1. SCOPE

This test report contains the results of a crash test performed at the Federal Outdoor Impact Laboratory (FOIL) in McLean, Virginia. The test was performed on a small sign support system at 20 mi/h (8.9 m/s), test 92F018. The vehicle used for this test was a 1984 Honda Civic. The purpose of this test was to evaluate the low speed safety performance of a triple legged steel 4 lb/ft u-channel sign support. The performance evaluation was based on the latest requirements for breakaway supports as specified in Volume 54, Number 3 of the Federal Register dated January 5, 1989. These criteria specify, in part, that the occupant change in velocity must be 16 ft/s (4.9 m/s) or less, that the significant test article stub height remaining after impact be no more than 4 in (102 mm), and that there can be no occupant compartment intrusion.

2. TEST MATRIX

The test was performed on a small sign support system. The test speed was 20 mi/h (8.9 m/s). The sign was buried in NCHRP Report Number 230, S-2 weak soil⁽¹⁾. A summary of the test conditions is presented in table 1.

		Table	1. Test	matrix.		
Test Number	Test Date	Test Vehicle	Test Weight (1b)	Test Speed (mi/h)	Test Article Description	Impact Location
92F018	7-8-92	'84 Honda Civic	1850	20	3 leg steel 4 lb/ft	2 leg hit

3. VEHICLE

The test vehicle was a 1984 Honda Civic two door hatchback with a manual transmission. Prior to the test, the vehicles' fluids were drained and its inertial properties measured. The vehicle was stripped of certain components which made space for the installation of test equipment. The vehicle was ballasted with a data acquisitions system, transducers, a brake system and weight plates (if necessary) to bring its inertial weight to approximately 1850 lb (839 kg). The actual weight of the test vehicle was 1850 lb (839 kg). After ballasting, the vehicles' inertial properties were remeasured.

4. SIGN SUPPORT

The sign support system consisted of three 4 lb/ft (5.95 kg/m) steel u-channel legs 15 ft (4.6 m) long. Three feet (0.9 m) of each leg was buried in NCHRP Report 230 S-2 weak soil (sand). Attached to the three legs was a 5-ft high by 12-ft wide (1.5-m by 3.7-m) aluminum sign panel. The panel was a 0.125-in (3-mm) thick aluminum sheet and was installed 7 ft (2.1 m) above ground. The three legs were installed 3.5 ft (1.1 m) apart. The whole sign support system was assembled and inserted in a hole in the weak soil. The hole was backfilled in 6-in (0.152-m) lifts and compacted until the final grade was reached. The centerline of the vehicle was aligned with the midpoint between the center post and the right post. Figure 1 is a drawing of the sign support system.

5. TEST RESULTS - TEST 92F018

The test vehicle was accelerated to 21.5 mi/h (31.5 ft/s (9.6 m/s)) prior to impacting the sign support. The centerline of the test vehicle was aligned with the midpoint between the center and right sign post.

The bumper made contact with two of the three sign legs and began to collapse. The bumper collapsed to the outside edge of the left bumper support and at the right bumper support. The u-channel legs began to bow away from the vehicle and push through the weak soil. Because two out of three sign posts were struck, the sign system was unable or unintended to be a basebending sign system. The required force to break the two u-channel posts was higher than the resisting force of the weak soil therefore the weak soil gave way before the u-channel and the vehicle forced the u-channel to plow through the sand. Contact was not made with the left sign post and therefore the sign pivoted counter-clockwise around the left sign post. The vehicle continued to force the two u-channel legs through the sand. The rotation around the left post causes the vehicle to turn to the left and consequently forces the right post through a greater distance than the center post. The induced moment on the right post causes the right u-channel to break. The vehicle passed over the remaining u-channel stub and yawed around the center post. The vehicle came to rest on top of the right posts' stub. The vehicle did not pass completely through the sign system. After the test, the stub was measured to be 21 in (0.533 m).

Damage to the vehicle consisted of damage to the bumper and grill. The majority of the damage occurred to the outside edge of the left bumper support where there was little structural support. The bumper collapsed to the left head-light socket and damaged plastic components. The right side of the vehicle was intact with the exception of one parking light. The occupant compartment was intact after the test.

Damage to the sign system consisted of three bent and twisted u-channel legs with one u-channel broken 21 in (0.533 m) above ground. Each of the two struck posts bent 12 in (0.305 m) below the ground line. The panel was in good condition after the test.

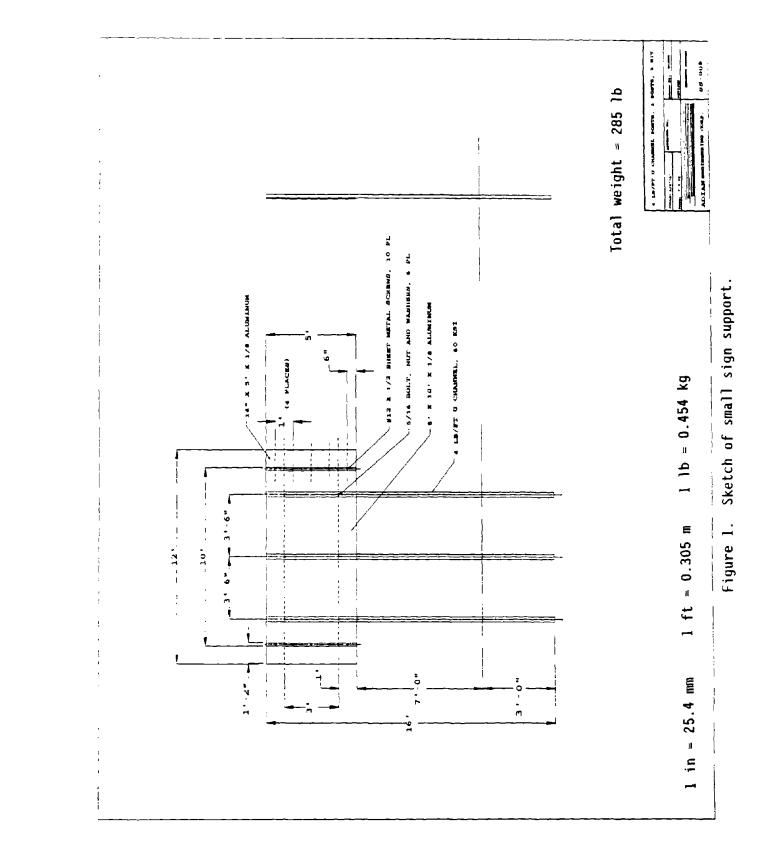

The occupant impact velocity using the 2-ft (0.6-m) flail space model outlined in NCHRP Report Number 230, was determined to be 20.2 ft/s (6.2 m/s). The occupant impact velocity was reached 0.182 s into the crash event. The ridedown acceleration was 2.7 g's. The peak force (300 Hz data) for the impact event was 8.1 g's (15.0 kips (66.6 kN)). Because the sign system stopped the vehicle, the vehicle change in velocity is equal to the impact velocity. The actual vehicle velocity change calculated by integration of the on-board accelerometers was 29.5 ft/s (9.0 m/s).

Photographs during the impact event are presented in figure 2. A summary of the impact conditions and the test results is presented in figure 3. Figures 4 through 7 are plots of data collected during the test. Pretest and post-test photographs of the vehicle and sign support system are presented in figures 8 through 11. Figure 12 is a sketch of the measured vehicle crush.

6. CONCLUSION

The test results indicate that the small sign support system does not meet all of the applicable criteria for the low-speed test in weak soil.

There was no occupant compartment intrusion, however the stub remaining after the test was measured to be 21 in (0.533 m) which is not less than or equal to the 4-in (0.102-m) limit specified by the FHWA. In addition, the occupant impact velocity was 20.2 ft/s (6.2 m/s) which is not less than or equal to the 16 ft/s (4.9 m/s) limit specified by the FHWA.
