#### 1. SCOPE

This test report contains the results of a crash test performed at the Federal Outdoor Impact Laboratory (FOIL) in McLean, Virginia. The test was performed on a small sign support system at 20 mi/h (8.9 m/s), test 92F011. The vehicle used for this test was a 1984 Honda Civic. The purpose of this test was to evaluate the low- speed safety performance of a dual legged steel 4 1b/ft (5.95 kg/m) u-channel sign support. The performance evaluation was based on the latest requirements for breakaway supports as specified in Volume 54, Number 3 of the Federal Register dated January 5, 1989. These criteria specify, in part, that the occupant change in velocity must be 16 ft/s (4.9 m/s) or less, that the significant test article stub height remaining after impact be no more than 4 inches (102 mm), and that there can be no occupant compartment intrusion.

#### 2. TEST MATRIX

The test was performed on a small sign support system. The test speed was 20 mi/h (8.9 m/s). The sign was buried in NCHRP Report Number 230, S-2 weak soil<sup>(1)</sup>. A summary of the test conditions is presented in table 1.

		Table 1.	Test ma	trix.	
Test Number	Test Vehicle	Test Weight (1b)	Test Speed (mi/h)	Test Article Description	Impact Location
92F011	'84 Honda Civic	1850	20	2 leg steel 4 lb/ft	center

#### 3. VEHICLE

The test vehicle was a 1984 Honda Civic two door hatchback with a manual transmission. Prior to the test, the vehicles' fluids were drained and its inertial properties measured. The vehicle was stripped of certain components which made space for the installation of test equipment. The vehicle was ballasted with a data acquisitions system, transducers, a brake system and weight plates (if necessary) to bring its inertial weight to approximately 1850 pounds (839 kg). The actual weight of the test vehicle was 1850 pounds (839 kg). After ballasting, the vehicles' inertial properties were remeasured.

#### 4. SIGN SUPPORT

The sign support system consisted of two 4 lb/ft (5.95 kg/m) u-channel steel posts 12 ft, 1 in (3.7 m) long. Attached to each leg was an additional 3 ft-1 in (0.9 m) section of 4 lb/ft (5.95 kg/m) u-channel. The two sections were spliced such that a 5 in (0.127 m) overlap was obtained. The splice was bolted together using two 5/16 in (8 mm) diameter grade 9 bolts. Each bolt was passed through the lower u-channel first then through the upper u-channel. A threaded spacer (washer) was installed between the two sections of u-channel. The legs were buried in NCHRP Report 230 S-2 weak soil (sand) such that 1 in (25 mm) of the splice was below ground level. Attached to the 2 legs was a 5-ft high by 6.5-ft (1.5-m by 2.0-m) wide aluminum sign panel. The aluminum panel was 0.125 in (3 mm) thick and was fastened to the u-channel using four 5/16 in (8 mm) bolts with a nut and washer and was installed 7 ft (2.1 m) above ground. The two legs were installed 3.5 ft (1.1 m) apart. The whole sign support system was assembled and inserted in a hole in the weak soil. The hole was backfilled in 6-in (0.152-m) lifts and compacted until the final grade was reached. Figure 1 is a drawing of the sign support system. Figure 2 is a copy of the splice joint instructions followed for installation of the sign system.

#### 5. TEST RESULTS - 20 MI/H (8.9 M/S), TEST 92F011

The test vehicle was accelerated to 20.3 mi/h (29.7 ft/s (9.1 m/s)) prior to impacting the sign support. The centerline of the test vehicle was aligned with the mid point between the two sign legs.

The bumper made contact with both sign legs and began to collapse and the u-channel legs began to bend away from the vehicle. The force required to break the four grade nine splice bolts was higher than the resistive force the weak soil could maintain. The u-channel began to plow through the weak soil. Additional energy was consumed pushing the u-channel through the weak soil and bending each sign leg. The breakaway mechanism, breaking the splice bolts, activated too late in the impact event for the vehicle to pass through the sign system. The splice bolts failed while the vehicle climbed the sign legs pushing the sign over backwards. Two grade 9 bolts, the upper bolt of each leg failed in tension while the lower two bolts failed in shear.

The brunt of the impact occurred to outside edges of each bumper support. The bumper was much softer than the bumper supports therefore damage to the vehicle consisted of damage to the bumper and other plastic elements but no structural damage. Both head light sockets were damaged. The maximum deflection of 9.5 in (0.241 m) was recorded at the left head light cavity. None of the sign components impaled the occupant compartment.

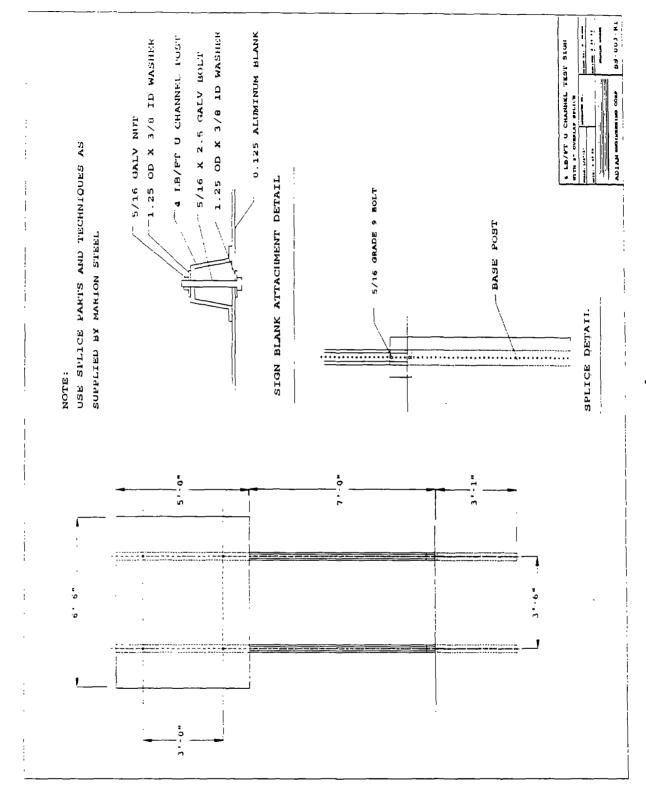

The sign damage consisted of bent and twisted u-channel and four broken grade 9 bolts. The upper and lower sections of the spliced leg were bent and not reusable. The lower sections bent approximately 1 ft (0.3 m) below the groundline. The aluminum sheet panel was in good condition after the test.

The occupant impact velocity using the 2 ft (0.6 m) flail space model outlined in NCHRP Report Number 230, was determined to be 21.4 ft/s (6.5 m/s). The occupant impact velocity was reached 0.184 s into the crash event. The ridedown acceleration was 3.0 g's. The peak force (300 Hz data) for the impact event was 12.3 g's (22.7 kips (101 kN)). Because the sign stopped the vehicle before the vehicle could exit the sign system, the vehicle change in velocity was equal to the impact speed. The actual vehicle change in velocity was calculated to be 28.4 ft/s (8.7 m/s).

Photographs during the impact event are presented in figure 3. A summary of the impact conditions and the test results is presented in figure 4. Figures 5 through 8 are plots of data collected during the test. Pre and post-test photographs of the vehicle and sign support system are presented in figures 9 through 12. The measured crush was confined to outside of each bumper support. A sketch depicting the crush is presented in figure 13.

#### 5. CONCLUSION

The test results indicate that the small sign support system does not meet all of the applicable criteria for the low speed test in weak soil. There was no occupant compartment intrusion and no significant stub remaining after the test, however the occupant impact velocity was 21.4 ft/s (6.5 m/s) which is not less than or equal to the 16 ft/s (4.9 m/s) limit specified by the FHWA.
