aspect ratio at Mach numbers up to approximately 0.90 to determine the fluctuations of the downwash in the zone of possible tail locations. Serious fluctuations occurred in the wake of the wing. The fluctuations extended beyond the wake boundaries but with decreasing amplitude. For a high angle of attack of the wing (7 deg) and high Mach numbers the fluctuations were very large (3 1/2 deg maximum) and extended as high as approximately 0.90 chord above the chord line of the wing. For medium angles of attack (0, 2, and 4 deg) important fluctuations occurred up to about 0.70 chord above the chord line of the wing.

Ferris, P. D.

"THE FORMATION AND FORECASTING OF CONDENSATION TRAILS BEHIND MODERN AIRCRAFT"

Meteorol. Appl., Vol. 3, 1996, pp. 301-306.

The formation of a condensation trail behind an aircraft gives away its presence. Despite the current use of radar for aircraft detection, contrail formation is still important to military aviation. Seeing a contrail only requires the unaided eye. The theory of contrail formation for a dry environment, using values of engine-dependent variables appropriate to modern jet aircraft, gives values of the critical temperature for contrail formation. These form a line nearly parallel to, but colder than, the MINTRA line on a tephigram. These values though, do not allow for the effect of environmental humidity, which may be significant at the levels where aircraft fly. A new forecasting technique is proposed which involves determining the exact critical temperature value. This can be done using a suitable contrail formation graph or with a tephigram, finding the necessary correction to the MINTRA temperature. If the atmospheric temperature is colder than this critical temperature, a contrail should be forecast to form.

Ferziger, J. H.

"LOW-FREQUENCY ACOUSTIC SCATTERING FROM A TRAILING VORTEX"

J. Acoustical Soc. America, Vol. 56, No. 6, December 1974, pp. 1705-1707

The cross section for the scattering of low-frequency (~ 100 Hz) sound by an aircraft trailing vortex is computed using the Born approximation. The predicted cross section is large enough to permit size and strength measurements. Although precise location of a vortex is better done with high-frequency refraction, a monitoring system based on low-frequency acoustic radar is possible, and a system combining the best features of each is also feasible.

Feuerle, T., Steen, M. and Hecker, P.

"A NEW CONCEPT FOR WAKE VORTEX HAZARD MITIGATION USING ON-BOARD MEASUREMENT EQUIPMENT"

AIAA Paper 2013-4426, August 2013, Los Angeles, CA.

Wake Vortex hazards are a huge threat in aviation. These hazards are well accepted in the vicinity of airports (both departure and arrival). But also enroute a number of incidents had happened in the past. Current wake vortex mitigation strategies are based on static distances (in space and/or time). In future air traffic management concepts of SESAR and NextGen these static distances will be replaced by dynamic separation strategies. Furthermore, concepts for self-separation of aircraft are described. This paper will discuss the work at TU Braunschweig, where a new concept for wake vortex hazard mitigation had been developed. Additionally, TU Braunschweig will install a wind turbulence measurement equipment on-board of its research aircraft. This installation will be also described and the possible usage will be discussed.

Feuerle, T., Steen, M. and Hecker, P.

"NEW CONCEPT FOR WAKE-VORTEX HAZARD MITIGATION USING ONBOARD MEASUREMENT EQUIPMENT"

Journal of Aircraft, Vol. 52, No. 1, January-February 2015, pp. 42-48.

Wake-vortex hazards are a huge threat in aviation. These hazards are well accepted in the vicinity of airports (both departure and arrival). But also a number of enroute incidents have happened in the past. Current wake-vortex mitigation strategies are based on static distances (in space and/or time). In future air traffic management concepts of Single European Sky Air Traffic Management Research and NextGen, these static distances will be replaced by dynamic separation strategies. Furthermore, concepts for self-separation of aircraft are described. This paper will discuss the work at Technische Universitat Braunschweig, where a new concept for wake-vortex hazard mitigation has been developed. The basic idea of the new concept is that only a criticality parameter will be transmitted between aircraft to ensure a safe separation even within new self-separation concepts. The criticality parameter will give an indication about the severity (and therefore criticality to the following aircraft) of the vortices. Additionally, Technische Universitat Braunschweig will install a wind-turbulence measurement equipment onboard its research aircraft. This installation will be also described, and the possible usage will be discussed.

Few, Jr, A. G.

"SOME EFFECTS OF SWEEP AND THICKNESS ON THE EXPERIMENTAL DOWNWASH CHARACTERISTICS AT TRANSONIC SPEEDS OF A SERIES OF HIGHLY TAPERED WINGS WITH AN ASPECT RATIO OF 3, TRANSONIC-BUMP METHOD"

NACA RM L55J12, February 1956, Langley Aeronautical Laboratory, Langley Field, VA.

An investigation by the transonic-bump technique of some effects of sweep and thickness on the transonic downwash and wake characteristics of a series of highly tapered semispan wings with an aspect ratio of 3 has been made in the Langley high-speed 7- by 10-foot tunnel. The Mach number range extended from 0.60 to 1.18 with corresponding Reynolds numbers ranging from about 780,000 to 930,000. The angle-of-attack range was from -2 to about 24 degrees. The measurements of downwash and dynamic pressure were made for a range of vertical distances from the wing chord plane extended, but at only one spanwise station and for a given wing plan form, at only one longitudinal station. Increases in wing sweep provided a decrease in the rate of change of downwash with angle of attack in the low angle-of-attack range for all Mach numbers, and provided less variation with Mach number at all distances from the wing chord plane. The rate of change of downwash with angle of attack reached a maximum near the wing chord plane for all wing sweep angles. Above the wing chord plane the rate of change of downwash with angle of attack increased to maximum values exceeding unity with an increase in angle of attack for all conditions of wing sweep and thickness. For a quarter-chord sweep angle of 14.03 degrees a decrease in wing thickness ratio from $t/c = 0.045$ to 0.02 produces increase in the rate of change of downwash with angle of attack at any distance from the wing chord plane extended up to a Mach number of about 1.09. Regardless of wing sweep or thickness, increasing the speed from subsonic to supersonic caused the wake center to be displaced toward the wing chord plane and, although the losses in wake dynamic pressure were reduced, there was a general thickening of the wake in going to supersonic speeds.

Fewings, R.

"ULTRA-HIGH-CAPACITY AIRCRAFT WILL INTENSIFY AIRPORT SAFETY ISSUES"

Airport Operations, Flight Safety Foundation, Vol. 21, No. 1, January-February 1995, pp. 1-7.

The new generation of transports will likely cause further pressures on ground maneuvers and emergency evacuations at airports, and possibility increase wake vortex hazards.

Fidler, J. E.

"APPROXIMATE METHOD FOR ESTIMATING WAKE VORTEX STRENGTH"

AIAA Journal, Vol. 12, No. 5, May 1974, pp. 633-635

An approximate method is presented for estimating the strength of slender-body wake vortices. The method is shown to yield good accuracy for the case of asymmetric vortices in the wake of a body at high angles of attack.

Fiduccia, P.

"NASA CONOPS TEAM AND THE IDENTIFICATION OF REQUIRED DATA TO ESTABLISH SAFETY OF PROPOSED ACTIVE PREDICTION WAKE VORTEX SOLUTIONS"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

This presentation on the NASA Conops Evaluation Team covers the following points: Wake Conops Team Goals and Objectives, Scope; Team Members and Expertise; Candidate Operational Enhancements to be Analyzed by the Evaluation Team; Order of Analysis; Baseline Report Contents; Conops Evaluation Report Contents; Description of Conops for Closely Spaced Parallel Runway Arrivals, dynamic separation based on active wind sensing and prediction; and Comparison of Conops with Related FAA Operational Enhancements. Results to date: Conops Definition and Analysis, Safety Analysis Methodology Selection, Research Issues Identified, and Issues Identified to Decision Makers.

"FAA/NASA WAKE TURBULENCE RESEARCH PROGRAM"

Journal of ATC, Vol. 46, No. 1, January-March 2004, pp. 17-21

This is the first of a series of articles on the FAA/NASA Wake Turbulence Research Program (Program) to revise wake turbulence separation standards, procedures, and criteria to increase airport capacity while maintaining or increasing safety. This article introduces the FAA and NASA elements of the Program, provides the status of the FAA Program elements already underway, and describes the Conops Evaluation Team (CET), which supports the planning for NASA's wake research and technology development activities.

Filippone, A.

"DATA AND PERFORMANCES OF SELECTED AIRCRAFT AND ROTORCRAFT"

Progress in Aerospace Sciences, Vol. 36, 2000, pp. 629-654.

The purpose of this article is to provide a synthetic and comparative view of selected aircraft and rotorcraft (nearly 300 of them) from past and present. We report geometric characteristics of wings (wing span, areas, aspect-ratios, sweep angles, dihedral/anhedral angles, thickness ratios at root and tips, taper ratios) and rotor blades (type of rotor, diameter, number of blades, solidity, rpm, tip Mach numbers); aerodynamic data (drag coefficients at zero lift, cruise and maximum absolute glide ratio); performances (wing and disk loadings, maximum absolute Mach number, cruise Mach number, service ceiling, rate of climb, centrifugal acceleration limits, maximum take-off weight, maximum payload, thrust-to-weight ratios). There are additional data on wing types, high-lift devices, noise levels at take-off and landing. The data are presented on tables for each aircraft class. A graphic analysis offers a comparative look at all types of data. Accuracy levels are provided wherever available.

Filippone, A., Bakker, R., Basset, P. M., Rodriguez, B., Green, R., Kutz, B., Bensing, F. and Visingardi, A.

"ROTOR WAKE MODELLING IN GROUND EFFECT CONDITIONS"

37th European Rotorcraft Forum, September 2011, Milano, Italy.

In this contribution we address the nature of helicopter rotor wakes in presence of the ground. We present some problems of helicopter flight on a flat surface, a validation exercise for a hover in ground effect (Light's experiment) and novel experiments on scaled rotor in advancing flight. We present briefly the computational methods used for this validation exercise. The methods range from lifting line to unsteady Reynolds-averaged Navier-Stokes equations. Validations are shown for out-of-ground and various ground clearances.

Filotas, L. T.

"DISTORTION OF A SHOCK WAVE TRAVERSED BY A VORTEX"

Tech. Note No. 96, January 1967, University of Toronto Institute for Aerospace Studies, Toronto, Canada.

A theoretical treatment of the sound field produced upon the interaction of a vortex and a normal shock wave was presented some time ago in UTIA Report No. 61 (Ribner, 1959). The techniques of this analysis are now used to derive expressions for the shape of the distorted shock front. It is found that outside of the section cut off by the cylindrical acoustic wave emanating from the vortex center, the shock remains essentially straight. The portion within this section has curvature, resulting in a finite displacement of the two straight segments. These theoretical predictions are in qualitative agreement with the features noted by experimental investigators of the same phenomenon. As no other presently published theory yields the shock wave shape, this work demonstrates the generality of the approach used.

Finch, R. V.

"VORTEX REDUCING WING TIP"

US Patent 4,108,403, August 1978.

An airfoil tip is constructed to droop downward and extend aft of the trailing edge of the air foil structure and to include air foil configuration both chordwise and spanwise with camber in both the chordwise and spanwise directions and further including a vortex opposing twist in the chordwise direction.

Finck, R. D.

"USAF STABILITY AND CONTROL DATCOM"

AFWAL-TR-83-3048, April 1978, McDonnell Douglas Corporation, Long Beach, CA.

This report is a collection, correlation, codification, and recording of best knowledge, opinion, and judgment in aerodynamic stability and control prediction methods. It presents substantiated techniques for use (1) early in the design or concept study phase, (2) to evaluate changes resulting from proposed engineering fixes, and (3) as a training or cross-training aid. It bridges the gap between theory and practice by including a combination of pertinent discussion and proven practical methods. For any given configuration and flight condition, a complete set of stability and control derivatives can be determined without resort to outside information. A spectrum of methods is presented, ranging from very simple and easily applied techniques to quite accurate and thorough procedures. Comparatively simple methods are presented in complete form, while the more complex methods are often handled by reference to separate treatments. Tables which compare calculated results with test data provide indications of method accuracy. Extensive references to related material are also included.

Findlater, P. A., Greenhill, S. E. and Scott, W. D.

"DESIGN AND TESTING OF A TURBULENCE PROBE FOR HARSH FLOWS"

Environmental Fluid Mechanics, Vol. 1, 2001, pp. 3-28.

The force of wind on the ground created by turbulent eddies is commonly used to describe the horizontal flux of material during wind erosion. Here we present the Murdoch Turbulence Probe, an instrument for use in both clean and eroding flows which uses pressure differences to measure the three components of wind velocity. Correlation techniques calculate the forces near the ground and turbulence statistics in nearly real time, including turbulent velocity fluctuations from less than 0.1 Hz to 200 Hz, mean flow velocities, Reynolds stresses as well as the integral length and time scales. In the portable wind-tunnel used by Agriculture Western Australia, turbulence statistics were recorded over stable surfaces and in blowing sand from the initiation of erosion up to the time the sand supply was exhausted. Estimates of the friction velocity derived from the turbulence probe were compared with estimates obtained from the wind speed profile measured with a rake of pitot and static tubes. The Murdoch Turbulence Probe appears to work well in sandblasting conditions. Relative turbulence intensities ranged from 0.11 to 0.2 and are in close agreement with values in the literature. The ratio of the turbulence to the friction velocity (3 to 3.2) is at the high end of the reported range. The Reynolds stress measurements agree closely with predictions of the threshold friction velocities of the sand and estimates from the wind speed profile with a von Karman constant of about 0.3, lower than the commonly accepted value of 0.4. We suggest that the wind-tunnel profile represents the 'outer layer' of the boundary-layer that may best be described by a 'Wake Law' or 'Defect Law'. At about 54 mm above the surface, the friction velocity decreases from 0.64 m/s to 0.39 m/s and the mean velocity increases from 9.6 m/s to 11.6 m/s as the supply of sand is depleted. In addition to the friction velocity, other scales may be necessary to characterize the overriding effect of the wind and in extending wind-tunnel results to the field.

Fine, N. E. and Kring, D.C.

"OPTO-ACOUSTIC TRACKING OF AIRCRAFT WAKE VORTICES"

AIAA-2005-2965, Monterey, CA, May 2005

Flight Safety Technologies, Inc. is developing an opto-acoustic sensor array called SOCRATES to detect and track the sound generated by the trailing wake vortices created by aircraft. Tracking these aircraft wake vortices during arrival and departure will allow for safer and more efficient airport operations. The sensor array, in essence a type of sonar, employs infrared lasers that act as microphones. This paper describes the sensor array and its ongoing field testing.

Fine, N., Rees, F. and Von Winkle, W.

"ACOUSTIC MEASUREMENTS IN AN AIRPORT ENVIRONMENT AND THE IDENTIFICATION OF THE SOUND RADIATED BY AIRCRAFT WAKE VORTICES"

135th Acoustical Soc. America Conf., Seattle, WA, May 1998

Results are presented of an effort to measure the sound generated by aircraft wake vortices. The objective of the research is to estimate the spectral shape and source levels characteristic of the sound generated by aircraft wakes during approach and landing. Measurements were made at JFK airport in August 1997, for various aircraft, using three Bruel and Kjaer outdoor microphones. The data were recorded to tape, and spectrum analysis was performed using a B&K portable spectrum analyzer. The three microphones were placed near the beginning of runways 13L and 22L, arrayed in several configurations parallel to and perpendicular to the runway centerline. Initial spectrum analysis of the data revealed a prominent broadband 'hump' in the one-third octave sound-pressure level spectra, centered at approximately 50-60 Hz for a B-747 landing (with a band-width of roughly 20-30 Hz). The timing of the hump is consistent with that expected for wake vortex sound and it is hypothesized to be generated by the wake vortices. Cross correlations between microphones arrayed parallel to the runway will test this hypothesis. Additional data, which are to be recorded in January 1998, will also aid in identifying the wake vortex sound characteristics.

Fink, P. T. and Soh, W. K.

"A NEW APPROACH TO ROLL-UP CALCULATIONS OF VORTEX SHEETS"

Proceedings of the Royal Society of London, Series A, Mathematical and Physical Sciences, Vol. 362, Issue 1709, July 1978, pp. 195-209

Careful discretization of two-dimensional vortex sheets has led to the discovery of the cause of inconsistency of the multi-vortex representation of such sheets. The method described here is applied to the calculation of roll-up of the trailing vortex sheet shed from an elliptically loaded wing. Contrary to the results obtained with multi-vortex methods, calculations are found to converge as the discretization is refined.

"COMPARISON OF WIND MONITORING SYSTEMS. PART II: DOPPLER SODARS"

Journal of Atmospheric and Oceanic Technology, Vol. 3, 1986, pp. 594-604.

Measurements of wind speed, wind direction, and the vertical component of turbulence, from four different commercially available Doppler sodars, are compared with similar measurements from in situ sensors on a 300 m instrumented tower. Results indicate that the four sodars measure wind speed and direction accurately and with reasonably high precision. The sodars tended to overestimate the vertical component of turbulence at night and to underestimate it during the day. Precision in those measurements was considerably poorer than for the averaged speeds and directions. Analysis of the vertical wind speed measurements from the sodars indicates that the measurement inaccuracies arise from a combination of aliasing and spatial averaging. Comparison of five in situ wind systems with a sonic anemometer are presented in Part I of this two-part series of papers.

Finkelstein, P. L., Kaimal, J. C., Gaynor, J. E., Graves, M. E. and Lockhart, T. J.

"COMPARISON OF WIND MONITORING SYSTEMS. PART I: IN SITU SENSORS"

Journal of Atmospheric and Oceanic Technology, Vol. 3, 1986, pp. 583-593.

It has recently become clear through advances in both theoretical and experimental meteorology, that improvements in modeling the transport and dispersion of pollutants will require on-site measurements of the atmosphere. This requirement has in turn generated questions about 1) our ability to make such measurements both near the surface and through the first few hundred meters of the atmosphere and 2) the expected accuracy and precision of such measurements using current technology. To help answer these questions an experiment was conducted at the Boulder Atmospheric Observatory to assess the ability of in situ and remote sensors to measure the mean and turbulent properties of the lower atmosphere. Two categories of sensors were tested. One consisted of lightweight in situ sensors of types that have been frequently used in the recent past for boundary layer studies. The other category consisted of four commercially available Doppler sodars, with the capability to measure wind speed, wind direction, and vertical component of turbulence, at various heights above the ground. Part one of this two-part study deals with comparisons of five in situ wind sensing systems with a three-axis sonic anemometer, all mounted on 10 m towers spaced approximately 5 m apart. Discussed in this paper are statistical measures of their accuracy, precision, and spectral response to fluctuations in the wind.

Finn, L. I. and Boghosian, B. M.

"A GLOBAL VARIATIONAL APPROACH TO VORTEX CORE IDENTIFICATION"

Physica A: Statistical Mechanics and Its Applications, Vol. 362, Issue 1, March 2006, pp. 11-16

We present a global variational definition of a vortex core in three-dimensional flows, and describe its implementation for tracking principal vortex cores in a viscous fluid. Our definition is motivated by the observation that the line integral of vorticity along any path worthy of being called a vortex core is likely to be large. Inverting this observation, we define a vortex core as a curve for which this line integral is a local maximum in the space of all such curves (with appropriate boundary conditions). We present an algorithm by which candidate curves are evolved using a Ginsburg-Landau equation to locate vortex cores. We demonstrate the implementation of this algorithm using initial vorticity fields generated with clearly identifiable vortex cores, and evolved using a lattice Boltzmann Navier-Stokes solver.

Fiorino, F.

"A300 INSPECTIONS LOOM FOLLOWING JFK CRASH"

Aviation Week & Space Technology, Vol. 155, No. 21, 19 November 2001, pp. 32-34

The FAA was poised to order inspections of the entire U.S. fleet of Airbus A300-600s as U.S. and French investigators late last week focused on wake turbulence and composite material structures as major factors in the Nov. 12 crash of American Airlines Flight 587. JFK's Automatic Terminal Information Service report at 8:15 a.m. indicated winds from 320 deg. at 11 kt. At 9:13 a.m. Japan Airlines Flight 47, a Boeing 747-400, began its takeoff roll. American Flight 587, N14053, followed, beginning its takeoff roll at 9:14:35 a.m., enroute to Santo Domingo, Dominican Republic, with the first officer at the controls. Preliminary radar readouts indicate Flight 587's flight path was offset to the east from that of JAL Flight 47 by about 0.7 naut. mi. and was behind it about 1.5 min. at the time of the last radar transponder return, as well as being about 800 ft. below. [To move 0.7 naut. mi. in 1.5 min. would have required a wind component of 28 kt. coming from the west.]

Fischbach, J. T.

"WAKE VORTEX VISUALIZER FOR AN AIRCRAFT"

US Patent 7,017,862 B1, March 2006.

A wake vortex visualizer for an aircraft having a self-contained device that is installed within the wing tip to emit a smoke-like trail from the wing tip automatically by the use of simple ball check valve connected between an orifice on the wing tip and a tank of vapor forming fluid during takeoff and landing of the aircraft such that other following aircraft may see and avoid the vortex generated by said aircraft during takeoff and landing.

Fischenberg, D.

"FLOW DETERMINATION METHOD"

US Patent Application 2011/0238330 A1, September 2011.

The invention relates to a method for determining a flow, wherein flow velocities in measuring direction are measured by means of sensors using at least one measuring position, comprising the following steps: a) Initializing parameters of a flow model representing the flow, b) Calculating simulated flow velocities in the measuring direction at least one measuring position according to the flow model representing the flow, c) comparing the measured flow velocities to the simulated flow velocities and adjusting the parameters of the flow model that influences the flow by minimizing a quality function that depends on the comparison result, and d) Repeating of steps b) and c) and determining the flow in dependency of the approximated flow model.

Fischenberg, D.

"WAKE ENCOUNTER FLIGHT TESTS PERFORMED WITHIN THE S-WAKE PROJECT"

First Workshop WakeNet2-Europe, 'Wake Data and Safety Assessment Methods', London, November 2003.

Within the fifth European framework technology project S-WAKE, full-scale wake vortex encounter flight tests were performed. In two campaigns (August 2001, March 2002) more than 100 encounters were flown with the aircraft Do128 and Cessna Citation, while the leading aircraft Vfw-614 ATTAS visualized its wake using a smoke generator installed on the outer left wing. Under favorable conditions, the smoke trace was visible up to 3 nm. Both follower aircraft were fully instrumented with inertial sensors and flow probes to measure the flow field characteristics of the wake vortex as well as the aircraft response during each encounter. The flight test data are of excellent quality and were used successfully for flow field determination as well as encounter model validation. The flight test data of the follower aircraft were evaluated to determine the flow field characteristics during each individual encounter. The flight path was reconstructed in high quality with system identification and flight path reconstruction methods. Using the flow sensor measurements, two different analytical velocity distributions (Burnham-Hallock, Lamb-Oseen) were investigated to match the measured flow field characteristics determining the model parameters with parameter identification techniques. The model parameters (circulation strength, core radius, separation, and vortex location) could be determined trustworthy for each encounter. The method seems to be a promising alternative to vortex parameter measurements by lidar. Two types of encounter models were successfully validated with the encounter flight test data: the Strip Method (SM) and the Lifting Surface Method (LSM). The encounter models were added to the basic flight mechanic models of the encountering aircraft (Do128, Cessna Citation) providing incremental aerodynamic coefficients. Measured control surface deflections as well as the determined vortex characteristics were considered. Comparing the model outputs to the measured flight test data, model benefits as well as model deficiencies could be demonstrated, the quality of both methods were compared.

Fischenberg, D.

"A METHOD TO VALIDATE WAKE VORTEX ENCOUNTER MODELS FROM FLIGHT TEST DATA"

ICAS Paper 2010-6.9.1, Sept. 2010, Nice, France.

A method is presented for assessing the accuracy of aerodynamic wake encounter models (also named 'aerodynamic interaction models'). The method uses real world data from in-situ measurements to produce the best possible fit of a given model structure. This process requires: (a) suitable encounter flight test data, (b) a high precision flight path reconstruction, (c) suitable parameters of an analytical vortex model, and (d) a high quality basic aerodynamic model. The vortex model parameters are identified in an a-priori step from the same wake encounter flight test data used for the subsequent validation of the aerodynamic interaction model. The accuracy assessment is done by analyzing the errors between model outputs and the corresponding flight test data. The paper reflects the used incremental Strip Model structure and recommends appropriate a-priori data. Simulation results are analyzed, and strip model extensions are implemented which imply a notable model quality improvement.

Fish, S.

"VORTEX DYNAMICS IN THE PRESENCE OF FREE SURFACE WAVES"

Physics of Fluids, Vol. A3, No. 4, April 1989, pp. 504-506.

Results are presented of flow visualization experiments on vortex pairs launched toward a free surface containing waves. The two-dimensional vortex pair is generated with an initial depth/separation value of 1.0 using a pivoting pair of flaps. Two-dimensional waves are generated with an oscillating-plate-type wavemaker. The resulting flows indicate a strong interaction between the waves and the vortex trajectories. The aspects of vortex/wave interactions examined are (1) elimination of the 'rebounding' effect on the upstream traveling vortex and (2) an increase in rebound effect on the downstream vortex. These influences of the surface waves on the vortex appear to be related to the near-surface drift current produced by the waves.

"NUMERICAL PREDICTION OF STEADY AND UNSTEADY TIP VORTEX CAVITATION ON HYDROFOILS"

Polish Maritime Research, Vol. 19, No. 3, 2012, pp. 3-15.

The article presents the numerical method for prediction of tip vortex cavitation generated on hydrofoils. This method has been developed in the course of numerical and experimental research described in earlier publications. The objective of the research was to design the optimum discrete grid

structure for this specific computational task and to select the best turbulence model for such an application. The article includes a short description of the method and a computational example demonstrating its performance. In this example the results of numerical prediction of the cavitating tip vortex obtained from two commercial CFD codes are compared with experimental photographs taken in the cavitation tunnel in the corresponding flow conditions. Altogether nine different flow conditions are tested and analyzed, but only selected results are included. The accuracy of the numerical predictions is discussed and the reasons for minor existing discrepancies are identified. The unsteady tip vortex calculations are also presented, showing the fluctuations of the transverse velocity components predicted for three cross-sections of the cavitating vortex kernel.

Flax, A. H.

"COMMENT ON 'SIMPLIFIED METHODS OF PREDICTING AIRCRAFT ROLLING MOMENTS DUE TO VORTEX ENCOUNTERS'"

J. Aircraft, Vol. 14, No. 11, November 1977, pp. 1151-1152

The simple formula derived by Barrows relating the aerodynamic rolling moment according to strip theory to the rolling moment according to lifting-line theory for a wing of elliptical planform subjected to an arbitrary antisymmetric angle-of-attack distribution is a long-established and well-known result in wing theory. Extensive applications of this formula to stability and control and to aeroelasticity have been given in the literature. There is a similar formula for the lift on an elliptic wing due to an arbitrary symmetric angle-of-attack distribution. These special results for the elliptic wing follow from the fact that for this planform all the coefficients of the Fourier series for spanwise circulation distribution in lifting-line theory may be determined explicitly and exactly by quadrature without solving simultaneous equations (which in principle are infinite in number). As is well known in lifting-line theory, for all planforms the total lift depends only on the first Fourier coefficient, whereas the total rolling moment depends only on the second coefficient.

"A HIGH SUBSONIC SPEED WIND-TUNNEL INVESTIGATION OF WINGLETS ON A REPRESENTATIVE SECOND-GENERATION JET TRANSPORT WING"

NASA TN D-8264, July 1976, NASA Langley Research Center, Hampton, VA.

This paper discusses the effects of winglets (described in NASA TN D-8260) on the aerodynamic forces and moments, loads, and crossflow velocities behind the wing tip. The results of the investigation indicate that winglets significantly reduce the drag coefficient at lifting conditions. The experiments were conducted in the Langley 8-foot transonic pressure tunnel at Mach numbers from 0.70 to 0.83 and over a lift coefficient range up to 0.65. A semispan model was used.

Fleig, O. and Arakawa, C.

"LARGE-EDDY SIMULATION OF TIP VORTEX FLOW AT HIGH REYNOLDS NUMBER"

AIAA Paper No. 2004-0261, Reno, NV, January 2004

Simulations using up to 300 million grid points are performed on the Earth Simulator in Japan, the fastest supercomputer in the world. The present work is the first attempt to simulate a finite blade with a tip in an incident flow and its associated tip vortex and acoustic field at a Reynolds number in the order of a million using direct compressible LES (Large-Eddy Simulation). For validation purposes, the flows around a NACA0012 blade section as well as finite blade at lower Reynolds number are simulated. It is a wall resolved simulation using the Smagorinsky eddy viscosity model. Angles of attack between 5 and 11 degrees are studied at Reynolds numbers ranging from $4.06 \times 100,000$ to $2.87 \times 1,000,000$. The simulation results showed that the tip vortex plays a major role in aerodynamic noise generation. The present large-scale simulation can provide information about the physical phenomena causing tip vortex flow and tip noise at high Reynolds numbers. This information can be used in various engineering applications such as aerospace and wind energy and could help to design blade tips for reduced noise emission.

"ANALYSIS OF WAKE SURFING BENEFITS USING A FAST UNSTEADY VORTEX LATTICE METHOD"

AIAA Paper 2019-0264, January 2019, San Diego, CA.

The computer simulation framework Flexit is used to analyze the fuel economy benefit of aircraft wake surfing. Wake surfing involves multiple aircraft flying in close formation during cruise conditions to reduce overall induced drag and improve overall fuel efficiency. The aircraft fly in echelon such that the kinetic energy lost in vortices generated by the lead aircraft can be partially recovered by the following aircraft flying in regions of the wake where induced velocities have an upwardly directed vertical component. We build on recent theoretical and flight test work by developing a medium fidelity methodology using Flexit for predicting potential performance benefits of wake surfing. We present results from a specific systematic parametric study that corresponds to a series of recent flight tests with two C-17 transport aircraft to demonstrate the methodology and predict the fuel savings that can be obtained by different arrangements of aircraft in a wake surfing formation. The predictions are compared with the flight test data and the trends observed in our simulations agree with the trends of the full-scale tests.

"A SIMULATION STUDY DEMONSTRATING THE IMPORTANCE OF LARGE-SCALE TRAILING VORTICES IN WAKE STEERING"

Wind Energy Science, Vol. 3, 2018, pp. 243-255.

In this paper, we investigate the role of flow structures generated in wind farm control through yaw misalignment. A pair of counter-rotating vortices is shown to be important in deforming the shape of

the wake and in explaining the asymmetry of wake steering in oppositely signed yaw angles. We also demonstrate that vortices generated by an upstream turbine that is performing wake steering can deflect wakes of downstream turbines, even if they are themselves aligned. We encourage the development of improvements to control-oriented engineering models of wind farm control, to include the effects of these large-scale flow structures. Such a new model would improve the predictability of control-oriented models. Further, we demonstrate that the vortex structures created in wake steering can lead to greater impact on power generation than currently modeled in control-oriented models. We propose that wind farm controllers can be made more effective if designed to take advantage of these effects.

"HELICOPTER TAIL ROTOR THRUST AND MAIN ROTOR WAKE COUPLING IN CROSSWIND FLIGHT"

Journal of Aircraft, Vol. 47, No. 6, November-December 2010, pp. 2136-2148.

The tail rotor of a helicopter with a single main rotor configuration can experience a significant reduction in thrust when the aircraft operates in crosswind flight. Brown's vorticity transport model has been used to simulate a main rotor and tail rotor system translating at a sideslip angle that causes the tail rotor to interact with the main rotor tip vortices as they propagate downstream at the lateral extremities of the wake. The tail rotor is shown to exhibit a distinct directionally dependent mode during which tail rotors that are configured so that the blades travel forward at the top of the disk develop less thrust than tail rotors with the reverse sense of rotation. The range of flight speeds over which this mode exists is shown to vary considerably with the vertical location of the tail rotor. At low flight speeds, the directionally dependent mode occurs because the tail rotor is immersed within not only the downwash from the main rotor but also the rotational flow associated with clusters of largely disorganized vorticity within the main rotor wake. At higher flight speeds, however, the tail rotor is immersed within a coherent super-vortex that strongly influences the velocity field surrounding the tail rotor.

"SOCRATES WAKE VORTEX DETECTION AND TRACKING: A TECHNICAL STATUS REPORT"

Report DTRS57-03-D-30024, November 2004, Volpe National Transportation Systems Center, Cambridge, MA

SOCRATES is a laser based passive opto-acoustic wake turbulence detection concept being developed by Flight Safety Technologies, Inc. and Lockheed Martin Corporation. The claim of the SOCRATES development team is that it can detect and track wake vortices by passively sensing the sound that emanates from aircraft wakes. In 2003, a fundamental wake acoustic testing to better understand the wake acoustic phenomenology was conducted at the Denver International Airport using a NASA-Volpe fielded phased microphone array. This fundamental test also provided an opportunity to better understand the status of the SOCRATES development up to that point in time. The purpose of this

report is to, from the developer's perspective, describe the status of the SOCRATES development effort. The system is described, along with other background information, in sections 2 and 3. The nature of the sound generated by aircraft wake vortices is discussed in section 4, and comparison between SOCRATES and LIDAR-derived wake tracks is presented in section 5. Remaining challenges and conclusions are presented in sections 6 and 7.

"VORTEX IN THE WAKES OF AIRPLANES"

Fluid Dynamics in Physics, Engineering and Environmental Applications, J. Klapp et al. (editors), Environmental Science and Engineering, 2013, Springer-Verlag Berlin Heidelberg, pp. 345-351.

This paper describes the disturbances caused by wing trailing vortices and their effect on aircraft flying into them. We briefly discuss the physical characteristics of the wing trailing vortices together with their control and alleviation and emphasis is done about the importance that it has in order to diminish the problems generated by the increase in air traffic and in the flight safety.

Fogg, J. G.

"VORTEX PAIR INSTABILITIES IN GROUND EFFECT"

MS Thesis, May 2001, Cornell University, Ithaca, NY.

In this thesis we investigate the development of the long-wavelength instability of a counter-rotating vortex pair in the presence of the ground. Our experiments involve detailed visualizations and velocimetry of the vortex pair, which is generated underwater by two rotating plates. We first investigate the dynamics of the instability far from the ground. We find that the instability amplitude grows exponentially to the point of reconnection, at which point the vortex pair transitions to a series of vortex rings. In the presence of the ground, we find that the reconnection and subsequent break-up of the vortex pair into a series of vortex rings can be inhibited. We find that there exists a critical initial height for the vortex pair, above which the vortices reconnect and form rings. Below this critical height, the vortices separate due to ground effects, even if partial reconnection has taken place. We also discover that the instability plane rotates as the vortex pair interacts with the ground, in a direction contrary to that one might expect, based on image vorticity considerations. We present experimental measurements using DPIV of the vortex-ground interaction, including the well-known rebound effect as well as measurement of the generation of secondary vorticity.

Follin, G. J.

"THE TURBULENCE STRUCTURE OF TRAILING VORTEX WAKES"

MS Thesis, 1996, Virginia Polytechnic Institute and State University, Blacksburg, VA.

The present investigation is a two-part study of the mean flow and turbulence structure of isolated vortices and counter-rotating vortex pairs. In the first part, the turbulence structure of an isolated vortex was studied using three-component velocity measurements. Vortices were generated using two symmetrical airfoils. Measurements were made in cross-sectional grids and profiles over a range of Reynolds numbers and downstream distances. Contours of axial normal stress were high-pass filtered to remove the contributions of wandering to the velocity fluctuations. This process reveals a vortex core which is laminar and is surrounded by a region of high turbulence. Core velocity profiles reveal that maximum tangential velocity increases with Reynolds number and decreases with distance downstream. Core radius increases with distance downstream and decreases with Reynolds number. In the second part, flow visualizations of the wake behind a delta wing model were made for a range of Reynolds numbers and lift coefficients. These visualizations reveal the near-instantaneous turbulence structure of the wing wake which is dominated by a vortex pair and a connecting 'braid' wake. The braid spacing decreases with increasing Reynolds number and is independent of lift coefficient. The extent of the braid downstream of the wing increases with lift coefficient and decreases with increasing Reynolds number. The large turbulent scales in the wing wake were found to increase in discrete jumps indicating some sort of reorganization of turbulence such as pairing. This reorganization of turbulence was found to occur more quickly as Reynolds number is increased.

Follin, G. J. and Devenport, W. J.

"EFFECTS ON THE TURBULENT STRUCTURE OF A COUNTER-ROTATING VORTEX PAIR"

AIAA Paper No. 1996-1959, New Orleans, June 1996

Flow visualizations of the wake of a 75deg delta wing were made by laser illumination of fluorescein dye over a range of Reynolds numbers and lift coefficients. These visualizations reveal the wing wake to be made up of a counter-rotating vortex pair connected by a spanwise periodic structure called the 'braid' wake. The wavelengths of the dominant structures in the wing wake were found to increase with distance behind the wing in discrete jumps, implying some sort of reorganization of turbulence from small to large scales. Increasing Reynolds number was found to decrease the braid spacing and the extent of the braid wake behind the wing. The redistribution of turbulence from small to large scales was found to speed up with increasing Reynolds number. Increasing lift coefficient was found to increase the extent of the braid. The vertical extent of the wake also appeared to increase with the lift coefficient.

Follin, G. J. and Devenport, W. J.

"THE TURBULENCE STRUCTURE OF TRAILING VORTEX WAKES"

Report VPI-AOE-235, 1996, Virginia Polytechnic Institute and State University, Blacksburg, VA.

The present investigation is a two-part study of the mean flow and turbulence structure of isolated vortices and counter-rotating vortex pairs. In the first part, the turbulence structure of an isolated vortex was studied using three-component velocity measurements. Vortices were generated using two

symmetrical airfoils. Measurements were made in cross-sectional grids and profiles over a range of Reynolds numbers and downstream distances. Contours of axial normal stress were high-pass filtered to remove the contributions of wandering to the velocity fluctuations. This process reveals a vortex core which is laminar and is surrounded by a region of high turbulence. Core velocity profiles reveal that maximum tangential velocity increases with Reynolds number and decreases with distance downstream. Core radius increases with distance downstream and decreases with Reynolds number. In the second part, flow visualizations of the wake behind a delta wing model were made for a range of Reynolds numbers and lift coefficients. These visualizations reveal the near-instantaneous turbulence structure of the wing wake which is dominated by a vortex pair and a connecting 'braid' wake. The braid spacing decreases with increasing Reynolds number and is independent of lift coefficient. The extent of the braid downstream of the wing increases with lift coefficient and decreases with increasing Reynolds number. The large turbulent scales in the wing wake were found to increase in discrete jumps indicating some sort of reorganization of turbulence such as pairing. This reorganization of turbulence was found to occur more quickly as Reynolds number is increased.

"NUMERICAL SIMULATION OF INVISCID INCOMPRESSIBLE TWO-DIMENSIONAL AIRFOIL-VORTEX INTERACTION IN GROUND EFFECT"

Journal of Aircraft, Vol. 40, No. 4, July-August 2003, pp. 653-661

A numerical inviscid vortex method is employed to study the unsteady, two-dimensional, incompressible flow that occurs during an airfoil-vortex interaction in the vicinity of a ground plane. The airfoil bound vorticity is modeled using a panel method with linear piecewise-continuous vorticity distribution. The vortex is considered to be a point vortex, and the ground effect is obtained using the method of images. Point vortices are also generated at the airfoil trailing edge to ensure that circulation is conserved and that the Kutta condition is satisfied. All vortices are convected using a first-order Lagrangian time-marching scheme. After code validation, numerical results for the airfoil-vortex interaction in ground effect reveal that the loading on the airfoil is affected by the thickness, angle of attack, and height of the airfoil above the ground, as well as the vortex strength, direction of rotation, and distance to the airfoil. The wake evolution is nonlinear and strongly influenced by the interaction, whereas the pressure distribution on the ground presents steep adverse gradients.

Fonseca, G. F., Bodstein, C. R. and Hirata, M. H.

"NUMERICAL SIMULATION OF INVISCID INCOMPRESSIBLE TWO-DIMENSIONAL AIRFOIL-VORTEX INTERACTION IN GROUND EFFECT"

Journal of Aircraft, Vol. 40, No. 4, July-August 2003, pp. 653-661.

"NONMODAL STABILITY ANALYSIS OF THE LAMB-OSEEN VORTEX"

International Workshop on Fundamental Issues Related to Aircraft Trailing Wakes, Marseille, France, May 2008

The present contribution aims to report the investigation of the vortex meandering phenomenon. Isolated columnar vortices are known to be asymptotically stable but often present behaviors not well understood. Among them, the vortex meandering consists in an erratic displacement of the vortex core acknowledged to considerably embarrass experimentalists. These phenomena of energy growth are related to the non-normality of the corresponding dynamical operator and need to be studied within the frame of the nonmodal stability analysis. We look first at the optimal perturbations, i.e. the initial conditions maximizing their energy growth for any given time. From the evolution of these disturbances, two mechanisms of energy growth are identified. The first one, called the anti-lift-up, leads to the generation of vortex rings in the potential region around the vortex. The second one is a resonance phenomenon leading to the emergence of a wave in the vortex core through a mechanism combining Orr and induction effects. The emergence of the displacement wave is thus a good candidate for the vortex meandering phenomenon. Secondly, the robustness of these perturbations is considered in a more realistic case. The vortex is continuously forced by a random white noise, aimed to be representative of any generic disturbance occurring in real flows. With this stochastic approach, optimal disturbances are generally observed to emerge, except in cases when there may exist strong sub-optimal perturbations that compete well with optimal ones.

Fonti, E.

"MEASUREMENTS OF AIRCRAFT WAKE VORTICES IN GROUND PROXIMITY WITHIN AN ATMOSPHERIC BOUNDARY LAYER WIND TUNNEL"

MS Thesis, 2010, Cranfield University, Cranfield, UK.

The vortex wake characteristics of aircraft during landing and take-off are of interest in connection with both the safety of following aircraft penetrating the vortex and the dispersion of engine exhaust plumes. A series of measurements were carried out in an Atmospheric Boundary Layer Wind Tunnel (ABLWT) to identify and characterize both the mean and turbulent flow field of a pair of wake vortices

in ground proximity. The ABLWT simulation at 1:200th scale utilized a flat plate delta planform wing to produce a wake vortex system with an initial vortex core separation consistent with that expected for the DLR VFW614 ATTAS aircraft during the final stages of the approach and flare prior to landing to aid possible future full- scale validation. Evaluation of the mean flow field was obtained in vertical planes downstream of the model 0.18b to 7.48b (b is the wing span) using a traversing 5-hole pressure probe. Vortex trajectory, circulation decay, vorticity decay and core radius evolution were tracked at wing heights of 0.93b to 2.24b within the wind tunnel working section, showing the ground proximity effect on the vortex system. The vortices were seen to sink behind the wing and diverge moving downstream, as expected. The rate of descent was shown to decrease as the wing approaches the ground. The circulation was fitted to a straight line with enough accuracy for all the wing heights investigated. An inviscid model for the prediction of the trajectory of a vortex pair was developed. It uses an infinite vortex sheet to simulate the interaction between the vortices and the ground when these are in the ground effect region. The experimental results were compared to the model showing good agreement. Measurements of the instantaneous flow field were acquired by means of a Stereo Particle Velocimetry system and were used to investigate the effect of turbulence on the vortex system. The mean field was compared to the fluctuating field showing the random and intermittent nature of the turbulence. Turbulence intensity, Reynolds stresses, spatial velocity correlations and correlation lengths were calculated and discussed. However, further work is needed to acquire a more comprehensive set of PIV data in the ABLWT to draw stronger conclusions.

Ford, R. and Smith, S. G. L.

"SCATTERING OF ACOUSTIC WAVES BY A VORTEX"

J. Fluid Mech., Vol. 386, 1999, pp. 305-328

We investigate the scattering of a plane acoustic wave by an axisymmetric vortex in two dimensions. We consider vortices with localized vorticity, arbitrary circulation, and small Mach number. The wavelength of the acoustic waves is assumed to be much longer than the scale of the vortex. This enables us to define two asymptotic regions: an inner, vortical region, and an outer, wave region. The solution is then developed in the two regions using matched asymptotic expansions, with the Mach number as the expansion parameter. The leading-order scattered wave field consists of two components. One component arises from the interaction in the vortical region, and takes the form of a dipolar wave. The other component arises from the interaction in the wave region.

Fox, S. M.

"C-17 AIRDROP SIMULATION"

MS Thesis, Air Force Institute of Technology, WPAFB, OH, March 1998

We develop an object-oriented simulation that models the airdrop mission of the newest U.S. transport aircraft, the C-17 Globemaster III. The simulation, written in MODSIM III is based on three basic object types: a C-17, a wake vortex, and a paratrooper. The aircraft object provides the required

aerodynamic constants for simulating the wake vortices generated off each wing tip; the vortex object includes velocity field and decay models as well as a position algorithm; and, the paratrooper object implements a 6-degree of freedom trajectory model. After considering two validation scenarios, we generate vortex encounter information for various formations and wind conditions, and quantify the associated risk of paratrooper/vortex encounters in a potential encounter rate. Time over the DZ is a primary concern in any airdrop operation, and the results of this analysis form a tool that allows the ground commander to assess the risk involved in decreasing that time. We also present a 3D visualization of the simulation output that may be used for mission planning and prototyping of new aircraft formations or tactics.

Fox, S. M., Bailey, T. G. and Carlton, W. B.

"PERSONNEL AIRDROP SIMULATION"

Simulation, Vol. 76, No. 1, Jan. 2001, pp. 4-21

We develop an object-oriented simulation that models the airdrop mission of a US transport aircraft, the C-17 Globemaster III. The simulation, written in MODSIM III, is based on three basic object types: an aircraft, a wake vortex, and a paratrooper. The aircraft object provides the required aerodynamic constants for simulating the wake vortices generated off each wingtip; the vortex object includes velocity field and decay models as well as a position algorithm; and the paratrooper object implements a 6-degree-of-freedom trajectory model. Using the simulation, we generate vortex encounter information for various formations and wind conditions, and quantify the associated risk of paratrooper/vortex encounters in a potential encounter rate. Time over the drop zone is a primary concern in any airdrop operation, and the results of this analysis form a tool that allows the ground commander to assess the risk involved in decreasing that time.

Frakes, J. F.

"WING TIP VORTICES SUPPRESSOR"

US Patent 4,478,380, October 1984.

A wing tip vortices suppressor utilizing a scoop having an inlet at the lower, leading surface of the wing and an outlet at the upper, trailing surface to reduce turbulence causing pressure differential across the wing. A turbulence fence is used at the tip to account for the frictional losses of the air flowing through the scoop and other phenomena that prevent exact pressure equalization.

Francis, D. G.

"DEVELOPMENT OF A VORTEX LASER DOPPLER VELOCIMETER"

Proceedings of the National Aerospace Electronics Conf., IEEE, 1971, pp. 36-40

The paper describes basic laser Doppler velocimeter theory and outlines the vortex laser Doppler velocimeter program at the Arnold Engineering Development Center. The object of the program is to design, develop, and place into operation a three-component laser Doppler velocimeter system capable of mapping velocity profiles of aircraft wake turbulence at altitudes up to 1000 feet.

Francis, M. S.

"AN EXPERIMENTAL INVESTIGATION OF WING TRAILING VORTEX FORMATION"

FJSRL TR-76-0013, August 1976, US Air Force Academy, Colorado Springs, CO.

The incompressible flow field in the vicinity of a lifting rectangular finite wing is investigated experimentally to ascertain the nature and detailed characteristics of the formation and early development of a trailing vortex. The apparatus was designed and fabricated to facilitate a direct comparison of real flow data with existing theories and flow models. The inboard potential flow region was observed to exhibit the simplifying characteristic of a spanwise cross-flow velocity component which is independent of the surface normal coordinate. As a result, a possible ambiguity in the determination of the stream-wise vorticity component was removed. Graphs of the near-surface (bound) vorticity distribution are presented along with a map of Prandtl bound vortex filaments. The associated bound circulation function could be expressed approximately as the product of two separable functions of the planform spatial coordinates. Measurements at the wing trailing edge are employed to show that the properly non-dimensionalized characteristic vorticity distribution in this region is independent of angle of attack.

Francis, M. S. and Kennedy, D. A.

"FORMATION OF A TRAILING VORTEX"

Journal of Aircraft, Vol. 16, No. 3, March 1979, pp. 148-154

The incompressible flow field in the vicinity of a lifting rectangular finite wing is investigated experimentally to ascertain the nature and detailed characteristics of the formation of a trailing vortex. The mean velocity field was mapped directly using a linearized constant temperature hot-wire anemometry probe in conjunction with a precision wind-tunnel traversing mechanism. The associated vorticity field was inferred from these measurements through a spatial contour integration procedure. The existence of several identifiable flow regions exhibiting similar characteristics was established and verified with both hot-wire and flow visualization data. The nature of the near surface bound vorticity distribution is described including a map of the Prandtl-bound vortex filaments. Measurements at the wing trailing edge show that the properly nondimensionalized characteristic vorticity distribution in this region is independent of angle of attack. Shed vorticity emanating from the lower aerodynamic surface near the wing tip was observed to roll up adjacent to the tip and roll over onto the upper wing surface at a chordwise location which depends on the wing orientation. The presence and behavior of this structure which possesses an identifiable core is suggested as the cause of the modified pressure distribution (lift increment) normally observed in this region.

"OBSERVATIONS ON THE DEVELOPMENT OF A TIP VORTEX ON A RECTANGULAR HYDROFOIL"

Journal of Fluids Engineering, Vol. 110, June 1988, pp. 208-215.

The present paper describes a flow visualization study that focuses the development of a tip vortex on a rectangular NACA-66 hydrofoil. The experiments have been performed in a towing tank. Illumination with a thin laser sheet together with distribution of dye have been utilized as a means of observation. The results demonstrate the growth of the vortex along the chord, the increase in its dimensions with increasing incidence angle and decreasing Reynolds number. They also show that the center of the vortex moves inward towards the root with increasing incidence angle, increasing chordwise location, and decreasing velocity. Empirical relations for these trends have been computed. The observations also demonstrate that the flow around the tip is dominated by multiple vortex structures that include the primary vortex, a counter rotating structure, shear layer eddies, and several other secondary vortices.

"ANALYSIS OF THE DYNAMICS OF WAKE VORTICES IN THE ATMOSPHERIC BOUNDARY LAYER"

ISBN-3-923624-27-1, 1995, University of Hannover, Hannover, Germany

The longevity and high intensity of wakes of landing aircraft may create hazards to subsequent air traffic. This study compares the results of extensive field experiments with results of numerical simulations and uses them to develop a wake displacement model. It was confirmed that vortex life is greatly determined by the wind conditions prevailing in the vortex propagation area. The increasing turbulent kinetic energy in higher main flows leads to premature disintegration phenomena of the wake. While the mean life of all measured wakes is only 78 s, lives of more than 2 minutes can be reached at lower horizontal wind speeds. The longest measured life of a wake is 192 s. It is shown that vortex life is also influenced by atmospheric stability. Under stable layering conditions a longer vortex life must be expected. The measure of this influence is more marked in the measurements than that apparent in numerical simulations. [In German.]

"A STATISTICAL EVALUATION OF NAVIGATIONAL PERFORMANCE OF ILS-APPROACHES AT FRANKFURT INTERNATIONAL AIRPORT"

FLIP Version 2.0, DFS Deutsche Flugsicherung GmbH, February 2001, Offenbach, Germany

This study involved extensive data collection, processing, and analysis for radar tracks of aircraft approaching Frankfurt International Airport. Data obtained over a limited period of three days using the high precision Skyguard radar system were used to validate 4 months of Airport Surveillance Radar

data. The data indicate that the deviations from the ILS localizer and glide slope are well within the tolerances set by ICAO (typically within 0.07 degrees, four times better than ICAO specifies for lateral deviations: typically 0.03 to 0.05 degrees (0.20-0.35 dots), for height deviations). The height deviations agree with statements of pilots that they avoid wake vortices by flying slightly above the glide slope.

"OPTIMUM DOWNWASH BEHIND WINGS IN FORMATION FLIGHT"

Journal of Aircraft, Vol. 40, No. 4, July 2003, pp. 799-803

The calculus-of-variations approach previously used by Jones for determining minimum induced drag of single wings has been extended to handle multiple wings in formation flight with constraints on the lift and rolling moment for each wing. The approach shows that the lift distributions for wings in formation flight with constraints on the lift and rolling moments on each wing must result in a linear variation in the Trefftz-plane downwash for the total induced drag of the formation to be a minimum. Like the constrained-minimization approach, the current formulation is also valid only for formation geometries in which the wake traces of the wings in the Trefftz plane do not intersect or overlap with each other. Although there does not appear to be any significant computational advantage to the present method when compared to that of a constrained-minimization technique, the present method provides a simple closed-form expression for the optimum downwash and, thus, provides additional insight into the aerodynamics of ideal formation flight.

"A SIMPLE METHOD TO ESTIMATE THE EDDY DISSIPATION RATE FROM SODAR/RASS MEASUREMENTS"

16th Symposium on Boundary Layers and Turbulence, AMS, 2004, Portland, Oregon.

The dissipation rates obtained from SODAR/RASS for the stable/neutral cases using a scaled TKE show an acceptable agreement with eddy dissipation rates obtained from LIDAR measurements. For unstable situation, a stability correction needs to be developed which is work currently under way.

Frech, M.

"ESTIMATING THE TURBULENT ENERGY DISSIPATION RATE IN AN AIRPORT ENVIRONMENT"

Boundary-Layer Meteorol, Vol. 123, 2007, pp. 385-393

This note reports on the influence of aircraft wake vortices on the estimation of the turbulent energy dissipation rate using sonic anemometer measurements near the runway threshold. The wake vortex traces, which are generated at a height of about 65 m and subsequently evolve in ground effect, are clearly visible in the velocity components and temperature. The observed temperature increase of 1 K appears related to the stably stratified atmospheric surface layer. The dissipation rate is estimated from the longitudinal velocity power spectrum for a sample in a nocturnal boundary layer with and

without a wake vortex signal. In both cases an inertial subrange is found. For the analyzed sample the estimated dissipation rate is a factor of ten larger compared to the undisturbed sample. Implications for operational wake avoidance systems are discussed.

"SKILL OF AN AIRCRAFT WAKE VORTEX TRANSPORT AND DECAY MODEL USING WEATHER PREDICTION AND OBSERVATION"

Proceedings of the Twelfth Conference on Aviation Range and Aerospace Meteorology, American Meteorological Society, Atlanta, Georgia, Feb. 2006

To safely reduce aircraft separation during approach and landing, the wake vortex behavior along the glide path must be known and predicted. This requires in principle the knowledge of wake vortex relevant meteorological parameters along the entire glide path where typically continuous meteorological measurements of all relevant variables are not feasible. For multiple purposes a one-year meteorological data base for the Frankfurt Terminal area has been generated using NOWVIV. The skill of the nowcasting system NOWVIV (Nowcasting Wake Vortex Impact Variables, Gerz et al. 2005) to predict these environmental parameters is assessed. This one-year data set comprises typical weather conditions and includes already typical features of a long-term surface wind climatology. It enables to test new operational concepts with realistic meteorological input and to estimate the potential for aircraft separation reduction. It may also be used within risk assessments for prototype wake-vortex advisory systems (Gerz et al. 2005). A subset of the one-year data base is analyzed in detail for a period of 40 days where a dedicated wake measurement campaign was carried out at Frankfurt airport in fall 2004 (Frech et al., 2005). In total 231 wake vortex pairs generated by heavy aircraft in ground proximity were tracked and characterized by LIDAR. During this measurement campaign a SODAR/RASS and a LIDAR provided profile measurements of meteorological variables. These data are used to analyze the quality of the predicted profiles of wind, temperature, and turbulence (Frech et al., 2005). Furthermore, we carry out a skill analysis to investigate the potential of NOWVIV as a real-time prediction system where we focus on the ability to predict pre-defined cross wind thresholds. The skill of NOWVIV is compared to the skill of a simple cross wind persistence model based on SODAR measurements. For this purpose, we assume that a given measured cross wind profile is valid over the whole forecast lead time and evaluate the skill of the forecast with increasing lead time every 10 minutes.

"SENSITIVITY OF A WAKE VORTEX MODEL TO METEOROLOGICAL INPUT VARIABLES"

XXV General Assembly, European Geophysical Society, Nice, France, April 2000

A large eddy simulation (LES) of the decay of wake vortices in the convective boundary (CBL) is used to investigate the predictive capabilities of a simple wake vortex transport and decay model (VORTEX) based on Corjon and Poinot (1996). The sensitivity of VORTEX forecasts on the quality of

meteorological input parameters is studied, since only limited meteorological background information is available operationally. We test three simple methods to account for the structure of the CBL. Area-averaged CBL profiles computed from LES and simple model assumptions on the structure of the CBL using surface data are used as input. A simple third approach uses meteorological LES data at $z=16$ m which is a height representative for tower measurements. For the trajectories, the first and second approach yields similar results. The predicted residence corridors are erroneous for some time steps. The errors are quantified. The third approach yields conservative results, which is an important result from an operational point of view. For the CBL case, this study shows that surface measurements would be sufficient to predict WV trajectories along the glide path with acceptable accuracy. We also test recently published parameterizations of the turbulent decay of wake vortices. We find a weak sensitivity of the predicted corridor on the type of parameterization. The precise knowledge of the meteorological background conditions is more important.

"A PROBABILISTIC PREDICTION SCHEME FOR WAKE VORTEX EVOLUTION IN A CONVECTIVE BOUNDARY LAYER"

Air Traffic Control Quarterly, Vol. 10, No. 1, 2002, pp. 23-41

The convective boundary layer's relationship to the formation and dissipation of wake vortices is studied in this research, which used large eddy simulation (LES) data in a parametric model. Profiles of the turbulent kinetic energy and variances created with LES data for an evolving convective boundary layer match profiles of a stationary convective boundary layer. The LES data is also used to verify wake vortex predictions by models, which have only limited meteorological data about elements such as cross winds which can dissipate wake vortices. Models and LES data tend to predict conservative rates of vertical dissipation for wake vortices until the rapid phase of decay starts. Then decay is underestimated, which produces conservative recommendations for separations of aircraft. The authors conclude that turbulent kinetic energy predictions are sufficient for predicting wake vortices. More work is needed to develop methods to predict short-term pictures of boundary layers every 30 minutes. Also needed is work on learning about meteorological conditions that contribute to wake vortices, particularly wind shear, with the goal of predicting wake vortices for an entire glide path.

Frech, M. and Holzaepfel, F.

"SKILL OF AN AIRCRAFT WAKE-VORTEX MODEL USING WEATHER PREDICTION AND OBSERVATION"

J. Aircraft, Vol. 45, No. 2, March-April 2008, pp. 461-470

The performance of the two-phase probabilistic wake-vortex transport and decay model using numerical weather prediction and weather observations as input is analyzed using data from a wake measurement campaign carried out at Frankfurt airport during fall 2004. The wake-vortex observations include wakes evolving in and out of ground effects. The best forecast quality is achieved for wakes evolving in ground effect. We include the simplified hazard-area prediction model to compute the time

to clear the corridor from hazardous wakes and to assess the potential capacity gain for single-runway operations. The highest-capacity potential can be expected when weather observations are employed for wake predictions. The limiting factor for capacity is wakes evolving in ground effect. Out of ground effect, the self-induced vertical transport of the wake vortex proves to be a robust mechanism to clear the approach corridor in an efficient way. This is found independently from the source of meteorological input. In contrast, the consideration of lateral wake transport alone leads to marginal-capacity potential. The analysis also shows that weather data along the glide path can be provided by numerical weather prediction for safe wake prediction.

Frech, M. and Zinner, T.

"CONCEPT OF WAKE VORTEX BEHAVIOR CLASSES"

Journal of Aircraft, Vol. 41, No. 3, May-June 2004, pp. 564-570

The concept of wake vortex behavior classes is introduced. Rather than consider the individual wake vortex evolution, diagnosis of the meteorological situation causing a characteristic wake vortex behavior is proposed. We define four wake vortex behavior classes that explicitly refer to both the wake vortex transport and the decay behavior. The statistical analysis of the Memphis wake vortex database supports this new concept and also shows the distinct influence of weather on wake vortex behavior. The analysis indicates that the high-level safety of International Civil Aviation Organization (ICAO) separations between consecutive aircraft is primarily due to the transport of wake vortices out of a flight corridor. It is found that, depending on atmospheric conditions, a significant fraction of wake vortices does not decay enough to satisfy the existing ICAO separations. Of these wake vortices, a small fraction is within a safety corridor and therefore poses a potential risk to a following aircraft. A simple crosswind criterion with a threshold of 2 m/s provides a safety corridor that is free of wake vortices under radar separation. This demonstrates the large potential for safe reduction of aircraft separation under crosswind conditions. This is supported by an analysis of a wind climatology representative for Frankfurt airport.

Frech, M. and Zinner, T.

"WAKE VORTEX BEHAVIOUR CLASSES AND THEIR INITIAL VALIDATION"

EUROMECH Colloquium No. 433, Dynamics of Trailing Vortices, Aachen, Germany, March 2002

Experimental and numerical results indicate that existing wake vortex separation standards appear most of the time over-conservative which means that atmospheric conditions often favor a rapid decay and/or transport of wake vortices (WV) out of the glide path corridor. In order to reduce the separation distances a Wake Vortex Prediction System (WVPS) is needed. A WVPS consists of a weather and a WV predictor which forecasts the decay and transport of WVs. The forecasted WV decay and trajectory is then used to re-stagger approaching aircraft if the WV poses no hazard to a following aircraft. This requires a validated wake vortex transport and decay model together with high resolution meteorological input data. Examples for such systems are AVOSS, the wake vortex warning system

(WVWS) at Frankfurt Airport and Syage. For various reasons none of these systems are operational to date. Typically, a real-time wake vortex model requires as meteorological input profiles of the wind components, temperature and turbulent kinetic energy or alternatively eddy dissipation rate. Especially profiles of turbulent kinetic energy are difficult to measure and predict with high vertical resolution in an operational environment. Our new approach is to establish meteorologically motivated 'wake vortex behavior classes' (WVBC) which favor a certain wake vortex evolution with respect to transport and decay out of and in ground effect. Rather than predicting the individual wake vortex trajectory it is suggested to predict the meteorological situation causing a characteristic wake vortex behavior. The WVBC names explicitly refer to their ability to cause a specific wake vortex behavior, namely Rapid Decay - Moderate Decay - Weak Decay - Transport - IGE.

"SHORT-TERM PREDICTION OF THE HORIZONTAL WIND VECTOR WITHIN A WAKE VORTEX WARNING SYSTEM"

Meteorological Applications, Vol. 9, 2002, pp. 9-20

A wake vortex warning system (WVWS) has been developed for Frankfurt Airport. This airport has two parallel runways which are separated by 518 m, a distance too short to operate them independently because wake vortices may be advected to the adjacent runway. The objective of the WVWS is to enable operation with reduced separation between two aircraft approaching the parallel runways during appropriate wind conditions. The WVWS applies a statistical persistence model to predict the crosswind within a 20-minute period. One of the main problems identified in the old WVWS is discontinuity between successive forecasts. These forecast breakdowns were not acceptable to air traffic controllers. At least part of the problem was related to the fact that the forecast was solely based on the prediction of crosswind. A new method is developed on the basis of 523 days of sonic anemometer measurements at Frankfurt Airport. It is demonstrated that the prediction of the horizontal wind vector avoids these difficulties and significantly improves the system's performance.

"HIGH-RESOLUTION WEATHER DATABASE FOR THE TERMINAL AREA OF FRANKFURT AIRPORT"

J. Applied Meteorology and Climatology, Vol. 46, Issue 11, Nov. 2007, pp. 1913-1932

A 1-year meteorological dataset for the terminal area of Frankfurt Airport in Germany has been generated with a numerical weather prediction system to provide a synthetic though realistic database for the evaluation of new operational aircraft arrival procedures and their associated risks. The comparison of the 1-year dataset with a local surface wind climatology indicates that the main climatological features are recovered. A subset of 40 days is validated against measurements from a sound detection and range/radio acoustic sounding system (SODAR/RASS) taken at Frankfurt Airport. The frequency distribution of meteorological parameters, such as wind component perpendicular to the glide path, shear, and thermal stratification, show good agreement with observations. The

magnitude of the turbulent energy dissipation rate near the surface is systematically overestimated, whereas above 100 m the authors find on average a slight underestimation. The analysis of the database with respect to crosswind conditions along the glide path indicates only a time fraction of 12 percent for which the crosswind is above a threshold of 2 m/sec. A similar result is obtained using a grid point near the airport that mimics a wind profiler, which suggests that in a majority of cases, a wind profiler appears sufficient to cover the expected crosswind conditions along the glide path. A simple parameterization to account for the crosswind variability along the glide path is proposed.

"DOPPLER LIDAR MEASUREMENTS OF WINDS AND TURBULENCE IN THE BOUNDARY LAYER"

14th International Symposium for the Advancement of Boundary Layer Remote Sensing, IOP Conf. Series: Earth and Environmental Science, Vol. 1, 2008, pp. 012017-1 to 012017-11.

Coherent Doppler lidar is ideally suited for accurate measurements of the profiles of wind and turbulence using various beam scanning and processing techniques. The most attractive scanning pattern is a three-dimensional pattern which samples the largest number of independent samples of the turbulent field. Careful processing of the radial velocity estimates is required to correct for the spatial filtering by the lidar pulse and to remove the bias introduced by the estimation error. The various processing techniques and fundamental assumptions will be presented. Lidar derived profiles of wind and turbulence will be compared with in situ data, when available. Results will also be presented from a field campaign focused on wind energy applications.

Frehlich, R. and Cornman, L.

"COHERENT DOPPLER LIDAR SIGNAL SPECTRUM WITH WIND TURBULENCE"

Applied Optics, Vol. 38, No. 36, December 1999, pp. 7456-7466.

The average signal spectrum (periodogram) for coherent Doppler lidar is calculated for a turbulent wind field. Simple approximations are compared with the exact calculation. The effects of random errors in the zero-velocity reference, the effects of averaging spectral estimates by use of multiple lidar pulses, and the effects of the range dependence of the lidar signal power over the range gate are included. For high spatial resolution measurements, the lidar signal power is concentrated around one spectral estimate (spectral bin) and correct interpretation of the contribution from turbulence is difficult because of the effects of spectral leakage. For range gates that are larger than the lidar pulse volume, the signal power is contained in many spectral bins and the effects of turbulence can be determined accurately for constant signal power over the range gate and for the far-field range dependence of the signal power.
